Step 3: Restart the Arbiter, and your Scheduler will now save its state between restarts. :) .. _forums.monitoring-fr.org/index.php?topic=5205.0: http://forums.monitoring-fr.org/index.php?topic=5205.0

How to enable and use Livestatus module

Define the Livestatus module Start by reviewing the ''/etc/shinken/shinken-specific.cfg" file for this module:

```
define module{
```

```
module_name      Livestatus
module_type      livestatus
host             *       ; * = listen on all configured IP addresses
port             50000   ; port to listen on
database_file    /var/lib/shinken/livestatus.db
```

}

With these parameters:

- module_name: name of the module called by the brokers
- module_type: livestatus
- host: IP interface to listen to. The default is *, which means "listen on all interfaces".
- port: TCP port to listen to.
- socket: Unix socket to listen to.
- database_file: the path to the sqlite database file which is used to store the log broks/messages. The default is "var/livelogs.db"
- max_logs_age: the maximum age of the log messages (before they are deleted from the database). The default is 1 year. The argument to this parameter takes the form <number>[<period of time>], where <period of time> can be d for days, w for weeks, m for months and y for years.
- allowed_hosts: a comma-separated list of IP-addresses which are allowed to contact the TCP port. Please keep in mind that these **must be IP-addresses, NOT host names**. Because DNS lookups for every incoming livestatus request could hang up and therefore block the module.

Enable the Livestatus module Still in ''/etc/shinken/shinken-specific.cfg'', find the object Broker and add "Livestatus" to its "modules":

```
define broker{
```

```
    broker_name      broker-1
[...]
```

```
    modules          Simple-log,Livestatus
}
```

Disable human readable logs In ''/etc/shinken/nagios.cfg'', verify that the option **human_timestamp_log** is set to **0**.

In version 0.6.5, you can not have at the same time a simple-log file with human readable timestamp and a Livestatus database.

Exporting data for reporting Shinken can export necessary data for reporting in 3rd party systems.

raw_socket module The raw socket module exports reporting data using a syslog format to a raw TCP socket. Theses logs can be captured, parsed and indexed by any log management system like Splunk or Logstash.

Why export reporting data Custom UIs like Thruk, Multisite, WebUI, Adagios, Nagios IX, etc. All have poor or inflexible reporting. Simply because these are not reporting engines.

This also permits to have a generic reporting method that can accept data from any Nagios, Shinken, Icinga or even Riemann.

Reporting module using Splunk Splunk was selected as the reporting platform for creating, managing and presenting reports. Though the raw_socket module does not have any Splunk specific particularities. It is notable that Splunk reports can be embedded in any 3rd party UI using its REST API.

Raw_socket log format The logs are plain-text and compliant with RFC3164. They use an intelligent date format, a configurable seperator " "(space by default), and key=value pairs in the message data portion of the log. Should a key or value contain a space they must be double quoted. This is syslog using structured data without going to full out JSON that may not be compatible with all log management systems.

The message fields that are supplied in each status update in addition to the standard syslog header are:

- Hostname
- Servicename
- Business impact
- Host/Service status
- Host/Service previous status
- Acknowedgement status
- Maintenance status

Any time the maintenance, host, service or acknowledgement status changes, a log is sent by the Shinken raw_socket module.

Having all relevant data in each log makes it very easy to compute reports for given time periods.

The hostgroup or service group memberships, custom variables or any other configuration related data should be queried from the monitoring system using its API (Livestatus in the case of Shinken and Nagios).

Raw_socket module availability The module is available in both Shinken 1.4 and Shinken 2.0. The module will be integrated in master branches once unit tests and end-to-end testing is completed. 3rd quarter 2013.

Monitoring Linux System with Glances and checkglances.py **'Glances'_** is a fantastic multiplatform system monitoring tool writen by Nicolargo. Glances can run on (Linux, Windows, MacOS ...). There is a growing ecosystem around Glances and of course a Nagios/Shinken plugin : checkglances.py.

How does it work Glances can run in server mode. It provide a XML-RPC server (over http) and allow to retrieve system information throuh a restful API. The only thing to do is to install and start Glances as server on the monitored host, then install checkglances.py on the shinken server and finaly install the glances pack.

Install glances See the glances documentation to install glances on Linux.

<code bash> easy_install glances </code>

There is a debian startup script in the glances repository. And another one for centos here.

Install checkglances.py Just follow the documentation for the checkglances.py prerequisites and put it in your nagios plugins folder.

Install the glances pack Open a terminal as the shinken user and just type the following command

<code bash> shinken install glances </code>

Then just edit the configuration for a linux monitored host and tag it as **glances**

```
define host{
 name mylinuxhost
 use glances
 ...
```

Finaly restart the shinken arbiter

```
service shinken-arbiter restart
```

What will be monitored ? For the moment just the basic system (ram, cpu, load, memory, filesystem and network).

If you want to modify the default thresholds for just a host you can do it by overiding the thresholds macro in your host definition. If you want to do it for several hosts, declare a new template and just add the desired thresholds macro to be overide.

Here is a list of the macros

```
::
```

> _LOAD_WARN 2 _LOAD_CRIT 3 _CPU_WARN 80 _CPU_CRIT 90 _MEMORY_WARN 90 _MEMORY_CRIT 95 _FS /, /home _FS_WARN 90 _FS_CRIT 95 _IFACES eth0, eth1 _NET_WARN 7500000 _NET_CRIT 10000000

Note the _FS and _IFACES macros. They leverage the ability to duplicate service for a given list of things to be monitored. Here you see that / and /home partitions will be monitored. If you want to modify this then just add your own in a new template that will inherit the glances template.

Shinken GLPI integration Shinken supports importing hosts from GLPI

For people not familiar with GLPI, it is an Open-Source CMDB. Applicable to servers, routers, printers or anything you want for that matter. It is also a help-desk tool. GLPI also integrates with tools like FusionInventory for IT inventory management.

You can still have flat files AND GLPI if you want. Hosts imported from GLPI will be treated as standard hosts from flat file (inheritance, groups, etc). In fact, in this first version the module only sends the host_name to Shinken, but there should be more information extracted like network connexions for parents relations in the future. :)

Requirements

- python module MySQLdb
- Compatible version of GLPI Shinken module and GLPI version - ...
- etc..

Enabling GLPI Shinken module In your shinken-specific.cfg file, just add (or uncomment):

```
#You know GLPI? You can load all configuration from this app(
#with the webservices plugins for GLPI, in xmlrpc mode
#and with plugin monitoring for GLPI)
# =============== Work with Plugin Monitoring of GLPI ===============
#All configuration read from this will be added to the others of the
#standard flat file
define module{
     module_name      GLPI
     module_type      glpi
     uri              http://localhost/glpi/plugins/webservices/xmlrpc.php
     login_name       glpi
     login_password   glpi
}
```

And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master
#    host_name       node1       ;result of the hostname command under Unix
     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           GLPI
     }
```

It's done :)

Ip Tag module

Why tag a host based on it's IP address? We learned on the *DMZ monitoring* that you can "tag" a host with a poller_tag so it will be checked only by DMZ pollers. It can be tedious process to manually tag all these hosts. Shinken provides an automated method to do this.

This is handled by the arbiter ip_tag module.

Ip_tag module The ip_tag module is an arbiter module that looks up the host address during the configuration parsing and compares it to an predefined IP range (IPV4 or IPV6). If the range matches, it can apply or add a property, such as poller_tag. Other types of tags could be related to locations, functions, administrative groups, etc.

Method: replace or append.

replace will put the value if the property is unset. This is the default method. .. warning:: Fix me: replace, implies overriding an existing value. And will cause user issues down the line. Rename it to set. Replace should be a different method altogether, so overall there should be 3 methods(set, append, replace).

append will add with a , if a value already exist

Here is an example that will set the poller_tag property with the value DMZ of all hosts that:

- have a their hostadress ip (or name resolved) in the range 192.168.0.1/24.
- do not already have a poller_tag property set

```
define module{
```

```
     module_name     IpTag
     module_type     ip_tag
     ip_range        192.168.0.1/24
     property        poller_tag
     value           DMZ
}
```

To use the module add it in the arbiter object:

```
::
```

define arbiter { [...] modules NSCA,IpTag

}

Add value instead of setting it In the previous example we set the property poller_tag to a value. But what if we want to "add" a value, like a template name? We can change the "method" property of the module to "append" so we can add the "value" to the host property instead of replace it.

Here is an example where we want to add the "dmz" template on the hosts, while also keeping any defined templates:

```
define module{
```

```
     module_name   IpTag
     module_type   ip_tag
     ip_range      192.168.0.1/24
     property      use
     value         dmz

     # Optional method
     method append
}
```

For a host defined as:

```
define host{
```

```
     host_name   example_host1
     address     192.168.0.2
     use         linux
}
```

It will be "changed" internaly in:

```
define host{
```

```
     host_name   example_host1
     address     192.168.0.2
     use         linux,dmz
}
```

Name resolution Of course you don't need to set IP address in the address of your host. You can set a hostname, and it will be resolved, and then compared to the range. :)

Ubuntu Landscape import

Description You can import data from Ubuntu Landscape into Shinken to create hosts.

Ubuntu Landscape, is a web app to manage all your linux servers (update and co), which is provided by Canonical, Ubuntu's parent company.

This is an Arbiter import module. The Arbiter manages the configuration.

Prerequisites

You will need the landscape-api package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

define module { module_name Landscape module_type landscape_import

Configure your REAL key and secret from Landscape key PAAAB2CILT80I0ZA0999 secret GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH default_template generic-host ; if the host is not tagged, use this one

If you are using a specific certificate for landscape_api #ca /path/to.ca.cert

If you need a proxy to access https://landscape.canonical.com/api/ #https_proxy http://user:secret@myproxy.com:3128

}

- Put in key and secret your private Landscape access.
- default_template will be used if your host is not "tagged" in Landscape
- If you are using a specific certificate for connexion, give the full path in ca
- You will certainly need an https proxy to access the Landscape API. If so, configure it there.

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master
#    host_name       node1       ;result of the hostname command under Unix
     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           Landscape
     }
```

Restart your Arbiter and it's done :)

Tip: Your "tags" will be applied as templates for your hosts.

Shinken Livestatus API

Overview

- Jump back to Getting Started
- Jump back to *Livestatus module configuration*

What is it Livestatus API is the modern method of interacting with Shinken and Nagios based systems alike.

Originally developed for Nagios, MK Livetstatus, was re-implemented in Python for use with Shinken by professional developers. The access methods and query languages are the same.

Why use it It is fast.

It is network based using TCP.

It is standard for all Nagios and Shinken monitoring systems.

It uses in-memory structures for status data

It uses a back-end database for historical reporting

It uses an SQL based query language

It has a host of powerful nuts and bolts features (authentication, caching, connection persistence, multiple object methods (JSON, Python)).

What can I do with it? All programs and scripts use (or should use) this method to :

- Obtain the current state of hosts and services
- Obtain the current configuration related to hosts and services
- Send administrative commands (downtimes, comments, forcing checks)
- Filter information to display
- Obtain basic reports and event statistics

Shinken being a modern re-implementation of Nagios has additional features that are available in addition to the standard Livestatus API.

Shinken Livestatus API unique features can :

- Obtain Business Impact information
- Obtain intelligent dependency status hosts or services (combines dependency and parent information)
- Obtain Business Process states (same syntax as standard host and service queries)

How does it work Livestatus uses a powerful SQL-like query language. The standard methods and parameters are defined at :

'MK Livestatus reference methods and query language definition'_

Full list of Shinken Livestatus API methods:

'Shinken mapping.py methods'_

What software uses Livestatus to interact with Shinken

Well known Web frontends

- MK Multisite
- Thruk
- NagVis

- Splunk for Nagios

Mobile Web frontends

- get list

Scripts

- Downtime management scripts
- Debug scripts

Installing Livestatus Have you installed the required packages to use the Livestatus module? You can look at the requirement section of the *10 minute installation guide* for the *requirement lists*.

How to enable Livestatus Very simple, jump to the *Shinken Broker configuration* section to enable it. .. _Shinken mapping.py methods: https://github.com/shinken-monitoring/mod-livestatus/blob/master/module/mapping.py .. _MK Livestatus reference methods and query language definition: http://mathias-kettner.de/checkmk_livestatus.html

NSCA module The NSCA daemon module is used to receive send_nsca packets and submit them to the Shinken command pipe. The NSCA module can be loaded by the Receiver or Arbiter process. It will listen on port TCP/5667 for send_nsca packets.

Tip: Passive checks can be submitted *natively to the Shinken command pipe* or from remote hosts to modules, such as NSCA, AMQP or collectd, loaded in the Shinken Arbiter or Receiver process. AMQP is implemented for integration with the Canopsis Hypervisor, but could be re-used for generic messaging.

Note: The Shinken NSCA module implementation is currently limited to the "xor" obfuscation/encryption.

In your shinken-specific.cfg file, just add (or uncomment):

```
::
```

#You can send check result to Shinken using NSCA #using send_nsca command define module{

module_name NSCA module_type nsca_server host * port 5667 encryption_method 0 password helloworld

}

define receiver{

```
receiver_name    receiver-1
address          localhost
port             7773
modules          NSCA

timeout          3             ; 'ping' timeout
data_timeout     120           ; 'data send' timeout
max_check_attempts       3     ;  if at least max_check_attempts ping failed, the node is DEAD

#advanced
realm    All
}
```

This daemon is totally optional.

It's main goal is to get all passive "things" (checks but why not other commands) in distant realms. It will act as a "passive receive buffer" and will then dispatch the data or commands directly to the appropriate Scheduler or Arbiter process.

Data can be received from any Realm, thus the Realm option is nonsensical.

For now there is no init.d script to launch it. .. note:: Verify that the init script has been added.

It is launched like all other daemons:

```
bin/shinken-receiver -c etc/receiverd.ini
```

Tip: Alternatively, for small installations with you can configure a modules inside your Arbiter instead of the Receiver. It will listen the TCP/5667 port for send_nsca packets.

To configure the NSCA module in your Arbiter instead of Receiver. Add the NSCA module to your Arbiter object configuration.

```
::
```

define arbiter{ arbiter_name Arbiter-Master

 # host_name node1 ;result of the hostname command under Unix address localhost ;IP or DNS adress port 7770 spare 0 modules NSCA

}

Retention troubleshooting The retention file contains the state of your host and services, so that they are kept when shinken is restarted.

Sometimes you'll want to inspect (and possibly fix) the retention file, in case you need to work-around a bug or simply better understand what is stored there.

When you use the PickleRetention module in the scheduler (cf. ''define scheduler" in ''shinken-specific.cfg''), you can simply manipulate the retention file using Python.

For this you can use the following code.

- It assumes Shinken is installed in ''/opt/shinken" with the retention file in ''/tmp/retention.dat'':
- Run and play with it interactively using ''ipython -i inspect_retention.py''.

```
#!/usr/bin/python
import pickle
import sys
sys.path.append('/opt/shinken')
import shinken

r = pickle.load(file('/tmp/retention.dat'))
h = r['hosts']

# Example:
# [(k,v) for (k,v) in h['your_host'].items() if k.find('downtime') >= 0]
#
# del h['your_host']
#
# for k,v in r['services'].items():
#     if 'your_host' in k:
#         del r['services'][k]
```

To save your changes:

- Stop Shinken: ‘’service shinken stop’‘
- Save the pickle: ‘’pickle.dump(r, open(‘/tmp/retention.dat’, ‘w’))’‘
- Start Shinken: ‘’service shinken start’‘

NRPE Module

What is it The NRPE module allows Shinken Pollers to bypass the launch of the check_nrpe process. It reads the check command and opens the connection by itself. It scales the use of NRPE for active supervision of servers hosting NRPE agents.

The command definitions should be identical to the check_nrpe calls.

How to define it The definition is very easy (and you probably just have to uncomment it):

```
define module{
     module_name       NrpeBooster
     module_type       nrpe_poller
}
```

Then you add it to your poller object:

```
define poller {
    [...]
    modules   NrpeBooster
}
```

Then just tag all your check_nrpe commands with this module:

```
define command {
   command_name   check_nrpe
   command_line   $USER1$/check_nrpe -H $HOSTADRESS$ -c $ARG1$ -a $ARG2$
   module_type    nrpe_poller
}
```

That’s it. From now on all checks that use this command will use Shinken’s NRPE module and will be launched by it.

Extending Shinken

Introduction There are a lot of “Modules” and “Addons” that are available for Shinken. Shinken can be extended by using different types of methods.

- Web interfaces from various open-source vendors can be used (Based on Livestatus API)
- Shinken itself can be extended using modules that are embedded into the various daemon processes

** (Arbiter, Poller, Receiver, Broker, Scheduler, Reactionner) * External software can provide functional enhancements for reporting, management or usability aspects

Shinken itself provides methods to extend the base functionality:

- *Broker modules* provide external access to runtime data from Shinken
- Poller modules such as *NRPE* and the *SNMP*
- Receiver modules like *NSCA* provide acquisition methods for Shinken

- Arbiter modules permit manipulating the configuration
- The webUI that permits embedding web interface elements

Independent software that works in concert with Shinken is available for:

- Monitoring remote hosts through agent software (*NIX, Windows, etc.)
- Submitting passive checks from remote hosts
- Managing the config files through a web interface
- Mobile phone UIs
- Desktop UIs and Hypervisors
- Desktop notification addons
- ...and much more

You can find many addons that are compatible with Shinken by visiting. The only caveat is that the addons should not use the status.dat file and preferably the modern API interfaces like Livestatus:

- Nagios.org
- SourceForge.net
- NagiosExchange.org
- Shinken community exchange for monitoring packs

Broker modules The broker module receives messages from the Schedulers related to host, service check results. In addition to that it receives a copy of the compiled configuration at startup. What is special about the broker, is that without modules, the broker does nothing. It makes the configuration and result data available to modules. Modules are the ones in charge of doing something with the data. This could be exporting this "raw" data into flat files, databases or exposing it as an API.

The modules are presented according to their use cases.

- Core modules
- Livestatus Module for frontends
- Exporting data to metric databases
- SQL based Modules for frontends
- Exporting data to logging management systems
- Legacy modules for migration purposes
- Modules no longer supported

Core modules

simple_log: get all logs into one file You can get a log for all your daemons in a single file. With the exception of Debug level logs which are not sent through the network as a safe guard. Shinken state messages are ONLY logged at the debug level in the local log files. These are the ALL CAPS states that some 3rd party interfaces use to mine data from the historical logs. Actual state messages are sent as objects between the various daemons.

It takes the parameters:

- module_name: name of the module called by the brokers

- module_type: simple_log
- path: path of the log file

Here is an example:

```
define module{
```

```
     module_name      Simple-log
     module_type      simple_log
     path             /usr/local/shinken/var/nagios.log
     archive_path     /usr/local/shinken/var/archives/
}
```

Syslog - Send all logs to a local syslog server Send all logs to a local syslog server. Support for remote syslog can be implemented if requested. Just lookup the syslog module, easy to modify. Use for example with Splunk, graylog2, Logstash, Elastic search, Kibana, or other log management and analysis system.

```
define module{
```

```
  module_name Syslog
  module_type syslog
}
```

Lightweight forwarder to Splunk Shinken state data from the local syslog can also be sent to a Splunk server for indexing, reports, SLA and analysis. Via syslog or better yet, the Splunk lightweight forwarder which supports, TCP, buffering and security parameters.

Livestatus API Module - Thruk, Nagvis and Multisite Web frontends There are three well known frontends and various small tools that can interface with the Livestatus API. This API is currently the most efficient method of sharing live data with external interfaces. It provides a rich query language similar to SQL, authentication, command execution, caching,connections persistence, multiple object methods (JSON, Python). All Livestatus data is kept in memory, there is no disk IO involved. It exposes configuration objects, the current state of the hosts and services as well as historical Shinken state log messages.

- MK Multisite
- Thruk
- NagVis

Have you installed the required packages to use the Livestatus module? You can look at the requirement section of the 10 minute installation guide for the requirement lists.

Livestatus Module

It takes the following parameters:

- module_name: name of the module called by the brokers
- module_type: livestatus
- host: IP interface to listen to. The default is '127.0.0.1'. '*' means 'listen on all interfaces'.
- port: TCP port to listen to.
- socket: Unix socket to listen to.

- allowed_hosts: a comma-separated list of IP-addresses which are allowed to contact the TCP port. Please keep in mind that these must be ip-addresses, NOT host names. (DNS lookups for every incoming livestatus request could hang up and therefore block the module)
- modules: a comma-separated list of modules (see below)
- pnp_path: relevant if you use the multisite gui. pnp_path points to the perfdata directory where the pnp4nagios data reside (it's the directory which contains a subdirectory for each host). Multisite needs it to display a small perfdata icon if a rrd file exists.
- To deactivate an input, the port- and socket-attributes can also take the value "none".

The Livestatus module itself can have sub-modules. In fact, it **must** have at least one submodule responsible for storing log events to a database, SQLite or MongoDB.

Livestatus module - Logstore Sqlite Stores log-broks to an sqlite database.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_sqlite
- use_aggressive_sql: Prefer the use of sql queries to pre-filter data prior to python filtering. This is required for very large installations, as the Python structures are not indexed when filtering. Optional argument set to 0 by default. To enable set the value to 1. Some erroneous output may occur, but informal testing has shown these corner cases do not occur.
- read_only: don't send any update to the database. Should be used when you run several livestatus modules : 1 instance is R/W, other are read only.
- database_file: the path to the sqlite database file which is used to store the log broks/messages. The default is 'var/livestatus.db'
- archive_path: the path to a subdirectory where database file archives will be created. Every day the data from the last day will be moved to an archive datafile. The default is 'var/archives'.
- max_logs_age: the maximum age of the log messages (before they are deleted from the database). The default is 1 year. The argument to this parameter takes the form <number>[<period of time>], where <period of time> can be d for days, w for weeks, m for months and y for years. This parameter is currently ignored. In future releases it will be used to automatically delete ancient database files.

Here is an example:

```
define module{
```

```
     module_name      Livestatus
     module_type      livestatus
     host             *       ; * = listen on all configured ip addresses
     port             50000   ; port to listen
     socket           /usr/local/shinken/var/rw/live
     modules          logsqlite
}
define module{
```

```
     module_name      logsqlite
     module_type      logstore_sqlite
     use_aggressive_sql     0 ; optional, by default set to 0. Only for large installations.
     database_file    /usr/local/shinken/var/livelogs.db
     max_logs_age     3m ; three months. Other time intervals are d=days, w=weeks, y=years
}
```

Livestatus module - Logstore MongoDB Stores historical log broks(inter daemon Shinken messages) to a MongoDB database. MongoDB is a distributed and very performant database that permits resilience and high availability. The current implementation has a few known broken pieces (some search functions are broken) and there are bugs in the implementation, so it is considered experimental until power users and developers have ironed out the bugs. It is the database of the future for Shinken.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_mongodb
- mongodb_uri: The address of the master. (Default: i_cant_write_the_uri_here_it_messes_the_wiki_up)
- replica_set: If you are running a MongoDB cluster (called a "replica set" in MongoDB), you need to specify it's name here. With this option set, you can also write the mongodb_uri as a comma-separated list of host:port items. (But one is enough, it will be used as a "seed")
- database: <undocumented>
- collection: <undocumented>
- max_logs_age: <undocumented>

The configuration looks quite similar to the sqlite one. **In a single-node installation and with decent amount of log traffic, the sqlite backend should be considered best practice, as it needs no extra software and is stable and fast (when run in-memory).**

Livestatus module - Logstore Null In case you don't need any logging (for instance, if you dedicate a livestatus module instance to nagvis), you can use this module.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_null

Network Based Modules - Graphite graphing Graphite is a graphing and data analysis tool. It is composed of a web frontend (graphite-web), fixed size databases (whisper) and data redistribution/munging daemon. (carbon) The first step is *having Graphite installed somewhere*, if you do not have Graphite installed, please do this and come back later.

Pre-requisite : Shinken 1.2.2+ is recommended for the best experience with Graphite.

graphite_perfdata: exports check result performance data to Graphite Export all performance data included in check results to Whisper databases managed by Graphite. Data is buffered, then exported once every broker time tick. (Once per second). Should a communication loss occur, it will buffer data for 5 minutes before dropping data. The tick_limit max is configurable, the only limitation is the amount of memory the buffered data can eat.

The graphite broker module (v1.2) sends data to graphite in the following format :

HOSTNAME.SERVICENAME.METRICNAME

It can be optionally enhanced to send it the following format :

_GRAPHITE_PRE.HOSTNAME.SOURCE.SERVICENAME.METRICNAME._GRAPHITE_POST

Each of the three variables are optional :

- The _GRAPHITE_PRE variable can be set per host/service to provide a more flexible naming convention. (ex. Prod.site1.Hostname.servicename)

- The _GRAPHITE_POST variable can be set per host/service to specify the more information concerning the variable being stored that graphite can use to determine the retention rule to use for the variable.
- The SOURCE variable can be set in shinken-specific.cfg for the WebUI module and the Graphite broker.

Metric names are converted from Shinken's format to a more restrictive Graphite naming. Unsupported characters are converted to "_" underscore. So do not be surprised to see that some names differ in the WebUI or directly in Graphite. Permitted characters in Graphite are "**A-Za-z_**.", the hyphen character is permitted from Shinken, though only future versions of Graphite will support it.

Performance data transfer method can be set to pickle, which is a binary format that can send data more efficiently than raw ascii.

It takes the following parameters:

- module_name: name of the module called by the brokers
- module_type: graphite_perfdata
- host: ip address of the graphite server running a carbon instance
- port: port where carbon listens for metrics (default: 2003 for raw socket, 2004 for pickle encoded data)
- use_pickle: Use a more efficient transport for sending check results to graphite instead of raw data on the socket (v1.2)
- tick_limit: Number of ticks to buffer performance data during a communication outage with Graphite. On tick limit exceeded, flush to /dev/null and start buffering again. (v1.2)
- graphite_data_source: Set the source name for all data coming from shinken sent to Graphite. This helps diferentiate between data from other sources for the same hostnames. (ex. Diamond, statsd, ganglia, shinken) (v1.2)

Here is an example:

```
define module {
```

```
module_name Graphite-Perfdata
host xx.xx.xx.xx
module_type graphite_perfdata
port 2004 ; default port 2003 for raw data on the socket, 2004 for pickled data
use_pickle 1 ; default value is 0, 1 for pickled data
tick_limit 300 ; Default value 300
graphite_data_source shinken ; default is that the variable is unset
}
```

SQL Based Modules - PNP4Nagios Graphing PNP4Nagios is a graphing tool that has a web interface for RRDTool based databases. Shinken can export performance data to an npcd database which will feed the RRD files (fixed sized round robin databases). You can *learn how to install PNP4Nagios* if you haven't done it already.

npcdmod: export perfdatas to a PNP interface Export all perfdata for PNP.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: npcdmod
- path: path to the npcd config file

Here is an example:

```
define module{
 module_name  NPCD
 module_type  npcdmod
 config_file  /usr/local/pnp4nagios/etc/npcd.cfg
}
```

SQL Based Modules - Frontend Centreon2 Centreon2 use a NDO database, so you will need the ndodb_mysql module for it.

ndodb_mysql: Export to a NDO Mysql database Export status into a NDO/Mysql database. It needs the python module MySQLdb (apt-get install python-mysqldb or easy_install MySQL-python).

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: ndodb_mysql
- database: database name (ex ndo)
- user: database user
- password: database user passworddt
- host: database host
- character_set: utf8 is a good one

Here is an example:

```
define module{
```

```
     module_name      ToNdodb_Mysql
     module_type      ndodb_mysql
     database         ndo       ; database name
     user             root      ; user of the database
     password         root      ; must be changed
     host             localhost ; host to connect to
     character_set    utf8      ;optionnal, UTF8 is the default
}
```

File based Legacy modules - perfdata export

service_perfdata: export service perfdatas to a flat file

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: service_perfdata
- path: path to the service perfdata file you want

Here is an example:

```
define module{
```

```
    module_name      Service-Perfdata
    module_type      service_perfdata
    path             /usr/local/shinken/src/var/service-perfdata
}
```

host_perfdata: export host perfdatas to a flat file

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: host_perfdata
- path: path to the host perfdata file you want

Here is an example:

```
define module{
```

```
    module_name      Host-Perfdata
    module_type      host_perfdata
    path             /usr/local/shinken/src/var/host-perfdata
}
```

Legacy File based Modules - Old CGI or VShell The Old CGI and VShell use the flat file export. If you can, avoid it! It has awful performance, all modern UIs no longer use this.

status_dat: export status into a flat file Export all status into a flat file in the old Nagios format. It's for small/medium environment because it's very slow to parse. It can be used by the Nagios CGI. It also export the objects.cache file for this interface.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: status_dat
- status_file: path of the status.dat file /usr/local/shinken/var/status.dat
- object_cache_file: path of the objects.cache file
- status_update_interval: interval in seconds to generate the status.dat file

Here is an example:

```
define module{
```

```
    module_name              Status-Dat
    module_type              status_dat
    status_file              /usr/local/shinken/var/status.data
    object_cache_file        /usr/local/shinken/var/objects.cache
    status_update_interval   15 ; update status.dat every 15s
}
```

Deprecated or unsupported modules

SQL Based MerlinDB This interface is no longer supported and is going to be completely removed from Shinken.

SQL based ndodb_oracle - Icinga web frontend using NDO Oracle This interface is no longer supported and is going to be completely removed from Shinken.

CouchDB: Export to a Couchdb database This interface is no longer supported and is going to be completely removed from Shinken.

TSCA (Thrift Service Check Acceptor) TSCA is a receiver/arbiter module to receive hosts and services check results. It provides the same functions as NSCA with additional features. High performance binary transmission, multi line output and auto generated clients for a variety of languages.

What is thrift ? Let's cut and paste the wikipedia definition from'en.wikipedia.org/wiki/Apache_Thrift'_ :

"Thrift is an interface definition language that is used to define and create services for numerous languages.[1] It is used as a remote procedure call (RPC) framework [..]. It combines a software stack with a code generation engine to build services that work efficiently to a varying degree and seamlessly between ActionScript, C#, C++ (on POSIX-compliant systems), Cappuccino, Cocoa, Erlang, Haskell, Java, OCaml, Perl, PHP, Python, Ruby, and Smalltalk."

Installation In any case, you have to install thrift with support for python (on the server side) and languages you want to use for clients.

Get it from thrift.apache.org or in your favorite distribution repository.

Server side Go to the tsca module directory and generate the python stub for the server side installation

```
cd shinken/modules/tsca
$ thrift --gen py tsca.thrift
```

Declare the module is shinken-specific.org

```
define module{
      module_name     TSCA
      module_type     tsca_server
      host            0.0.0.0
      port            9090
}
```

Samples clients There are three(3) client samples written in python, ruby and java in contrib/clients/TSCA of the Shinken distribution. You can use and extend them to send data directly in your code directly to Shinken's TSCA receiver/arbiter module.

The samples clients read a CSV file from stdin and send them the the TSCA running on localhost:9090. The CSV has the following format :

```
hostname,service description,output,rc
```

Any use of TCP in an application should take care not to block the program and to have very short timeouts. For applications that need non blocking functions, prefer a UDP based transport or a local buffer file with a separate application(send_nsca, thrift, etc) to forward your data to Shinken.

Ruby Generate the stub

```
$ thrift --gen rb ../../../shinken/modules/tsca/tsca.thrift
```

Run the client

```
$ cat file_state | ruby RubyClient.rb
```

Python Generate the stub

```
$ thrift --gen py ../../../shinken/modules/tsca/tsca.thrift
```

Run the client

```
$ cat file_state | python PythonClient.py
```

java Generate the stub

```
$ thrift --gen java ../../../shinken/modules/tsca/tsca.thrift
```

Compile the client

```
$ ant
```

Run the client

```
$ cat file_state | java JavaClientThrift
```

VMWare Arbiter module

How it works The arbiter has a module that allows the host->VM automatic host dependency creation. In fact, the module is far more generic than just this. It's a generic "host link dependencies" module.

It reads a mapping file (simple json format) with son->father links. It call an external script at a regular interval : the one I wrote is a VMWare mapping one. It used the check_esx3.pl (that all ESX admin should have) plugin and generate the mapping file. When this file is changed, the module reloads it, creates new links and deletes old ones. So when you VMotion a virtual machine, in the next pass, there will be creation of a new link and deletion of the old one in the scheduler that manages it :)

How to define it The definition is very easy :

```
define module{
     module_name       VMWare_auto_linking
     module_type       hot_dependencies
     mapping_file      /tmp/vmware_mapping_file.json
     mapping_command   /usr/local/shinken/libexec/link_vmware_host_vm.py -x '/usr/local/shinken/libex
     mapping_command_interval 60   ; optionnal
     mapping_command_timeout   300 ; optionnal
}
```

Then you add it in you arbiter object :

```
define arbiter {
    [...]
    modules   VMWare_auto_linking
}
```

So here, it will call the script /usr/local/shinken/libexec/link_vmware_host_vm.py with a listing of the vCenter vcenter.mydomain.com and generate the mapping file /tmp/vmware_mapping_file.json.

You can call : /usr/local/shinken/libexec/link_vmware_host_vm.py –help

for the full help on this script.

It looks at the file modification time each second. This command can also be launch by an external cron of course.

Note: So if you want to write a script that does this for XEN servers, all you need is to generate a json file with all the mapping. I didn't wrote the doc about this, but you can look in the test file for it, the format is very very easy :)

Here is an example of the JSON mapping file syntax:

%%:ref:*["host", "physical_host"], ["host", "virtual_machine"* <["host", "physical_host"], ["host", "virtual_machine">, "host", "physical_host"], ["host", "other_virtual_machine" <"host", "physical_host"], ["host", "other_virtual_machine">]%%

So just a list of couple 'host' string (from now only host are managed) and the host name.

Beware about it : you need the real host_name, including case.

Web Service Module The Ws_arbiter module is a Receiver or Arbiter module to receive passive check results from remote hosts via HTTP(s). This module is considered a work in progress but can be used for testing and improvement.

Configuring the Web Service Module If data is POSTed to this page, it will validate the data to determine if it is a service or host check result and submit the data to the Shinken external command queue.

The web service listens by default to TCP port 7760. The web service supports anonymous or authenticated access. Web service parameters are set in the Shinken-specific.cfg file, in the Ws_arbiter module. To enable the web service, simply add the module to your Arbiter or Receiver daemon configuration in Shinken-specific.cfg

Using the Web Service Module The web service listens for POSTs to: /push_check_result

Use curl or embed the HTTP calls in your software to submit check results.

curl -u user:password -d "time_stamp=$(date +%s)&host_name=host-checked&service_description=service-checked&return_code=0&output=Everything OK" http://shinken-srv:7760/push_check_result

Example with more readability:

```
curl
```

-u user:password -d "time_stamp=$(date +%s)

```
&host_name=host-checked
&service_description=service-checked
&return_code=0
&output=Everything OK
http://shinken-srv:7760/push_check_result
```

SNMP module This part must be splitted and sent in all module repositories

Shinken integrated SNMP Module

SnmpBooster Download Install and Configure

- *What is the SnmpBooster module*
- Install and configure the SNMP acquisition module. [You are here]
- *Reference - SnmpBooster troubleshooting*
- *Reference - SnmpBooster design specification*
- *Reference - SnmpBooster configuration dictionnary*

Downloads

The SnmpBooster module and genDevConfig are currently in public beta prior to integration within Shinken. You can consult t

- github.com/xkilian/genDevConfig
- github.com/titilambert/shinken/tree/snmp_booster/shinken/modules (snmp_booster branch) * Simply right-click and download snmp_poller.py then copy it to shinken/modules/

Requirements The SnmpBooster module requires:

- Python 2.6+
- Shinken 1.2+
- PySNMP 4.2.1+ (Python module and its dependencies)
- ConfigObj (Python module)
- python-memcached
- memcachedb or memcached package for your operating system (ex. For Ubuntu: apt-get install memcachedb) *Note*

The genDevConfig profile generator depends on:

- Perl 5.004+
- 4 perl modules available from CPAN and network repositories. genDevConfig/INSTALL has the installation details.

STRONGLY RECOMMENDED: Use the same version of Python and Pyro on all hosts running Shinken processes.

Installation SnmpBooster:

- Install the dependencies
- Copy the file snmp_poller.py from the git repository to your shinken/modules directory.
- Configuration steps are listed in the present web page.

genDevConfig:

- Download and extract the archive to your server.
- See genDevConfig/INSTALL on how to install and configure it.

Configuration

How to define the SnmpBooster module in the Shinken daemons You need to modify shinken-specific.cfg, which is located in $shinken/etc/shinken-specific.cfg

Arbiter daemon configuration Simply declare the module:

```
modules SnmpBooster</code>
```

Scheduler daemon configuration

Simply declare the module:

<code>modules SnmpBooster

Poller daemon configuration Simply declare the module:

```
modules SnmpBooster</code>
```

SnmpBooster Module declaration

Included in Shinken v1.2.1 shinken-specific.cfg.

<code>define module {

```
module_name          SnmpBooster
module_type          snmp_poller
datasource           /usr/local/shinken/etc/packs/network/SnmpBooster/   ; SET THE DIRECTORY FOR YOUR
memcached_host       x.x.x.x  ; SET THE IP ADDRESS OF YOUR memcached SERVER
memcached_port       11211  ; default port for a memcached process
```

}

If you do not know the IP adress on which your memcache is listening, check under /etc/memcached.conf. Or do a:

```
netstat -a | grep memcached</code>
If you are running a test on the local machine you can leave memcached on 127.0.0.1 (localhost), but
```

How to define a Host and Service

Step 1

Create a template for your SNMP enabled devices.

Sample template:

<code>cd shinken/etc/packs/network/ mkdir SnmpBooster

vi shinken/etc/packs/network/SnmpBooster/templates.cfg

```
define command {
```

```
command_name    check_snmp_booster
command_line    check_snmp_booster -H $HOSTNAME$ -C $SNMPCOMMUNITYREAD$ -V 2c -t $ARG1$ -i $_SERVICE
module_type     snmp_poller
```

}

```
define service {
```

```
name                    default-snmp-template
check_command           check_snmp_booster!$_SERVICEDSTEMPLATE$!$_SERVICEINST$!$_SERVICETRIGGERGROUP
_inst                   None
_triggergroup           None
max_check_attempts      3
check_interval          1
retry_interval          1
register                0
```

}

```
define host{
```

```
name                    SnmpBooster-host
alias                   SnmpBooster-host template
check_command           check_host_alive
max_check_attempts      3
check_interval          1
retry_interval          1
use                     generic-host
register                0
```

}

Step 2 Define some hosts and services. You would typically use genDevConfig or another configuration generator to create these for you.

Mandatory service arguments related to SNMP polling:

```
_dstemplate                Cisco-Generic-Router  ; Name of a DSTEMPLATE defined in the SnmpBooster co
```

```
snmpcommunityread    which is set in your resource.cfg file
```

Optional service arguments related to SNMP polling with default values:

```
_inst                   None   ; Could be numeric: 0, None or an instance mapping function like: map
```

```
_triggergroup           None   ; Name of the triggergroup defined in the SnmpBooster config.ini file
```

Sample Shinken host and service configuration:

```
# Generated by genDevConfig 3.0.0
# Args: --showunused -c publicstring 192.168.2.63
# Date: Thu Aug 30 17:47:59 2012

#######################################################################
# Description: Cisco IOS Software, C2960 Software (C2960-LANBASEK9-M), Version 12.2(50)SE4, RELEASE S
#     Contact:
# System Name: SITE1-ASW-Lab04
#    Location:
#######################################################################

define host {
```

```
 host_name            192.168.2.63
 display_name         192.168.2.63
 _sys_location
 address              192.168.2.63
 hostgroups
 notes
 parents
 use                  default-snmp-host-template
 register             1
}

define service {
```

```
 host_name            192.168.2.63
 service_description  chassis
 display_name         C2960 class chassis
 _dstemplate          Cisco-Generic-Router
 _inst                0
 use                  default-snmp-template
 register             1
}

define service {
```

```
 host_name            192.168.2.63
 service_description  chassis.device-traffic
 display_name         Switch fabric statistics - Packets per Second
 _dstemplate          Device-Traffic
 use                  default-snmp-template
 register             1
}

define service {
```

```
host_name            192.168.2.63
service_description  if.FastEthernet0_1
display_name         FastEthernet0_1 Description: Link to Router-1 100.0 MBits/s ethernetCsmacd
_dstemplate          standard-interface
_inst                map(interface-name,FastEthernet0_1)
use                  default-snmp-template
register             1
```

}

Here is an example configuration of the config.ini file

```
[DATASOURCE]
```

```
  OidmyOidDefinition = .1.3.6.1.45.0
  [myOidDefinition] ; Use the same name as the myOidDeiniftion, but omit the leading "Oid"
      ds_type = DERIVE
      ds_calc = 8,*  ; RPN expression : Oid, 8, *  Which means Oid * 8 = ds_calc
      ds_oid = $OidmyOidDefinition
[DSTEMPLATE]
```

```
  [myCiscoRouter]
      ds = myOidDefinition
[TRIGGER]
```

```
  [trigger1]
      warning = RPN expression
      critical = RPN expression
  [trigger2]
      warning = RPN expression
      critical = RPN expression
[TRIGGERGROUP]
```

```
[CiscoRouterTriggers]
    triggers = trigger1, trigger2
```

Shinken integrated SNMP Module

Overview

What is it The SnmpBooster module allows Shinken Pollers to directly manage SNMP data acquisition. This is an all Python cross-platform SNMP module. It is tightly integrated with the Shinken Poller, Scheduler and Arbiter daemons to provide the best possible user experience.

- Jump back to *SnmpBooster documentation index*

Design specification summary

- STATUS - DESIGN SPEC PERFORMANCE
- [Done] Functions as an integrated Shinken Poller module
- [Done] Necessary integration code commited to Shinken official release (Integrated starting at v1.2)
- [Done] Ability to collect thousands of SNMP metrics per second
- [Done] Be compatible with distributed data acquisition
- [Done] Collect data for a host/check_interval tuple via SNMP in a single pass
- [Done] Use all builtin Shinken scheduler logic for retries, forced checks, timeouts, dependencies, parents
- [Done] Store collected data for the duration of the check_interval in a memcached/membase
- [Done] On a restart, after the first collection, be able to pick up where the last check left and calculate derived values
- [Done] Forced check are not allowed within 30 seconds of last SNMP query to the same host/check_interval, all other requests get data from the cache.
- [Done] Only a single request to the host/check_interval via SNMP is allowed at a time, all other requests get data from the cache.
- STATUS - DESIGN SPEC USABILITY
- [Done] Usage documentation
- [xxxx] SkonfUI and Discovery usage documentation
- [xxxx] Provide sample configuration packs in Shinken
- [Done] Provide sample config.ini with examples of all types of data * SNMP OIDS, DATASOURCES, DSTEMPLATES, TRIGGERS and TRIGGERGROUPS

- [Done] Directly compatible for use with genDevConfig Shinken SNMP configuration generator
- [Done] Provide meaningful feedback for users on errors
- [Done] Capture all tracebacks and convert them to actual error or warning messages
- STATUS - DESIGN SPEC FEATURES
- [Done] Return state and performance metrics
- [Done] Performance metrics can be returned in a Weathermap compatible format
- [Done] Configuration file format is ConfigObj INI
- [Done] Load all valid INI configuration files from a directory and merge them
- [Done] Load a single INI configuration file
- [xxxx] Load a list of INI configuration files
- [Done] Configuration file describes all generic acquisition parameters (OID, DATASOURCE, DSTEMPLATE, MAP, TRIGGER, TRIGGERGROUP)
- [Done] Supports Triggers which are calculation rules to determine states
- [Done] Triggers support an RPN (Reverse Polish Notation) calculation engine which includes mathematical and logical operators
- [Done] Each TRIGGER is associated with a severity level, WARNING or CRITICAL
- [Done] Multiple TRIGGERS can be associated with a TRIGGERGROUP
- [Done] Use builtin Python Operators
- [Done] Support DERIVE, TEXT, GAUGE and COUNTER data types
- [xxxx] Support TIMETICKS data type
- [Done] Support applying RPN based calculations to received metric for scaling or conversion purposes
- [Done] Use a Python SNMP library which supports asynchronous acquisition PySNMP
- [Done] Datasources can use rule based runtime instance mapping
- [Done] Set Snmp version as a check runtime option
- [Done] Set Snmp DSTEMPLATE as a check runtime option
- [Done] Set Snmp TRIGGERGROUP as a check runtime option
- [Done] Set Snmp COMMUNITY as a check runtime option
- [Done] Use Snmp version 2c GetBulk
- [xxxx] Support Snmp version 2c GetNext if GetBulk is not supported
- [xxxx] Support Snmp version 1 GetNext
- [xxxx] Set Snmp Timeout as a check runtime option, instead of a hardcoded value at 5 seconds
- STATUS - DESIGN SPEC MAINTAINABILITY
- [xxxx] Functions documented in the source code
- [Done] Critical functions documented in the source code
- [Done] Locking sections identified in the code
- [xxxx] Unit tests with at least 80% coverage

- [xxxx] Unit tests integrated with Shinken test suite
- [Done] Code hosted on github
- [xxxx] configuration validity and integrity checking of all INI files
- [xxxx] Pep8 compliant
- [xxxx] Pylint pass

genDevConfig Plugins - Compatibility status with SnmpBooster

- STATUS - genDevConfig maintained Plugins
- [Done] Avaya ES switches
- [Done] Avaya ERS routing switches
- [Done] Cisco 29x0 switches
- [Done] MIB-II Interfaces
- [Done] Cisco PIX/ASA
- [Done] JUNOS devices
- [Done] Cisco IOS routers
- [Done] NetSNMP unix hosts ** Validation required**
- [Done] Packeteer devices ** Validation required**
- [Done] Sensatronics devices ** Validation required**
- [Done] Foundry devices ** Validation required**
- [Done] Packeteer devices ** Validation required**
- [Done] Cisco CSS ** Validation required**

SnmpBooster.ini dictionary

There are five dictionaries:

- [DATASOURCE]
- [DSTEMPLATE]
- [MAP]
- [TRIGGER]

- [TRIGGERGROUP]

DATASOURCE DICTIONARY OidVariableName refers to an actual OID that can be queries using SNMP against the device on the network.

[VariableName] refers to a Datasource and all the information required to gather and prepare the data using SNMP ds_type refers to how the data should be prepared ds_calc refers to any scaling manipulations to make the data more understandable. This is an RPN expression, where the first variable is omitted, as it is always the $OidVariable ds_oid refers to the actual $OidVariable name. An instance identifier can be appended to the name to signify that an instance is provided by the Shinken service definition. This information is passed when the check is called. ...

DSTEMPLATE DICTIONNARY [DsTemplateName] refers to the name of the DSTEMPLATE that will be referred to in the Shinken service definitions. ds refers to the list of DATASOURCES to be collected. If an instance is expected for the list of DATASOURCES, it MUST be the same instance for all Oids. If a different instance is required, use a second DSTEMPLATE.

TRIGGER DICTIONNARY

TRIGGERGROUP DICTIONNARY

MAP DICTIONNARY

SnmpBooster.ini example configuration This example definition will be used to explain each section.

[DATASOURCE]

```
OidmyOidDefinition = .1.3.6.1.45.0
[myOidDefinition] ; Use the same name as the myOidDeiniftion, but omit the leading "Oid"
    ds_type = DERIVE
    ds_calc = 8,*  ; RPN expression : Oid, 8, *  Which means Oid * 8 = Total
    ds_oid = $OidmyOidDefinition
```

[DSTEMPLATE]

```
[myCiscoRouter]
    ds = myOidDefinition
```

[TRIGGER]

```
[trigger1]
    warning = RPN expression
    critical = RPN expression
[trigger2]
    warning = RPN expression
    critical = RPN expression
```

[TRIGGERGROUP]

```
[CiscoRouterTriggers]
    triggers = trigger1, trigger2
```

SnmpBooster.ini configuring SNMP Datasources

The first location is generic data related to SNMP parameters.

- DATASOURCE information * SNMP OID * Type of data and how can it be interpreted (GAUGE, COUNTER, COUNTER64, DERIVE, DERIVE64, TEXT, TIMETICK) * Data format preparation (Scaling the data for example bits to bytes) * Is there an instance to append to the
- Instance MAP function * Mapping the instance dynamically using a function * Data or rules related to the mapping function

SnmpBooster.ini configuring SNMP DSTEMPLATES

- DSTEMPLATEs to associate DATASOURCE to actual device classes * List of DATASOURCES associated with a, for example, Cisco 1900 router. Which in turn can be applied to a Shinken service

SnmpBooster.ini setting triggers/thresholds

- TRIGGER and TRIGGERGROUPS to apply thresholding rules * Define triggers and associate them with a TRIGGERGROUP name that can be applied to a Shinken Service

Shinken integrated SNMP Module

Overview

- Jump back to *SnmpBooster documentation index*

Tip: The module is now in public beta as of 2012-10-26! Have Fun!

Nothing new to add, more to come in 2013. 2013-01-19.

What is it The SnmpBooster module allows Shinken Pollers to directly manage SNMP data acquisition. This is an all Python cross-platform SNMP module. It is tightly integrated with the Shinken Poller, Scheduler and Arbiter daemons to provide the best possible user experience.

Why use it The SnmpBooster module is designed to be very efficient and scalable. It has a very flexible configuration method to make it easy to use with Shinken Monitoring Packs and Shinken discovery runners like genDevConfig.

This acquisition module was professionally designed and developed.

It is meant to be used by the very capable discovery engine genDevConfig (**v3.0.5 and newer**) originally developed for the Cricket SNMP monitoring tool and converted for use with Shinken.

It is one of the very few serious SNMP v2c implementation making use of SnmpGetBulk type requests.

How does it work

Shinken Integration

1. The SnmpBooster Arbiter module reads the Shinken SnmpBooster configuration file(s). It reads the check commands and based on the values in the check commands that use the snmp_poller module it will creates a shared configuration cache using memcached/memcachedb. The memcache key is always the combination of the hostname. This permits to tie together Shinken Hosts and Services with the SNMP specific configuration. (MongoDB and Redis are planned to be supported in the future) The Scheduler daemon schedules Host and Service checks as it normally does.

3. The SnmpBooster module will check that a memcache host key exists for the check to be launched. Then the SnmpBooster poller module will query all services related to a host for a given acquisition frequency in one pass. (all checks done every 2 minutes will be executed in bulk, same for those every 5 minutes)

5. Check results are cached for the acquisition check_interval. The next time a check request for data from the same host is received from the Scheduler, the data will be fetched from memcache. Resulting is extremely low check latency.

2. 6. The SNMP checks still benefit from retries, timeouts, forced checks, dependencies and the powerful Scheduler daemon logic.

6. The Scheduler daemon can still force an immediate re-check by flushing the cache. This is required for the dependency model.

Performance SnmpBooster uses SNMP v2c getbulk for high efficiency, unless forced to use SNMP v2c get-next or SNMPv1 get-next. GetBulk uses a single request PDU to ask for multiple OIDs or even entire tables, instead of sending one request PDU per OID.

For example: *A typical 24 port network switch with two uplinks might use 375 OIDS (8 OIDs per interface, plus general OIDs for chassis health, memory, cpu, fans, etc.). **SnmpBooster will only require around 4 request PDUs*

*instead of 375 request PDUs**. Each PDU is a request packet which takes time to create, send get processed and return. More timeouts to manage, more connections, more impact on the remote device and more latency means much fewer checks per second.*

The SnmpBooster module supports automatic instance mapping for OIDs. (Ex. Based on the interface name it will figure out that the SNMP index(or instance) is 136. This is automatically handled by genDevConfig and SnmpBooster, no user input required. :-)

The generic SNMP configuration information is stored in the Shinken SnmpBooster INI files. There is a Defaults_unified.ini and a series of other Defaults files, one per discovery plugin for genDevConfig.

Important: genDevConfig plugins have all been converted to use the new dynamic instance mapping methods. You are now free to use most if not all Defaults*.ini files included with genDevConfig. 2012-10-28

Limitations You should have memcached instances running on each poller responsible for snmp polling. You should have your pollers with SnmpBooster in the same datacenter, as they need to be on the same machine with good connectivity to the active memcached instance. SnmpBooster is not compatible with distributed pollers in multiple datacenters, sorry, the current design of SnmpBooster uses a single centralized memcached instance for storing the timeseries data. For distributed datacenters to be supported, each poller+scheduler+memcached must be realm restrained, which is not the case today.

Design specification *SnmpBooster design specification* and current development status.

Data model The information required to define the data is split in two locations.

The first location is the host and service Shinken configuration (You need to generate or write this)

- Device specific information
  - IP addresses, host_names, device types, instance keys
  - A DSTEMPLATE must be referred to in the Service definition
  - A static SNMP instance could be referred to in the Service definition
  - An SNMP instance MAP function could be referred to in the Service definition
  - A TRIGGERGROUP could be refered to in the Service definition

The second location is SNMP Defaults.* templates. (Here you can create new devices or add new data sources)

- DATASOURCE information
  - SNMP OID
  - Type of data and how can it be interpreted (GAUGE, COUNTER, COUNTER64, DERIVE, DERIVE64, TEXT, TIMETICK)
  - Data format preparation (Scaling the data for example bits to bytes)
  - Is there an instance to append to the
- Instance MAP function * Mapping the instance dynamically using a function * Data or rules related to the mapping function
- DSTEMPLATEs to associate DATASOURCE to actual device classes * List of DATASOURCES associated with a, for example, Cisco 1900 router. Which in turn can be applied to a Shinken service
- TRIGGER and TRIGGERGROUPS to apply thresholding rules * Define triggers and associate them with a TRIGGERGROUP name that can be applied to a Shinken Service

A final location containes rules to build your Shinken configuration.

- genDevConfig plugins create Shinken configurations

Installation and configuration *SnmpBooster installation*

Reference Dictionnary *SnmpBooster reference dictionary*

Troubleshooting *SnmpBooster troubleshooting*

Graph templates These are .graph files defined in your Shinken configuration directory. Refer to the Shinken graphite templates(Not yet created) or PNP4Nagios how-to documentation. The graph templates are independent from SnmpBooster and provide templates for any collected data from Shinken.

SnmpBooster Troubleshooting

- Jump back to *SnmpBooster documentation index*

Check your config

- Have you defined the poller module name?
- Have you defined the correct path to the directory containing your Defaults*.ini files?
- Have you addded the Snmpbooster module to your arbiter, poller, scheduler?
- Have you added copied the genDevConfig templates.cfg in shinken/packs/network/SnmpBooster/
- Have you installed PySNMP, memcached and other dependencies?

Software version consistency Shinken and SnmpBooster now require **the same Python and Pyro version on all hosts running a Shinken daemon**.

If you cannot use the packaged version of Python and its modules (Pyro, memcached, etc.). Use virtualenv to declare a python version to use and install all required modules in that virtualenv.

Software version requirements Have you verified that the *requirements* are met. Python, PySNMP, Shinken, Pyro, memcached, etc.

Validate your check command arguments Use the check_plugin command and comment out the module to learn what were the exact arguments sent by the poller. This will permit you to validate all the arguments, like snmp community string, inheritance, template application, etc.

Validate connectivity

Take a packet trace using a tool like Wireshark to validate that the remote host is responding.

- Has the host responded
- **Is SnmpBooster repeating the request more often than the polling interval.**
  - If you are seeing repeated requests your device may have a compatibility issues.

- Save an snmpwalk of the device, get a packet trace using Wireshark, set the poller to debug and save the poller.log file (shinken/var/poller.log). Send all three to the SnmpBooster developers.
- Note: It is normal to see one or more bulkGet requests if you are getting large amounts of data. Ex. a 24 port switch will take 2-3 request packets.

Performance Make sure you have a low latency connection to your memcache from the Poller. Your memcache server can be replicated to all your poller hosts that should also run memcache instances. Check that memcached is running: netstat -a | grep memcached

Faulty Template A bad snmp_template file was distributed in the genDevConfig sample-config directory, there were two glaring errors.

This was fixed on 2012-10-16. Make sure you update your template, or use the data from the wiki.

Note that the template should be called: SnmpBooster-template.cfg to make it easier to troubleshoot in the logs. So when you search for SnmpBooster in your logs it will show up as well.

Log files All warnings and errors generated by the SnmpBooster module start with "[SnmpBooster] error text" and are logged using the standard Shinken logger.

The Arbiter daemon can output initial configuration, loading of host keys and intervals in memcached type error messages. The Scheduler daemon can output scheduling and alert related messages. The Poller daemon can output messages related to instance mapping, acquisition timeouts, invalid community strings, cache failures and more. These are available in the Web interface, as they are placed in the check results for the service.

You can simply do a "grep SnmpBooster *" in your shinken/var directory to see the latest messages related to the SnmpBooster module. You can also sort messages by timestamp to make it easy to find where and when errors occurred.

cd shinken/var grep SnmpBooster *

memcache persistence If you restart your memcache server or memcache crashes, your poller will no longer be able to validate that a host exists in memcache prior to writing.

You should use memcachedb to achieve persistence in case of memcache failures.

Common errors returned by SnmpBooster in the log file Errors should be fairly explicit and mean what they say, though there can be exceptions. Lets try to clear some of them.

__Arbiter log **errors__**

Missing ds_oid : This means that a variable in your OID definitions is missing, or your DATASOURCE is not named correctly or your ds_oid variable is missing. There is a typo in your ds_oid variable (ex. ds-oid, or ds_oid = $OidNameIncorrectFFFRA.%(instance)s).

Datasource not defined : Your DSTEMPLATE uses a DATASOURCE that doesn't exist check the [DataSourceName] you are referring to. Does it contain the expected OID variable, $OidName.

Missing ds_type : The DATASOURCE always needs to have a ds_type definition, GAUGE, COUNTER, DERIVE, TEXT, TIMETICK, DERIVE64, COUNTER64.

__Poller log **errors__**

Problems with calculations, repeated polling, hosts not responding, etc.

__Memcached **errors__**

memcachedb and memcached do not use the same default port. Configure the correct memcachedb port to match what is declared in your SnmpBooster module under shinken-specific.cfg.

On Ubuntu 12.04 the default installation is on port 21201 instead of 11211. This causes the error "[SnmpBooster] Memcache server (127.0.0.1:11211) is not reachable" when Shinken starts.

To change it, you must edit the file /etc/memcachedb.conf

Memcached Notes On Ubuntu 12.04 the default instalation is on port 21201 instead of 11211. This causes the error "[SnmpBooster] Memcache server (127.0.0.1:11211) is not reachable" when shinken starts.

To change it, you must edit the file /etc/memcachedb.conf

WebUI module This part must be splitted and sent in all module repositories

WebUI integration with Shinken The WebUI is an external broker module. So it's an external process launched by the broker that "eats" broks (broker messages) from the brokers. So it can get *all* broks if you place this broker in your top level realm.

The WebUI does not use a database to get data. Instead, it use a "regenerator" object that will eat each broks, and will "recreate" all Hosts/Services/Contacts objects as if the code was in the scheduler daemon. So basically, WebUI and pages always reflect the CURRENT state of hosts/services objects.

The WebUI http layer is managed by bottle.py. It's a small but powerful framework.

How does the WebUI function globally ?

There a 2 Threads running:

- the main thread is the bottle.py (http) listener. It will use the best backend it finds. We recommend using python-paste. If it does not find one, it will use the default swsgi. Paste is multi-thread, swsgi is mon-thread, so please use paste if you want to avoid locking problems.
- the 2nd thread is the regenerator one. It only gets broks and gives them to the regenerator object.

There is a lock system between the threads. You can have N Http requests in progress without problem, but during this time the renererator one will wait. During execution of the regenerator, no requests are processed. This is not considered a problem, as the regenerator is very quick, and there is only a 1s lock for a 7k service conf loading, so it's not a huge problem.

What is a WebUI User? A WebUI user is a contact. A true contact object. You must match a contact name for your user.

To create a new page? All pages are in the shinken/webui/plugins directory. Each "part" has it's own directory. A part (like the eltdetail, element detail) can have more than one "page" (like /host or /service for eltdetail).

From here we will supose you want to create a "/contact" page.

You can copy the dummy example in the plugins directory into a contact directory.

You need to change the contact/dummy.py file into a contact/contact.py file, because the webui will search for a dir/dir.py file to "load".

Templates Templates are HTML with some Python code in it in the plugins/*/views direcotry for specific templates, and the "global layout" (menu and all common part) in the webui/views directory.

Your template must call the template layout (layout.tpl in the webui/views directory) wit ha "rebase" call.

If you put the rebase call at the beginning of your template, all there is below will be place "inside" the layout that will call the common javascripts and css, make the menu adn then call your html/python code.

The rebase call can take arguments. You MUST give it:

- user: the user you give it in the return dict of your .py code

Then all is optional:

- title: title of the page
- top_right_banner_state: int, global state with clouds to put in your top right page. Look at the problem.tpl code for an example.
- js and css list: list of YOUR specific javascript or css to call AFTER the common ones.
- refresh: boolean, set the refresh to 60s or do not refresh at all

- menu_part: will put the little "^" under this part of the menu.

Example of a call, taken from the problems view:

```
rebase layout title='All problems', top_right_banner_state=top_right_banner_state, js=['problems/js/a
roblems/js/autocompleter.Request.js', 'problems/js/autocompleterObserver.js'], css=['problems/css/acc
ms/css/autocompleter.css', 'problems/css/perfometer.css'], refresh=True, menu_part='/'+page, user=use
```

Call Python objects in your templates Your templates are mainly HTML code. But of course you can call python code in it. The dict you returns in the plugin.py call will be available in this page.

For example, the my_host variable will be available in the page with the host object you find (or None if your give it a bad name of course). Then you can "call" python with for example here to show the host_name: `<span>My host name is *my_host.host_name* </span>` is a way in the templates to "call a variable or function" that will return a string, here the host_name.

If the function or property you call must return HTML code that SHOULD be output as it, without "protection", you must put a ! before your call.

Let use an example where the output value of an host is in fact an html output. If you use the code `my_host.output`, bottle.py will "protect" the html generated by escaping the string, and change <> characters with escaped value. You can change this by calling `my_host.output`. Of course, it's a security problem if the output is with a javascript code...

You can also "loop" or put "if" in your template. You just need to put your code with a % before. Like

```
%for i in xrange(1, 10):
  My valus is  {{i}}
%end
```

You must put the %end here, the indentation will NOT be enougth, sorry.

For an if it's also easy:

```
%if host.active_checks_enabled:
  The host got active checks enabled
%else:
  The host DO NOT have active check enabled
%end
```

Which javascript lib are you using? It's mootools 1.3 with all options :)

What to do?

- Finish the /mobile part
- List of current alerts
- Host info
- Host status
- Host interfaces
- Hostgroup status
- dashboard hierachique with states, and BP
- Nagvis
- add bp in nagvis auto-map

- event sources
- correlation
- pre-filtering/enrichment
- user profile
- host/srv conf

WebUI search syntax work in progress

not that we couldn't tell. ;) eh eh

beware the working men and flying tools!

WebUI SSL Certification Lets start: the goal to to have the server.pem and client.pem file in etc/certs.

Go to the etc/certs directory.

```
openssl req -new -nodes -out server.req -keyout server.key -config ./shinken_openssl_cnf
openssl ca -out server.pem -config ./shinken_openssl_cnf -infiles server.req
cp server.pem server.pem.bkp
cp server.key server.pem
cat server.pem.bkp >> server.pem
cp server.pem client.pem
```

You can try to get the validity with for the arbiter with:

```
openssl s_client -connect localhost:7770</code>
```

Amazon AWS/EC2 import

Description You can import data from Amazon AWS/EC2 **'AWS'**_ into Shinken to create hosts.

Amazon provide VM hosting with EC2. With this arbiter module, you will be able to load your EC2 hosts into Shinken.

Prerequisites

You will need the **'libcloud'**_ package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

```
define module {
 module_name      AWS
 module_type      aws_import

 # Configure your REAL key and secret for AWS
 api_key              PAAAB2CILT80I0ZA0999
 secret           GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH
 default_template generic-host        ; if the host is not tagged, use this one
 }
```

- Put in key and secret your private Landscape access. * default_template will be used if your host is not "tagged" in Landscape

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master

     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           AWS
     }
```

Restart your Arbiter and it's done :)

Generated hosts The configuration generated will look as below :

```
define host {
    host_name            i-3fc56e5a
    address              8.8.4.4
    use                  t1.micro,MyTag,EC2,generic-host
    _EC2_AVAILABILITY    us-east-1a
    _EC2_CLIENTTOKEN
    _EC2_DNS_NAME
    _EC2_GROUPS          quicklaunch-1
    _EC2_IMAGEID         ami-1b814f72
    _EC2_INSTANCEID      i-3fc56e5a
    _EC2_INSTANCETYPE    t1.micro
    _EC2_KERNELID        aki-825ea7eb
    _EC2_KEYNAME         testaws
    _EC2_LAUNCHDATETIME  2012-09-26T12:19:38.000Z
    _EC2_LAUNCHINDEX     0
    _EC2_PRIVATE_DNS
    _EC2_PRIVATE_IP
    _EC2_PRODUCTCODE
    _EC2_PUBLIC_IP       8.8.4.4
    _EC2_RAMDISKID       None
    _EC2_STATUS          stopped
    _EC2_TAGS            demo:myvalue,use:MyTag
 }
```

Here with a stopped t1.micro instance with no name. You can put your how "use" parameter by adding a EC2 tag "use" on your VM. It will be output on the host configuration so you can setup the monitoring as you want. .. _libcloud: http://libcloud.apache.org/index.html .. _AWS: https://console.aws.amazon.com

Amazon AWS/EC2 import

Description You can import data from Amazon AWS/EC3 **'AWS'**_ into Shinken to create hosts.

Amazon provide VM hosting with EC3. With this arbiter module, you will be able to load your EC2 hosts into Shinken.

Prerequisites

You will need the **'libcloud'**_ package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

```
define module {
 module_name      AWS
 module_type      aws_import

 # Configure your REAL key and secret for AWS
 api_key              PAAAB2CILT80I0ZA0999
 secret           GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH
 default_template generic-host        ; if the host is not tagged, use this one
 }
```

- Put in key and secret your private Landscape access. * default_template will be used if your host is not "tagged" in Landscape

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master

     address          localhost                  ;IP or DNS adress
     port             7770
     spare            0
     modules           AWS
     }
```

Restart your Arbiter and it's done :)

Generated hosts The configuration generated will look as below :

```
define host {
    host_name            i-3fc56e5a
    address              8.8.4.4
    use                  t1.micro,MyTag,EC2,generic-host
    _EC2_AVAILABILITY    us-east-1a
    _EC2_CLIENTTOKEN
    _EC2_DNS_NAME
    _EC2_GROUPS          quicklaunch-1
    _EC2_IMAGEID         ami-1b814f72
    _EC2_INSTANCEID      i-3fc56e5a
    _EC2_INSTANCETYPE    t1.micro
    _EC2_KERNELID        aki-825ea7eb
    _EC2_KEYNAME         testaws
    _EC2_LAUNCHDATETIME  2012-09-26T12:19:38.000Z
    _EC2_LAUNCHINDEX     0
    _EC2_PRIVATE_DNS
    _EC2_PRIVATE_IP
    _EC2_PRODUCTCODE
    _EC2_PUBLIC_IP       8.8.4.4
    _EC2_RAMDISKID       None
    _EC2_STATUS          stopped
    _EC2_TAGS            demo:myvalue,use:MyTag
 }
```

Here with a stopped t1.micro instance with no name. You can put your how "use" parameter by adding a EC2 tag "use" on your VM. It will be output on the host configuration so you can setup the monitoring as you want. .. _libcloud: http://libcloud.apache.org/index.html .. _AWS: https://console.aws.amazon.com

The distributed retention modules The high availability allow the Arbiter to send a configuration to a spare scheduler, but a spare scheduler does not have any saved states for hosts and services. It will have to recheck them all. It's better to use a distributed retention module so spares will have all the information they need to start with an accurate picture of the current states and scheduling :)

Non distributed retention modules If you are just running tests on a single server, use the pickle or memcache retention modules You can also use MongoDB if you already have it installed for use with the WebUI.

MongoDB MongoDB is a scalable, high-performance, open source NoSQL database written in C++.

Step 1: Install MongoDB:

We will use mongodb package from 10gen repository, so we start by adding it in apt sources list:

```
echo 'deb http://downloads-distro.mongodb.org/repo/debian-sysvinit dist 10gen' > /etc/apt/sources.lis
apt-get update
```

And we install it:

```
apt-get install mongodb-10gen
```

And we install pymongo, the python interface to MongoDB, with easy_install to avoid packages versions problems (like here **'forums.monitoring-fr.org/index.php?topic=5205.0'_**):

```
apt-get remove python-pymongo
easy_install pymongo
```

And finally we start MongoDB :

```
/etc/init.d/mongodb start
```

Step 2: define a mongodb_retention module in your shinken-specific.cfg file:

```
define module {
  module_name MongodbRetention
  module_type mongodb_retention
  uri mongodb://localhost/?safe=true
  database shinken
}
```

Step 3: Declare a retention module for your scheduler(s) :)

Example:

```
#The scheduler is a "Host manager". It get hosts and theirs
#services. It scheduler checks for them.
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
     port     7768                  ; tcp port of the daemon

     #optionnal: modules for things as retention
     modules    MongodbRetention
     }
```

Step 4: Restart the Arbiter, and your Scheduler will now save its state between restarts. :)

Memcached Memcached is a distributed memory resident key/value server. It's very easy to install:

```
sudo apt-get install memcached
sudo /etc/init.d/memcached start
```

The shinken module also needs the python-memcache package to talk to this server.

```
sudo apt-get install python-memcache
```

To use it,

Step 1: define a memcache_retention module in your shinken-specific.cfg file:

```
define module{
     module_name      MemcacheRetention
     module_type      memcache_retention
     server           127.0.0.1
     port             11211
}
```

Step 2: Declare a retention module for your scheduler(s) :)

Example:

```
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
     port     7768                  ; tcp port of the daemon

     #optional: modules for things as retention
     modules    MemcacheRetention
     }
```

Step 3: Restart the Arbiter, and your Scheduler will now save its state between restarts. :)

Redis Redis is a distributed key/value server (on disk and in-memory). It's very easy to install:

```
sudo apt-get install redis-server
sudo /etc/init.d/redis-server start
```

The shinken module also need the python-redis package to talk to this server.

```
sudo apt-get install python-redis
```

Step 1: define a redis_retention module in your shinken-specific.cfg file:

```
define module{
     module_name      RedisRetention
     module_type      redis_retention
     server           127.0.0.1
}
```

Step 2: Declare a retention module for your scheduler(s) :)

Example:

```
#The scheduler is a "Host manager". It get hosts and theirs
#services. It scheduler checks for them.
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
```

```
    port     7768                  ; tcp port of the daemon

    #optionnal: modules for things as retention
    modules    RedisRetention
    }
```

Step 3: Restart the Arbiter, and your Scheduler will now save its state between restarts. :) .. _forums.monitoring-fr.org/index.php?topic=5205.0: http://forums.monitoring-fr.org/index.php?topic=5205.0

How to enable and use Livestatus module

Define the Livestatus module Start by reviewing the ''/etc/shinken/shinken-specific.cfg" file for this module:

```
define module{
```

```
module_name      Livestatus
module_type      livestatus
host             *       ; * = listen on all configured IP addresses
port             50000   ; port to listen on
database_file    /var/lib/shinken/livestatus.db
```

}

With these parameters:

- module_name: name of the module called by the brokers
- module_type: livestatus
- host: IP interface to listen to. The default is *, which means "listen on all interfaces".
- port: TCP port to listen to.
- socket: Unix socket to listen to.
- database_file: the path to the sqlite database file which is used to store the log broks/messages. The default is "var/livelogs.db"
- max_logs_age: the maximum age of the log messages (before they are deleted from the database). The default is 1 year. The argument to this parameter takes the form <number>[<period of time>], where <period of time> can be d for days, w for weeks, m for months and y for years.
- allowed_hosts: a comma-separated list of IP-addresses which are allowed to contact the TCP port. Please keep in mind that these **must be IP-addresses, NOT host names**. Because DNS lookups for every incoming livestatus request could hang up and therefore block the module.

Enable the Livestatus module Still in ''/etc/shinken/shinken-specific.cfg'', find the object Broker and add "Livestatus" to its "modules":

```
define broker{
```

```
    broker_name      broker-1
[...]
```

```
    modules          Simple-log,Livestatus
}
```

Disable human readable logs In ''/etc/shinken/nagios.cfg'', verify that the option **human_timestamp_log** is set to **0**.

In version 0.6.5, you can not have at the same time a simple-log file with human readable timestamp and a Livestatus database.

Exporting data for reporting Shinken can export necessary data for reporting in 3rd party systems.

raw_socket module The raw socket module exports reporting data using a syslog format to a raw TCP socket. Theses logs can be captured, parsed and indexed by any log management system like Splunk or Logstash.

Why export reporting data Custom UIs like Thruk, Multisite, WebUI, Adagios, Nagios IX, etc. All have poor or inflexible reporting. Simply because these are not reporting engines.

This also permits to have a generic reporting method that can accept data from any Nagios, Shinken, Icinga or even Riemann.

Reporting module using Splunk Splunk was selected as the reporting platform for creating, managing and presenting reports. Though the raw_socket module does not have any Splunk specific particularities. It is notable that Splunk reports can be embedded in any 3rd party UI using its REST API.

Raw_socket log format The logs are plain-text and compliant with RFC3164. They use an intelligent date format, a configurable seperator " "(space by default), and key=value pairs in the message data portion of the log. Should a key or value contain a space they must be double quoted. This is syslog using structured data without going to full out JSON that may not be compatible with all log management systems.

The message fields that are supplied in each status update in addition to the standard syslog header are:

- Hostname
- Servicename
- Business impact
- Host/Service status
- Host/Service previous status
- Acknowedgement status
- Maintenance status

Any time the maintenance, host, service or acknowledgement status changes, a log is sent by the Shinken raw_socket module.

Having all relevant data in each log makes it very easy to compute reports for given time periods.

The hostgroup or service group memberships, custom variables or any other configuration related data should be queried from the monitoring system using its API (Livestatus in the case of Shinken and Nagios).

Raw_socket module availability The module is available in both Shinken 1.4 and Shinken 2.0. The module will be integrated in master branches once unit tests and end-to-end testing is completed. 3rd quarter 2013.

Monitoring Linux System with Glances and checkglances.py **'Glances'_** is a fantastic multiplatform system monitoring tool writen by Nicolargo. Glances can run on (Linux, Windows, MacOS ...). There is a growing ecosystem around Glances and of course a Nagios/Shinken plugin : checkglances.py.

How does it work Glances can run in server mode. It provide a XML-RPC server (over http) and allow to retrieve system information throuh a restful API. The only thing to do is to install and start Glances as server on the monitored host, then install checkglances.py on the shinken server and finaly install the glances pack.

Install glances See the glances documentation to install glances on Linux.

<code bash> easy_install glances </code>

There is a debian startup script in the glances repository. And another one for centos here.

Install checkglances.py Just follow the documentation for the checkglances.py prerequisites and put it in your nagios plugins folder.

Install the glances pack Open a terminal as the shinken user and just type the following command

<code bash> shinken install glances </code>

Then just edit the configuration for a linux monitored host and tag it as **glances**

```
define host{
 name mylinuxhost
 use glances
 ...
```

Finaly restart the shinken arbiter

```
service shinken-arbiter restart
```

What will be monitored ? For the moment just the basic system (ram, cpu, load, memory, filesystem and network).

If you want to modify the default thresholds for just a host you can do it by overiding the thresholds macro in your host definition. If you want to do it for several hosts, declare a new template and just add the desired thresholds macro to be overide.

Here is a list of the macros

```
::
```

> _LOAD_WARN 2 _LOAD_CRIT 3 _CPU_WARN 80 _CPU_CRIT 90 _MEMORY_WARN 90 _MEMORY_CRIT 95 _FS /, /home _FS_WARN 90 _FS_CRIT 95 _IFACES eth0, eth1 _NET_WARN 7500000 _NET_CRIT 10000000

Note the _FS and _IFACES macros. They leverage the ability to duplicate service for a given list of things to be monitored. Here you see that / and /home partitions will be monitored. If you want to modify this then just add your own in a new template that will inherit the glances template.

Shinken GLPI integration Shinken supports importing hosts from GLPI

For people not familiar with GLPI, it is an Open-Source CMDB. Applicable to servers, routers, printers or anything you want for that matter. It is also a help-desk tool. GLPI also integrates with tools like FusionInventory for IT inventory management.

You can still have flat files AND GLPI if you want. Hosts imported from GLPI will be treated as standard hosts from flat file (inheritance, groups, etc). In fact, in this first version the module only sends the host_name to Shinken, but there should be more information extracted like network connexions for parents relations in the future. :)

Requirements

- python module MySQLdb
- Compatible version of GLPI Shinken module and GLPI version - ...
- etc..

Enabling GLPI Shinken module In your shinken-specific.cfg file, just add (or uncomment):

```
#You know GLPI? You can load all configuration from this app(
#with the webservices plugins for GLPI, in xmlrpc mode
#and with plugin monitoring for GLPI)
# =============== Work with Plugin Monitoring of GLPI ===============
#All configuration read from this will be added to the others of the
#standard flat file
define module{
     module_name      GLPI
     module_type      glpi
     uri              http://localhost/glpi/plugins/webservices/xmlrpc.php
     login_name       glpi
     login_password   glpi
}
```

And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master
#    host_name       node1       ;result of the hostname command under Unix
     address          localhost                  ;IP or DNS adress
     port             7770
     spare            0
     modules           GLPI
     }
```

It's done :)

Ip Tag module

Why tag a host based on it's IP address? We learned on the *DMZ monitoring* that you can "tag" a host with a poller_tag so it will be checked only by DMZ pollers. It can be tedious process to manually tag all these hosts. Shinken provides an automated method to do this.

This is handled by the arbiter ip_tag module.

Ip_tag module The ip_tag module is an arbiter module that looks up the host address during the configuration parsing and compares it to an predefined IP range (IPV4 or IPV6). If the range matches, it can apply or add a property, such as poller_tag. Other types of tags could be related to locations, functions, administrative groups, etc.

Method: replace or append.

replace will put the value if the property is unset. This is the default method. .. warning:: Fix me: replace, implies overriding an existing value. And will cause user issues down the line. Rename it to set. Replace should be a different method altogether, so overall there should be 3 methods(set, append, replace).

append will add with a , if a value already exist

Here is an example that will set the poller_tag property with the value DMZ of all hosts that:

- have a their hostadress ip (or name resolved) in the range 192.168.0.1/24.
- do not already have a poller_tag property set

```
define module{
```

```
     module_name     IpTag
     module_type     ip_tag
     ip_range        192.168.0.1/24
     property        poller_tag
     value           DMZ
}
```

To use the module add it in the arbiter object:

```
::
```

define arbiter { [...] modules NSCA,IpTag

}

Add value instead of setting it In the previous example we set the property poller_tag to a value. But what if we want to "add" a value, like a template name? We can change the "method" property of the module to "append" so we can add the "value" to the host property instead of replace it.

Here is an example where we want to add the "dmz" template on the hosts, while also keeping any defined templates:

```
define module{
```

```
     module_name   IpTag
     module_type   ip_tag
     ip_range      192.168.0.1/24
     property      use
     value         dmz

     # Optional method
     method append
}
```

For a host defined as:

```
define host{
```

```
     host_name   example_host1
     address     192.168.0.2
     use         linux
}
```

It will be "changed" internaly in:

```
define host{
```

```
     host_name   example_host1
     address     192.168.0.2
     use         linux,dmz
}
```

Name resolution Of course you don't need to set IP address in the address of your host. You can set a hostname, and it will be resolved, and then compared to the range. :)

Ubuntu Landscape import

Description You can import data from Ubuntu Landscape into Shinken to create hosts.

Ubuntu Landscape, is a web app to manage all your linux servers (update and co), which is provided by Canonical, Ubuntu's parent company.

This is an Arbiter import module. The Arbiter manages the configuration.

Prerequisites

You will need the landscape-api package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

define module { module_name Landscape module_type landscape_import

Configure your REAL key and secret from Landscape key PAAAB2CILT80I0ZA0999 secret GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH default_template generic-host ; if the host is not tagged, use this one

If you are using a specific certificate for landscape_api #ca /path/to.ca.cert

If you need a proxy to access https://landscape.canonical.com/api/ #https_proxy http://user:secret@myproxy.com:3128

}

- Put in key and secret your private Landscape access.
- default_template will be used if your host is not "tagged" in Landscape
- If you are using a specific certificate for connexion, give the full path in ca
- You will certainly need an https proxy to access the Landscape API. If so, configure it there.

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master
#    host_name       node1       ;result of the hostname command under Unix
     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           Landscape
     }
```

Restart your Arbiter and it's done :)

Tip: Your "tags" will be applied as templates for your hosts.

Shinken Livestatus API

Overview

- Jump back to Getting Started
- Jump back to *Livestatus module configuration*

What is it Livestatus API is the modern method of interacting with Shinken and Nagios based systems alike.

Originally developed for Nagios, MK Livetstatus, was re-implemented in Python for use with Shinken by professional developers. The access methods and query languages are the same.

Why use it It is fast.

It is network based using TCP.

It is standard for all Nagios and Shinken monitoring systems.

It uses in-memory structures for status data

It uses a back-end database for historical reporting

It uses an SQL based query language

It has a host of powerful nuts and bolts features (authentication, caching, connection persistence, multiple object methods (JSON, Python)).

What can I do with it? All programs and scripts use (or should use) this method to :

- Obtain the current state of hosts and services
- Obtain the current configuration related to hosts and services
- Send administrative commands (downtimes, comments, forcing checks)
- Filter information to display
- Obtain basic reports and event statistics

Shinken being a modern re-implementation of Nagios has additional features that are available in addition to the standard Livestatus API.

Shinken Livestatus API unique features can :

- Obtain Business Impact information
- Obtain intelligent dependency status hosts or services (combines dependency and parent information)
- Obtain Business Process states (same syntax as standard host and service queries)

How does it work Livestatus uses a powerful SQL-like query language. The standard methods and parameters are defined at :

'MK Livestatus reference methods and query language definition'_

Full list of Shinken Livestatus API methods:

'Shinken mapping.py methods'_

What software uses Livestatus to interact with Shinken

Well known Web frontends

- MK Multisite
- Thruk
- NagVis

- Splunk for Nagios

Mobile Web frontends

- get list

Scripts

- Downtime management scripts
- Debug scripts

Installing Livestatus Have you installed the required packages to use the Livestatus module? You can look at the requirement section of the *10 minute installation guide* for the *requirement lists*.

How to enable Livestatus Very simple, jump to the *Shinken Broker configuration* section to enable it. .. _Shinken mapping.py methods: https://github.com/shinken-monitoring/mod-livestatus/blob/master/module/mapping.py .. _MK Livestatus reference methods and query language definition: http://mathias-kettner.de/checkmk_livestatus.html

NSCA module The NSCA daemon module is used to receive send_nsca packets and submit them to the Shinken command pipe. The NSCA module can be loaded by the Receiver or Arbiter process. It will listen on port TCP/5667 for send_nsca packets.

Tip: Passive checks can be submitted *natively to the Shinken command pipe* or from remote hosts to modules, such as NSCA, AMQP or collectd, loaded in the Shinken Arbiter or Receiver process. AMQP is implemented for integration with the Canopsis Hypervisor, but could be re-used for generic messaging.

Note: The Shinken NSCA module implementation is currently limited to the "xor" obfuscation/encryption.

In your shinken-specific.cfg file, just add (or uncomment):

```
::
```

#You can send check result to Shinken using NSCA #using send_nsca command define module{

module_name NSCA module_type nsca_server host * port 5667 encryption_method 0 password helloworld

}

define receiver{

```
receiver_name    receiver-1
address          localhost
port             7773
modules          NSCA

timeout          3             ; 'ping' timeout
data_timeout     120           ; 'data send' timeout
max_check_attempts       3     ;  if at least max_check_attempts ping failed, the node is DEAD

#advanced
realm    All
}
```

This daemon is totally optional.

It's main goal is to get all passive "things" (checks but why not other commands) in distant realms. It will act as a "passive receive buffer" and will then dispatch the data or commands directly to the appropriate Scheduler or Arbiter process.

Data can be received from any Realm, thus the Realm option is nonsensical.

For now there is no init.d script to launch it. .. note:: Verify that the init script has been added.

It is launched like all other daemons:

```
bin/shinken-receiver -c etc/receiverd.ini
```

Tip: Alternatively, for small installations with you can configure a modules inside your Arbiter instead of the Receiver. It will listen the TCP/5667 port for send_nsca packets.

To configure the NSCA module in your Arbiter instead of Receiver. Add the NSCA module to your Arbiter object configuration.

```
::
```

define arbiter{ arbiter_name Arbiter-Master

 # host_name node1 ;result of the hostname command under Unix address localhost ;IP or DNS adress port 7770 spare 0 modules NSCA

}

Retention troubleshooting The retention file contains the state of your host and services, so that they are kept when shinken is restarted.

Sometimes you'll want to inspect (and possibly fix) the retention file, in case you need to work-around a bug or simply better understand what is stored there.

When you use the PickleRetention module in the scheduler (cf. ''define scheduler" in ''shinken-specific.cfg''), you can simply manipulate the retention file using Python.

For this you can use the following code.

- It assumes Shinken is installed in ''/opt/shinken" with the retention file in ''/tmp/retention.dat'':
- Run and play with it interactively using ''ipython -i inspect_retention.py''.

```
#!/usr/bin/python
import pickle
import sys
sys.path.append('/opt/shinken')
import shinken

r = pickle.load(file('/tmp/retention.dat'))
h = r['hosts']

# Example:
# [(k,v) for (k,v) in h['your_host'].items() if k.find('downtime') >= 0]
#
# del h['your_host']
#
# for k,v in r['services'].items():
#     if 'your_host' in k:
#         del r['services'][k]
```

To save your changes:

- Stop Shinken: ‘’service shinken stop’‘
- Save the pickle: ‘’pickle.dump(r, open(‘/tmp/retention.dat’, ‘w’))’‘
- Start Shinken: ‘’service shinken start’‘

NRPE Module

What is it The NRPE module allows Shinken Pollers to bypass the launch of the check_nrpe process. It reads the check command and opens the connection by itself. It scales the use of NRPE for active supervision of servers hosting NRPE agents.

The command definitions should be identical to the check_nrpe calls.

How to define it The definition is very easy (and you probably just have to uncomment it):

```
define module{
     module_name       NrpeBooster
     module_type       nrpe_poller
}
```

Then you add it to your poller object:

```
define poller {
    [...]
    modules   NrpeBooster
}
```

Then just tag all your check_nrpe commands with this module:

```
define command {
   command_name   check_nrpe
   command_line   $USER1$/check_nrpe -H $HOSTADRESS$ -c $ARG1$ -a $ARG2$
   module_type    nrpe_poller
}
```

That’s it. From now on all checks that use this command will use Shinken’s NRPE module and will be launched by it.

Extending Shinken

Introduction There are a lot of “Modules” and “Addons” that are available for Shinken. Shinken can be extended by using different types of methods.

- Web interfaces from various open-source vendors can be used (Based on Livestatus API)
- Shinken itself can be extended using modules that are embedded into the various daemon processes

** (Arbiter, Poller, Receiver, Broker, Scheduler, Reactionner) * External software can provide functional enhancements for reporting, management or usability aspects

Shinken itself provides methods to extend the base functionality:

- *Broker modules* provide external access to runtime data from Shinken
- Poller modules such as *NRPE* and the *SNMP*
- Receiver modules like *NSCA* provide acquisition methods for Shinken

- Arbiter modules permit manipulating the configuration
- The webUI that permits embedding web interface elements

Independent software that works in concert with Shinken is available for:

- Monitoring remote hosts through agent software (*NIX, Windows, etc.)
- Submitting passive checks from remote hosts
- Managing the config files through a web interface
- Mobile phone UIs
- Desktop UIs and Hypervisors
- Desktop notification addons
- ...and much more

You can find many addons that are compatible with Shinken by visiting. The only caveat is that the addons should not use the status.dat file and preferably the modern API interfaces like Livestatus:

- Nagios.org
- SourceForge.net
- NagiosExchange.org
- Shinken community exchange for monitoring packs

Broker modules The broker module receives messages from the Schedulers related to host, service check results. In addition to that it receives a copy of the compiled configuration at startup. What is special about the broker, is that without modules, the broker does nothing. It makes the configuration and result data available to modules. Modules are the ones in charge of doing something with the data. This could be exporting this "raw" data into flat files, databases or exposing it as an API.

The modules are presented according to their use cases.

- Core modules
- Livestatus Module for frontends
- Exporting data to metric databases
- SQL based Modules for frontends
- Exporting data to logging management systems
- Legacy modules for migration purposes
- Modules no longer supported

Core modules

simple_log: get all logs into one file You can get a log for all your daemons in a single file. With the exception of Debug level logs which are not sent through the network as a safe guard. Shinken state messages are ONLY logged at the debug level in the local log files. These are the ALL CAPS states that some 3rd party interfaces use to mine data from the historical logs. Actual state messages are sent as objects between the various daemons.

It takes the parameters:

- module_name: name of the module called by the brokers

- module_type: simple_log
- path: path of the log file

Here is an example:

```
define module{
```

```
     module_name      Simple-log
     module_type      simple_log
     path             /usr/local/shinken/var/nagios.log
     archive_path     /usr/local/shinken/var/archives/
}
```

Syslog - Send all logs to a local syslog server Send all logs to a local syslog server. Support for remote syslog can be implemented if requested. Just lookup the syslog module, easy to modify. Use for example with Splunk, graylog2, Logstash, Elastic search, Kibana, or other log management and analysis system.

```
define module{
```

```
  module_name Syslog
  module_type syslog
}
```

Lightweight forwarder to Splunk Shinken state data from the local syslog can also be sent to a Splunk server for indexing, reports, SLA and analysis. Via syslog or better yet, the Splunk lightweight forwarder which supports, TCP, buffering and security parameters.

Livestatus API Module - Thruk, Nagvis and Multisite Web frontends There are three well known frontends and various small tools that can interface with the Livestatus API. This API is currently the most efficient method of sharing live data with external interfaces. It provides a rich query language similar to SQL, authentication, command execution, caching,connections persistence, multiple object methods (JSON, Python). All Livestatus data is kept in memory, there is no disk IO involved. It exposes configuration objects, the current state of the hosts and services as well as historical Shinken state log messages.

- MK Multisite
- Thruk
- NagVis

Have you installed the required packages to use the Livestatus module? You can look at the requirement section of the 10 minute installation guide for the requirement lists.

Livestatus Module

It takes the following parameters:

- module_name: name of the module called by the brokers
- module_type: livestatus
- host: IP interface to listen to. The default is '127.0.0.1'. '*' means 'listen on all interfaces'.
- port: TCP port to listen to.
- socket: Unix socket to listen to.

- allowed_hosts: a comma-separated list of IP-addresses which are allowed to contact the TCP port. Please keep in mind that these must be ip-addresses, NOT host names. (DNS lookups for every incoming livestatus request could hang up and therefore block the module)
- modules: a comma-separated list of modules (see below)
- pnp_path: relevant if you use the multisite gui. pnp_path points to the perfdata directory where the pnp4nagios data reside (it's the directory which contains a subdirectory for each host). Multisite needs it to display a small perfdata icon if a rrd file exists.
- To deactivate an input, the port- and socket-attributes can also take the value "none".

The Livestatus module itself can have sub-modules. In fact, it **must** have at least one submodule responsible for storing log events to a database, SQLite or MongoDB.

Livestatus module - Logstore Sqlite Stores log-broks to an sqlite database.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_sqlite
- use_aggressive_sql: Prefer the use of sql queries to pre-filter data prior to python filtering. This is required for very large installations, as the Python structures are not indexed when filtering. Optional argument set to 0 by default. To enable set the value to 1. Some erroneous output may occur, but informal testing has shown these corner cases do not occur.
- read_only: don't send any update to the database. Should be used when you run several livestatus modules : 1 instance is R/W, other are read only.
- database_file: the path to the sqlite database file which is used to store the log broks/messages. The default is 'var/livestatus.db'
- archive_path: the path to a subdirectory where database file archives will be created. Every day the data from the last day will be moved to an archive datafile. The default is 'var/archives'.
- max_logs_age: the maximum age of the log messages (before they are deleted from the database). The default is 1 year. The argument to this parameter takes the form <number>[<period of time>], where <period of time> can be d for days, w for weeks, m for months and y for years. This parameter is currently ignored. In future releases it will be used to automatically delete ancient database files.

Here is an example:

```
define module{
```

```
     module_name      Livestatus
     module_type      livestatus
     host             *       ; * = listen on all configured ip addresses
     port             50000   ; port to listen
     socket           /usr/local/shinken/var/rw/live
     modules          logsqlite
}
define module{
```

```
     module_name      logsqlite
     module_type      logstore_sqlite
     use_aggressive_sql     0 ; optional, by default set to 0. Only for large installations.
     database_file    /usr/local/shinken/var/livelogs.db
     max_logs_age     3m ; three months. Other time intervals are d=days, w=weeks, y=years
}
```

Livestatus module - Logstore MongoDB Stores historical log broks(inter daemon Shinken messages) to a MongoDB database. MongoDB is a distributed and very performant database that permits resilience and high availability. The current implementation has a few known broken pieces (some search functions are broken) and there are bugs in the implementation, so it is considered experimental until power users and developers have ironed out the bugs. It is the database of the future for Shinken.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_mongodb
- mongodb_uri: The address of the master. (Default: i_cant_write_the_uri_here_it_messes_the_wiki_up)
- replica_set: If you are running a MongoDB cluster (called a "replica set" in MongoDB), you need to specify it's name here. With this option set, you can also write the mongodb_uri as a comma-separated list of host:port items. (But one is enough, it will be used as a "seed")
- database: <undocumented>
- collection: <undocumented>
- max_logs_age: <undocumented>

The configuration looks quite similar to the sqlite one. **In a single-node installation and with decent amount of log traffic, the sqlite backend should be considered best practice, as it needs no extra software and is stable and fast (when run in-memory).**

Livestatus module - Logstore Null In case you don't need any logging (for instance, if you dedicate a livestatus module instance to nagvis), you can use this module.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_null

Network Based Modules - Graphite graphing Graphite is a graphing and data analysis tool. It is composed of a web frontend (graphite-web), fixed size databases (whisper) and data redistribution/munging daemon. (carbon) The first step is *having Graphite installed somewhere*, if you do not have Graphite installed, please do this and come back later.

Pre-requisite : Shinken 1.2.2+ is recommended for the best experience with Graphite.

graphite_perfdata: exports check result performance data to Graphite Export all performance data included in check results to Whisper databases managed by Graphite. Data is buffered, then exported once every broker time tick. (Once per second). Should a communication loss occur, it will buffer data for 5 minutes before dropping data. The tick_limit max is configurable, the only limitation is the amount of memory the buffered data can eat.

The graphite broker module (v1.2) sends data to graphite in the following format :

HOSTNAME.SERVICENAME.METRICNAME

It can be optionally enhanced to send it the following format :

_GRAPHITE_PRE.HOSTNAME.SOURCE.SERVICENAME.METRICNAME._GRAPHITE_POST

Each of the three variables are optional :

- The _GRAPHITE_PRE variable can be set per host/service to provide a more flexible naming convention. (ex. Prod.site1.Hostname.servicename)

- The _GRAPHITE_POST variable can be set per host/service to specify the more information concerning the variable being stored that graphite can use to determine the retention rule to use for the variable.
- The SOURCE variable can be set in shinken-specific.cfg for the WebUI module and the Graphite broker.

Metric names are converted from Shinken's format to a more restrictive Graphite naming. Unsupported characters are converted to "_" underscore. So do not be surprised to see that some names differ in the WebUI or directly in Graphite. Permitted characters in Graphite are "**A-Za-z_**.", the hyphen character is permitted from Shinken, though only future versions of Graphite will support it.

Performance data transfer method can be set to pickle, which is a binary format that can send data more efficiently than raw ascii.

It takes the following parameters:

- module_name: name of the module called by the brokers
- module_type: graphite_perfdata
- host: ip address of the graphite server running a carbon instance
- port: port where carbon listens for metrics (default: 2003 for raw socket, 2004 for pickle encoded data)
- use_pickle: Use a more efficient transport for sending check results to graphite instead of raw data on the socket (v1.2)
- tick_limit: Number of ticks to buffer performance data during a communication outage with Graphite. On tick limit exceeded, flush to /dev/null and start buffering again. (v1.2)
- graphite_data_source: Set the source name for all data coming from shinken sent to Graphite. This helps diferentiate between data from other sources for the same hostnames. (ex. Diamond, statsd, ganglia, shinken) (v1.2)

Here is an example:

```
define module {
```

```
module_name Graphite-Perfdata
host xx.xx.xx.xx
module_type graphite_perfdata
port 2004 ; default port 2003 for raw data on the socket, 2004 for pickled data
use_pickle 1 ; default value is 0, 1 for pickled data
tick_limit 300 ; Default value 300
graphite_data_source shinken ; default is that the variable is unset
}
```

SQL Based Modules - PNP4Nagios Graphing PNP4Nagios is a graphing tool that has a web interface for RRDTool based databases. Shinken can export performance data to an npcd database which will feed the RRD files (fixed sized round robin databases). You can *learn how to install PNP4Nagios* if you haven't done it already.

npcdmod: export perfdatas to a PNP interface Export all perfdata for PNP.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: npcdmod
- path: path to the npcd config file

Here is an example:

```
define module{
 module_name  NPCD
 module_type  npcdmod
 config_file  /usr/local/pnp4nagios/etc/npcd.cfg
}
```

SQL Based Modules - Frontend Centreon2 Centreon2 use a NDO database, so you will need the ndodb_mysql module for it.

ndodb_mysql: Export to a NDO Mysql database Export status into a NDO/Mysql database. It needs the python module MySQLdb (apt-get install python-mysqldb or easy_install MySQL-python).

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: ndodb_mysql
- database: database name (ex ndo)
- user: database user
- password: database user passworddt
- host: database host
- character_set: utf8 is a good one

Here is an example:

```
define module{
```

```
     module_name      ToNdodb_Mysql
     module_type      ndodb_mysql
     database         ndo       ; database name
     user             root      ; user of the database
     password         root      ; must be changed
     host             localhost ; host to connect to
     character_set    utf8      ;optionnal, UTF8 is the default
}
```

File based Legacy modules - perfdata export

service_perfdata: export service perfdatas to a flat file

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: service_perfdata
- path: path to the service perfdata file you want

Here is an example:

```
define module{
```

```
    module_name      Service-Perfdata
    module_type      service_perfdata
    path             /usr/local/shinken/src/var/service-perfdata
}
```

host_perfdata: export host perfdatas to a flat file

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: host_perfdata
- path: path to the host perfdata file you want

Here is an example:

```
define module{
```

```
    module_name      Host-Perfdata
    module_type      host_perfdata
    path             /usr/local/shinken/src/var/host-perfdata
}
```

Legacy File based Modules - Old CGI or VShell The Old CGI and VShell use the flat file export. If you can, avoid it! It has awful performance, all modern UIs no longer use this.

status_dat: export status into a flat file Export all status into a flat file in the old Nagios format. It's for small/medium environment because it's very slow to parse. It can be used by the Nagios CGI. It also export the objects.cache file for this interface.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: status_dat
- status_file: path of the status.dat file /usr/local/shinken/var/status.dat
- object_cache_file: path of the objects.cache file
- status_update_interval: interval in seconds to generate the status.dat file

Here is an example:

```
define module{
```

```
    module_name              Status-Dat
    module_type              status_dat
    status_file              /usr/local/shinken/var/status.data
    object_cache_file        /usr/local/shinken/var/objects.cache
    status_update_interval   15 ; update status.dat every 15s
}
```

Deprecated or unsupported modules

SQL Based MerlinDB This interface is no longer supported and is going to be completely removed from Shinken.

SQL based ndodb_oracle - Icinga web frontend using NDO Oracle This interface is no longer supported and is going to be completely removed from Shinken.

CouchDB: Export to a Couchdb database This interface is no longer supported and is going to be completely removed from Shinken.

TSCA (Thrift Service Check Acceptor) TSCA is a receiver/arbiter module to receive hosts and services check results. It provides the same functions as NSCA with additional features. High performance binary transmission, multi line output and auto generated clients for a variety of languages.

What is thrift ? Let's cut and paste the wikipedia definition from'en.wikipedia.org/wiki/Apache_Thrift'_ :

"Thrift is an interface definition language that is used to define and create services for numerous languages.[1] It is used as a remote procedure call (RPC) framework [..]. It combines a software stack with a code generation engine to build services that work efficiently to a varying degree and seamlessly between ActionScript, C#, C++ (on POSIX-compliant systems), Cappuccino, Cocoa, Erlang, Haskell, Java, OCaml, Perl, PHP, Python, Ruby, and Smalltalk."

Installation In any case, you have to install thrift with support for python (on the server side) and languages you want to use for clients.

Get it from thrift.apache.org or in your favorite distribution repository.

Server side Go to the tsca module directory and generate the python stub for the server side installation

```
cd shinken/modules/tsca
$ thrift --gen py tsca.thrift
```

Declare the module is shinken-specific.org

```
define module{
      module_name     TSCA
      module_type     tsca_server
      host            0.0.0.0
      port            9090
}
```

Samples clients There are three(3) client samples written in python, ruby and java in contrib/clients/TSCA of the Shinken distribution. You can use and extend them to send data directly in your code directly to Shinken's TSCA receiver/arbiter module.

The samples clients read a CSV file from stdin and send them the the TSCA running on localhost:9090. The CSV has the following format :

```
hostname,service description,output,rc
```

Any use of TCP in an application should take care not to block the program and to have very short timeouts. For applications that need non blocking functions, prefer a UDP based transport or a local buffer file with a separate application(send_nsca, thrift, etc) to forward your data to Shinken.

Ruby Generate the stub

```
$ thrift --gen rb ../../../shinken/modules/tsca/tsca.thrift
```

Run the client

```
$ cat file_state | ruby RubyClient.rb
```

Python Generate the stub

```
$ thrift --gen py ../../../shinken/modules/tsca/tsca.thrift
```

Run the client

```
$ cat file_state | python PythonClient.py
```

java Generate the stub

```
$ thrift --gen java ../../../shinken/modules/tsca/tsca.thrift
```

Compile the client

```
$ ant
```

Run the client

```
$ cat file_state | java JavaClientThrift
```

VMWare Arbiter module

How it works The arbiter has a module that allows the host->VM automatic host dependency creation. In fact, the module is far more generic than just this. It's a generic "host link dependencies" module.

It reads a mapping file (simple json format) with son->father links. It call an external script at a regular interval : the one I wrote is a VMWare mapping one. It used the check_esx3.pl (that all ESX admin should have) plugin and generate the mapping file. When this file is changed, the module reloads it, creates new links and deletes old ones. So when you VMotion a virtual machine, in the next pass, there will be creation of a new link and deletion of the old one in the scheduler that manages it :)

How to define it The definition is very easy :

```
define module{
     module_name       VMWare_auto_linking
     module_type       hot_dependencies
     mapping_file      /tmp/vmware_mapping_file.json
     mapping_command   /usr/local/shinken/libexec/link_vmware_host_vm.py -x '/usr/local/shinken/libex
     mapping_command_interval 60   ; optionnal
     mapping_command_timeout   300 ; optionnal
}
```

Then you add it in you arbiter object :

```
define arbiter {
    [...]
    modules   VMWare_auto_linking
}
```

So here, it will call the script /usr/local/shinken/libexec/link_vmware_host_vm.py with a listing of the vCenter vcenter.mydomain.com and generate the mapping file /tmp/vmware_mapping_file.json.

You can call : /usr/local/shinken/libexec/link_vmware_host_vm.py –help

for the full help on this script.

It looks at the file modification time each second. This command can also be launch by an external cron of course.

Note: So if you want to write a script that does this for XEN servers, all you need is to generate a json file with all the mapping. I didn't wrote the doc about this, but you can look in the test file for it, the format is very very easy :)

Here is an example of the JSON mapping file syntax:

%%:ref:*["host", "physical_host"], ["host", "virtual_machine"* <["host", "physical_host"], ["host", "virtual_machine">, "host", "physical_host"], ["host", "other_virtual_machine" <"host", "physical_host"], ["host", "other_virtual_machine">]%%

So just a list of couple 'host' string (from now only host are managed) and the host name.

Beware about it : you need the real host_name, including case.

Web Service Module The Ws_arbiter module is a Receiver or Arbiter module to receive passive check results from remote hosts via HTTP(s). This module is considered a work in progress but can be used for testing and improvement.

Configuring the Web Service Module If data is POSTed to this page, it will validate the data to determine if it is a service or host check result and submit the data to the Shinken external command queue.

The web service listens by default to TCP port 7760. The web service supports anonymous or authenticated access. Web service parameters are set in the Shinken-specific.cfg file, in the Ws_arbiter module. To enable the web service, simply add the module to your Arbiter or Receiver daemon configuration in Shinken-specific.cfg

Using the Web Service Module The web service listens for POSTs to: /push_check_result

Use curl or embed the HTTP calls in your software to submit check results.

curl -u user:password -d "time_stamp=$(date +%s)&host_name=host-checked&service_description=service-checked&return_code=0&output=Everything OK" http://shinken-srv:7760/push_check_result

Example with more readability:

```
curl
```

-u user:password -d "time_stamp=$(date +%s)

```
&host_name=host-checked
&service_description=service-checked
&return_code=0
&output=Everything OK
http://shinken-srv:7760/push_check_result
```

SNMP module This part must be splitted and sent in all module repositories

Shinken integrated SNMP Module

SnmpBooster Download Install and Configure

- *What is the SnmpBooster module*
- Install and configure the SNMP acquisition module. [You are here]
- *Reference - SnmpBooster troubleshooting*
- *Reference - SnmpBooster design specification*
- *Reference - SnmpBooster configuration dictionnary*

Downloads

The SnmpBooster module and genDevConfig are currently in public beta prior to integration within Shinken. You can consult t

- github.com/xkilian/genDevConfig
- github.com/titilambert/shinken/tree/snmp_booster/shinken/modules (snmp_booster branch) * Simply right-click and download snmp_poller.py then copy it to shinken/modules/

Requirements The SnmpBooster module requires:

- Python 2.6+
- Shinken 1.2+
- PySNMP 4.2.1+ (Python module and its dependencies)
- ConfigObj (Python module)
- python-memcached
- memcachedb or memcached package for your operating system (ex. For Ubuntu: apt-get install memcachedb) *Note*

The genDevConfig profile generator depends on:

- Perl 5.004+
- 4 perl modules available from CPAN and network repositories. genDevConfig/INSTALL has the installation details.

STRONGLY RECOMMENDED: Use the same version of Python and Pyro on all hosts running Shinken processes.

Installation SnmpBooster:

- Install the dependencies
- Copy the file snmp_poller.py from the git repository to your shinken/modules directory.
- Configuration steps are listed in the present web page.

genDevConfig:

- Download and extract the archive to your server.
- See genDevConfig/INSTALL on how to install and configure it.

Configuration

How to define the SnmpBooster module in the Shinken daemons You need to modify shinken-specific.cfg, which is located in $shinken/etc/shinken-specific.cfg

Arbiter daemon configuration Simply declare the module:

```
modules SnmpBooster</code>
```

Scheduler daemon configuration

Simply declare the module:

<code>modules SnmpBooster

Poller daemon configuration Simply declare the module:

```
modules SnmpBooster</code>
```

SnmpBooster Module declaration

Included in Shinken v1.2.1 shinken-specific.cfg.

<code>define module {

```
module_name          SnmpBooster
module_type          snmp_poller
datasource           /usr/local/shinken/etc/packs/network/SnmpBooster/   ; SET THE DIRECTORY FOR YOUR
memcached_host       x.x.x.x  ; SET THE IP ADDRESS OF YOUR memcached SERVER
memcached_port       11211  ; default port for a memcached process
```

}

If you do not know the IP adress on which your memcache is listening, check under /etc/memcached.conf. Or do a:

```
netstat -a | grep memcached</code>
If you are running a test on the local machine you can leave memcached on 127.0.0.1 (localhost), but
```

How to define a Host and Service

Step 1

Create a template for your SNMP enabled devices.

Sample template:

<code>cd shinken/etc/packs/network/ mkdir SnmpBooster

vi shinken/etc/packs/network/SnmpBooster/templates.cfg

```
define command {
```

```
command_name    check_snmp_booster
command_line    check_snmp_booster -H $HOSTNAME$ -C $SNMPCOMMUNITYREAD$ -V 2c -t $ARG1$ -i $_SERVICE
module_type     snmp_poller
```

}

```
define service {
```

```
name                    default-snmp-template
check_command           check_snmp_booster!$_SERVICEDSTEMPLATE$!$_SERVICEINST$!$_SERVICETRIGGERGROUP
_inst                   None
_triggergroup           None
max_check_attempts      3
check_interval          1
retry_interval          1
register                0
```

}

```
define host{
```

```
name                    SnmpBooster-host
alias                   SnmpBooster-host template
check_command           check_host_alive
max_check_attempts      3
check_interval          1
retry_interval          1
use                     generic-host
register                0
```

}

Step 2 Define some hosts and services. You would typically use genDevConfig or another configuration generator to create these for you.

Mandatory service arguments related to SNMP polling:

```
_dstemplate                Cisco-Generic-Router  ; Name of a DSTEMPLATE defined in the SnmpBooster co
```

```
snmpcommunityread    which is set in your resource.cfg file
```

Optional service arguments related to SNMP polling with default values:

```
_inst                   None   ; Could be numeric: 0, None or an instance mapping function like: map
```

```
_triggergroup           None   ; Name of the triggergroup defined in the SnmpBooster config.ini file
```

Sample Shinken host and service configuration:

```
# Generated by genDevConfig 3.0.0
# Args: --showunused -c publicstring 192.168.2.63
# Date: Thu Aug 30 17:47:59 2012

#######################################################################
# Description: Cisco IOS Software, C2960 Software (C2960-LANBASEK9-M), Version 12.2(50)SE4, RELEASE S
#     Contact:
# System Name: SITE1-ASW-Lab04
#    Location:
#######################################################################

define host {
```

```
 host_name            192.168.2.63
 display_name         192.168.2.63
 _sys_location
 address              192.168.2.63
 hostgroups
 notes
 parents
 use                  default-snmp-host-template
 register             1
}

define service {
```

```
 host_name            192.168.2.63
 service_description  chassis
 display_name         C2960 class chassis
 _dstemplate          Cisco-Generic-Router
 _inst                0
 use                  default-snmp-template
 register             1
}

define service {
```

```
 host_name            192.168.2.63
 service_description  chassis.device-traffic
 display_name         Switch fabric statistics - Packets per Second
 _dstemplate          Device-Traffic
 use                  default-snmp-template
 register             1
}

define service {
```

```
host_name            192.168.2.63
service_description  if.FastEthernet0_1
display_name         FastEthernet0_1 Description: Link to Router-1 100.0 MBits/s ethernetCsmacd
_dstemplate          standard-interface
_inst                map(interface-name,FastEthernet0_1)
use                  default-snmp-template
register             1
```

}

Here is an example configuration of the config.ini file

```
[DATASOURCE]
```

```
  OidmyOidDefinition = .1.3.6.1.45.0
  [myOidDefinition] ; Use the same name as the myOidDeiniftion, but omit the leading "Oid"
      ds_type = DERIVE
      ds_calc = 8,*  ; RPN expression : Oid, 8, *  Which means Oid * 8 = ds_calc
      ds_oid = $OidmyOidDefinition
[DSTEMPLATE]
```

```
  [myCiscoRouter]
      ds = myOidDefinition
[TRIGGER]
```

```
  [trigger1]
      warning = RPN expression
      critical = RPN expression
  [trigger2]
      warning = RPN expression
      critical = RPN expression
[TRIGGERGROUP]
```

```
[CiscoRouterTriggers]
    triggers = trigger1, trigger2
```

Shinken integrated SNMP Module

Overview

What is it The SnmpBooster module allows Shinken Pollers to directly manage SNMP data acquisition. This is an all Python cross-platform SNMP module. It is tightly integrated with the Shinken Poller, Scheduler and Arbiter daemons to provide the best possible user experience.

- Jump back to *SnmpBooster documentation index*

Design specification summary

- STATUS - DESIGN SPEC PERFORMANCE
- [Done] Functions as an integrated Shinken Poller module
- [Done] Necessary integration code commited to Shinken official release (Integrated starting at v1.2)
- [Done] Ability to collect thousands of SNMP metrics per second
- [Done] Be compatible with distributed data acquisition
- [Done] Collect data for a host/check_interval tuple via SNMP in a single pass
- [Done] Use all builtin Shinken scheduler logic for retries, forced checks, timeouts, dependencies, parents
- [Done] Store collected data for the duration of the check_interval in a memcached/membase
- [Done] On a restart, after the first collection, be able to pick up where the last check left and calculate derived values
- [Done] Forced check are not allowed within 30 seconds of last SNMP query to the same host/check_interval, all other requests get data from the cache.
- [Done] Only a single request to the host/check_interval via SNMP is allowed at a time, all other requests get data from the cache.
- STATUS - DESIGN SPEC USABILITY
- [Done] Usage documentation
- [xxxx] SkonfUI and Discovery usage documentation
- [xxxx] Provide sample configuration packs in Shinken
- [Done] Provide sample config.ini with examples of all types of data * SNMP OIDS, DATASOURCES, DSTEMPLATES, TRIGGERS and TRIGGERGROUPS

- [Done] Directly compatible for use with genDevConfig Shinken SNMP configuration generator
- [Done] Provide meaningful feedback for users on errors
- [Done] Capture all tracebacks and convert them to actual error or warning messages
- STATUS - DESIGN SPEC FEATURES
- [Done] Return state and performance metrics
- [Done] Performance metrics can be returned in a Weathermap compatible format
- [Done] Configuration file format is ConfigObj INI
- [Done] Load all valid INI configuration files from a directory and merge them

SnmpBooster reference dictionary

- Jump back to *SnmpBooster documentation index*

SnmpBooster.ini dictionary

There are five dictionaries:

- [DATASOURCE]
- [DSTEMPLATE]
- [MAP]
- [TRIGGER]

- [TRIGGERGROUP]

DATASOURCE DICTIONARY OidVariableName refers to an actual OID that can be queries using SNMP against the device on the network.

[VariableName] refers to a Datasource and all the information required to gather and prepare the data using SNMP ds_type refers to how the data should be prepared ds_calc refers to any scaling manipulations to make the data more understandable. This is an RPN expression, where the first variable is omitted, as it is always the $OidVariable ds_oid refers to the actual $OidVariable name. An instance identifier can be appended to the name to signify that an instance is provided by the Shinken service definition. This information is passed when the check is called. ...

DSTEMPLATE DICTIONNARY [DsTemplateName] refers to the name of the DSTEMPLATE that will be referred to in the Shinken service definitions. ds refers to the list of DATASOURCES to be collected. If an instance is expected for the list of DATASOURCES, it MUST be the same instance for all Oids. If a different instance is required, use a second DSTEMPLATE.

TRIGGER DICTIONNARY

TRIGGERGROUP DICTIONNARY

MAP DICTIONNARY

SnmpBooster.ini example configuration This example definition will be used to explain each section.

[DATASOURCE]

```
OidmyOidDefinition = .1.3.6.1.45.0
[myOidDefinition] ; Use the same name as the myOidDeiniftion, but omit the leading "Oid"
    ds_type = DERIVE
    ds_calc = 8,*  ; RPN expression : Oid, 8, *  Which means Oid * 8 = Total
    ds_oid = $OidmyOidDefinition
```

[DSTEMPLATE]

```
[myCiscoRouter]
    ds = myOidDefinition
```

[TRIGGER]

```
[trigger1]
    warning = RPN expression
    critical = RPN expression
[trigger2]
    warning = RPN expression
    critical = RPN expression
```

[TRIGGERGROUP]

```
[CiscoRouterTriggers]
    triggers = trigger1, trigger2
```

SnmpBooster.ini configuring SNMP Datasources

The first location is generic data related to SNMP parameters.

- DATASOURCE information * SNMP OID * Type of data and how can it be interpreted (GAUGE, COUNTER, COUNTER64, DERIVE, DERIVE64, TEXT, TIMETICK) * Data format preparation (Scaling the data for example bits to bytes) * Is there an instance to append to the
- Instance MAP function * Mapping the instance dynamically using a function * Data or rules related to the mapping function

SnmpBooster.ini configuring SNMP DSTEMPLATES

- DSTEMPLATEs to associate DATASOURCE to actual device classes * List of DATASOURCES associated with a, for example, Cisco 1900 router. Which in turn can be applied to a Shinken service

SnmpBooster.ini setting triggers/thresholds

- TRIGGER and TRIGGERGROUPS to apply thresholding rules * Define triggers and associate them with a TRIGGERGROUP name that can be applied to a Shinken Service

Shinken integrated SNMP Module

Overview

- Jump back to *SnmpBooster documentation index*

Tip: The module is now in public beta as of 2012-10-26! Have Fun!

Nothing new to add, more to come in 2013. 2013-01-19.

What is it The SnmpBooster module allows Shinken Pollers to directly manage SNMP data acquisition. This is an all Python cross-platform SNMP module. It is tightly integrated with the Shinken Poller, Scheduler and Arbiter daemons to provide the best possible user experience.

Why use it The SnmpBooster module is designed to be very efficient and scalable. It has a very flexible configuration method to make it easy to use with Shinken Monitoring Packs and Shinken discovery runners like genDevConfig.

This acquisition module was professionally designed and developed.

It is meant to be used by the very capable discovery engine genDevConfig (**v3.0.5 and newer**) originally developed for the Cricket SNMP monitoring tool and converted for use with Shinken.

It is one of the very few serious SNMP v2c implementation making use of SnmpGetBulk type requests.

How does it work

Shinken Integration

1. The SnmpBooster Arbiter module reads the Shinken SnmpBooster configuration file(s). It reads the check commands and based on the values in the check commands that use the snmp_poller module it will creates a shared configuration cache using memcached/memcachedb. The memcache key is always the combination of the hostname. This permits to tie together Shinken Hosts and Services with the SNMP specific configuration. (MongoDB and Redis are planned to be supported in the future) The Scheduler daemon schedules Host and Service checks as it normally does.

3. The SnmpBooster module will check that a memcache host key exists for the check to be launched. Then the SnmpBooster poller module will query all services related to a host for a given acquisition frequency in one pass. (all checks done every 2 minutes will be executed in bulk, same for those every 5 minutes)

5. Check results are cached for the acquisition check_interval. The next time a check request for data from the same host is received from the Scheduler, the data will be fetched from memcache. Resulting is extremely low check latency.

2. 6. The SNMP checks still benefit from retries, timeouts, forced checks, dependencies and the powerful Scheduler daemon logic.

6. The Scheduler daemon can still force an immediate re-check by flushing the cache. This is required for the dependency model.

Performance SnmpBooster uses SNMP v2c getbulk for high efficiency, unless forced to use SNMP v2c get-next or SNMPv1 get-next. GetBulk uses a single request PDU to ask for multiple OIDs or even entire tables, instead of sending one request PDU per OID.

For example: *A typical 24 port network switch with two uplinks might use 375 OIDS (8 OIDs per interface, plus general OIDs for chassis health, memory, cpu, fans, etc.). **SnmpBooster will only require around 4 request PDUs*

*instead of 375 request PDUs**. Each PDU is a request packet which takes time to create, send get processed and return. More timeouts to manage, more connections, more impact on the remote device and more latency means much fewer checks per second.*

The SnmpBooster module supports automatic instance mapping for OIDs. (Ex. Based on the interface name it will figure out that the SNMP index(or instance) is 136. This is automatically handled by genDevConfig and SnmpBooster, no user input required. :-)

The generic SNMP configuration information is stored in the Shinken SnmpBooster INI files. There is a Defaults_unified.ini and a series of other Defaults files, one per discovery plugin for genDevConfig.

Important: genDevConfig plugins have all been converted to use the new dynamic instance mapping methods. You are now free to use most if not all Defaults*.ini files included with genDevConfig. 2012-10-28

Limitations You should have memcached instances running on each poller responsible for snmp polling. You should have your pollers with SnmpBooster in the same datacenter, as they need to be on the same machine with good connectivity to the active memcached instance. SnmpBooster is not compatible with distributed pollers in multiple datacenters, sorry, the current design of SnmpBooster uses a single centralized memcached instance for storing the timeseries data. For distributed datacenters to be supported, each poller+scheduler+memcached must be realm restrained, which is not the case today.

Design specification *SnmpBooster design specification* and current development status.

Data model The information required to define the data is split in two locations.

The first location is the host and service Shinken configuration (You need to generate or write this)

- Device specific information
  - IP addresses, host_names, device types, instance keys
  - A DSTEMPLATE must be referred to in the Service definition
  - A static SNMP instance could be referred to in the Service definition
  - An SNMP instance MAP function could be referred to in the Service definition
  - A TRIGGERGROUP could be refered to in the Service definition

The second location is SNMP Defaults.* templates. (Here you can create new devices or add new data sources)

- DATASOURCE information
  - SNMP OID
  - Type of data and how can it be interpreted (GAUGE, COUNTER, COUNTER64, DERIVE, DERIVE64, TEXT, TIMETICK)
  - Data format preparation (Scaling the data for example bits to bytes)
  - Is there an instance to append to the
- Instance MAP function * Mapping the instance dynamically using a function * Data or rules related to the mapping function
- DSTEMPLATEs to associate DATASOURCE to actual device classes * List of DATASOURCES associated with a, for example, Cisco 1900 router. Which in turn can be applied to a Shinken service
- TRIGGER and TRIGGERGROUPS to apply thresholding rules * Define triggers and associate them with a TRIGGERGROUP name that can be applied to a Shinken Service

A final location containes rules to build your Shinken configuration.

- genDevConfig plugins create Shinken configurations

Installation and configuration *SnmpBooster installation*

Reference Dictionnary *SnmpBooster reference dictionary*

Troubleshooting *SnmpBooster troubleshooting*

Graph templates These are .graph files defined in your Shinken configuration directory. Refer to the Shinken graphite templates(Not yet created) or PNP4Nagios how-to documentation. The graph templates are independent from SnmpBooster and provide templates for any collected data from Shinken.

SnmpBooster Troubleshooting

- Jump back to *SnmpBooster documentation index*

Check your config

- Have you defined the poller module name?
- Have you defined the correct path to the directory containing your Defaults*.ini files?
- Have you addded the Snmpbooster module to your arbiter, poller, scheduler?
- Have you added copied the genDevConfig templates.cfg in shinken/packs/network/SnmpBooster/
- Have you installed PySNMP, memcached and other dependencies?

Software version consistency Shinken and SnmpBooster now require **the same Python and Pyro version on all hosts running a Shinken daemon**.

If you cannot use the packaged version of Python and its modules (Pyro, memcached, etc.). Use virtualenv to declare a python version to use and install all required modules in that virtualenv.

Software version requirements Have you verified that the *requirements* are met. Python, PySNMP, Shinken, Pyro, memcached, etc.

Validate your check command arguments Use the check_plugin command and comment out the module to learn what were the exact arguments sent by the poller. This will permit you to validate all the arguments, like snmp community string, inheritance, template application, etc.

Validate connectivity

Take a packet trace using a tool like Wireshark to validate that the remote host is responding.

- Has the host responded
- **Is SnmpBooster repeating the request more often than the polling interval.**
  - If you are seeing repeated requests your device may have a compatibility issues.

- Save an snmpwalk of the device, get a packet trace using Wireshark, set the poller to debug and save the poller.log file (shinken/var/poller.log). Send all three to the SnmpBooster developers.
- Note: It is normal to see one or more bulkGet requests if you are getting large amounts of data. Ex. a 24 port switch will take 2-3 request packets.

Performance Make sure you have a low latency connection to your memcache from the Poller. Your memcache server can be replicated to all your poller hosts that should also run memcache instances. Check that memcached is running: netstat -a | grep memcached

Faulty Template A bad snmp_template file was distributed in the genDevConfig sample-config directory, there were two glaring errors.

This was fixed on 2012-10-16. Make sure you update your template, or use the data from the wiki.

Note that the template should be called: SnmpBooster-template.cfg to make it easier to troubleshoot in the logs. So when you search for SnmpBooster in your logs it will show up as well.

Log files All warnings and errors generated by the SnmpBooster module start with "[SnmpBooster] error text" and are logged using the standard Shinken logger.

The Arbiter daemon can output initial configuration, loading of host keys and intervals in memcached type error messages. The Scheduler daemon can output scheduling and alert related messages. The Poller daemon can output messages related to instance mapping, acquisition timeouts, invalid community strings, cache failures and more. These are available in the Web interface, as they are placed in the check results for the service.

You can simply do a "grep SnmpBooster *" in your shinken/var directory to see the latest messages related to the SnmpBooster module. You can also sort messages by timestamp to make it easy to find where and when errors occurred.

cd shinken/var grep SnmpBooster *

memcache persistence If you restart your memcache server or memcache crashes, your poller will no longer be able to validate that a host exists in memcache prior to writing.

You should use memcachedb to achieve persistence in case of memcache failures.

Common errors returned by SnmpBooster in the log file Errors should be fairly explicit and mean what they say, though there can be exceptions. Lets try to clear some of them.

__Arbiter log **errors__**

Missing ds_oid : This means that a variable in your OID definitions is missing, or your DATASOURCE is not named correctly or your ds_oid variable is missing. There is a typo in your ds_oid variable (ex. ds-oid, or ds_oid = $OidNameIncorrectFFFRA.%(instance)s).

Datasource not defined : Your DSTEMPLATE uses a DATASOURCE that doesn't exist check the [DataSourceName] you are referring to. Does it contain the expected OID variable, $OidName.

Missing ds_type : The DATASOURCE always needs to have a ds_type definition, GAUGE, COUNTER, DERIVE, TEXT, TIMETICK, DERIVE64, COUNTER64.

__Poller log **errors__**

Problems with calculations, repeated polling, hosts not responding, etc.

__Memcached **errors__**

memcachedb and memcached do not use the same default port. Configure the correct memcachedb port to match what is declared in your SnmpBooster module under shinken-specific.cfg.

On Ubuntu 12.04 the default installation is on port 21201 instead of 11211. This causes the error "[SnmpBooster] Memcache server (127.0.0.1:11211) is not reachable" when Shinken starts.

To change it, you must edit the file /etc/memcachedb.conf

Memcached Notes On Ubuntu 12.04 the default instalation is on port 21201 instead of 11211. This causes the error "[SnmpBooster] Memcache server (127.0.0.1:11211) is not reachable" when shinken starts.

To change it, you must edit the file /etc/memcachedb.conf

WebUI module This part must be splitted and sent in all module repositories

WebUI integration with Shinken The WebUI is an external broker module. So it's an external process launched by the broker that "eats" broks (broker messages) from the brokers. So it can get *all* broks if you place this broker in your top level realm.

The WebUI does not use a database to get data. Instead, it use a "regenerator" object that will eat each broks, and will "recreate" all Hosts/Services/Contacts objects as if the code was in the scheduler daemon. So basically, WebUI and pages always reflect the CURRENT state of hosts/services objects.

The WebUI http layer is managed by bottle.py. It's a small but powerful framework.

How does the WebUI function globally ?

There a 2 Threads running:

- the main thread is the bottle.py (http) listener. It will use the best backend it finds. We recommend using python-paste. If it does not find one, it will use the default swsgi. Paste is multi-thread, swsgi is mon-thread, so please use paste if you want to avoid locking problems.
- the 2nd thread is the regenerator one. It only gets broks and gives them to the regenerator object.

There is a lock system between the threads. You can have N Http requests in progress without problem, but during this time the renererator one will wait. During execution of the regenerator, no requests are processed. This is not considered a problem, as the regenerator is very quick, and there is only a 1s lock for a 7k service conf loading, so it's not a huge problem.

What is a WebUI User? A WebUI user is a contact. A true contact object. You must match a contact name for your user.

To create a new page? All pages are in the shinken/webui/plugins directory. Each "part" has it's own directory. A part (like the eltdetail, element detail) can have more than one "page" (like /host or /service for eltdetail).

From here we will supose you want to create a "/contact" page.

You can copy the dummy example in the plugins directory into a contact directory.

You need to change the contact/dummy.py file into a contact/contact.py file, because the webui will search for a dir/dir.py file to "load".

Templates Templates are HTML with some Python code in it in the plugins/*/views direcotry for specific templates, and the "global layout" (menu and all common part) in the webui/views directory.

Your template must call the template layout (layout.tpl in the webui/views directory) wit ha "rebase" call.

If you put the rebase call at the beginning of your template, all there is below will be place "inside" the layout that will call the common javascripts and css, make the menu adn then call your html/python code.

The rebase call can take arguments. You MUST give it:

- user: the user you give it in the return dict of your .py code

Then all is optional:

- title: title of the page
- top_right_banner_state: int, global state with clouds to put in your top right page. Look at the problem.tpl code for an example.
- js and css list: list of YOUR specific javascript or css to call AFTER the common ones.
- refresh: boolean, set the refresh to 60s or do not refresh at all

- menu_part: will put the little "^" under this part of the menu.

Example of a call, taken from the problems view:

```
rebase layout title='All problems', top_right_banner_state=top_right_banner_state, js=['problems/js/a
roblems/js/autocompleter.Request.js', 'problems/js/autocompleterObserver.js'], css=['problems/css/acc
ms/css/autocompleter.css', 'problems/css/perfometer.css'], refresh=True, menu_part='/'+page, user=use
```

Call Python objects in your templates Your templates are mainly HTML code. But of course you can call python code in it. The dict you returns in the plugin.py call will be available in this page.

For example, the my_host variable will be available in the page with the host object you find (or None if your give it a bad name of course). Then you can "call" python with for example here to show the host_name: `<span>My host name is *my_host.host_name* </span>` is a way in the templates to "call a variable or function" that will return a string, here the host_name.

If the function or property you call must return HTML code that SHOULD be output as it, without "protection", you must put a ! before your call.

Let use an example where the output value of an host is in fact an html output. If you use the code `my_host.output`, bottle.py will "protect" the html generated by escaping the string, and change <> characters with escaped value. You can change this by calling `my_host.output`. Of course, it's a security problem if the output is with a javascript code...

You can also "loop" or put "if" in your template. You just need to put your code with a % before. Like

```
%for i in xrange(1, 10):
  My valus is  {{i}}
%end
```

You must put the %end here, the indentation will NOT be enougth, sorry.

For an if it's also easy:

```
%if host.active_checks_enabled:
  The host got active checks enabled
%else:
  The host DO NOT have active check enabled
%end
```

Which javascript lib are you using? It's mootools 1.3 with all options :)

What to do?

- Finish the /mobile part
- List of current alerts
- Host info
- Host status
- Host interfaces
- Hostgroup status
- dashboard hierachique with states, and BP
- Nagvis
- add bp in nagvis auto-map

- event sources
- correlation
- pre-filtering/enrichment
- user profile
- host/srv conf

WebUI search syntax work in progress

not that we couldn't tell. ;) eh eh

beware the working men and flying tools!

WebUI SSL Certification Lets start: the goal to to have the server.pem and client.pem file in etc/certs.

Go to the etc/certs directory.

```
openssl req -new -nodes -out server.req -keyout server.key -config ./shinken_openssl_cnf
openssl ca -out server.pem -config ./shinken_openssl_cnf -infiles server.req
cp server.pem server.pem.bkp
cp server.key server.pem
cat server.pem.bkp >> server.pem
cp server.pem client.pem
```

You can try to get the validity with for the arbiter with:

```
openssl s_client -connect localhost:7770</code>
```

Amazon AWS/EC2 import

Description You can import data from Amazon AWS/EC2 **'AWS'**_ into Shinken to create hosts.

Amazon provide VM hosting with EC2. With this arbiter module, you will be able to load your EC2 hosts into Shinken.

Prerequisites

You will need the **'libcloud'**_ package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

```
define module {
 module_name      AWS
 module_type      aws_import

 # Configure your REAL key and secret for AWS
 api_key              PAAAB2CILT80I0ZA0999
 secret           GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH
 default_template generic-host        ; if the host is not tagged, use this one
 }
```

- Put in key and secret your private Landscape access. * default_template will be used if your host is not "tagged" in Landscape

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master

     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           AWS
     }
```

Restart your Arbiter and it's done :)

Generated hosts The configuration generated will look as below :

```
define host {
    host_name            i-3fc56e5a
    address              8.8.4.4
    use                  t1.micro,MyTag,EC2,generic-host
    _EC2_AVAILABILITY    us-east-1a
    _EC2_CLIENTTOKEN
    _EC2_DNS_NAME
    _EC2_GROUPS          quicklaunch-1
    _EC2_IMAGEID         ami-1b814f72
    _EC2_INSTANCEID      i-3fc56e5a
    _EC2_INSTANCETYPE    t1.micro
    _EC2_KERNELID        aki-825ea7eb
    _EC2_KEYNAME         testaws
    _EC2_LAUNCHDATETIME  2012-09-26T12:19:38.000Z
    _EC2_LAUNCHINDEX     0
    _EC2_PRIVATE_DNS
    _EC2_PRIVATE_IP
    _EC2_PRODUCTCODE
    _EC2_PUBLIC_IP       8.8.4.4
    _EC2_RAMDISKID       None
    _EC2_STATUS          stopped
    _EC2_TAGS            demo:myvalue,use:MyTag
 }
```

Here with a stopped t1.micro instance with no name. You can put your how "use" parameter by adding a EC2 tag "use" on your VM. It will be output on the host configuration so you can setup the monitoring as you want. .. _libcloud: http://libcloud.apache.org/index.html .. _AWS: https://console.aws.amazon.com

Amazon AWS/EC2 import

Description You can import data from Amazon AWS/EC3 **'AWS'**_ into Shinken to create hosts.

Amazon provide VM hosting with EC3. With this arbiter module, you will be able to load your EC2 hosts into Shinken.

Prerequisites

You will need the **'libcloud'**_ package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

```
define module {
 module_name      AWS
 module_type      aws_import

 # Configure your REAL key and secret for AWS
 api_key              PAAAB2CILT80I0ZA0999
 secret           GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH
 default_template generic-host        ; if the host is not tagged, use this one
 }
```

- Put in key and secret your private Landscape access. * default_template will be used if your host is not "tagged" in Landscape

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master

     address          localhost                  ;IP or DNS adress
     port             7770
     spare            0
     modules           AWS
     }
```

Restart your Arbiter and it's done :)

Generated hosts The configuration generated will look as below :

```
define host {
    host_name            i-3fc56e5a
    address              8.8.4.4
    use                  t1.micro,MyTag,EC2,generic-host
    _EC2_AVAILABILITY    us-east-1a
    _EC2_CLIENTTOKEN
    _EC2_DNS_NAME
    _EC2_GROUPS          quicklaunch-1
    _EC2_IMAGEID         ami-1b814f72
    _EC2_INSTANCEID      i-3fc56e5a
    _EC2_INSTANCETYPE    t1.micro
    _EC2_KERNELID        aki-825ea7eb
    _EC2_KEYNAME         testaws
    _EC2_LAUNCHDATETIME  2012-09-26T12:19:38.000Z
    _EC2_LAUNCHINDEX     0
    _EC2_PRIVATE_DNS
    _EC2_PRIVATE_IP
    _EC2_PRODUCTCODE
    _EC2_PUBLIC_IP       8.8.4.4
    _EC2_RAMDISKID       None
    _EC2_STATUS          stopped
    _EC2_TAGS            demo:myvalue,use:MyTag
 }
```

Here with a stopped t1.micro instance with no name. You can put your how "use" parameter by adding a EC2 tag "use" on your VM. It will be output on the host configuration so you can setup the monitoring as you want. .. _libcloud: http://libcloud.apache.org/index.html .. _AWS: https://console.aws.amazon.com

The distributed retention modules The high availability allow the Arbiter to send a configuration to a spare scheduler, but a spare scheduler does not have any saved states for hosts and services. It will have to recheck them all. It's better to use a distributed retention module so spares will have all the information they need to start with an accurate picture of the current states and scheduling :)

Non distributed retention modules If you are just running tests on a single server, use the pickle or memcache retention modules You can also use MongoDB if you already have it installed for use with the WebUI.

MongoDB MongoDB is a scalable, high-performance, open source NoSQL database written in C++.

Step 1: Install MongoDB:

We will use mongodb package from 10gen repository, so we start by adding it in apt sources list:

```
echo 'deb http://downloads-distro.mongodb.org/repo/debian-sysvinit dist 10gen' > /etc/apt/sources.lis
apt-get update
```

And we install it:

```
apt-get install mongodb-10gen
```

And we install pymongo, the python interface to MongoDB, with easy_install to avoid packages versions problems (like here **'forums.monitoring-fr.org/index.php?topic=5205.0'_**):

```
apt-get remove python-pymongo
easy_install pymongo
```

And finally we start MongoDB :

```
/etc/init.d/mongodb start
```

Step 2: define a mongodb_retention module in your shinken-specific.cfg file:

```
define module {
  module_name MongodbRetention
  module_type mongodb_retention
  uri mongodb://localhost/?safe=true
  database shinken
}
```

Step 3: Declare a retention module for your scheduler(s) :)

Example:

```
#The scheduler is a "Host manager". It get hosts and theirs
#services. It scheduler checks for them.
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
     port     7768                  ; tcp port of the daemon

     #optionnal: modules for things as retention
     modules    MongodbRetention
     }
```

Step 4: Restart the Arbiter, and your Scheduler will now save its state between restarts. :)

Memcached Memcached is a distributed memory resident key/value server. It's very easy to install:

```
sudo apt-get install memcached
sudo /etc/init.d/memcached start
```

The shinken module also needs the python-memcache package to talk to this server.

```
sudo apt-get install python-memcache
```

To use it,

Step 1: define a memcache_retention module in your shinken-specific.cfg file:

```
define module{
     module_name      MemcacheRetention
     module_type      memcache_retention
     server           127.0.0.1
     port             11211
}
```

Step 2: Declare a retention module for your scheduler(s) :)

Example:

```
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
     port     7768                  ; tcp port of the daemon

     #optional: modules for things as retention
     modules    MemcacheRetention
     }
```

Step 3: Restart the Arbiter, and your Scheduler will now save its state between restarts. :)

Redis Redis is a distributed key/value server (on disk and in-memory). It's very easy to install:

```
sudo apt-get install redis-server
sudo /etc/init.d/redis-server start
```

The shinken module also need the python-redis package to talk to this server.

```
sudo apt-get install python-redis
```

Step 1: define a redis_retention module in your shinken-specific.cfg file:

```
define module{
     module_name      RedisRetention
     module_type      redis_retention
     server           127.0.0.1
}
```

Step 2: Declare a retention module for your scheduler(s) :)

Example:

```
#The scheduler is a "Host manager". It get hosts and theirs
#services. It scheduler checks for them.
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
```

```
    port     7768                  ; tcp port of the daemon

    #optionnal: modules for things as retention
    modules    RedisRetention
    }
```

Step 3: Restart the Arbiter, and your Scheduler will now save its state between restarts. :) .. _forums.monitoring-fr.org/index.php?topic=5205.0: http://forums.monitoring-fr.org/index.php?topic=5205.0

How to enable and use Livestatus module

Define the Livestatus module Start by reviewing the ''/etc/shinken/shinken-specific.cfg" file for this module:

```
define module{
```

```
module_name      Livestatus
module_type      livestatus
host             *       ; * = listen on all configured IP addresses
port             50000   ; port to listen on
database_file    /var/lib/shinken/livestatus.db
```

}

With these parameters:

- module_name: name of the module called by the brokers
- module_type: livestatus
- host: IP interface to listen to. The default is *, which means "listen on all interfaces".
- port: TCP port to listen to.
- socket: Unix socket to listen to.
- database_file: the path to the sqlite database file which is used to store the log broks/messages. The default is "var/livelogs.db"
- max_logs_age: the maximum age of the log messages (before they are deleted from the database). The default is 1 year. The argument to this parameter takes the form <number>[<period of time>], where <period of time> can be d for days, w for weeks, m for months and y for years.
- allowed_hosts: a comma-separated list of IP-addresses which are allowed to contact the TCP port. Please keep in mind that these **must be IP-addresses, NOT host names**. Because DNS lookups for every incoming livestatus request could hang up and therefore block the module.

Enable the Livestatus module Still in ''/etc/shinken/shinken-specific.cfg'', find the object Broker and add "Livestatus" to its "modules":

```
define broker{
```

```
    broker_name      broker-1
[...]
```

```
    modules          Simple-log,Livestatus
}
```

Disable human readable logs In ''/etc/shinken/nagios.cfg'', verify that the option **human_timestamp_log** is set to **0**.

In version 0.6.5, you can not have at the same time a simple-log file with human readable timestamp and a Livestatus database.

Exporting data for reporting Shinken can export necessary data for reporting in 3rd party systems.

raw_socket module The raw socket module exports reporting data using a syslog format to a raw TCP socket. Theses logs can be captured, parsed and indexed by any log management system like Splunk or Logstash.

Why export reporting data Custom UIs like Thruk, Multisite, WebUI, Adagios, Nagios IX, etc. All have poor or inflexible reporting. Simply because these are not reporting engines.

This also permits to have a generic reporting method that can accept data from any Nagios, Shinken, Icinga or even Riemann.

Reporting module using Splunk Splunk was selected as the reporting platform for creating, managing and presenting reports. Though the raw_socket module does not have any Splunk specific particularities. It is notable that Splunk reports can be embedded in any 3rd party UI using its REST API.

Raw_socket log format The logs are plain-text and compliant with RFC3164. They use an intelligent date format, a configurable seperator " "(space by default), and key=value pairs in the message data portion of the log. Should a key or value contain a space they must be double quoted. This is syslog using structured data without going to full out JSON that may not be compatible with all log management systems.

The message fields that are supplied in each status update in addition to the standard syslog header are:

- Hostname
- Servicename
- Business impact
- Host/Service status
- Host/Service previous status
- Acknowedgement status
- Maintenance status

Any time the maintenance, host, service or acknowledgement status changes, a log is sent by the Shinken raw_socket module.

Having all relevant data in each log makes it very easy to compute reports for given time periods.

The hostgroup or service group memberships, custom variables or any other configuration related data should be queried from the monitoring system using its API (Livestatus in the case of Shinken and Nagios).

Raw_socket module availability The module is available in both Shinken 1.4 and Shinken 2.0. The module will be integrated in master branches once unit tests and end-to-end testing is completed. 3rd quarter 2013.

Monitoring Linux System with Glances and checkglances.py **'Glances'_** is a fantastic multiplatform system monitoring tool writen by Nicolargo. Glances can run on (Linux, Windows, MacOS ...). There is a growing ecosystem around Glances and of course a Nagios/Shinken plugin : checkglances.py.

How does it work Glances can run in server mode. It provide a XML-RPC server (over http) and allow to retrieve system information throuh a restful API. The only thing to do is to install and start Glances as server on the monitored host, then install checkglances.py on the shinken server and finaly install the glances pack.

Install glances See the glances documentation to install glances on Linux.

<code bash> easy_install glances </code>

There is a debian startup script in the glances repository. And another one for centos here.

Install checkglances.py Just follow the documentation for the checkglances.py prerequisites and put it in your nagios plugins folder.

Install the glances pack Open a terminal as the shinken user and just type the following command

<code bash> shinken install glances </code>

Then just edit the configuration for a linux monitored host and tag it as **glances**

```
define host{
 name mylinuxhost
 use glances
 ...
```

Finaly restart the shinken arbiter

```
service shinken-arbiter restart
```

What will be monitored ? For the moment just the basic system (ram, cpu, load, memory, filesystem and network).

If you want to modify the default thresholds for just a host you can do it by overiding the thresholds macro in your host definition. If you want to do it for several hosts, declare a new template and just add the desired thresholds macro to be overide.

Here is a list of the macros

```
::
```

> _LOAD_WARN 2 _LOAD_CRIT 3 _CPU_WARN 80 _CPU_CRIT 90 _MEMORY_WARN 90 _MEMORY_CRIT 95 _FS /, /home _FS_WARN 90 _FS_CRIT 95 _IFACES eth0, eth1 _NET_WARN 7500000 _NET_CRIT 10000000

Note the _FS and _IFACES macros. They leverage the ability to duplicate service for a given list of things to be monitored. Here you see that / and /home partitions will be monitored. If you want to modify this then just add your own in a new template that will inherit the glances template.

Shinken GLPI integration Shinken supports importing hosts from GLPI

For people not familiar with GLPI, it is an Open-Source CMDB. Applicable to servers, routers, printers or anything you want for that matter. It is also a help-desk tool. GLPI also integrates with tools like FusionInventory for IT inventory management.

You can still have flat files AND GLPI if you want. Hosts imported from GLPI will be treated as standard hosts from flat file (inheritance, groups, etc). In fact, in this first version the module only sends the host_name to Shinken, but there should be more information extracted like network connexions for parents relations in the future. :)

Requirements

- python module MySQLdb
- Compatible version of GLPI Shinken module and GLPI version - ...
- etc..

Enabling GLPI Shinken module In your shinken-specific.cfg file, just add (or uncomment):

```
#You know GLPI? You can load all configuration from this app(
#with the webservices plugins for GLPI, in xmlrpc mode
#and with plugin monitoring for GLPI)
# =============== Work with Plugin Monitoring of GLPI ===============
#All configuration read from this will be added to the others of the
#standard flat file
define module{
     module_name      GLPI
     module_type      glpi
     uri              http://localhost/glpi/plugins/webservices/xmlrpc.php
     login_name       glpi
     login_password   glpi
}
```

And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master
#    host_name       node1       ;result of the hostname command under Unix
     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           GLPI
     }
```

It's done :)

Ip Tag module

Why tag a host based on it's IP address? We learned on the *DMZ monitoring* that you can "tag" a host with a poller_tag so it will be checked only by DMZ pollers. It can be tedious process to manually tag all these hosts. Shinken provides an automated method to do this.

This is handled by the arbiter ip_tag module.

Ip_tag module The ip_tag module is an arbiter module that looks up the host address during the configuration parsing and compares it to an predefined IP range (IPV4 or IPV6). If the range matches, it can apply or add a property, such as poller_tag. Other types of tags could be related to locations, functions, administrative groups, etc.

Method: replace or append.

replace will put the value if the property is unset. This is the default method. .. warning:: Fix me: replace, implies overriding an existing value. And will cause user issues down the line. Rename it to set. Replace should be a different method altogether, so overall there should be 3 methods(set, append, replace).

append will add with a , if a value already exist

Here is an example that will set the poller_tag property with the value DMZ of all hosts that:

- have a their hostadress ip (or name resolved) in the range 192.168.0.1/24.
- do not already have a poller_tag property set

```
define module{
```

```
     module_name     IpTag
     module_type     ip_tag
     ip_range        192.168.0.1/24
     property        poller_tag
     value           DMZ
}
```

To use the module add it in the arbiter object:

```
::
```

define arbiter { [...] modules NSCA,IpTag

}

Add value instead of setting it In the previous example we set the property poller_tag to a value. But what if we want to "add" a value, like a template name? We can change the "method" property of the module to "append" so we can add the "value" to the host property instead of replace it.

Here is an example where we want to add the "dmz" template on the hosts, while also keeping any defined templates:

```
define module{
```

```
     module_name   IpTag
     module_type   ip_tag
     ip_range      192.168.0.1/24
     property      use
     value         dmz

     # Optional method
     method append
}
```

For a host defined as:

```
define host{
```

```
     host_name   example_host1
     address     192.168.0.2
     use         linux
}
```

It will be "changed" internaly in:

```
define host{
```

```
     host_name   example_host1
     address     192.168.0.2
     use         linux,dmz
}
```

Name resolution Of course you don't need to set IP address in the address of your host. You can set a hostname, and it will be resolved, and then compared to the range. :)

Ubuntu Landscape import

Description You can import data from Ubuntu Landscape into Shinken to create hosts.

Ubuntu Landscape, is a web app to manage all your linux servers (update and co), which is provided by Canonical, Ubuntu's parent company.

This is an Arbiter import module. The Arbiter manages the configuration.

Prerequisites

You will need the landscape-api package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

define module { module_name Landscape module_type landscape_import

Configure your REAL key and secret from Landscape key PAAAB2CILT80I0ZA0999 secret GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH default_template generic-host ; if the host is not tagged, use this one

If you are using a specific certificate for landscape_api #ca /path/to.ca.cert

If you need a proxy to access https://landscape.canonical.com/api/ #https_proxy http://user:secret@myproxy.com:3128

}

- Put in key and secret your private Landscape access.
- default_template will be used if your host is not "tagged" in Landscape
- If you are using a specific certificate for connexion, give the full path in ca
- You will certainly need an https proxy to access the Landscape API. If so, configure it there.

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master
#    host_name       node1       ;result of the hostname command under Unix
     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           Landscape
     }
```

Restart your Arbiter and it's done :)

Tip: Your "tags" will be applied as templates for your hosts.

Shinken Livestatus API

Overview

- Jump back to Getting Started
- Jump back to *Livestatus module configuration*

What is it Livestatus API is the modern method of interacting with Shinken and Nagios based systems alike.

Originally developed for Nagios, MK Livetstatus, was re-implemented in Python for use with Shinken by professional developers. The access methods and query languages are the same.

Why use it It is fast.

It is network based using TCP.

It is standard for all Nagios and Shinken monitoring systems.

It uses in-memory structures for status data

It uses a back-end database for historical reporting

It uses an SQL based query language

It has a host of powerful nuts and bolts features (authentication, caching, connection persistence, multiple object methods (JSON, Python)).

What can I do with it? All programs and scripts use (or should use) this method to :

- Obtain the current state of hosts and services
- Obtain the current configuration related to hosts and services
- Send administrative commands (downtimes, comments, forcing checks)
- Filter information to display
- Obtain basic reports and event statistics

Shinken being a modern re-implementation of Nagios has additional features that are available in addition to the standard Livestatus API.

Shinken Livestatus API unique features can :

- Obtain Business Impact information
- Obtain intelligent dependency status hosts or services (combines dependency and parent information)
- Obtain Business Process states (same syntax as standard host and service queries)

How does it work Livestatus uses a powerful SQL-like query language. The standard methods and parameters are defined at :

'MK Livestatus reference methods and query language definition'_

Full list of Shinken Livestatus API methods:

'Shinken mapping.py methods'_

What software uses Livestatus to interact with Shinken

Well known Web frontends

- MK Multisite
- Thruk
- NagVis

- Splunk for Nagios

Mobile Web frontends

- get list

Scripts

- Downtime management scripts
- Debug scripts

Installing Livestatus Have you installed the required packages to use the Livestatus module? You can look at the requirement section of the *10 minute installation guide* for the *requirement lists*.

How to enable Livestatus Very simple, jump to the *Shinken Broker configuration* section to enable it. .. _Shinken mapping.py methods: https://github.com/shinken-monitoring/mod-livestatus/blob/master/module/mapping.py .. _MK Livestatus reference methods and query language definition: http://mathias-kettner.de/checkmk_livestatus.html

NSCA module The NSCA daemon module is used to receive send_nsca packets and submit them to the Shinken command pipe. The NSCA module can be loaded by the Receiver or Arbiter process. It will listen on port TCP/5667 for send_nsca packets.

Tip: Passive checks can be submitted *natively to the Shinken command pipe* or from remote hosts to modules, such as NSCA, AMQP or collectd, loaded in the Shinken Arbiter or Receiver process. AMQP is implemented for integration with the Canopsis Hypervisor, but could be re-used for generic messaging.

Note: The Shinken NSCA module implementation is currently limited to the "xor" obfuscation/encryption.

In your shinken-specific.cfg file, just add (or uncomment):

```
::
```

#You can send check result to Shinken using NSCA #using send_nsca command define module{

module_name NSCA module_type nsca_server host * port 5667 encryption_method 0 password helloworld

}

define receiver{

```
receiver_name    receiver-1
address          localhost
port             7773
modules          NSCA

timeout          3             ; 'ping' timeout
data_timeout     120           ; 'data send' timeout
max_check_attempts       3     ;  if at least max_check_attempts ping failed, the node is DEAD

#advanced
realm    All
}
```

This daemon is totally optional.

It's main goal is to get all passive "things" (checks but why not other commands) in distant realms. It will act as a "passive receive buffer" and will then dispatch the data or commands directly to the appropriate Scheduler or Arbiter process.

Data can be received from any Realm, thus the Realm option is nonsensical.

For now there is no init.d script to launch it. .. note:: Verify that the init script has been added.

It is launched like all other daemons:

```
bin/shinken-receiver -c etc/receiverd.ini
```

Tip: Alternatively, for small installations with you can configure a modules inside your Arbiter instead of the Receiver. It will listen the TCP/5667 port for send_nsca packets.

To configure the NSCA module in your Arbiter instead of Receiver. Add the NSCA module to your Arbiter object configuration.

```
::
```

define arbiter{ arbiter_name Arbiter-Master

 # host_name node1 ;result of the hostname command under Unix address localhost ;IP or DNS adress port 7770 spare 0 modules NSCA

}

Retention troubleshooting The retention file contains the state of your host and services, so that they are kept when shinken is restarted.

Sometimes you'll want to inspect (and possibly fix) the retention file, in case you need to work-around a bug or simply better understand what is stored there.

When you use the PickleRetention module in the scheduler (cf. ''define scheduler" in ''shinken-specific.cfg''), you can simply manipulate the retention file using Python.

For this you can use the following code.

- It assumes Shinken is installed in ''/opt/shinken" with the retention file in ''/tmp/retention.dat'':
- Run and play with it interactively using ''ipython -i inspect_retention.py''.

```
#!/usr/bin/python
import pickle
import sys
sys.path.append('/opt/shinken')
import shinken

r = pickle.load(file('/tmp/retention.dat'))
h = r['hosts']

# Example:
# [(k,v) for (k,v) in h['your_host'].items() if k.find('downtime') >= 0]
#
# del h['your_host']
#
# for k,v in r['services'].items():
#     if 'your_host' in k:
#         del r['services'][k]
```

To save your changes:

- Stop Shinken: ‘’service shinken stop’‘
- Save the pickle: ‘’pickle.dump(r, open(‘/tmp/retention.dat’, ‘w’))’‘
- Start Shinken: ‘’service shinken start’‘

NRPE Module

What is it The NRPE module allows Shinken Pollers to bypass the launch of the check_nrpe process. It reads the check command and opens the connection by itself. It scales the use of NRPE for active supervision of servers hosting NRPE agents.

The command definitions should be identical to the check_nrpe calls.

How to define it The definition is very easy (and you probably just have to uncomment it):

```
define module{
     module_name       NrpeBooster
     module_type       nrpe_poller
}
```

Then you add it to your poller object:

```
define poller {
    [...]
    modules   NrpeBooster
}
```

Then just tag all your check_nrpe commands with this module:

```
define command {
   command_name   check_nrpe
   command_line   $USER1$/check_nrpe -H $HOSTADRESS$ -c $ARG1$ -a $ARG2$
   module_type    nrpe_poller
}
```

That’s it. From now on all checks that use this command will use Shinken’s NRPE module and will be launched by it.

Extending Shinken

Introduction There are a lot of “Modules” and “Addons” that are available for Shinken. Shinken can be extended by using different types of methods.

- Web interfaces from various open-source vendors can be used (Based on Livestatus API)
- Shinken itself can be extended using modules that are embedded into the various daemon processes

** (Arbiter, Poller, Receiver, Broker, Scheduler, Reactionner) * External software can provide functional enhancements for reporting, management or usability aspects

Shinken itself provides methods to extend the base functionality:

- *Broker modules* provide external access to runtime data from Shinken
- Poller modules such as *NRPE* and the *SNMP*
- Receiver modules like *NSCA* provide acquisition methods for Shinken

- Arbiter modules permit manipulating the configuration
- The webUI that permits embedding web interface elements

Independent software that works in concert with Shinken is available for:

- Monitoring remote hosts through agent software (*NIX, Windows, etc.)
- Submitting passive checks from remote hosts
- Managing the config files through a web interface
- Mobile phone UIs
- Desktop UIs and Hypervisors
- Desktop notification addons
- ...and much more

You can find many addons that are compatible with Shinken by visiting. The only caveat is that the addons should not use the status.dat file and preferably the modern API interfaces like Livestatus:

- Nagios.org
- SourceForge.net
- NagiosExchange.org
- Shinken community exchange for monitoring packs

Broker modules The broker module receives messages from the Schedulers related to host, service check results. In addition to that it receives a copy of the compiled configuration at startup. What is special about the broker, is that without modules, the broker does nothing. It makes the configuration and result data available to modules. Modules are the ones in charge of doing something with the data. This could be exporting this "raw" data into flat files, databases or exposing it as an API.

The modules are presented according to their use cases.

- Core modules
- Livestatus Module for frontends
- Exporting data to metric databases
- SQL based Modules for frontends
- Exporting data to logging management systems
- Legacy modules for migration purposes
- Modules no longer supported

Core modules

simple_log: get all logs into one file You can get a log for all your daemons in a single file. With the exception of Debug level logs which are not sent through the network as a safe guard. Shinken state messages are ONLY logged at the debug level in the local log files. These are the ALL CAPS states that some 3rd party interfaces use to mine data from the historical logs. Actual state messages are sent as objects between the various daemons.

It takes the parameters:

- module_name: name of the module called by the brokers

- module_type: simple_log
- path: path of the log file

Here is an example:

```
define module{
```

```
     module_name      Simple-log
     module_type      simple_log
     path             /usr/local/shinken/var/nagios.log
     archive_path     /usr/local/shinken/var/archives/
}
```

Syslog - Send all logs to a local syslog server Send all logs to a local syslog server. Support for remote syslog can be implemented if requested. Just lookup the syslog module, easy to modify. Use for example with Splunk, graylog2, Logstash, Elastic search, Kibana, or other log management and analysis system.

```
define module{
```

```
  module_name Syslog
  module_type syslog
}
```

Lightweight forwarder to Splunk Shinken state data from the local syslog can also be sent to a Splunk server for indexing, reports, SLA and analysis. Via syslog or better yet, the Splunk lightweight forwarder which supports, TCP, buffering and security parameters.

Livestatus API Module - Thruk, Nagvis and Multisite Web frontends There are three well known frontends and various small tools that can interface with the Livestatus API. This API is currently the most efficient method of sharing live data with external interfaces. It provides a rich query language similar to SQL, authentication, command execution, caching,connections persistence, multiple object methods (JSON, Python). All Livestatus data is kept in memory, there is no disk IO involved. It exposes configuration objects, the current state of the hosts and services as well as historical Shinken state log messages.

- MK Multisite
- Thruk
- NagVis

Have you installed the required packages to use the Livestatus module? You can look at the requirement section of the 10 minute installation guide for the requirement lists.

Livestatus Module

It takes the following parameters:

- module_name: name of the module called by the brokers
- module_type: livestatus
- host: IP interface to listen to. The default is '127.0.0.1'. '*' means 'listen on all interfaces'.
- port: TCP port to listen to.
- socket: Unix socket to listen to.

- allowed_hosts: a comma-separated list of IP-addresses which are allowed to contact the TCP port. Please keep in mind that these must be ip-addresses, NOT host names. (DNS lookups for every incoming livestatus request could hang up and therefore block the module)
- modules: a comma-separated list of modules (see below)
- pnp_path: relevant if you use the multisite gui. pnp_path points to the perfdata directory where the pnp4nagios data reside (it's the directory which contains a subdirectory for each host). Multisite needs it to display a small perfdata icon if a rrd file exists.
- To deactivate an input, the port- and socket-attributes can also take the value "none".

The Livestatus module itself can have sub-modules. In fact, it **must** have at least one submodule responsible for storing log events to a database, SQLite or MongoDB.

Livestatus module - Logstore Sqlite Stores log-broks to an sqlite database.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_sqlite
- use_aggressive_sql: Prefer the use of sql queries to pre-filter data prior to python filtering. This is required for very large installations, as the Python structures are not indexed when filtering. Optional argument set to 0 by default. To enable set the value to 1. Some erroneous output may occur, but informal testing has shown these corner cases do not occur.
- read_only: don't send any update to the database. Should be used when you run several livestatus modules : 1 instance is R/W, other are read only.
- database_file: the path to the sqlite database file which is used to store the log broks/messages. The default is 'var/livestatus.db'
- archive_path: the path to a subdirectory where database file archives will be created. Every day the data from the last day will be moved to an archive datafile. The default is 'var/archives'.
- max_logs_age: the maximum age of the log messages (before they are deleted from the database). The default is 1 year. The argument to this parameter takes the form <number>[<period of time>], where <period of time> can be d for days, w for weeks, m for months and y for years. This parameter is currently ignored. In future releases it will be used to automatically delete ancient database files.

Here is an example:

```
define module{
```

```
     module_name      Livestatus
     module_type      livestatus
     host             *       ; * = listen on all configured ip addresses
     port             50000   ; port to listen
     socket           /usr/local/shinken/var/rw/live
     modules          logsqlite
}
define module{
```

```
     module_name      logsqlite
     module_type      logstore_sqlite
     use_aggressive_sql     0 ; optional, by default set to 0. Only for large installations.
     database_file    /usr/local/shinken/var/livelogs.db
     max_logs_age     3m ; three months. Other time intervals are d=days, w=weeks, y=years
}
```

Livestatus module - Logstore MongoDB Stores historical log broks(inter daemon Shinken messages) to a MongoDB database. MongoDB is a distributed and very performant database that permits resilience and high availability. The current implementation has a few known broken pieces (some search functions are broken) and there are bugs in the implementation, so it is considered experimental until power users and developers have ironed out the bugs. It is the database of the future for Shinken.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_mongodb
- mongodb_uri: The address of the master. (Default: i_cant_write_the_uri_here_it_messes_the_wiki_up)
- replica_set: If you are running a MongoDB cluster (called a "replica set" in MongoDB), you need to specify it's name here. With this option set, you can also write the mongodb_uri as a comma-separated list of host:port items. (But one is enough, it will be used as a "seed")
- database: <undocumented>
- collection: <undocumented>
- max_logs_age: <undocumented>

The configuration looks quite similar to the sqlite one. **In a single-node installation and with decent amount of log traffic, the sqlite backend should be considered best practice, as it needs no extra software and is stable and fast (when run in-memory).**

Livestatus module - Logstore Null In case you don't need any logging (for instance, if you dedicate a livestatus module instance to nagvis), you can use this module.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_null

Network Based Modules - Graphite graphing Graphite is a graphing and data analysis tool. It is composed of a web frontend (graphite-web), fixed size databases (whisper) and data redistribution/munging daemon. (carbon) The first step is *having Graphite installed somewhere*, if you do not have Graphite installed, please do this and come back later.

Pre-requisite : Shinken 1.2.2+ is recommended for the best experience with Graphite.

graphite_perfdata: exports check result performance data to Graphite Export all performance data included in check results to Whisper databases managed by Graphite. Data is buffered, then exported once every broker time tick. (Once per second). Should a communication loss occur, it will buffer data for 5 minutes before dropping data. The tick_limit max is configurable, the only limitation is the amount of memory the buffered data can eat.

The graphite broker module (v1.2) sends data to graphite in the following format :

HOSTNAME.SERVICENAME.METRICNAME

It can be optionally enhanced to send it the following format :

_GRAPHITE_PRE.HOSTNAME.SOURCE.SERVICENAME.METRICNAME._GRAPHITE_POST

Each of the three variables are optional :

- The _GRAPHITE_PRE variable can be set per host/service to provide a more flexible naming convention. (ex. Prod.site1.Hostname.servicename)

- The _GRAPHITE_POST variable can be set per host/service to specify the more information concerning the variable being stored that graphite can use to determine the retention rule to use for the variable.
- The SOURCE variable can be set in shinken-specific.cfg for the WebUI module and the Graphite broker.

Metric names are converted from Shinken's format to a more restrictive Graphite naming. Unsupported characters are converted to "_" underscore. So do not be surprised to see that some names differ in the WebUI or directly in Graphite. Permitted characters in Graphite are "**A-Za-z_**.", the hyphen character is permitted from Shinken, though only future versions of Graphite will support it.

Performance data transfer method can be set to pickle, which is a binary format that can send data more efficiently than raw ascii.

It takes the following parameters:

- module_name: name of the module called by the brokers
- module_type: graphite_perfdata
- host: ip address of the graphite server running a carbon instance
- port: port where carbon listens for metrics (default: 2003 for raw socket, 2004 for pickle encoded data)
- use_pickle: Use a more efficient transport for sending check results to graphite instead of raw data on the socket (v1.2)
- tick_limit: Number of ticks to buffer performance data during a communication outage with Graphite. On tick limit exceeded, flush to /dev/null and start buffering again. (v1.2)
- graphite_data_source: Set the source name for all data coming from shinken sent to Graphite. This helps diferentiate between data from other sources for the same hostnames. (ex. Diamond, statsd, ganglia, shinken) (v1.2)

Here is an example:

```
define module {
```

```
module_name Graphite-Perfdata
host xx.xx.xx.xx
module_type graphite_perfdata
port 2004 ; default port 2003 for raw data on the socket, 2004 for pickled data
use_pickle 1 ; default value is 0, 1 for pickled data
tick_limit 300 ; Default value 300
graphite_data_source shinken ; default is that the variable is unset
}
```

SQL Based Modules - PNP4Nagios Graphing PNP4Nagios is a graphing tool that has a web interface for RRDTool based databases. Shinken can export performance data to an npcd database which will feed the RRD files (fixed sized round robin databases). You can *learn how to install PNP4Nagios* if you haven't done it already.

npcdmod: export perfdatas to a PNP interface Export all perfdata for PNP.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: npcdmod
- path: path to the npcd config file

Here is an example:

```
define module{
 module_name  NPCD
 module_type  npcdmod
 config_file  /usr/local/pnp4nagios/etc/npcd.cfg
}
```

SQL Based Modules - Frontend Centreon2 Centreon2 use a NDO database, so you will need the ndodb_mysql module for it.

ndodb_mysql: Export to a NDO Mysql database Export status into a NDO/Mysql database. It needs the python module MySQLdb (apt-get install python-mysqldb or easy_install MySQL-python).

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: ndodb_mysql
- database: database name (ex ndo)
- user: database user
- password: database user passworddt
- host: database host
- character_set: utf8 is a good one

Here is an example:

```
define module{
```

```
     module_name      ToNdodb_Mysql
     module_type      ndodb_mysql
     database         ndo       ; database name
     user             root      ; user of the database
     password         root      ; must be changed
     host             localhost ; host to connect to
     character_set    utf8      ;optionnal, UTF8 is the default
}
```

File based Legacy modules - perfdata export

service_perfdata: export service perfdatas to a flat file

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: service_perfdata
- path: path to the service perfdata file you want

Here is an example:

```
define module{
```

```
    module_name      Service-Perfdata
    module_type      service_perfdata
    path             /usr/local/shinken/src/var/service-perfdata
}
```

host_perfdata: export host perfdatas to a flat file

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: host_perfdata
- path: path to the host perfdata file you want

Here is an example:

```
define module{
```

```
    module_name      Host-Perfdata
    module_type      host_perfdata
    path             /usr/local/shinken/src/var/host-perfdata
}
```

Legacy File based Modules - Old CGI or VShell The Old CGI and VShell use the flat file export. If you can, avoid it! It has awful performance, all modern UIs no longer use this.

status_dat: export status into a flat file Export all status into a flat file in the old Nagios format. It's for small/medium environment because it's very slow to parse. It can be used by the Nagios CGI. It also export the objects.cache file for this interface.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: status_dat
- status_file: path of the status.dat file /usr/local/shinken/var/status.dat
- object_cache_file: path of the objects.cache file
- status_update_interval: interval in seconds to generate the status.dat file

Here is an example:

```
define module{
```

```
    module_name              Status-Dat
    module_type              status_dat
    status_file              /usr/local/shinken/var/status.data
    object_cache_file        /usr/local/shinken/var/objects.cache
    status_update_interval   15 ; update status.dat every 15s
}
```

Deprecated or unsupported modules

SQL Based MerlinDB This interface is no longer supported and is going to be completely removed from Shinken.

SQL based ndodb_oracle - Icinga web frontend using NDO Oracle This interface is no longer supported and is going to be completely removed from Shinken.

CouchDB: Export to a Couchdb database This interface is no longer supported and is going to be completely removed from Shinken.

TSCA (Thrift Service Check Acceptor) TSCA is a receiver/arbiter module to receive hosts and services check results. It provides the same functions as NSCA with additional features. High performance binary transmission, multi line output and auto generated clients for a variety of languages.

What is thrift ? Let's cut and paste the wikipedia definition from'en.wikipedia.org/wiki/Apache_Thrift'_ :

"Thrift is an interface definition language that is used to define and create services for numerous languages.[1] It is used as a remote procedure call (RPC) framework [..]. It combines a software stack with a code generation engine to build services that work efficiently to a varying degree and seamlessly between ActionScript, C#, C++ (on POSIX-compliant systems), Cappuccino, Cocoa, Erlang, Haskell, Java, OCaml, Perl, PHP, Python, Ruby, and Smalltalk."

Installation In any case, you have to install thrift with support for python (on the server side) and languages you want to use for clients.

Get it from thrift.apache.org or in your favorite distribution repository.

Server side Go to the tsca module directory and generate the python stub for the server side installation

```
cd shinken/modules/tsca
$ thrift --gen py tsca.thrift
```

Declare the module is shinken-specific.org

```
define module{
      module_name     TSCA
      module_type     tsca_server
      host            0.0.0.0
      port            9090
}
```

Samples clients There are three(3) client samples written in python, ruby and java in contrib/clients/TSCA of the Shinken distribution. You can use and extend them to send data directly in your code directly to Shinken's TSCA receiver/arbiter module.

The samples clients read a CSV file from stdin and send them the the TSCA running on localhost:9090. The CSV has the following format :

```
hostname,service description,output,rc
```

Any use of TCP in an application should take care not to block the program and to have very short timeouts. For applications that need non blocking functions, prefer a UDP based transport or a local buffer file with a separate application(send_nsca, thrift, etc) to forward your data to Shinken.

Ruby Generate the stub

```
$ thrift --gen rb ../../../shinken/modules/tsca/tsca.thrift
```

Run the client

```
$ cat file_state | ruby RubyClient.rb
```

Python Generate the stub

```
$ thrift --gen py ../../../shinken/modules/tsca/tsca.thrift
```

Run the client

```
$ cat file_state | python PythonClient.py
```

java Generate the stub

```
$ thrift --gen java ../../../shinken/modules/tsca/tsca.thrift
```

Compile the client

```
$ ant
```

Run the client

```
$ cat file_state | java JavaClientThrift
```

VMWare Arbiter module

How it works The arbiter has a module that allows the host->VM automatic host dependency creation. In fact, the module is far more generic than just this. It's a generic "host link dependencies" module.

It reads a mapping file (simple json format) with son->father links. It call an external script at a regular interval : the one I wrote is a VMWare mapping one. It used the check_esx3.pl (that all ESX admin should have) plugin and generate the mapping file. When this file is changed, the module reloads it, creates new links and deletes old ones. So when you VMotion a virtual machine, in the next pass, there will be creation of a new link and deletion of the old one in the scheduler that manages it :)

How to define it The definition is very easy :

```
define module{
     module_name       VMWare_auto_linking
     module_type       hot_dependencies
     mapping_file      /tmp/vmware_mapping_file.json
     mapping_command   /usr/local/shinken/libexec/link_vmware_host_vm.py -x '/usr/local/shinken/libex
     mapping_command_interval 60   ; optionnal
     mapping_command_timeout   300 ; optionnal
}
```

Then you add it in you arbiter object :

```
define arbiter {
    [...]
    modules   VMWare_auto_linking
}
```

So here, it will call the script /usr/local/shinken/libexec/link_vmware_host_vm.py with a listing of the vCenter vcenter.mydomain.com and generate the mapping file /tmp/vmware_mapping_file.json.

You can call : /usr/local/shinken/libexec/link_vmware_host_vm.py –help

for the full help on this script.

It looks at the file modification time each second. This command can also be launch by an external cron of course.

Note: So if you want to write a script that does this for XEN servers, all you need is to generate a json file with all the mapping. I didn't wrote the doc about this, but you can look in the test file for it, the format is very very easy :)

Here is an example of the JSON mapping file syntax:

%%:ref:*["host", "physical_host"], ["host", "virtual_machine"* <["host", "physical_host"], ["host", "virtual_machine">, "host", "physical_host"], ["host", "other_virtual_machine" <"host", "physical_host"], ["host", "other_virtual_machine">]%%

So just a list of couple 'host' string (from now only host are managed) and the host name.

Beware about it : you need the real host_name, including case.

Web Service Module The Ws_arbiter module is a Receiver or Arbiter module to receive passive check results from remote hosts via HTTP(s). This module is considered a work in progress but can be used for testing and improvement.

Configuring the Web Service Module If data is POSTed to this page, it will validate the data to determine if it is a service or host check result and submit the data to the Shinken external command queue.

The web service listens by default to TCP port 7760. The web service supports anonymous or authenticated access. Web service parameters are set in the Shinken-specific.cfg file, in the Ws_arbiter module. To enable the web service, simply add the module to your Arbiter or Receiver daemon configuration in Shinken-specific.cfg

Using the Web Service Module The web service listens for POSTs to: /push_check_result

Use curl or embed the HTTP calls in your software to submit check results.

curl -u user:password -d "time_stamp=$(date +%s)&host_name=host-checked&service_description=service-checked&return_code=0&output=Everything OK" http://shinken-srv:7760/push_check_result

Example with more readability:

```
curl
```

-u user:password -d "time_stamp=$(date +%s)

```
&host_name=host-checked
&service_description=service-checked
&return_code=0
&output=Everything OK
http://shinken-srv:7760/push_check_result
```

SNMP module This part must be splitted and sent in all module repositories

Shinken integrated SNMP Module

SnmpBooster Download Install and Configure

- *What is the SnmpBooster module*
- Install and configure the SNMP acquisition module. [You are here]
- *Reference - SnmpBooster troubleshooting*
- *Reference - SnmpBooster design specification*
- *Reference - SnmpBooster configuration dictionnary*

Downloads

The SnmpBooster module and genDevConfig are currently in public beta prior to integration within Shinken. You can consult t

- github.com/xkilian/genDevConfig
- github.com/titilambert/shinken/tree/snmp_booster/shinken/modules (snmp_booster branch) * Simply right-click and download snmp_poller.py then copy it to shinken/modules/

Requirements The SnmpBooster module requires:

- Python 2.6+
- Shinken 1.2+
- PySNMP 4.2.1+ (Python module and its dependencies)
- ConfigObj (Python module)
- python-memcached
- memcachedb or memcached package for your operating system (ex. For Ubuntu: apt-get install memcachedb) *Note*

The genDevConfig profile generator depends on:

- Perl 5.004+
- 4 perl modules available from CPAN and network repositories. genDevConfig/INSTALL has the installation details.

STRONGLY RECOMMENDED: Use the same version of Python and Pyro on all hosts running Shinken processes.

Installation SnmpBooster:

- Install the dependencies
- Copy the file snmp_poller.py from the git repository to your shinken/modules directory.
- Configuration steps are listed in the present web page.

genDevConfig:

- Download and extract the archive to your server.
- See genDevConfig/INSTALL on how to install and configure it.

Configuration

How to define the SnmpBooster module in the Shinken daemons You need to modify shinken-specific.cfg, which is located in $shinken/etc/shinken-specific.cfg

Arbiter daemon configuration Simply declare the module:

```
modules SnmpBooster</code>
```

Scheduler daemon configuration

Simply declare the module:

<code>modules SnmpBooster

Poller daemon configuration Simply declare the module:

```
modules SnmpBooster</code>
```

SnmpBooster Module declaration

Included in Shinken v1.2.1 shinken-specific.cfg.

<code>define module {

```
module_name          SnmpBooster
module_type          snmp_poller
datasource           /usr/local/shinken/etc/packs/network/SnmpBooster/   ; SET THE DIRECTORY FOR YOUR
memcached_host       x.x.x.x  ; SET THE IP ADDRESS OF YOUR memcached SERVER
memcached_port       11211  ; default port for a memcached process
```

}

If you do not know the IP adress on which your memcache is listening, check under /etc/memcached.conf. Or do a:

```
netstat -a | grep memcached</code>
If you are running a test on the local machine you can leave memcached on 127.0.0.1 (localhost), but
```

How to define a Host and Service

Step 1

Create a template for your SNMP enabled devices.

Sample template:

<code>cd shinken/etc/packs/network/ mkdir SnmpBooster

vi shinken/etc/packs/network/SnmpBooster/templates.cfg

```
define command {
```

```
command_name    check_snmp_booster
command_line    check_snmp_booster -H $HOSTNAME$ -C $SNMPCOMMUNITYREAD$ -V 2c -t $ARG1$ -i $_SERVICE
module_type     snmp_poller
```

}

```
define service {
```

```
name                    default-snmp-template
check_command           check_snmp_booster!$_SERVICEDSTEMPLATE$!$_SERVICEINST$!$_SERVICETRIGGERGROUP
_inst                   None
_triggergroup           None
max_check_attempts      3
check_interval          1
retry_interval          1
register                0
```

}

```
define host{
```

```
name                    SnmpBooster-host
alias                   SnmpBooster-host template
check_command           check_host_alive
max_check_attempts      3
check_interval          1
retry_interval          1
use                     generic-host
register                0
```

}

Step 2 Define some hosts and services. You would typically use genDevConfig or another configuration generator to create these for you.

Mandatory service arguments related to SNMP polling:

```
_dstemplate                Cisco-Generic-Router  ; Name of a DSTEMPLATE defined in the SnmpBooster co
```

```
snmpcommunityread    which is set in your resource.cfg file
```

Optional service arguments related to SNMP polling with default values:

```
_inst                   None   ; Could be numeric: 0, None or an instance mapping function like: map
```

```
_triggergroup           None   ; Name of the triggergroup defined in the SnmpBooster config.ini file
```

Sample Shinken host and service configuration:

```
# Generated by genDevConfig 3.0.0
# Args: --showunused -c publicstring 192.168.2.63
# Date: Thu Aug 30 17:47:59 2012

```
 host_name            192.168.2.63
 service_description  chassis
 display_name         C2960 class chassis
 _dstemplate          Cisco-Generic-Router
 _inst                0
 use                  default-snmp-template
 register             1
}

define service {
```

```
 host_name            192.168.2.63
 service_description  chassis.device-traffic
 display_name         Switch fabric statistics - Packets per Second
 _dstemplate          Device-Traffic
 use                  default-snmp-template
 register             1
}

define service {
```

```
host_name            192.168.2.63
service_description  if.FastEthernet0_1
display_name         FastEthernet0_1 Description: Link to Router-1 100.0 MBits/s ethernetCsmacd
_dstemplate          standard-interface
_inst                map(interface-name,FastEthernet0_1)
use                  default-snmp-template
register             1
```

}

Here is an example configuration of the config.ini file

```
[DATASOURCE]
```

```
  OidmyOidDefinition = .1.3.6.1.45.0

Shinken integrated SNMP Module

Overview

What is it The SnmpBooster module allows Shinken Pollers to directly manage SNMP data acquisition. This is an all Python cross-platform SNMP module. It is tightly integrated with the Shinken Poller, Scheduler and Arbiter daemons to provide the best possible user experience.

- Jump back to *SnmpBooster documentation index*

Design specification summary

- STATUS - DESIGN SPEC PERFORMANCE
- [Done] Functions as an integrated Shinken Poller module
- [Done] Necessary integration code commited to Shinken official release (Integrated starting at v1.2)
- [Done] Ability to collect thousands of SNMP metrics per second
- [Done] Be compatible with distributed data acquisition
- [Done] Collect data for a host/check_interval tuple via SNMP in a single pass
- [Done] Use all builtin Shinken scheduler logic for retries, forced checks, timeouts, dependencies, parents
- [Done] Store collected data for the duration of the check_interval in a memcached/membase
- [Done] On a restart, after the first collection, be able to pick up where the last check left and calculate derived values
- [Done] Forced check are not allowed within 30 seconds of last SNMP query to the same host/check_interval, all other requests get data from the cache.
- [Done] Only a single request to the host/check_interval via SNMP is allowed at a time, all other requests get data from the cache.
- STATUS - DESIGN SPEC USABILITY
- [Done] Usage documentation
- [xxxx] SkonfUI and Discovery usage documentation
- [xxxx] Provide sample configuration packs in Shinken
- [Done] Provide sample config.ini with examples of all types of data * SNMP OIDS, DATASOURCES, DSTEMPLATES, TRIGGERS and TRIGGERGROUPS

- [Done] Directly compatible for use with genDevConfig Shinken SNMP configuration generator
- [Done] Provide meaningful feedback for users on errors
- [Done] Capture all tracebacks and convert them to actual error or warning messages
- STATUS - DESIGN SPEC FEATURES
- [Done] Return state and performance metrics
- [Done] Performance metrics can be returned in a Weathermap compatible format
- [Done] Configuration file format is ConfigObj INI
- [Done] Load all valid INI configuration files from a directory and merge them
- [Done] Load a single INI configuration file
- [xxxx] Load a list of INI configuration files
- [Done] Configuration file describes all generic acquisition parameters (OID, DATASOURCE, DSTEMPLATE, MAP, TRIGGER, TRIGGERGROUP)
- [Done] Supports Triggers which are calculation rules to determine states
- [Done] Triggers support an RPN (Reverse Polish Notation) calculation engine which includes mathematical and logical operators
- [Done] Each TRIGGER is associated with a severity level, WARNING or CRITICAL
- [Done] Multiple TRIGGERS can be associated with a TRIGGERGROUP
- [Done] Use builtin Python Operators
- [Done] Support DERIVE, TEXT, GAUGE and COUNTER data types
- [xxxx] Support TIMETICKS data type
- [Done] Support applying RPN based calculations to received metric for scaling or conversion purposes
- [Done] Use a Python SNMP library which supports asynchronous acquisition PySNMP
- [Done] Datasources can use rule based runtime instance mapping
- [Done] Set Snmp version as a check runtime option
- [Done] Set Snmp DSTEMPLATE as a check runtime option
- [Done] Set Snmp TRIGGERGROUP as a check runtime option
- [Done] Set Snmp COMMUNITY as a check runtime option
- [Done] Use Snmp version 2c GetBulk
- [xxxx] Support Snmp version 2c GetNext if GetBulk is not supported
- [xxxx] Support Snmp version 1 GetNext
- [xxxx] Set Snmp Timeout as a check runtime option, instead of a hardcoded value at 5 seconds
- STATUS - DESIGN SPEC MAINTAINABILITY
- [xxxx] Functions documented in the source code
- [Done] Critical functions documented in the source code
- [Done] Locking sections identified in the code
- [xxxx] Unit tests with at least 80% coverage

- [xxxx] Unit tests integrated with Shinken test suite
- [Done] Code hosted on github
- [xxxx] configuration validity and integrity checking of all INI files
- [xxxx] Pep8 compliant
- [xxxx] Pylint pass

genDevConfig Plugins - Compatibility status with SnmpBooster

- STATUS - genDevConfig maintained Plugins
- [Done] Avaya ES switches
- [Done] Avaya ERS routing switches
- [Done] Cisco 29x0 switches
- [Done] MIB-II Interfaces
- [Done] Cisco PIX/ASA
- [Done] JUNOS devices
- [Done] Cisco IOS routers
- [Done] NetSNMP unix hosts ** Validation required**
- [Done] Packeteer devices ** Validation required**
- [Done] Sensatronics devices ** Validation required**
- [Done] Foundry devices ** Validation required**
- [Done] Packeteer devices ** Validation required**
- [Done] Cisco CSS ** Validation required**
- [InProgress] New Cisco Access points
- STATUS - Other maintained Plugins

Tip: [xxxx] Denotes a specification that is planned but not implemented

[InProgress] Denotes a specification that is under development

[Done] Denotes a specification that is implemented

SnmpBooster reference dictionary

- Jump back to *SnmpBooster documentation index*

SnmpBooster.ini dictionary

There are five dictionaries:

- [DATASOURCE]
- [DSTEMPLATE]
- [MAP]
- [TRIGGER]

- [TRIGGERGROUP]

DATASOURCE DICTIONARY OidVariableName refers to an actual OID that can be queries using SNMP against the device on the network.

[VariableName] refers to a Datasource and all the information required to gather and prepare the data using SNMP ds_type refers to how the data should be prepared ds_calc refers to any scaling manipulations to make the data more understandable. This is an RPN expression, where the first variable is omitted, as it is always the $OidVariable ds_oid refers to the actual $OidVariable name. An instance identifier can be appended to the name to signify that an instance is provided by the Shinken service definition. This information is passed when the check is called. ...

DSTEMPLATE DICTIONNARY [DsTemplateName] refers to the name of the DSTEMPLATE that will be referred to in the Shinken service definitions. ds refers to the list of DATASOURCES to be collected. If an instance is expected for the list of DATASOURCES, it MUST be the same instance for all Oids. If a different instance is required, use a second DSTEMPLATE.

TRIGGER DICTIONNARY

TRIGGERGROUP DICTIONNARY

MAP DICTIONNARY

SnmpBooster.ini example configuration This example definition will be used to explain each section.

[DATASOURCE]

```
OidmyOidDefinition = .1.3.6.1.45.0
[myOidDefinition] ; Use the same name as the myOidDeiniftion, but omit the leading "Oid"
    ds_type = DERIVE
    ds_calc = 8,*  ; RPN expression : Oid, 8, *  Which means Oid * 8 = Total
    ds_oid = $OidmyOidDefinition
```

[DSTEMPLATE]

```
[myCiscoRouter]
    ds = myOidDefinition
```

[TRIGGER]

```
[trigger1]
    warning = RPN expression
    critical = RPN expression
[trigger2]
    warning = RPN expression
    critical = RPN expression
```

[TRIGGERGROUP]

```
[CiscoRouterTriggers]
    triggers = trigger1, trigger2
```

SnmpBooster.ini configuring SNMP Datasources

The first location is generic data related to SNMP parameters.

- DATASOURCE information * SNMP OID * Type of data and how can it be interpreted (GAUGE, COUNTER, COUNTER64, DERIVE, DERIVE64, TEXT, TIMETICK) * Data format preparation (Scaling the data for example bits to bytes) * Is there an instance to append to the
- Instance MAP function * Mapping the instance dynamically using a function * Data or rules related to the mapping function

SnmpBooster.ini configuring SNMP DSTEMPLATES

- DSTEMPLATEs to associate DATASOURCE to actual device classes * List of DATASOURCES associated with a, for example, Cisco 1900 router. Which in turn can be applied to a Shinken service

SnmpBooster.ini setting triggers/thresholds

- TRIGGER and TRIGGERGROUPS to apply thresholding rules * Define triggers and associate them with a TRIGGERGROUP name that can be applied to a Shinken Service

Shinken integrated SNMP Module

Overview

- Jump back to *SnmpBooster documentation index*

Tip: The module is now in public beta as of 2012-10-26! Have Fun!

Nothing new to add, more to come in 2013. 2013-01-19.

What is it The SnmpBooster module allows Shinken Pollers to directly manage SNMP data acquisition. This is an all Python cross-platform SNMP module. It is tightly integrated with the Shinken Poller, Scheduler and Arbiter daemons to provide the best possible user experience.

Why use it The SnmpBooster module is designed to be very efficient and scalable. It has a very flexible configuration method to make it easy to use with Shinken Monitoring Packs and Shinken discovery runners like genDevConfig.

This acquisition module was professionally designed and developed.

It is meant to be used by the very capable discovery engine genDevConfig (**v3.0.5 and newer**) originally developed for the Cricket SNMP monitoring tool and converted for use with Shinken.

It is one of the very few serious SNMP v2c implementation making use of SnmpGetBulk type requests.

How does it work

Shinken Integration

1. The SnmpBooster Arbiter module reads the Shinken SnmpBooster configuration file(s). It reads the check commands and based on the values in the check commands that use the snmp_poller module it will creates a shared configuration cache using memcached/memcachedb. The memcache key is always the combination of the hostname. This permits to tie together Shinken Hosts and Services with the SNMP specific configuration. (MongoDB and Redis are planned to be supported in the future) The Scheduler daemon schedules Host and Service checks as it normally does.

3. The SnmpBooster module will check that a memcache host key exists for the check to be launched. Then the SnmpBooster poller module will query all services related to a host for a given acquisition frequency in one pass. (all checks done every 2 minutes will be executed in bulk, same for those every 5 minutes)

5. Check results are cached for the acquisition check_interval. The next time a check request for data from the same host is received from the Scheduler, the data will be fetched from memcache. Resulting is extremely low check latency.

2. 6. The SNMP checks still benefit from retries, timeouts, forced checks, dependencies and the powerful Scheduler daemon logic.

6. The Scheduler daemon can still force an immediate re-check by flushing the cache. This is required for the dependency model.

Performance SnmpBooster uses SNMP v2c getbulk for high efficiency, unless forced to use SNMP v2c get-next or SNMPv1 get-next. GetBulk uses a single request PDU to ask for multiple OIDs or even entire tables, instead of sending one request PDU per OID.

For example: *A typical 24 port network switch with two uplinks might use 375 OIDS (8 OIDs per interface, plus general OIDs for chassis health, memory, cpu, fans, etc.). **SnmpBooster will only require around 4 request PDUs*

*instead of 375 request PDUs**. Each PDU is a request packet which takes time to create, send get processed and return. More timeouts to manage, more connections, more impact on the remote device and more latency means much fewer checks per second.*

The SnmpBooster module supports automatic instance mapping for OIDs. (Ex. Based on the interface name it will figure out that the SNMP index(or instance) is 136. This is automatically handled by genDevConfig and SnmpBooster, no user input required. :-)

The generic SNMP configuration information is stored in the Shinken SnmpBooster INI files. There is a Defaults_unified.ini and a series of other Defaults files, one per discovery plugin for genDevConfig.

Important: genDevConfig plugins have all been converted to use the new dynamic instance mapping methods. You are now free to use most if not all Defaults*.ini files included with genDevConfig. 2012-10-28

Limitations You should have memcached instances running on each poller responsible for snmp polling. You should have your pollers with SnmpBooster in the same datacenter, as they need to be on the same machine with good connectivity to the active memcached instance. SnmpBooster is not compatible with distributed pollers in multiple datacenters, sorry, the current design of SnmpBooster uses a single centralized memcached instance for storing the timeseries data. For distributed datacenters to be supported, each poller+scheduler+memcached must be realm restrained, which is not the case today.

Design specification *SnmpBooster design specification* and current development status.

Data model The information required to define the data is split in two locations.

The first location is the host and service Shinken configuration (You need to generate or write this)

- Device specific information
  - IP addresses, host_names, device types, instance keys
  - A DSTEMPLATE must be referred to in the Service definition
  - A static SNMP instance could be referred to in the Service definition
  - An SNMP instance MAP function could be referred to in the Service definition
  - A TRIGGERGROUP could be refered to in the Service definition

The second location is SNMP Defaults.* templates. (Here you can create new devices or add new data sources)

- DATASOURCE information
  - SNMP OID
  - Type of data and how can it be interpreted (GAUGE, COUNTER, COUNTER64, DERIVE, DERIVE64, TEXT, TIMETICK)
  - Data format preparation (Scaling the data for example bits to bytes)
  - Is there an instance to append to the
- Instance MAP function * Mapping the instance dynamically using a function * Data or rules related to the mapping function
- DSTEMPLATEs to associate DATASOURCE to actual device classes * List of DATASOURCES associated with a, for example, Cisco 1900 router. Which in turn can be applied to a Shinken service
- TRIGGER and TRIGGERGROUPS to apply thresholding rules * Define triggers and associate them with a TRIGGERGROUP name that can be applied to a Shinken Service

A final location containes rules to build your Shinken configuration.

- genDevConfig plugins create Shinken configurations

Installation and configuration *SnmpBooster installation*

Reference Dictionnary *SnmpBooster reference dictionary*

Troubleshooting *SnmpBooster troubleshooting*

Graph templates These are .graph files defined in your Shinken configuration directory. Refer to the Shinken graphite templates(Not yet created) or PNP4Nagios how-to documentation. The graph templates are independent from SnmpBooster and provide templates for any collected data from Shinken.

SnmpBooster Troubleshooting

- Jump back to *SnmpBooster documentation index*

Check your config

- Have you defined the poller module name?
- Have you defined the correct path to the directory containing your Defaults*.ini files?
- Have you addded the Snmpbooster module to your arbiter, poller, scheduler?
- Have you added copied the genDevConfig templates.cfg in shinken/packs/network/SnmpBooster/
- Have you installed PySNMP, memcached and other dependencies?

Software version consistency Shinken and SnmpBooster now require **the same Python and Pyro version on all hosts running a Shinken daemon**.

If you cannot use the packaged version of Python and its modules (Pyro, memcached, etc.). Use virtualenv to declare a python version to use and install all required modules in that virtualenv.

Software version requirements Have you verified that the *requirements* are met. Python, PySNMP, Shinken, Pyro, memcached, etc.

Validate your check command arguments Use the check_plugin command and comment out the module to learn what were the exact arguments sent by the poller. This will permit you to validate all the arguments, like snmp community string, inheritance, template application, etc.

Validate connectivity

Take a packet trace using a tool like Wireshark to validate that the remote host is responding.

- Has the host responded
- **Is SnmpBooster repeating the request more often than the polling interval.**
  - If you are seeing repeated requests your device may have a compatibility issues.

- Save an snmpwalk of the device, get a packet trace using Wireshark, set the poller to debug and save the poller.log file (shinken/var/poller.log). Send all three to the SnmpBooster developers.
- Note: It is normal to see one or more bulkGet requests if you are getting large amounts of data. Ex. a 24 port switch will take 2-3 request packets.

Performance Make sure you have a low latency connection to your memcache from the Poller. Your memcache server can be replicated to all your poller hosts that should also run memcache instances. Check that memcached is running: netstat -a | grep memcached

Faulty Template A bad snmp_template file was distributed in the genDevConfig sample-config directory, there were two glaring errors.

This was fixed on 2012-10-16. Make sure you update your template, or use the data from the wiki.

Note that the template should be called: SnmpBooster-template.cfg to make it easier to troubleshoot in the logs. So when you search for SnmpBooster in your logs it will show up as well.

Log files All warnings and errors generated by the SnmpBooster module start with "[SnmpBooster] error text" and are logged using the standard Shinken logger.

The Arbiter daemon can output initial configuration, loading of host keys and intervals in memcached type error messages. The Scheduler daemon can output scheduling and alert related messages. The Poller daemon can output messages related to instance mapping, acquisition timeouts, invalid community strings, cache failures and more. These are available in the Web interface, as they are placed in the check results for the service.

You can simply do a "grep SnmpBooster *" in your shinken/var directory to see the latest messages related to the SnmpBooster module. You can also sort messages by timestamp to make it easy to find where and when errors occurred.

cd shinken/var grep SnmpBooster *

memcache persistence If you restart your memcache server or memcache crashes, your poller will no longer be able to validate that a host exists in memcache prior to writing.

You should use memcachedb to achieve persistence in case of memcache failures.

Common errors returned by SnmpBooster in the log file Errors should be fairly explicit and mean what they say, though there can be exceptions. Lets try to clear some of them.

__Arbiter log **errors__**

Missing ds_oid : This means that a variable in your OID definitions is missing, or your DATASOURCE is not named correctly or your ds_oid variable is missing. There is a typo in your ds_oid variable (ex. ds-oid, or ds_oid = $OidNameIncorrectFFFRA.%(instance)s).

Datasource not defined : Your DSTEMPLATE uses a DATASOURCE that doesn't exist check the [DataSourceName] you are referring to. Does it contain the expected OID variable, $OidName.

Missing ds_type : The DATASOURCE always needs to have a ds_type definition, GAUGE, COUNTER, DERIVE, TEXT, TIMETICK, DERIVE64, COUNTER64.

__Poller log **errors__**

Problems with calculations, repeated polling, hosts not responding, etc.

__Memcached **errors__**

memcachedb and memcached do not use the same default port. Configure the correct memcachedb port to match what is declared in your SnmpBooster module under shinken-specific.cfg.

On Ubuntu 12.04 the default installation is on port 21201 instead of 11211. This causes the error "[SnmpBooster] Memcache server (127.0.0.1:11211) is not reachable" when Shinken starts.

To change it, you must edit the file /etc/memcachedb.conf

Memcached Notes On Ubuntu 12.04 the default instalation is on port 21201 instead of 11211. This causes the error "[SnmpBooster] Memcache server (127.0.0.1:11211) is not reachable" when shinken starts.

To change it, you must edit the file /etc/memcachedb.conf

WebUI module This part must be splitted and sent in all module repositories

WebUI integration with Shinken The WebUI is an external broker module. So it's an external process launched by the broker that "eats" broks (broker messages) from the brokers. So it can get *all* broks if you place this broker in your top level realm.

The WebUI does not use a database to get data. Instead, it use a "regenerator" object that will eat each broks, and will "recreate" all Hosts/Services/Contacts objects as if the code was in the scheduler daemon. So basically, WebUI and pages always reflect the CURRENT state of hosts/services objects.

The WebUI http layer is managed by bottle.py. It's a small but powerful framework.

How does the WebUI function globally ?

There a 2 Threads running:

- the main thread is the bottle.py (http) listener. It will use the best backend it finds. We recommend using python-paste. If it does not find one, it will use the default swsgi. Paste is multi-thread, swsgi is mon-thread, so please use paste if you want to avoid locking problems.
- the 2nd thread is the regenerator one. It only gets broks and gives them to the regenerator object.

There is a lock system between the threads. You can have N Http requests in progress without problem, but during this time the renererator one will wait. During execution of the regenerator, no requests are processed. This is not considered a problem, as the regenerator is very quick, and there is only a 1s lock for a 7k service conf loading, so it's not a huge problem.

What is a WebUI User? A WebUI user is a contact. A true contact object. You must match a contact name for your user.

To create a new page? All pages are in the shinken/webui/plugins directory. Each "part" has it's own directory. A part (like the eltdetail, element detail) can have more than one "page" (like /host or /service for eltdetail).

From here we will supose you want to create a "/contact" page.

You can copy the dummy example in the plugins directory into a contact directory.

You need to change the contact/dummy.py file into a contact/contact.py file, because the webui will search for a dir/dir.py file to "load".

Templates Templates are HTML with some Python code in it in the plugins/*/views direcotry for specific templates, and the "global layout" (menu and all common part) in the webui/views directory.

Your template must call the template layout (layout.tpl in the webui/views directory) wit ha "rebase" call.

If you put the rebase call at the beginning of your template, all there is below will be place "inside" the layout that will call the common javascripts and css, make the menu adn then call your html/python code.

The rebase call can take arguments. You MUST give it:

- user: the user you give it in the return dict of your .py code

Then all is optional:

- title: title of the page
- top_right_banner_state: int, global state with clouds to put in your top right page. Look at the problem.tpl code for an example.
- js and css list: list of YOUR specific javascript or css to call AFTER the common ones.
- refresh: boolean, set the refresh to 60s or do not refresh at all

- menu_part: will put the little "^" under this part of the menu.

Example of a call, taken from the problems view:

```
rebase layout title='All problems', top_right_banner_state=top_right_banner_state, js=['problems/js/a
roblems/js/autocompleter.Request.js', 'problems/js/autocompleterObserver.js'], css=['problems/css/acc
ms/css/autocompleter.css', 'problems/css/perfometer.css'], refresh=True, menu_part='/'+page, user=use
```

Call Python objects in your templates Your templates are mainly HTML code. But of course you can call python code in it. The dict you returns in the plugin.py call will be available in this page.

For example, the my_host variable will be available in the page with the host object you find (or None if your give it a bad name of course). Then you can "call" python with for example here to show the host_name: `<span>My host name is *my_host.host_name* </span>` is a way in the templates to "call a variable or function" that will return a string, here the host_name.

If the function or property you call must return HTML code that SHOULD be output as it, without "protection", you must put a ! before your call.

Let use an example where the output value of an host is in fact an html output. If you use the code `my_host.output`, bottle.py will "protect" the html generated by escaping the string, and change <> characters with escaped value. You can change this by calling `my_host.output`. Of course, it's a security problem if the output is with a javascript code...

You can also "loop" or put "if" in your template. You just need to put your code with a % before. Like

```
%for i in xrange(1, 10):
  My valus is  {{i}}
%end
```

You must put the %end here, the indentation will NOT be enougth, sorry.

For an if it's also easy:

```
%if host.active_checks_enabled:
  The host got active checks enabled
%else:
  The host DO NOT have active check enabled
%end
```

Which javascript lib are you using? It's mootools 1.3 with all options :)

What to do?

- Finish the /mobile part
- List of current alerts
- Host info
- Host status
- Host interfaces
- Hostgroup status
- dashboard hierachique with states, and BP
- Nagvis
- add bp in nagvis auto-map

- event sources
- correlation
- pre-filtering/enrichment
- user profile
- host/srv conf

WebUI search syntax work in progress

not that we couldn't tell. ;) eh eh

beware the working men and flying tools!

WebUI SSL Certification Lets start: the goal to to have the server.pem and client.pem file in etc/certs.

Go to the etc/certs directory.

```
openssl req -new -nodes -out server.req -keyout server.key -config ./shinken_openssl_cnf
openssl ca -out server.pem -config ./shinken_openssl_cnf -infiles server.req
cp server.pem server.pem.bkp
cp server.key server.pem
cat server.pem.bkp >> server.pem
cp server.pem client.pem
```

You can try to get the validity with for the arbiter with:

```
openssl s_client -connect localhost:7770</code>
```

Amazon AWS/EC2 import

Description You can import data from Amazon AWS/EC2 **'AWS'**_ into Shinken to create hosts.

Amazon provide VM hosting with EC2. With this arbiter module, you will be able to load your EC2 hosts into Shinken.

Prerequisites

You will need the **'libcloud'**_ package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

```
define module {
 module_name      AWS
 module_type      aws_import

 # Configure your REAL key and secret for AWS
 api_key              PAAAB2CILT80I0ZA0999
 secret           GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH
 default_template generic-host        ; if the host is not tagged, use this one
 }
```

- Put in key and secret your private Landscape access. * default_template will be used if your host is not "tagged" in Landscape

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master

     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           AWS
     }
```

Restart your Arbiter and it's done :)

Generated hosts The configuration generated will look as below :

```
define host {
    host_name            i-3fc56e5a
    address              8.8.4.4
    use                  t1.micro,MyTag,EC2,generic-host
    _EC2_AVAILABILITY    us-east-1a
    _EC2_CLIENTTOKEN
    _EC2_DNS_NAME
    _EC2_GROUPS          quicklaunch-1
    _EC2_IMAGEID         ami-1b814f72
    _EC2_INSTANCEID      i-3fc56e5a
    _EC2_INSTANCETYPE    t1.micro
    _EC2_KERNELID        aki-825ea7eb
    _EC2_KEYNAME         testaws
    _EC2_LAUNCHDATETIME  2012-09-26T12:19:38.000Z
    _EC2_LAUNCHINDEX     0
    _EC2_PRIVATE_DNS
    _EC2_PRIVATE_IP
    _EC2_PRODUCTCODE
    _EC2_PUBLIC_IP       8.8.4.4
    _EC2_RAMDISKID       None
    _EC2_STATUS          stopped
    _EC2_TAGS            demo:myvalue,use:MyTag
 }
```

Here with a stopped t1.micro instance with no name. You can put your how "use" parameter by adding a EC2 tag "use" on your VM. It will be output on the host configuration so you can setup the monitoring as you want. .. _libcloud: http://libcloud.apache.org/index.html .. _AWS: https://console.aws.amazon.com

Amazon AWS/EC2 import

Description You can import data from Amazon AWS/EC3 **'AWS'**_ into Shinken to create hosts.

Amazon provide VM hosting with EC3. With this arbiter module, you will be able to load your EC2 hosts into Shinken.

Prerequisites

You will need the **'libcloud'**_ package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

```
define module {
 module_name      AWS
 module_type      aws_import

 # Configure your REAL key and secret for AWS
 api_key              PAAAB2CILT80I0ZA0999
 secret           GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH
 default_template generic-host        ; if the host is not tagged, use this one
 }
```

- Put in key and secret your private Landscape access. * default_template will be used if your host is not "tagged" in Landscape

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master

     address          localhost                  ;IP or DNS adress
     port             7770
     spare            0
     modules           AWS
     }
```

Restart your Arbiter and it's done :)

Generated hosts The configuration generated will look as below :

```
define host {
    host_name            i-3fc56e5a
    address              8.8.4.4
    use                  t1.micro,MyTag,EC2,generic-host
    _EC2_AVAILABILITY    us-east-1a
    _EC2_CLIENTTOKEN
    _EC2_DNS_NAME
    _EC2_GROUPS          quicklaunch-1
    _EC2_IMAGEID         ami-1b814f72
    _EC2_INSTANCEID      i-3fc56e5a
    _EC2_INSTANCETYPE    t1.micro
    _EC2_KERNELID        aki-825ea7eb
    _EC2_KEYNAME         testaws
    _EC2_LAUNCHDATETIME  2012-09-26T12:19:38.000Z
    _EC2_LAUNCHINDEX     0
    _EC2_PRIVATE_DNS
    _EC2_PRIVATE_IP
    _EC2_PRODUCTCODE
    _EC2_PUBLIC_IP       8.8.4.4
    _EC2_RAMDISKID       None
    _EC2_STATUS          stopped
    _EC2_TAGS            demo:myvalue,use:MyTag
 }
```

Here with a stopped t1.micro instance with no name. You can put your how "use" parameter by adding a EC2 tag "use" on your VM. It will be output on the host configuration so you can setup the monitoring as you want. .. _libcloud: http://libcloud.apache.org/index.html .. _AWS: https://console.aws.amazon.com

The distributed retention modules The high availability allow the Arbiter to send a configuration to a spare scheduler, but a spare scheduler does not have any saved states for hosts and services. It will have to recheck them all. It's better to use a distributed retention module so spares will have all the information they need to start with an accurate picture of the current states and scheduling :)

Non distributed retention modules If you are just running tests on a single server, use the pickle or memcache retention modules You can also use MongoDB if you already have it installed for use with the WebUI.

MongoDB MongoDB is a scalable, high-performance, open source NoSQL database written in C++.

Step 1: Install MongoDB:

We will use mongodb package from 10gen repository, so we start by adding it in apt sources list:

```
echo 'deb http://downloads-distro.mongodb.org/repo/debian-sysvinit dist 10gen' > /etc/apt/sources.lis
apt-get update
```

And we install it:

```
apt-get install mongodb-10gen
```

And we install pymongo, the python interface to MongoDB, with easy_install to avoid packages versions problems (like here **'forums.monitoring-fr.org/index.php?topic=5205.0'_**):

```
apt-get remove python-pymongo
easy_install pymongo
```

And finally we start MongoDB :

```
/etc/init.d/mongodb start
```

Step 2: define a mongodb_retention module in your shinken-specific.cfg file:

```
define module {
  module_name MongodbRetention
  module_type mongodb_retention
  uri mongodb://localhost/?safe=true
  database shinken
}
```

Step 3: Declare a retention module for your scheduler(s) :)

Example:

```
#The scheduler is a "Host manager". It get hosts and theirs
#services. It scheduler checks for them.
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
     port     7768                  ; tcp port of the daemon

     #optionnal: modules for things as retention
     modules    MongodbRetention
     }
```

Step 4: Restart the Arbiter, and your Scheduler will now save its state between restarts. :)

Memcached Memcached is a distributed memory resident key/value server. It's very easy to install:

```
sudo apt-get install memcached
sudo /etc/init.d/memcached start
```

The shinken module also needs the python-memcache package to talk to this server.

```
sudo apt-get install python-memcache
```

To use it,

Step 1: define a memcache_retention module in your shinken-specific.cfg file:

```
define module{
     module_name      MemcacheRetention
     module_type      memcache_retention
     server           127.0.0.1
     port             11211
}
```

Step 2: Declare a retention module for your scheduler(s) :)

Example:

```
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
     port     7768                  ; tcp port of the daemon

     #optional: modules for things as retention
     modules    MemcacheRetention
     }
```

Step 3: Restart the Arbiter, and your Scheduler will now save its state between restarts. :)

Redis Redis is a distributed key/value server (on disk and in-memory). It's very easy to install:

```
sudo apt-get install redis-server
sudo /etc/init.d/redis-server start
```

The shinken module also need the python-redis package to talk to this server.

```
sudo apt-get install python-redis
```

Step 1: define a redis_retention module in your shinken-specific.cfg file:

```
define module{
     module_name      RedisRetention
     module_type      redis_retention
     server           127.0.0.1
}
```

Step 2: Declare a retention module for your scheduler(s) :)

Example:

```
#The scheduler is a "Host manager". It get hosts and theirs
#services. It scheduler checks for them.
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
```

```
    port     7768                  ; tcp port of the daemon

    #optionnal: modules for things as retention
    modules    RedisRetention
    }
```

Step 3: Restart the Arbiter, and your Scheduler will now save its state between restarts. :) .. _forums.monitoring-fr.org/index.php?topic=5205.0: http://forums.monitoring-fr.org/index.php?topic=5205.0

How to enable and use Livestatus module

Define the Livestatus module Start by reviewing the ''/etc/shinken/shinken-specific.cfg" file for this module:

```
define module{
```

```
module_name      Livestatus
module_type      livestatus
host             *       ; * = listen on all configured IP addresses
port             50000   ; port to listen on
database_file    /var/lib/shinken/livestatus.db
```

}

With these parameters:

- module_name: name of the module called by the brokers
- module_type: livestatus
- host: IP interface to listen to. The default is *, which means "listen on all interfaces".
- port: TCP port to listen to.
- socket: Unix socket to listen to.
- database_file: the path to the sqlite database file which is used to store the log broks/messages. The default is "var/livelogs.db"
- max_logs_age: the maximum age of the log messages (before they are deleted from the database). The default is 1 year. The argument to this parameter takes the form <number>[<period of time>], where <period of time> can be d for days, w for weeks, m for months and y for years.
- allowed_hosts: a comma-separated list of IP-addresses which are allowed to contact the TCP port. Please keep in mind that these **must be IP-addresses, NOT host names**. Because DNS lookups for every incoming livestatus request could hang up and therefore block the module.

Enable the Livestatus module Still in ''/etc/shinken/shinken-specific.cfg'', find the object Broker and add "Livestatus" to its "modules":

```
define broker{
```

```
    broker_name      broker-1
[...]
```

```
    modules          Simple-log,Livestatus
}
```

Disable human readable logs In ‘’/etc/shinken/nagios.cfg’‘, verify that the option **human_timestamp_log** is set to **0**.

In version 0.6.5, you can not have at the same time a simple-log file with human readable timestamp and a Livestatus database.

Exporting data for reporting Shinken can export necessary data for reporting in 3rd party systems.

raw_socket module The raw socket module exports reporting data using a syslog format to a raw TCP socket. Theses logs can be captured, parsed and indexed by any log management system like Splunk or Logstash.

Why export reporting data Custom UIs like Thruk, Multisite, WebUI, Adagios, Nagios IX, etc. All have poor or inflexible reporting. Simply because these are not reporting engines.

This also permits to have a generic reporting method that can accept data from any Nagios, Shinken, Icinga or even Riemann.

Reporting module using Splunk Splunk was selected as the reporting platform for creating, managing and presenting reports. Though the raw_socket module does not have any Splunk specific particularities. It is notable that Splunk reports can be embedded in any 3rd party UI using its REST API.

Raw_socket log format The logs are plain-text and compliant with RFC3164. They use an intelligent date format, a configurable seperator ” “(space by default), and key=value pairs in the message data portion of the log. Should a key or value contain a space they must be double quoted. This is syslog using structured data without going to full out JSON that may not be compatible with all log management systems.

The message fields that are supplied in each status update in addition to the standard syslog header are:

- Hostname
- Servicename
- Business impact
- Host/Service status
- Host/Service previous status
- Acknowedgement status
- Maintenance status

Any time the maintenance, host, service or acknowledgement status changes, a log is sent by the Shinken raw_socket module.

Having all relevant data in each log makes it very easy to compute reports for given time periods.

The hostgroup or service group memberships, custom variables or any other configuration related data should be queried from the monitoring system using its API (Livestatus in the case of Shinken and Nagios).

Raw_socket module availability The module is available in both Shinken 1.4 and Shinken 2.0. The module will be integrated in master branches once unit tests and end-to-end testing is completed. 3rd quarter 2013.

Monitoring Linux System with Glances and checkglances.py **‘Glances‘_** is a fantastic multiplatform system monitoring tool writen by Nicolargo. Glances can run on (Linux, Windows, MacOS ...). There is a growing ecosystem around Glances and of course a Nagios/Shinken plugin : checkglances.py.

How does it work Glances can run in server mode. It provide a XML-RPC server (over http) and allow to retrieve system information throuh a restful API. The only thing to do is to install and start Glances as server on the monitored host, then install checkglances.py on the shinken server and finaly install the glances pack.

Install glances See the glances documentation to install glances on Linux.

<code bash> easy_install glances </code>

There is a debian startup script in the glances repository. And another one for centos here.

Install checkglances.py Just follow the documentation for the checkglances.py prerequisites and put it in your nagios plugins folder.

Install the glances pack Open a terminal as the shinken user and just type the following command

<code bash> shinken install glances </code>

Then just edit the configuration for a linux monitored host and tag it as **glances**

```
define host{
 name mylinuxhost
 use glances
 ...
```

Finaly restart the shinken arbiter

```
service shinken-arbiter restart
```

What will be monitored ? For the moment just the basic system (ram, cpu, load, memory, filesystem and network).

If you want to modify the default thresholds for just a host you can do it by overiding the thresholds macro in your host definition. If you want to do it for several hosts, declare a new template and just add the desired thresholds macro to be overide.

Here is a list of the macros

```
::
```

> _LOAD_WARN 2 _LOAD_CRIT 3 _CPU_WARN 80 _CPU_CRIT 90 _MEMORY_WARN 90 _MEMORY_CRIT 95 _FS /, /home _FS_WARN 90 _FS_CRIT 95 _IFACES eth0, eth1 _NET_WARN 7500000 _NET_CRIT 10000000

Note the _FS and _IFACES macros. They leverage the ability to duplicate service for a given list of things to be monitored. Here you see that / and /home partitions will be monitored. If you want to modify this then just add your own in a new template that will inherit the glances template.

Shinken GLPI integration Shinken supports importing hosts from GLPI

For people not familiar with GLPI, it is an Open-Source CMDB. Applicable to servers, routers, printers or anything you want for that matter. It is also a help-desk tool. GLPI also integrates with tools like FusionInventory for IT inventory management.

You can still have flat files AND GLPI if you want. Hosts imported from GLPI will be treated as standard hosts from flat file (inheritance, groups, etc). In fact, in this first version the module only sends the host_name to Shinken, but there should be more information extracted like network connexions for parents relations in the future. :)

Requirements

- python module MySQLdb
- Compatible version of GLPI Shinken module and GLPI version - ...
- etc..

Enabling GLPI Shinken module In your shinken-specific.cfg file, just add (or uncomment):

```
#You know GLPI? You can load all configuration from this app(
#with the webservices plugins for GLPI, in xmlrpc mode
#and with plugin monitoring for GLPI)
# =============== Work with Plugin Monitoring of GLPI ===============
#All configuration read from this will be added to the others of the
#standard flat file
define module{
     module_name      GLPI
     module_type      glpi
     uri              http://localhost/glpi/plugins/webservices/xmlrpc.php
     login_name       glpi
     login_password   glpi
}
```

And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master
#    host_name       node1       ;result of the hostname command under Unix
     address          localhost                  ;IP or DNS adress
     port             7770
     spare            0
     modules           GLPI
     }
```

It's done :)

Ip Tag module

Why tag a host based on it's IP address? We learned on the *DMZ monitoring* that you can "tag" a host with a poller_tag so it will be checked only by DMZ pollers. It can be tedious process to manually tag all these hosts. Shinken provides an automated method to do this.

This is handled by the arbiter ip_tag module.

Ip_tag module The ip_tag module is an arbiter module that looks up the host address during the configuration parsing and compares it to an predefined IP range (IPV4 or IPV6). If the range matches, it can apply or add a property, such as poller_tag. Other types of tags could be related to locations, functions, administrative groups, etc.

Method: replace or append.

replace will put the value if the property is unset. This is the default method. .. warning:: Fix me: replace, implies overriding an existing value. And will cause user issues down the line. Rename it to set. Replace should be a different method altogether, so overall there should be 3 methods(set, append, replace).

append will add with a , if a value already exist

Here is an example that will set the poller_tag property with the value DMZ of all hosts that:

- have a their hostadress ip (or name resolved) in the range 192.168.0.1/24.
- do not already have a poller_tag property set

```
define module{
```

```
     module_name     IpTag
     module_type     ip_tag
     ip_range        192.168.0.1/24
     property        poller_tag
     value           DMZ
}
```

To use the module add it in the arbiter object:

```
::
```

define arbiter { [...] modules NSCA,IpTag

}

Add value instead of setting it In the previous example we set the property poller_tag to a value. But what if we want to "add" a value, like a template name? We can change the "method" property of the module to "append" so we can add the "value" to the host property instead of replace it.

Here is an example where we want to add the "dmz" template on the hosts, while also keeping any defined templates:

```
define module{
```

```
     module_name   IpTag
     module_type   ip_tag
     ip_range      192.168.0.1/24
     property      use
     value         dmz

     # Optional method
     method append
}
```

For a host defined as:

```
define host{
```

```
     host_name   example_host1
     address     192.168.0.2
     use         linux
}
```

It will be "changed" internaly in:

```
define host{
```

```
     host_name   example_host1
     address     192.168.0.2
     use         linux,dmz
}
```

Name resolution Of course you don't need to set IP address in the address of your host. You can set a hostname, and it will be resolved, and then compared to the range. :)

Ubuntu Landscape import

Description You can import data from Ubuntu Landscape into Shinken to create hosts.

Ubuntu Landscape, is a web app to manage all your linux servers (update and co), which is provided by Canonical, Ubuntu's parent company.

This is an Arbiter import module. The Arbiter manages the configuration.

Prerequisites

You will need the landscape-api package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

define module { module_name Landscape module_type landscape_import

Configure your REAL key and secret from Landscape key PAAAB2CILT80I0ZA0999 secret GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH default_template generic-host ; if the host is not tagged, use this one

If you are using a specific certificate for landscape_api #ca /path/to.ca.cert

If you need a proxy to access https://landscape.canonical.com/api/ #https_proxy http://user:secret@myproxy.com:3128

}

- Put in key and secret your private Landscape access.
- default_template will be used if your host is not "tagged" in Landscape
- If you are using a specific certificate for connexion, give the full path in ca
- You will certainly need an https proxy to access the Landscape API. If so, configure it there.

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master
#    host_name       node1       ;result of the hostname command under Unix
     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           Landscape
     }
```

Restart your Arbiter and it's done :)

Tip: Your "tags" will be applied as templates for your hosts.

Shinken Livestatus API

Overview

- Jump back to Getting Started
- Jump back to *Livestatus module configuration*

What is it Livestatus API is the modern method of interacting with Shinken and Nagios based systems alike.

Originally developed for Nagios, MK Livetstatus, was re-implemented in Python for use with Shinken by professional developers. The access methods and query languages are the same.

Why use it It is fast.

It is network based using TCP.

It is standard for all Nagios and Shinken monitoring systems.

It uses in-memory structures for status data

It uses a back-end database for historical reporting

It uses an SQL based query language

It has a host of powerful nuts and bolts features (authentication, caching, connection persistence, multiple object methods (JSON, Python)).

What can I do with it? All programs and scripts use (or should use) this method to :

- Obtain the current state of hosts and services
- Obtain the current configuration related to hosts and services
- Send administrative commands (downtimes, comments, forcing checks)
- Filter information to display
- Obtain basic reports and event statistics

Shinken being a modern re-implementation of Nagios has additional features that are available in addition to the standard Livestatus API.

Shinken Livestatus API unique features can :

- Obtain Business Impact information
- Obtain intelligent dependency status hosts or services (combines dependency and parent information)
- Obtain Business Process states (same syntax as standard host and service queries)

How does it work Livestatus uses a powerful SQL-like query language. The standard methods and parameters are defined at :

'MK Livestatus reference methods and query language definition'_

Full list of Shinken Livestatus API methods:

'Shinken mapping.py methods'_

What software uses Livestatus to interact with Shinken

Well known Web frontends

- MK Multisite
- Thruk
- NagVis

- Splunk for Nagios

Mobile Web frontends

- get list

Scripts

- Downtime management scripts
- Debug scripts

Installing Livestatus Have you installed the required packages to use the Livestatus module? You can look at the requirement section of the *10 minute installation guide* for the *requirement lists*.

How to enable Livestatus Very simple, jump to the *Shinken Broker configuration* section to enable it. .. _Shinken mapping.py methods: https://github.com/shinken-monitoring/mod-livestatus/blob/master/module/mapping.py .. _MK Livestatus reference methods and query language definition: http://mathias-kettner.de/checkmk_livestatus.html

NSCA module The NSCA daemon module is used to receive send_nsca packets and submit them to the Shinken command pipe. The NSCA module can be loaded by the Receiver or Arbiter process. It will listen on port TCP/5667 for send_nsca packets.

Tip: Passive checks can be submitted *natively to the Shinken command pipe* or from remote hosts to modules, such as NSCA, AMQP or collectd, loaded in the Shinken Arbiter or Receiver process. AMQP is implemented for integration with the Canopsis Hypervisor, but could be re-used for generic messaging.

Note: The Shinken NSCA module implementation is currently limited to the "xor" obfuscation/encryption.

In your shinken-specific.cfg file, just add (or uncomment):

```
::
```

#You can send check result to Shinken using NSCA #using send_nsca command define module{

module_name NSCA module_type nsca_server host * port 5667 encryption_method 0 password helloworld

}

define receiver{

```
receiver_name    receiver-1
address          localhost
port             7773
modules          NSCA

timeout          3             ; 'ping' timeout
data_timeout     120           ; 'data send' timeout
max_check_attempts       3     ;  if at least max_check_attempts ping failed, the node is DEAD

#advanced
realm    All
}
```

This daemon is totally optional.

It's main goal is to get all passive "things" (checks but why not other commands) in distant realms. It will act as a "passive receive buffer" and will then dispatch the data or commands directly to the appropriate Scheduler or Arbiter process.

Data can be received from any Realm, thus the Realm option is nonsensical.

For now there is no init.d script to launch it. .. note:: Verify that the init script has been added.

It is launched like all other daemons:

```
bin/shinken-receiver -c etc/receiverd.ini
```

Tip: Alternatively, for small installations with you can configure a modules inside your Arbiter instead of the Receiver. It will listen the TCP/5667 port for send_nsca packets.

To configure the NSCA module in your Arbiter instead of Receiver. Add the NSCA module to your Arbiter object configuration.

```
::
```

define arbiter{ arbiter_name Arbiter-Master

 # host_name node1 ;result of the hostname command under Unix address localhost ;IP or DNS adress port 7770 spare 0 modules NSCA

}

Retention troubleshooting The retention file contains the state of your host and services, so that they are kept when shinken is restarted.

Sometimes you'll want to inspect (and possibly fix) the retention file, in case you need to work-around a bug or simply better understand what is stored there.

When you use the PickleRetention module in the scheduler (cf. ''define scheduler" in ''shinken-specific.cfg''), you can simply manipulate the retention file using Python.

For this you can use the following code.

- It assumes Shinken is installed in ''/opt/shinken" with the retention file in ''/tmp/retention.dat'':
- Run and play with it interactively using ''ipython -i inspect_retention.py''.

```
#!/usr/bin/python
import pickle
import sys
sys.path.append('/opt/shinken')
import shinken

r = pickle.load(file('/tmp/retention.dat'))
h = r['hosts']

# Example:
# [(k,v) for (k,v) in h['your_host'].items() if k.find('downtime') >= 0]
#
# del h['your_host']
#
# for k,v in r['services'].items():
#     if 'your_host' in k:
#         del r['services'][k]
```

To save your changes:

- Stop Shinken: ‘’service shinken stop’‘
- Save the pickle: ‘’pickle.dump(r, open(‘/tmp/retention.dat’, ‘w’))’‘
- Start Shinken: ‘’service shinken start’‘

NRPE Module

What is it The NRPE module allows Shinken Pollers to bypass the launch of the check_nrpe process. It reads the check command and opens the connection by itself. It scales the use of NRPE for active supervision of servers hosting NRPE agents.

The command definitions should be identical to the check_nrpe calls.

How to define it The definition is very easy (and you probably just have to uncomment it):

```
define module{
     module_name       NrpeBooster
     module_type       nrpe_poller
}
```

Then you add it to your poller object:

```
define poller {
    [...]
    modules   NrpeBooster
}
```

Then just tag all your check_nrpe commands with this module:

```
define command {
   command_name   check_nrpe
   command_line   $USER1$/check_nrpe -H $HOSTADRESS$ -c $ARG1$ -a $ARG2$
   module_type    nrpe_poller
}
```

That’s it. From now on all checks that use this command will use Shinken’s NRPE module and will be launched by it.

Extending Shinken

Introduction There are a lot of “Modules” and “Addons” that are available for Shinken. Shinken can be extended by using different types of methods.

- Web interfaces from various open-source vendors can be used (Based on Livestatus API)
- Shinken itself can be extended using modules that are embedded into the various daemon processes

** (Arbiter, Poller, Receiver, Broker, Scheduler, Reactionner) * External software can provide functional enhancements for reporting, management or usability aspects

Shinken itself provides methods to extend the base functionality:

- *Broker modules* provide external access to runtime data from Shinken
- Poller modules such as *NRPE* and the *SNMP*
- Receiver modules like *NSCA* provide acquisition methods for Shinken

- Arbiter modules permit manipulating the configuration
- The webUI that permits embedding web interface elements

Independent software that works in concert with Shinken is available for:

- Monitoring remote hosts through agent software (*NIX, Windows, etc.)
- Submitting passive checks from remote hosts
- Managing the config files through a web interface
- Mobile phone UIs
- Desktop UIs and Hypervisors
- Desktop notification addons
- ...and much more

You can find many addons that are compatible with Shinken by visiting. The only caveat is that the addons should not use the status.dat file and preferably the modern API interfaces like Livestatus:

- Nagios.org
- SourceForge.net
- NagiosExchange.org
- Shinken community exchange for monitoring packs

Broker modules The broker module receives messages from the Schedulers related to host, service check results. In addition to that it receives a copy of the compiled configuration at startup. What is special about the broker, is that without modules, the broker does nothing. It makes the configuration and result data available to modules. Modules are the ones in charge of doing something with the data. This could be exporting this "raw" data into flat files, databases or exposing it as an API.

The modules are presented according to their use cases.

- Core modules
- Livestatus Module for frontends
- Exporting data to metric databases
- SQL based Modules for frontends
- Exporting data to logging management systems
- Legacy modules for migration purposes
- Modules no longer supported

Core modules

simple_log: get all logs into one file You can get a log for all your daemons in a single file. With the exception of Debug level logs which are not sent through the network as a safe guard. Shinken state messages are ONLY logged at the debug level in the local log files. These are the ALL CAPS states that some 3rd party interfaces use to mine data from the historical logs. Actual state messages are sent as objects between the various daemons.

It takes the parameters:

- module_name: name of the module called by the brokers

- module_type: simple_log
- path: path of the log file

Here is an example:

```
define module{
```

```
     module_name      Simple-log
     module_type      simple_log
     path             /usr/local/shinken/var/nagios.log
     archive_path     /usr/local/shinken/var/archives/
}
```

Syslog - Send all logs to a local syslog server Send all logs to a local syslog server. Support for remote syslog can be implemented if requested. Just lookup the syslog module, easy to modify. Use for example with Splunk, graylog2, Logstash, Elastic search, Kibana, or other log management and analysis system.

```
define module{
```

```
  module_name Syslog
  module_type syslog
}
```

Lightweight forwarder to Splunk Shinken state data from the local syslog can also be sent to a Splunk server for indexing, reports, SLA and analysis. Via syslog or better yet, the Splunk lightweight forwarder which supports, TCP, buffering and security parameters.

Livestatus API Module - Thruk, Nagvis and Multisite Web frontends There are three well known frontends and various small tools that can interface with the Livestatus API. This API is currently the most efficient method of sharing live data with external interfaces. It provides a rich query language similar to SQL, authentication, command execution, caching,connections persistence, multiple object methods (JSON, Python). All Livestatus data is kept in memory, there is no disk IO involved. It exposes configuration objects, the current state of the hosts and services as well as historical Shinken state log messages.

- MK Multisite
- Thruk
- NagVis

Have you installed the required packages to use the Livestatus module? You can look at the requirement section of the 10 minute installation guide for the requirement lists.

Livestatus Module

It takes the following parameters:

- module_name: name of the module called by the brokers
- module_type: livestatus
- host: IP interface to listen to. The default is '127.0.0.1'. '*' means 'listen on all interfaces'.
- port: TCP port to listen to.
- socket: Unix socket to listen to.

- allowed_hosts: a comma-separated list of IP-addresses which are allowed to contact the TCP port. Please keep in mind that these must be ip-addresses, NOT host names. (DNS lookups for every incoming livestatus request could hang up and therefore block the module)
- modules: a comma-separated list of modules (see below)
- pnp_path: relevant if you use the multisite gui. pnp_path points to the perfdata directory where the pnp4nagios data reside (it's the directory which contains a subdirectory for each host). Multisite needs it to display a small perfdata icon if a rrd file exists.
- To deactivate an input, the port- and socket-attributes can also take the value "none".

The Livestatus module itself can have sub-modules. In fact, it **must** have at least one submodule responsible for storing log events to a database, SQLite or MongoDB.

Livestatus module - Logstore Sqlite Stores log-broks to an sqlite database.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_sqlite
- use_aggressive_sql: Prefer the use of sql queries to pre-filter data prior to python filtering. This is required for very large installations, as the Python structures are not indexed when filtering. Optional argument set to 0 by default. To enable set the value to 1. Some erroneous output may occur, but informal testing has shown these corner cases do not occur.
- read_only: don't send any update to the database. Should be used when you run several livestatus modules : 1 instance is R/W, other are read only.
- database_file: the path to the sqlite database file which is used to store the log broks/messages. The default is 'var/livestatus.db'
- archive_path: the path to a subdirectory where database file archives will be created. Every day the data from the last day will be moved to an archive datafile. The default is 'var/archives'.
- max_logs_age: the maximum age of the log messages (before they are deleted from the database). The default is 1 year. The argument to this parameter takes the form <number>[<period of time>], where <period of time> can be d for days, w for weeks, m for months and y for years. This parameter is currently ignored. In future releases it will be used to automatically delete ancient database files.

Here is an example:

```
define module{
```

```
     module_name      Livestatus
     module_type      livestatus
     host             *       ; * = listen on all configured ip addresses
     port             50000   ; port to listen
     socket           /usr/local/shinken/var/rw/live
     modules          logsqlite
}
define module{
```

```
     module_name      logsqlite
     module_type      logstore_sqlite
     use_aggressive_sql     0 ; optional, by default set to 0. Only for large installations.
     database_file    /usr/local/shinken/var/livelogs.db
     max_logs_age     3m ; three months. Other time intervals are d=days, w=weeks, y=years
}
```

Livestatus module - Logstore MongoDB Stores historical log broks(inter daemon Shinken messages) to a MongoDB database. MongoDB is a distributed and very performant database that permits resilience and high availability. The current implementation has a few known broken pieces (some search functions are broken) and there are bugs in the implementation, so it is considered experimental until power users and developers have ironed out the bugs. It is the database of the future for Shinken.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_mongodb
- mongodb_uri: The address of the master. (Default: i_cant_write_the_uri_here_it_messes_the_wiki_up)
- replica_set: If you are running a MongoDB cluster (called a "replica set" in MongoDB), you need to specify it's name here. With this option set, you can also write the mongodb_uri as a comma-separated list of host:port items. (But one is enough, it will be used as a "seed")
- database: <undocumented>
- collection: <undocumented>
- max_logs_age: <undocumented>

The configuration looks quite similar to the sqlite one. **In a single-node installation and with decent amount of log traffic, the sqlite backend should be considered best practice, as it needs no extra software and is stable and fast (when run in-memory).**

Livestatus module - Logstore Null In case you don't need any logging (for instance, if you dedicate a livestatus module instance to nagvis), you can use this module.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_null

Network Based Modules - Graphite graphing Graphite is a graphing and data analysis tool. It is composed of a web frontend (graphite-web), fixed size databases (whisper) and data redistribution/munging daemon. (carbon) The first step is *having Graphite installed somewhere*, if you do not have Graphite installed, please do this and come back later.

Pre-requisite : Shinken 1.2.2+ is recommended for the best experience with Graphite.

graphite_perfdata: exports check result performance data to Graphite Export all performance data included in check results to Whisper databases managed by Graphite. Data is buffered, then exported once every broker time tick. (Once per second). Should a communication loss occur, it will buffer data for 5 minutes before dropping data. The tick_limit max is configurable, the only limitation is the amount of memory the buffered data can eat.

The graphite broker module (v1.2) sends data to graphite in the following format :

HOSTNAME.SERVICENAME.METRICNAME

It can be optionally enhanced to send it the following format :

_GRAPHITE_PRE.HOSTNAME.SOURCE.SERVICENAME.METRICNAME._GRAPHITE_POST

Each of the three variables are optional :

- The _GRAPHITE_PRE variable can be set per host/service to provide a more flexible naming convention. (ex. Prod.site1.Hostname.servicename)

- The _GRAPHITE_POST variable can be set per host/service to specify the more information concerning the variable being stored that graphite can use to determine the retention rule to use for the variable.
- The SOURCE variable can be set in shinken-specific.cfg for the WebUI module and the Graphite broker.

Metric names are converted from Shinken's format to a more restrictive Graphite naming. Unsupported characters are converted to "_" underscore. So do not be surprised to see that some names differ in the WebUI or directly in Graphite. Permitted characters in Graphite are "**A-Za-z_**.", the hyphen character is permitted from Shinken, though only future versions of Graphite will support it.

Performance data transfer method can be set to pickle, which is a binary format that can send data more efficiently than raw ascii.

It takes the following parameters:

- module_name: name of the module called by the brokers
- module_type: graphite_perfdata
- host: ip address of the graphite server running a carbon instance
- port: port where carbon listens for metrics (default: 2003 for raw socket, 2004 for pickle encoded data)
- use_pickle: Use a more efficient transport for sending check results to graphite instead of raw data on the socket (v1.2)
- tick_limit: Number of ticks to buffer performance data during a communication outage with Graphite. On tick limit exceeded, flush to /dev/null and start buffering again. (v1.2)
- graphite_data_source: Set the source name for all data coming from shinken sent to Graphite. This helps diferentiate between data from other sources for the same hostnames. (ex. Diamond, statsd, ganglia, shinken) (v1.2)

Here is an example:

```
define module {
```

```
module_name Graphite-Perfdata
host xx.xx.xx.xx
module_type graphite_perfdata
port 2004 ; default port 2003 for raw data on the socket, 2004 for pickled data
use_pickle 1 ; default value is 0, 1 for pickled data
tick_limit 300 ; Default value 300
graphite_data_source shinken ; default is that the variable is unset
}
```

SQL Based Modules - PNP4Nagios Graphing PNP4Nagios is a graphing tool that has a web interface for RRDTool based databases. Shinken can export performance data to an npcd database which will feed the RRD files (fixed sized round robin databases). You can *learn how to install PNP4Nagios* if you haven't done it already.

npcdmod: export perfdatas to a PNP interface Export all perfdata for PNP.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: npcdmod
- path: path to the npcd config file

Here is an example:

```
define module{
 module_name  NPCD
 module_type  npcdmod
 config_file  /usr/local/pnp4nagios/etc/npcd.cfg
}
```

SQL Based Modules - Frontend Centreon2 Centreon2 use a NDO database, so you will need the ndodb_mysql module for it.

ndodb_mysql: Export to a NDO Mysql database Export status into a NDO/Mysql database. It needs the python module MySQLdb (apt-get install python-mysqldb or easy_install MySQL-python).

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: ndodb_mysql
- database: database name (ex ndo)
- user: database user
- password: database user passworddt
- host: database host
- character_set: utf8 is a good one

Here is an example:

```
define module{
```

```
     module_name      ToNdodb_Mysql
     module_type      ndodb_mysql
     database         ndo       ; database name
     user             root      ; user of the database
     password         root      ; must be changed
     host             localhost ; host to connect to
     character_set    utf8      ;optionnal, UTF8 is the default
}
```

File based Legacy modules - perfdata export

service_perfdata: export service perfdatas to a flat file

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: service_perfdata
- path: path to the service perfdata file you want

Here is an example:

```
define module{
```

```
    module_name      Service-Perfdata
    module_type      service_perfdata
    path             /usr/local/shinken/src/var/service-perfdata
}
```

host_perfdata: export host perfdatas to a flat file

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: host_perfdata
- path: path to the host perfdata file you want

Here is an example:

```
define module{
```

```
    module_name      Host-Perfdata
    module_type      host_perfdata
    path             /usr/local/shinken/src/var/host-perfdata
}
```

Legacy File based Modules - Old CGI or VShell The Old CGI and VShell use the flat file export. If you can, avoid it! It has awful performance, all modern UIs no longer use this.

status_dat: export status into a flat file Export all status into a flat file in the old Nagios format. It's for small/medium environment because it's very slow to parse. It can be used by the Nagios CGI. It also export the objects.cache file for this interface.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: status_dat
- status_file: path of the status.dat file /usr/local/shinken/var/status.dat
- object_cache_file: path of the objects.cache file
- status_update_interval: interval in seconds to generate the status.dat file

Here is an example:

```
define module{
```

```
    module_name              Status-Dat
    module_type              status_dat
    status_file              /usr/local/shinken/var/status.data
    object_cache_file        /usr/local/shinken/var/objects.cache
    status_update_interval   15 ; update status.dat every 15s
}
```

Deprecated or unsupported modules

SQL Based MerlinDB This interface is no longer supported and is going to be completely removed from Shinken.

SQL based ndodb_oracle - Icinga web frontend using NDO Oracle This interface is no longer supported and is going to be completely removed from Shinken.

CouchDB: Export to a Couchdb database This interface is no longer supported and is going to be completely removed from Shinken.

TSCA (Thrift Service Check Acceptor) TSCA is a receiver/arbiter module to receive hosts and services check results. It provides the same functions as NSCA with additional features. High performance binary transmission, multi line output and auto generated clients for a variety of languages.

What is thrift ? Let's cut and paste the wikipedia definition from'en.wikipedia.org/wiki/Apache_Thrift'_ :

"Thrift is an interface definition language that is used to define and create services for numerous languages.[1] It is used as a remote procedure call (RPC) framework [..]. It combines a software stack with a code generation engine to build services that work efficiently to a varying degree and seamlessly between ActionScript, C#, C++ (on POSIX-compliant systems), Cappuccino, Cocoa, Erlang, Haskell, Java, OCaml, Perl, PHP, Python, Ruby, and Smalltalk."

Installation In any case, you have to install thrift with support for python (on the server side) and languages you want to use for clients.

Get it from thrift.apache.org or in your favorite distribution repository.

Server side Go to the tsca module directory and generate the python stub for the server side installation

```
cd shinken/modules/tsca
$ thrift --gen py tsca.thrift
```

Declare the module is shinken-specific.org

```
define module{
      module_name     TSCA
      module_type     tsca_server
      host            0.0.0.0
      port            9090
}
```

Samples clients There are three(3) client samples written in python, ruby and java in contrib/clients/TSCA of the Shinken distribution. You can use and extend them to send data directly in your code directly to Shinken's TSCA receiver/arbiter module.

The samples clients read a CSV file from stdin and send them the the TSCA running on localhost:9090. The CSV has the following format :

```
hostname,service description,output,rc
```

Any use of TCP in an application should take care not to block the program and to have very short timeouts. For applications that need non blocking functions, prefer a UDP based transport or a local buffer file with a separate application(send_nsca, thrift, etc) to forward your data to Shinken.

Ruby Generate the stub

```
$ thrift --gen rb ../../../shinken/modules/tsca/tsca.thrift
```

Run the client

```
$ cat file_state | ruby RubyClient.rb
```

Python Generate the stub

```
$ thrift --gen py ../../../shinken/modules/tsca/tsca.thrift
```

Run the client

```
$ cat file_state | python PythonClient.py
```

java Generate the stub

```
$ thrift --gen java ../../../shinken/modules/tsca/tsca.thrift
```

Compile the client

```
$ ant
```

Run the client

```
$ cat file_state | java JavaClientThrift
```

VMWare Arbiter module

How it works The arbiter has a module that allows the host->VM automatic host dependency creation. In fact, the module is far more generic than just this. It's a generic "host link dependencies" module.

It reads a mapping file (simple json format) with son->father links. It call an external script at a regular interval : the one I wrote is a VMWare mapping one. It used the check_esx3.pl (that all ESX admin should have) plugin and generate the mapping file. When this file is changed, the module reloads it, creates new links and deletes old ones. So when you VMotion a virtual machine, in the next pass, there will be creation of a new link and deletion of the old one in the scheduler that manages it :)

How to define it The definition is very easy :

```
define module{
     module_name       VMWare_auto_linking
     module_type       hot_dependencies
     mapping_file      /tmp/vmware_mapping_file.json
     mapping_command   /usr/local/shinken/libexec/link_vmware_host_vm.py -x '/usr/local/shinken/libex
     mapping_command_interval 60   ; optionnal
     mapping_command_timeout   300 ; optionnal
}
```

Then you add it in you arbiter object :

```
define arbiter {
    [...]
    modules   VMWare_auto_linking
}
```

So here, it will call the script /usr/local/shinken/libexec/link_vmware_host_vm.py with a listing of the vCenter vcenter.mydomain.com and generate the mapping file /tmp/vmware_mapping_file.json.

You can call : /usr/local/shinken/libexec/link_vmware_host_vm.py –help

for the full help on this script.

It looks at the file modification time each second. This command can also be launch by an external cron of course.

Note: So if you want to write a script that does this for XEN servers, all you need is to generate a json file with all the mapping. I didn't wrote the doc about this, but you can look in the test file for it, the format is very very easy :)

Here is an example of the JSON mapping file syntax:

%%:ref:*["host", "physical_host"], ["host", "virtual_machine"* <["host", "physical_host"], ["host", "virtual_machine">, "host", "physical_host"], ["host", "other_virtual_machine" <"host", "physical_host"], ["host", "other_virtual_machine">]%%

So just a list of couple 'host' string (from now only host are managed) and the host name.

Beware about it : you need the real host_name, including case.

Web Service Module The Ws_arbiter module is a Receiver or Arbiter module to receive passive check results from remote hosts via HTTP(s). This module is considered a work in progress but can be used for testing and improvement.

Configuring the Web Service Module If data is POSTed to this page, it will validate the data to determine if it is a service or host check result and submit the data to the Shinken external command queue.

The web service listens by default to TCP port 7760. The web service supports anonymous or authenticated access. Web service parameters are set in the Shinken-specific.cfg file, in the Ws_arbiter module. To enable the web service, simply add the module to your Arbiter or Receiver daemon configuration in Shinken-specific.cfg

Using the Web Service Module The web service listens for POSTs to: /push_check_result

Use curl or embed the HTTP calls in your software to submit check results.

curl -u user:password -d "time_stamp=$(date +%s)&host_name=host-checked&service_description=service-checked&return_code=0&output=Everything OK" http://shinken-srv:7760/push_check_result

Example with more readability:

```
curl
```

-u user:password -d "time_stamp=$(date +%s)

```
&host_name=host-checked
&service_description=service-checked
&return_code=0
&output=Everything OK
http://shinken-srv:7760/push_check_result
```

SNMP module This part must be splitted and sent in all module repositories

Shinken integrated SNMP Module

SnmpBooster Download Install and Configure

- *What is the SnmpBooster module*
- Install and configure the SNMP acquisition module. [You are here]
- *Reference - SnmpBooster troubleshooting*
- *Reference - SnmpBooster design specification*
- *Reference - SnmpBooster configuration dictionnary*

Downloads

The SnmpBooster module and genDevConfig are currently in public beta prior to integration within Shinken. You can consult t

- github.com/xkilian/genDevConfig
- github.com/titilambert/shinken/tree/snmp_booster/shinken/modules (snmp_booster branch) * Simply right-click and download snmp_poller.py then copy it to shinken/modules/

Requirements The SnmpBooster module requires:

- Python 2.6+
- Shinken 1.2+
- PySNMP 4.2.1+ (Python module and its dependencies)
- ConfigObj (Python module)
- python-memcached
- memcachedb or memcached package for your operating system (ex. For Ubuntu: apt-get install memcachedb) *Note*

The genDevConfig profile generator depends on:

- Perl 5.004+
- 4 perl modules available from CPAN and network repositories. genDevConfig/INSTALL has the installation details.

STRONGLY RECOMMENDED: Use the same version of Python and Pyro on all hosts running Shinken processes.

Installation SnmpBooster:

- Install the dependencies
- Copy the file snmp_poller.py from the git repository to your shinken/modules directory.
- Configuration steps are listed in the present web page.

genDevConfig:

- Download and extract the archive to your server.
- See genDevConfig/INSTALL on how to install and configure it.

Configuration

How to define the SnmpBooster module in the Shinken daemons You need to modify shinken-specific.cfg, which is located in $shinken/etc/shinken-specific.cfg

Arbiter daemon configuration Simply declare the module:

```
modules SnmpBooster</code>
```

Scheduler daemon configuration

Simply declare the module:

<code>modules SnmpBooster

Poller daemon configuration Simply declare the module:

```
modules SnmpBooster</code>
```

SnmpBooster Module declaration

Included in Shinken v1.2.1 shinken-specific.cfg.

<code>define module {

```
module_name          SnmpBooster
module_type          snmp_poller
datasource           /usr/local/shinken/etc/packs/network/SnmpBooster/   ; SET THE DIRECTORY FOR YOUR
memcached_host       x.x.x.x  ; SET THE IP ADDRESS OF YOUR memcached SERVER
memcached_port       11211  ; default port for a memcached process
```

}

If you do not know the IP adress on which your memcache is listening, check under /etc/memcached.conf. Or do a:

```
netstat -a | grep memcached</code>
If you are running a test on the local machine you can leave memcached on 127.0.0.1 (localhost), but
```

How to define a Host and Service

Step 1

Create a template for your SNMP enabled devices.

Sample template:

<code>cd shinken/etc/packs/network/ mkdir SnmpBooster

vi shinken/etc/packs/network/SnmpBooster/templates.cfg

```
define command {
```

```
command_name    check_snmp_booster
command_line    check_snmp_booster -H $HOSTNAME$ -C $SNMPCOMMUNITYREAD$ -V 2c -t $ARG1$ -i $_SERVICE
module_type     snmp_poller
```

}

```
define service {
```

```
name                    default-snmp-template
check_command           check_snmp_booster!$_SERVICEDSTEMPLATE$!$_SERVICEINST$!$_SERVICETRIGGERGROUP
_inst                   None
_triggergroup           None
max_check_attempts      3
check_interval          1
retry_interval          1
register                0
```

}

```
define host{
```

```
name                    SnmpBooster-host
alias                   SnmpBooster-host template
check_command           check_host_alive
max_check_attempts      3
check_interval          1
retry_interval          1
use                     generic-host
register                0
```

}

Step 2 Define some hosts and services. You would typically use genDevConfig or another configuration generator to create these for you.

Mandatory service arguments related to SNMP polling:

```
_dstemplate                Cisco-Generic-Router  ; Name of a DSTEMPLATE defined in the SnmpBooster co
```

```
snmpcommunityread    which is set in your resource.cfg file
```

Optional service arguments related to SNMP polling with default values:

```
_inst                   None   ; Could be numeric: 0, None or an instance mapping function like: map
```

```
_triggergroup           None   ; Name of the triggergroup defined in the SnmpBooster config.ini file
```

Sample Shinken host and service configuration:

```
# Generated by genDevConfig 3.0.0
# Args: --showunused -c publicstring 192.168.2.63
# Date: Thu Aug 30 17:47:59 2012

#######################################################################

Shinken integrated SNMP Module

Overview

What is it The SnmpBooster module allows Shinken Pollers to directly manage SNMP data acquisition. This is an all Python cross-platform SNMP module. It is tightly integrated with the Shinken Poller, Scheduler and Arbiter daemons to provide the best possible user experience.

- Jump back to *SnmpBooster documentation index*

Design specification summary

- STATUS - DESIGN SPEC PERFORMANCE
- [Done] Functions as an integrated Shinken Poller module
- [Done] Necessary integration code commited to Shinken official release (Integrated starting at v1.2)
- [Done] Ability to collect thousands of SNMP metrics per second
- [Done] Be compatible with distributed data acquisition
- [Done] Collect data for a host/check_interval tuple via SNMP in a single pass
- [Done] Use all builtin Shinken scheduler logic for retries, forced checks, timeouts, dependencies, parents
- [Done] Store collected data for the duration of the check_interval in a memcached/membase
- [Done] On a restart, after the first collection, be able to pick up where the last check left and calculate derived values
- [Done] Forced check are not allowed within 30 seconds of last SNMP query to the same host/check_interval, all other requests get data from the cache.
- [Done] Only a single request to the host/check_interval via SNMP is allowed at a time, all other requests get data from the cache.
- STATUS - DESIGN SPEC USABILITY
- [Done] Usage documentation
- [xxxx] SkonfUI and Discovery usage documentation
- [xxxx] Provide sample configuration packs in Shinken
- [Done] Provide sample config.ini with examples of all types of data * SNMP OIDS, DATASOURCES, DSTEMPLATES, TRIGGERS and TRIGGERGROUPS

- [Done] Directly compatible for use with genDevConfig Shinken SNMP configuration generator
- [Done] Provide meaningful feedback for users on errors
- [Done] Capture all tracebacks and convert them to actual error or warning messages
- STATUS - DESIGN SPEC FEATURES
- [Done] Return state and performance metrics
- [Done] Performance metrics can be returned in a Weathermap compatible format
- [Done] Configuration file format is ConfigObj INI
- [Done] Load all valid INI configuration files from a directory and merge them
- [Done] Load a single INI configuration file
- [xxxx] Load a list of INI configuration files
- [Done] Configuration file describes all generic acquisition parameters (OID, DATASOURCE, DSTEMPLATE, MAP, TRIGGER, TRIGGERGROUP)
- [Done] Supports Triggers which are calculation rules to determine states
- [Done] Triggers support an RPN (Reverse Polish Notation) calculation engine which includes mathematical and logical operators
- [Done] Each TRIGGER is associated with a severity level, WARNING or CRITICAL
- [Done] Multiple TRIGGERS can be associated with a TRIGGERGROUP
- [Done] Use builtin Python Operators
- [Done] Support DERIVE, TEXT, GAUGE and COUNTER data types
- [xxxx] Support TIMETICKS data type
- [Done] Support applying RPN based calculations to received metric for scaling or conversion purposes
- [Done] Use a Python SNMP library which supports asynchronous acquisition PySNMP
- [Done] Datasources can use rule based runtime instance mapping
- [Done] Set Snmp version as a check runtime option
- [Done] Set Snmp DSTEMPLATE as a check runtime option
- [Done] Set Snmp TRIGGERGROUP as a check runtime option
- [Done] Set Snmp COMMUNITY as a check runtime option
- [Done] Use Snmp version 2c GetBulk
- [xxxx] Support Snmp version 2c GetNext if GetBulk is not supported
- [xxxx] Support Snmp version 1 GetNext
- [xxxx] Set Snmp Timeout as a check runtime option, instead of a hardcoded value at 5 seconds
- STATUS - DESIGN SPEC MAINTAINABILITY
- [xxxx] Functions documented in the source code
- [Done] Critical functions documented in the source code
- [Done] Locking sections identified in the code
- [xxxx] Unit tests with at least 80% coverage

- [xxxx] Unit tests integrated with Shinken test suite
- [Done] Code hosted on github
- [xxxx] configuration validity and integrity checking of all INI files
- [xxxx] Pep8 compliant
- [xxxx] Pylint pass

genDevConfig Plugins - Compatibility status with SnmpBooster

- STATUS - genDevConfig maintained Plugins
- [Done] Avaya ES switches
- [Done] Avaya ERS routing switches
- [Done] Cisco 29x0 switches
- [Done] MIB-II Interfaces
- [Done] Cisco PIX/ASA
- [Done] JUNOS devices
- [Done] Cisco IOS routers
- [Done] NetSNMP unix hosts ** Validation required**
- [Done] Packeteer devices ** Validation required**
- [Done] Sensatronics devices ** Validation required**
- [Done] Foundry devices ** Validation required**
- [Done] Packeteer devices ** Validation required**
- [Done] Cisco CSS ** Validation required**
- [InProgress] New Cisco Access points
- STATUS - Other maintained Plugins

Tip: [xxxx] Denotes a specification that is planned but not implemented

[InProgress] Denotes a specification that is under development

[Done] Denotes a specification that is implemented

SnmpBooster reference dictionary

- Jump back to *SnmpBooster documentation index*

SnmpBooster.ini dictionary

There are five dictionaries:

- [DATASOURCE]
- [DSTEMPLATE]
- [MAP]
- [TRIGGER]

- [TRIGGERGROUP]

DATASOURCE DICTIONARY OidVariableName refers to an actual OID that can be queries using SNMP against the device on the network.

[VariableName] refers to a Datasource and all the information required to gather and prepare the data using SNMP ds_type refers to how the data should be prepared ds_calc refers to any scaling manipulations to make the data more understandable. This is an RPN expression, where the first variable is omitted, as it is always the $OidVariable ds_oid refers to the actual $OidVariable name. An instance identifier can be appended to the name to signify that an instance is provided by the Shinken service definition. This information is passed when the check is called. ...

DSTEMPLATE DICTIONNARY [DsTemplateName] refers to the name of the DSTEMPLATE that will be referred to in the Shinken service definitions. ds refers to the list of DATASOURCES to be collected. If an instance is expected for the list of DATASOURCES, it MUST be the same instance for all Oids. If a different instance is required, use a second DSTEMPLATE.

TRIGGER DICTIONNARY

TRIGGERGROUP DICTIONNARY

MAP DICTIONNARY

SnmpBooster.ini example configuration This example definition will be used to explain each section.

[DATASOURCE]

```
OidmyOidDefinition = .1.3.6.1.45.0
[myOidDefinition] ; Use the same name as the myOidDeiniftion, but omit the leading "Oid"
    ds_type = DERIVE
    ds_calc = 8,*  ; RPN expression : Oid, 8, *  Which means Oid * 8 = Total
    ds_oid = $OidmyOidDefinition
```

[DSTEMPLATE]

```
[myCiscoRouter]
    ds = myOidDefinition
```

[TRIGGER]

```
[trigger1]
    warning = RPN expression
    critical = RPN expression
[trigger2]
    warning = RPN expression
    critical = RPN expression
```

[TRIGGERGROUP]

```
[CiscoRouterTriggers]
    triggers = trigger1, trigger2
```

SnmpBooster.ini configuring SNMP Datasources

The first location is generic data related to SNMP parameters.

- DATASOURCE information * SNMP OID * Type of data and how can it be interpreted (GAUGE, COUNTER, COUNTER64, DERIVE, DERIVE64, TEXT, TIMETICK) * Data format preparation (Scaling the data for example bits to bytes) * Is there an instance to append to the
- Instance MAP function * Mapping the instance dynamically using a function * Data or rules related to the mapping function

SnmpBooster.ini configuring SNMP DSTEMPLATES

- DSTEMPLATEs to associate DATASOURCE to actual device classes * List of DATASOURCES associated with a, for example, Cisco 1900 router. Which in turn can be applied to a Shinken service

SnmpBooster.ini setting triggers/thresholds

- TRIGGER and TRIGGERGROUPS to apply thresholding rules * Define triggers and associate them with a TRIGGERGROUP name that can be applied to a Shinken Service

Shinken integrated SNMP Module

Overview

- Jump back to *SnmpBooster documentation index*

Tip: The module is now in public beta as of 2012-10-26! Have Fun!

Nothing new to add, more to come in 2013. 2013-01-19.

What is it The SnmpBooster module allows Shinken Pollers to directly manage SNMP data acquisition. This is an all Python cross-platform SNMP module. It is tightly integrated with the Shinken Poller, Scheduler and Arbiter daemons to provide the best possible user experience.

Why use it The SnmpBooster module is designed to be very efficient and scalable. It has a very flexible configuration method to make it easy to use with Shinken Monitoring Packs and Shinken discovery runners like genDevConfig.

This acquisition module was professionally designed and developed.

It is meant to be used by the very capable discovery engine genDevConfig (**v3.0.5 and newer**) originally developed for the Cricket SNMP monitoring tool and converted for use with Shinken.

It is one of the very few serious SNMP v2c implementation making use of SnmpGetBulk type requests.

How does it work

Shinken Integration

1. The SnmpBooster Arbiter module reads the Shinken SnmpBooster configuration file(s). It reads the check commands and based on the values in the check commands that use the snmp_poller module it will creates a shared configuration cache using memcached/memcachedb. The memcache key is always the combination of the hostname. This permits to tie together Shinken Hosts and Services with the SNMP specific configuration. (MongoDB and Redis are planned to be supported in the future) The Scheduler daemon schedules Host and Service checks as it normally does.

3. The SnmpBooster module will check that a memcache host key exists for the check to be launched. Then the SnmpBooster poller module will query all services related to a host for a given acquisition frequency in one pass. (all checks done every 2 minutes will be executed in bulk, same for those every 5 minutes)

5. Check results are cached for the acquisition check_interval. The next time a check request for data from the same host is received from the Scheduler, the data will be fetched from memcache. Resulting is extremely low check latency.

2. 6. The SNMP checks still benefit from retries, timeouts, forced checks, dependencies and the powerful Scheduler daemon logic.

6. The Scheduler daemon can still force an immediate re-check by flushing the cache. This is required for the dependency model.

Performance SnmpBooster uses SNMP v2c getbulk for high efficiency, unless forced to use SNMP v2c get-next or SNMPv1 get-next. GetBulk uses a single request PDU to ask for multiple OIDs or even entire tables, instead of sending one request PDU per OID.

For example: *A typical 24 port network switch with two uplinks might use 375 OIDS (8 OIDs per interface, plus general OIDs for chassis health, memory, cpu, fans, etc.). **SnmpBooster will only require around 4 request PDUs*

*instead of 375 request PDUs**. Each PDU is a request packet which takes time to create, send get processed and return. More timeouts to manage, more connections, more impact on the remote device and more latency means much fewer checks per second.*

The SnmpBooster module supports automatic instance mapping for OIDs. (Ex. Based on the interface name it will figure out that the SNMP index(or instance) is 136. This is automatically handled by genDevConfig and SnmpBooster, no user input required. :-)

The generic SNMP configuration information is stored in the Shinken SnmpBooster INI files. There is a Defaults_unified.ini and a series of other Defaults files, one per discovery plugin for genDevConfig.

Important: genDevConfig plugins have all been converted to use the new dynamic instance mapping methods. You are now free to use most if not all Defaults*.ini files included with genDevConfig. 2012-10-28

Limitations You should have memcached instances running on each poller responsible for snmp polling. You should have your pollers with SnmpBooster in the same datacenter, as they need to be on the same machine with good connectivity to the active memcached instance. SnmpBooster is not compatible with distributed pollers in multiple datacenters, sorry, the current design of SnmpBooster uses a single centralized memcached instance for storing the timeseries data. For distributed datacenters to be supported, each poller+scheduler+memcached must be realm restrained, which is not the case today.

Design specification *SnmpBooster design specification* and current development status.

Data model The information required to define the data is split in two locations.

The first location is the host and service Shinken configuration (You need to generate or write this)

- Device specific information
  - IP addresses, host_names, device types, instance keys
  - A DSTEMPLATE must be referred to in the Service definition
  - A static SNMP instance could be referred to in the Service definition
  - An SNMP instance MAP function could be referred to in the Service definition
  - A TRIGGERGROUP could be refered to in the Service definition

The second location is SNMP Defaults.* templates. (Here you can create new devices or add new data sources)

- DATASOURCE information
  - SNMP OID
  - Type of data and how can it be interpreted (GAUGE, COUNTER, COUNTER64, DERIVE, DERIVE64, TEXT, TIMETICK)
  - Data format preparation (Scaling the data for example bits to bytes)
  - Is there an instance to append to the
- Instance MAP function * Mapping the instance dynamically using a function * Data or rules related to the mapping function
- DSTEMPLATEs to associate DATASOURCE to actual device classes * List of DATASOURCES associated with a, for example, Cisco 1900 router. Which in turn can be applied to a Shinken service
- TRIGGER and TRIGGERGROUPS to apply thresholding rules * Define triggers and associate them with a TRIGGERGROUP name that can be applied to a Shinken Service

A final location containes rules to build your Shinken configuration.

- genDevConfig plugins create Shinken configurations

Installation and configuration *SnmpBooster installation*

Reference Dictionnary *SnmpBooster reference dictionary*

Troubleshooting *SnmpBooster troubleshooting*

Graph templates These are .graph files defined in your Shinken configuration directory. Refer to the Shinken graphite templates(Not yet created) or PNP4Nagios how-to documentation. The graph templates are independent from SnmpBooster and provide templates for any collected data from Shinken.

SnmpBooster Troubleshooting

- Jump back to *SnmpBooster documentation index*

Check your config

- Have you defined the poller module name?
- Have you defined the correct path to the directory containing your Defaults*.ini files?
- Have you addded the Snmpbooster module to your arbiter, poller, scheduler?
- Have you added copied the genDevConfig templates.cfg in shinken/packs/network/SnmpBooster/
- Have you installed PySNMP, memcached and other dependencies?

Software version consistency Shinken and SnmpBooster now require **the same Python and Pyro version on all hosts running a Shinken daemon**.

If you cannot use the packaged version of Python and its modules (Pyro, memcached, etc.). Use virtualenv to declare a python version to use and install all required modules in that virtualenv.

Software version requirements Have you verified that the *requirements* are met. Python, PySNMP, Shinken, Pyro, memcached, etc.

Validate your check command arguments Use the check_plugin command and comment out the module to learn what were the exact arguments sent by the poller. This will permit you to validate all the arguments, like snmp community string, inheritance, template application, etc.

Validate connectivity

Take a packet trace using a tool like Wireshark to validate that the remote host is responding.

- Has the host responded
- **Is SnmpBooster repeating the request more often than the polling interval.**
  - If you are seeing repeated requests your device may have a compatibility issues.

- Save an snmpwalk of the device, get a packet trace using Wireshark, set the poller to debug and save the poller.log file (shinken/var/poller.log). Send all three to the SnmpBooster developers.
- Note: It is normal to see one or more bulkGet requests if you are getting large amounts of data. Ex. a 24 port switch will take 2-3 request packets.

Performance Make sure you have a low latency connection to your memcache from the Poller. Your memcache server can be replicated to all your poller hosts that should also run memcache instances. Check that memcached is running: netstat -a | grep memcached

Faulty Template A bad snmp_template file was distributed in the genDevConfig sample-config directory, there were two glaring errors.

This was fixed on 2012-10-16. Make sure you update your template, or use the data from the wiki.

Note that the template should be called: SnmpBooster-template.cfg to make it easier to troubleshoot in the logs. So when you search for SnmpBooster in your logs it will show up as well.

Log files All warnings and errors generated by the SnmpBooster module start with "[SnmpBooster] error text" and are logged using the standard Shinken logger.

The Arbiter daemon can output initial configuration, loading of host keys and intervals in memcached type error messages. The Scheduler daemon can output scheduling and alert related messages. The Poller daemon can output messages related to instance mapping, acquisition timeouts, invalid community strings, cache failures and more. These are available in the Web interface, as they are placed in the check results for the service.

You can simply do a "grep SnmpBooster *" in your shinken/var directory to see the latest messages related to the SnmpBooster module. You can also sort messages by timestamp to make it easy to find where and when errors occurred.

cd shinken/var grep SnmpBooster *

memcache persistence If you restart your memcache server or memcache crashes, your poller will no longer be able to validate that a host exists in memcache prior to writing.

You should use memcachedb to achieve persistence in case of memcache failures.

Common errors returned by SnmpBooster in the log file Errors should be fairly explicit and mean what they say, though there can be exceptions. Lets try to clear some of them.

__Arbiter log **errors__**

Missing ds_oid : This means that a variable in your OID definitions is missing, or your DATASOURCE is not named correctly or your ds_oid variable is missing. There is a typo in your ds_oid variable (ex. ds-oid, or ds_oid = $OidNameIncorrectFFFRA.%(instance)s).

Datasource not defined : Your DSTEMPLATE uses a DATASOURCE that doesn't exist check the [DataSourceName] you are referring to. Does it contain the expected OID variable, $OidName.

Missing ds_type : The DATASOURCE always needs to have a ds_type definition, GAUGE, COUNTER, DERIVE, TEXT, TIMETICK, DERIVE64, COUNTER64.

__Poller log **errors__**

Problems with calculations, repeated polling, hosts not responding, etc.

__Memcached **errors__**

memcachedb and memcached do not use the same default port. Configure the correct memcachedb port to match what is declared in your SnmpBooster module under shinken-specific.cfg.

On Ubuntu 12.04 the default installation is on port 21201 instead of 11211. This causes the error "[SnmpBooster] Memcache server (127.0.0.1:11211) is not reachable" when Shinken starts.

To change it, you must edit the file /etc/memcachedb.conf

Memcached Notes On Ubuntu 12.04 the default instalation is on port 21201 instead of 11211. This causes the error "[SnmpBooster] Memcache server (127.0.0.1:11211) is not reachable" when shinken starts.

To change it, you must edit the file /etc/memcachedb.conf

WebUI module This part must be splitted and sent in all module repositories

WebUI integration with Shinken The WebUI is an external broker module. So it's an external process launched by the broker that "eats" broks (broker messages) from the brokers. So it can get *all* broks if you place this broker in your top level realm.

The WebUI does not use a database to get data. Instead, it use a "regenerator" object that will eat each broks, and will "recreate" all Hosts/Services/Contacts objects as if the code was in the scheduler daemon. So basically, WebUI and pages always reflect the CURRENT state of hosts/services objects.

The WebUI http layer is managed by bottle.py. It's a small but powerful framework.

How does the WebUI function globally ?

There a 2 Threads running:

- the main thread is the bottle.py (http) listener. It will use the best backend it finds. We recommend using python-paste. If it does not find one, it will use the default swsgi. Paste is multi-thread, swsgi is mon-thread, so please use paste if you want to avoid locking problems.
- the 2nd thread is the regenerator one. It only gets broks and gives them to the regenerator object.

There is a lock system between the threads. You can have N Http requests in progress without problem, but during this time the renererator one will wait. During execution of the regenerator, no requests are processed. This is not considered a problem, as the regenerator is very quick, and there is only a 1s lock for a 7k service conf loading, so it's not a huge problem.

What is a WebUI User? A WebUI user is a contact. A true contact object. You must match a contact name for your user.

To create a new page? All pages are in the shinken/webui/plugins directory. Each "part" has it's own directory. A part (like the eltdetail, element detail) can have more than one "page" (like /host or /service for eltdetail).

From here we will supose you want to create a "/contact" page.

You can copy the dummy example in the plugins directory into a contact directory.

You need to change the contact/dummy.py file into a contact/contact.py file, because the webui will search for a dir/dir.py file to "load".

Templates Templates are HTML with some Python code in it in the plugins/*/views direcotry for specific templates, and the "global layout" (menu and all common part) in the webui/views directory.

Your template must call the template layout (layout.tpl in the webui/views directory) wit ha "rebase" call.

If you put the rebase call at the beginning of your template, all there is below will be place "inside" the layout that will call the common javascripts and css, make the menu adn then call your html/python code.

The rebase call can take arguments. You MUST give it:

- user: the user you give it in the return dict of your .py code

Then all is optional:

- title: title of the page
- top_right_banner_state: int, global state with clouds to put in your top right page. Look at the problem.tpl code for an example.
- js and css list: list of YOUR specific javascript or css to call AFTER the common ones.
- refresh: boolean, set the refresh to 60s or do not refresh at all

- menu_part: will put the little "^" under this part of the menu.

Example of a call, taken from the problems view:

```
rebase layout title='All problems', top_right_banner_state=top_right_banner_state, js=['problems/js/a
roblems/js/autocompleter.Request.js', 'problems/js/autocompleterObserver.js'], css=['problems/css/acc
ms/css/autocompleter.css', 'problems/css/perfometer.css'], refresh=True, menu_part='/'+page, user=use
```

Call Python objects in your templates Your templates are mainly HTML code. But of course you can call python code in it. The dict you returns in the plugin.py call will be available in this page.

For example, the my_host variable will be available in the page with the host object you find (or None if your give it a bad name of course). Then you can "call" python with for example here to show the host_name: `<span>My host name is *my_host.host_name* </span>` is a way in the templates to "call a variable or function" that will return a string, here the host_name.

If the function or property you call must return HTML code that SHOULD be output as it, without "protection", you must put a ! before your call.

Let use an example where the output value of an host is in fact an html output. If you use the code `my_host.output`, bottle.py will "protect" the html generated by escaping the string, and change <> characters with escaped value. You can change this by calling `my_host.output`. Of course, it's a security problem if the output is with a javascript code...

You can also "loop" or put "if" in your template. You just need to put your code with a % before. Like

```
%for i in xrange(1, 10):
  My valus is  {{i}}
%end
```

You must put the %end here, the indentation will NOT be enougth, sorry.

For an if it's also easy:

```
%if host.active_checks_enabled:
  The host got active checks enabled
%else:
  The host DO NOT have active check enabled
%end
```

Which javascript lib are you using? It's mootools 1.3 with all options :)

What to do?

- Finish the /mobile part
- List of current alerts
- Host info
- Host status
- Host interfaces
- Hostgroup status
- dashboard hierachique with states, and BP
- Nagvis
- add bp in nagvis auto-map

- event sources
- correlation
- pre-filtering/enrichment
- user profile
- host/srv conf

WebUI search syntax work in progress

not that we couldn't tell. ;) eh eh

beware the working men and flying tools!

WebUI SSL Certification Lets start: the goal to to have the server.pem and client.pem file in etc/certs.

Go to the etc/certs directory.

```
openssl req -new -nodes -out server.req -keyout server.key -config ./shinken_openssl_cnf
openssl ca -out server.pem -config ./shinken_openssl_cnf -infiles server.req
cp server.pem server.pem.bkp
cp server.key server.pem
cat server.pem.bkp >> server.pem
cp server.pem client.pem
```

You can try to get the validity with for the arbiter with:

```
openssl s_client -connect localhost:7770</code>
```

Amazon AWS/EC2 import

Description You can import data from Amazon AWS/EC2 **'AWS'**_ into Shinken to create hosts.

Amazon provide VM hosting with EC2. With this arbiter module, you will be able to load your EC2 hosts into Shinken.

Prerequisites

You will need the **'libcloud'**_ package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

```
define module {
 module_name      AWS
 module_type      aws_import

 # Configure your REAL key and secret for AWS
 api_key              PAAAB2CILT80I0ZA0999
 secret           GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH
 default_template generic-host        ; if the host is not tagged, use this one
 }
```

- Put in key and secret your private Landscape access. * default_template will be used if your host is not "tagged" in Landscape

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master

     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           AWS
     }
```

Restart your Arbiter and it's done :)

Generated hosts The configuration generated will look as below :

```
define host {
    host_name            i-3fc56e5a
    address              8.8.4.4
    use                  t1.micro,MyTag,EC2,generic-host
    _EC2_AVAILABILITY    us-east-1a
    _EC2_CLIENTTOKEN
    _EC2_DNS_NAME
    _EC2_GROUPS          quicklaunch-1
    _EC2_IMAGEID         ami-1b814f72
    _EC2_INSTANCEID      i-3fc56e5a
    _EC2_INSTANCETYPE    t1.micro
    _EC2_KERNELID        aki-825ea7eb
    _EC2_KEYNAME         testaws
    _EC2_LAUNCHDATETIME  2012-09-26T12:19:38.000Z
    _EC2_LAUNCHINDEX     0
    _EC2_PRIVATE_DNS
    _EC2_PRIVATE_IP
    _EC2_PRODUCTCODE
    _EC2_PUBLIC_IP       8.8.4.4
    _EC2_RAMDISKID       None
    _EC2_STATUS          stopped
    _EC2_TAGS            demo:myvalue,use:MyTag
 }
```

Here with a stopped t1.micro instance with no name. You can put your how "use" parameter by adding a EC2 tag "use" on your VM. It will be output on the host configuration so you can setup the monitoring as you want. .. _libcloud: http://libcloud.apache.org/index.html .. _AWS: https://console.aws.amazon.com

Amazon AWS/EC2 import

Description You can import data from Amazon AWS/EC3 **'AWS'**_ into Shinken to create hosts.

Amazon provide VM hosting with EC3. With this arbiter module, you will be able to load your EC2 hosts into Shinken.

Prerequisites

You will need the **'libcloud'**_ package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

```
define module {
 module_name      AWS
 module_type      aws_import

 # Configure your REAL key and secret for AWS
 api_key              PAAAB2CILT80I0ZA0999
 secret           GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH
 default_template generic-host        ; if the host is not tagged, use this one
 }
```

- Put in key and secret your private Landscape access. * default_template will be used if your host is not "tagged" in Landscape

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master

     address          localhost                  ;IP or DNS adress
     port             7770
     spare            0
     modules           AWS
     }
```

Restart your Arbiter and it's done :)

Generated hosts The configuration generated will look as below :

```
define host {
    host_name            i-3fc56e5a
    address              8.8.4.4
    use                  t1.micro,MyTag,EC2,generic-host
    _EC2_AVAILABILITY    us-east-1a
    _EC2_CLIENTTOKEN
    _EC2_DNS_NAME
    _EC2_GROUPS          quicklaunch-1
    _EC2_IMAGEID         ami-1b814f72
    _EC2_INSTANCEID      i-3fc56e5a
    _EC2_INSTANCETYPE    t1.micro
    _EC2_KERNELID        aki-825ea7eb
    _EC2_KEYNAME         testaws
    _EC2_LAUNCHDATETIME  2012-09-26T12:19:38.000Z
    _EC2_LAUNCHINDEX     0
    _EC2_PRIVATE_DNS
    _EC2_PRIVATE_IP
    _EC2_PRODUCTCODE
    _EC2_PUBLIC_IP       8.8.4.4
    _EC2_RAMDISKID       None
    _EC2_STATUS          stopped
    _EC2_TAGS            demo:myvalue,use:MyTag
 }
```

Here with a stopped t1.micro instance with no name. You can put your how "use" parameter by adding a EC2 tag "use" on your VM. It will be output on the host configuration so you can setup the monitoring as you want. .. _libcloud: http://libcloud.apache.org/index.html .. _AWS: https://console.aws.amazon.com

The distributed retention modules The high availability allow the Arbiter to send a configuration to a spare scheduler, but a spare scheduler does not have any saved states for hosts and services. It will have to recheck them all. It's better to use a distributed retention module so spares will have all the information they need to start with an accurate picture of the current states and scheduling :)

Non distributed retention modules If you are just running tests on a single server, use the pickle or memcache retention modules You can also use MongoDB if you already have it installed for use with the WebUI.

MongoDB MongoDB is a scalable, high-performance, open source NoSQL database written in C++.

Step 1: Install MongoDB:

We will use mongodb package from 10gen repository, so we start by adding it in apt sources list:

```
echo 'deb http://downloads-distro.mongodb.org/repo/debian-sysvinit dist 10gen' > /etc/apt/sources.lis
apt-get update
```

And we install it:

```
apt-get install mongodb-10gen
```

And we install pymongo, the python interface to MongoDB, with easy_install to avoid packages versions problems (like here **'forums.monitoring-fr.org/index.php?topic=5205.0'_**):

```
apt-get remove python-pymongo
easy_install pymongo
```

And finally we start MongoDB :

```
/etc/init.d/mongodb start
```

Step 2: define a mongodb_retention module in your shinken-specific.cfg file:

```
define module {
  module_name MongodbRetention
  module_type mongodb_retention
  uri mongodb://localhost/?safe=true
  database shinken
}
```

Step 3: Declare a retention module for your scheduler(s) :)

Example:

```
#The scheduler is a "Host manager". It get hosts and theirs
#services. It scheduler checks for them.
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
     port     7768                  ; tcp port of the daemon

     #optionnal: modules for things as retention
     modules    MongodbRetention
     }
```

Step 4: Restart the Arbiter, and your Scheduler will now save its state between restarts. :)

Memcached Memcached is a distributed memory resident key/value server. It's very easy to install:

```
sudo apt-get install memcached
sudo /etc/init.d/memcached start
```

The shinken module also needs the python-memcache package to talk to this server.

```
sudo apt-get install python-memcache
```

To use it,

Step 1: define a memcache_retention module in your shinken-specific.cfg file:

```
define module{
     module_name      MemcacheRetention
     module_type      memcache_retention
     server           127.0.0.1
     port             11211
}
```

Step 2: Declare a retention module for your scheduler(s) :)

Example:

```
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
     port     7768                  ; tcp port of the daemon

     #optional: modules for things as retention
     modules    MemcacheRetention
     }
```

Step 3: Restart the Arbiter, and your Scheduler will now save its state between restarts. :)

Redis Redis is a distributed key/value server (on disk and in-memory). It's very easy to install:

```
sudo apt-get install redis-server
sudo /etc/init.d/redis-server start
```

The shinken module also need the python-redis package to talk to this server.

```
sudo apt-get install python-redis
```

Step 1: define a redis_retention module in your shinken-specific.cfg file:

```
define module{
     module_name      RedisRetention
     module_type      redis_retention
     server           127.0.0.1
}
```

Step 2: Declare a retention module for your scheduler(s) :)

Example:

```
#The scheduler is a "Host manager". It get hosts and theirs
#services. It scheduler checks for them.
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
```

```
    port     7768                  ; tcp port of the daemon

    #optionnal: modules for things as retention
    modules    RedisRetention
    }
```

Step 3: Restart the Arbiter, and your Scheduler will now save its state between restarts. :) .. _forums.monitoring-fr.org/index.php?topic=5205.0: http://forums.monitoring-fr.org/index.php?topic=5205.0

How to enable and use Livestatus module

Define the Livestatus module Start by reviewing the ''/etc/shinken/shinken-specific.cfg" file for this module:

```
define module{
```

```
module_name      Livestatus
module_type      livestatus
host             *       ; * = listen on all configured IP addresses
port             50000   ; port to listen on
database_file    /var/lib/shinken/livestatus.db
```

}

With these parameters:

- module_name: name of the module called by the brokers
- module_type: livestatus
- host: IP interface to listen to. The default is *, which means "listen on all interfaces".
- port: TCP port to listen to.
- socket: Unix socket to listen to.
- database_file: the path to the sqlite database file which is used to store the log broks/messages. The default is "var/livelogs.db"
- max_logs_age: the maximum age of the log messages (before they are deleted from the database). The default is 1 year. The argument to this parameter takes the form <number>[<period of time>], where <period of time> can be d for days, w for weeks, m for months and y for years.
- allowed_hosts: a comma-separated list of IP-addresses which are allowed to contact the TCP port. Please keep in mind that these **must be IP-addresses, NOT host names**. Because DNS lookups for every incoming livestatus request could hang up and therefore block the module.

Enable the Livestatus module Still in ''/etc/shinken/shinken-specific.cfg'', find the object Broker and add "Livestatus" to its "modules":

```
define broker{
```

```
    broker_name      broker-1
[...]
```

```
    modules          Simple-log,Livestatus
}
```

Disable human readable logs In ''/etc/shinken/nagios.cfg'', verify that the option **human_timestamp_log** is set to **0**.

In version 0.6.5, you can not have at the same time a simple-log file with human readable timestamp and a Livestatus database.

Exporting data for reporting Shinken can export necessary data for reporting in 3rd party systems.

raw_socket module The raw socket module exports reporting data using a syslog format to a raw TCP socket. Theses logs can be captured, parsed and indexed by any log management system like Splunk or Logstash.

Why export reporting data Custom UIs like Thruk, Multisite, WebUI, Adagios, Nagios IX, etc. All have poor or inflexible reporting. Simply because these are not reporting engines.

This also permits to have a generic reporting method that can accept data from any Nagios, Shinken, Icinga or even Riemann.

Reporting module using Splunk Splunk was selected as the reporting platform for creating, managing and presenting reports. Though the raw_socket module does not have any Splunk specific particularities. It is notable that Splunk reports can be embedded in any 3rd party UI using its REST API.

Raw_socket log format The logs are plain-text and compliant with RFC3164. They use an intelligent date format, a configurable seperator " "(space by default), and key=value pairs in the message data portion of the log. Should a key or value contain a space they must be double quoted. This is syslog using structured data without going to full out JSON that may not be compatible with all log management systems.

The message fields that are supplied in each status update in addition to the standard syslog header are:

- Hostname
- Servicename
- Business impact
- Host/Service status
- Host/Service previous status
- Acknowedgement status
- Maintenance status

Any time the maintenance, host, service or acknowledgement status changes, a log is sent by the Shinken raw_socket module.

Having all relevant data in each log makes it very easy to compute reports for given time periods.

The hostgroup or service group memberships, custom variables or any other configuration related data should be queried from the monitoring system using its API (Livestatus in the case of Shinken and Nagios).

Raw_socket module availability The module is available in both Shinken 1.4 and Shinken 2.0. The module will be integrated in master branches once unit tests and end-to-end testing is completed. 3rd quarter 2013.

Monitoring Linux System with Glances and checkglances.py **'Glances'_** is a fantastic multiplatform system monitoring tool writen by Nicolargo. Glances can run on (Linux, Windows, MacOS ...). There is a growing ecosystem around Glances and of course a Nagios/Shinken plugin : checkglances.py.

How does it work Glances can run in server mode. It provide a XML-RPC server (over http) and allow to retrieve system information throuh a restful API. The only thing to do is to install and start Glances as server on the monitored host, then install checkglances.py on the shinken server and finaly install the glances pack.

Install glances See the glances documentation to install glances on Linux.

<code bash> easy_install glances </code>

There is a debian startup script in the glances repository. And another one for centos here.

Install checkglances.py Just follow the documentation for the checkglances.py prerequisites and put it in your nagios plugins folder.

Install the glances pack Open a terminal as the shinken user and just type the following command

<code bash> shinken install glances </code>

Then just edit the configuration for a linux monitored host and tag it as **glances**

```
define host{
 name mylinuxhost
 use glances
 ...
```

Finaly restart the shinken arbiter

```
service shinken-arbiter restart
```

What will be monitored ? For the moment just the basic system (ram, cpu, load, memory, filesystem and network).

If you want to modify the default thresholds for just a host you can do it by overiding the thresholds macro in your host definition. If you want to do it for several hosts, declare a new template and just add the desired thresholds macro to be overide.

Here is a list of the macros

```
::
```

> _LOAD_WARN 2 _LOAD_CRIT 3 _CPU_WARN 80 _CPU_CRIT 90 _MEMORY_WARN 90 _MEMORY_CRIT 95 _FS /, /home _FS_WARN 90 _FS_CRIT 95 _IFACES eth0, eth1 _NET_WARN 7500000 _NET_CRIT 10000000

Note the _FS and _IFACES macros. They leverage the ability to duplicate service for a given list of things to be monitored. Here you see that / and /home partitions will be monitored. If you want to modify this then just add your own in a new template that will inherit the glances template.

Shinken GLPI integration Shinken supports importing hosts from GLPI

For people not familiar with GLPI, it is an Open-Source CMDB. Applicable to servers, routers, printers or anything you want for that matter. It is also a help-desk tool. GLPI also integrates with tools like FusionInventory for IT inventory management.

You can still have flat files AND GLPI if you want. Hosts imported from GLPI will be treated as standard hosts from flat file (inheritance, groups, etc). In fact, in this first version the module only sends the host_name to Shinken, but there should be more information extracted like network connexions for parents relations in the future. :)

Requirements

- python module MySQLdb
- Compatible version of GLPI Shinken module and GLPI version - ...
- etc..

Enabling GLPI Shinken module In your shinken-specific.cfg file, just add (or uncomment):

```
#You know GLPI? You can load all configuration from this app(
#with the webservices plugins for GLPI, in xmlrpc mode
#and with plugin monitoring for GLPI)
# =============== Work with Plugin Monitoring of GLPI ===============
#All configuration read from this will be added to the others of the
#standard flat file
define module{
     module_name      GLPI
     module_type      glpi
     uri              http://localhost/glpi/plugins/webservices/xmlrpc.php
     login_name       glpi
     login_password   glpi
}
```

And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master
#    host_name       node1       ;result of the hostname command under Unix
     address          localhost                  ;IP or DNS adress
     port             7770
     spare            0
     modules           GLPI
     }
```

It's done :)

Ip Tag module

Why tag a host based on it's IP address? We learned on the *DMZ monitoring* that you can "tag" a host with a poller_tag so it will be checked only by DMZ pollers. It can be tedious process to manually tag all these hosts. Shinken provides an automated method to do this.

This is handled by the arbiter ip_tag module.

Ip_tag module The ip_tag module is an arbiter module that looks up the host address during the configuration parsing and compares it to an predefined IP range (IPV4 or IPV6). If the range matches, it can apply or add a property, such as poller_tag. Other types of tags could be related to locations, functions, administrative groups, etc.

Method: replace or append.

replace will put the value if the property is unset. This is the default method. .. warning:: Fix me: replace, implies overriding an existing value. And will cause user issues down the line. Rename it to set. Replace should be a different method altogether, so overall there should be 3 methods(set, append, replace).

append will add with a , if a value already exist

Here is an example that will set the poller_tag property with the value DMZ of all hosts that:

- have a their hostadress ip (or name resolved) in the range 192.168.0.1/24.
- do not already have a poller_tag property set

```
define module{
```

```
     module_name     IpTag
     module_type     ip_tag
     ip_range        192.168.0.1/24
     property        poller_tag
     value           DMZ
}
```

To use the module add it in the arbiter object:

```
::
```

define arbiter { [...] modules NSCA,IpTag

}

Add value instead of setting it In the previous example we set the property poller_tag to a value. But what if we want to "add" a value, like a template name? We can change the "method" property of the module to "append" so we can add the "value" to the host property instead of replace it.

Here is an example where we want to add the "dmz" template on the hosts, while also keeping any defined templates:

```
define module{
```

```
     module_name   IpTag
     module_type   ip_tag
     ip_range      192.168.0.1/24
     property      use
     value         dmz

     # Optional method
     method append
}
```

For a host defined as:

```
define host{
```

```
     host_name   example_host1
     address     192.168.0.2
     use         linux
}
```

It will be "changed" internaly in:

```
define host{
```

```
     host_name   example_host1
     address     192.168.0.2
     use         linux,dmz
}
```

Name resolution Of course you don't need to set IP address in the address of your host. You can set a hostname, and it will be resolved, and then compared to the range. :)

Ubuntu Landscape import

Description You can import data from Ubuntu Landscape into Shinken to create hosts.

Ubuntu Landscape, is a web app to manage all your linux servers (update and co), which is provided by Canonical, Ubuntu's parent company.

This is an Arbiter import module. The Arbiter manages the configuration.

Prerequisites

You will need the landscape-api package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

define module { module_name Landscape module_type landscape_import

Configure your REAL key and secret from Landscape key PAAAB2CILT80I0ZA0999 secret GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH default_template generic-host ; if the host is not tagged, use this one

If you are using a specific certificate for landscape_api #ca /path/to.ca.cert

If you need a proxy to access https://landscape.canonical.com/api/ #https_proxy http://user:secret@myproxy.com:3128

}

- Put in key and secret your private Landscape access.
- default_template will be used if your host is not "tagged" in Landscape
- If you are using a specific certificate for connexion, give the full path in ca
- You will certainly need an https proxy to access the Landscape API. If so, configure it there.

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master
#    host_name       node1       ;result of the hostname command under Unix
     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           Landscape
     }
```

Restart your Arbiter and it's done :)

Tip: Your "tags" will be applied as templates for your hosts.

Shinken Livestatus API

Overview

- Jump back to Getting Started
- Jump back to *Livestatus module configuration*

What is it Livestatus API is the modern method of interacting with Shinken and Nagios based systems alike.

Originally developed for Nagios, MK Livetstatus, was re-implemented in Python for use with Shinken by professional developers. The access methods and query languages are the same.

Why use it It is fast.

It is network based using TCP.

It is standard for all Nagios and Shinken monitoring systems.

It uses in-memory structures for status data

It uses a back-end database for historical reporting

It uses an SQL based query language

It has a host of powerful nuts and bolts features (authentication, caching, connection persistence, multiple object methods (JSON, Python)).

What can I do with it? All programs and scripts use (or should use) this method to :

- Obtain the current state of hosts and services
- Obtain the current configuration related to hosts and services
- Send administrative commands (downtimes, comments, forcing checks)
- Filter information to display
- Obtain basic reports and event statistics

Shinken being a modern re-implementation of Nagios has additional features that are available in addition to the standard Livestatus API.

Shinken Livestatus API unique features can :

- Obtain Business Impact information
- Obtain intelligent dependency status hosts or services (combines dependency and parent information)
- Obtain Business Process states (same syntax as standard host and service queries)

How does it work Livestatus uses a powerful SQL-like query language. The standard methods and parameters are defined at :

'MK Livestatus reference methods and query language definition'_

Full list of Shinken Livestatus API methods:

'Shinken mapping.py methods'_

What software uses Livestatus to interact with Shinken

Well known Web frontends

- MK Multisite
- Thruk
- NagVis

- Splunk for Nagios

Mobile Web frontends

- get list

Scripts

- Downtime management scripts
- Debug scripts

Installing Livestatus Have you installed the required packages to use the Livestatus module? You can look at the requirement section of the *10 minute installation guide* for the *requirement lists*.

How to enable Livestatus Very simple, jump to the *Shinken Broker configuration* section to enable it. .. _Shinken mapping.py methods: https://github.com/shinken-monitoring/mod-livestatus/blob/master/module/mapping.py .. _MK Livestatus reference methods and query language definition: http://mathias-kettner.de/checkmk_livestatus.html

NSCA module The NSCA daemon module is used to receive send_nsca packets and submit them to the Shinken command pipe. The NSCA module can be loaded by the Receiver or Arbiter process. It will listen on port TCP/5667 for send_nsca packets.

Tip: Passive checks can be submitted *natively to the Shinken command pipe* or from remote hosts to modules, such as NSCA, AMQP or collectd, loaded in the Shinken Arbiter or Receiver process. AMQP is implemented for integration with the Canopsis Hypervisor, but could be re-used for generic messaging.

Note: The Shinken NSCA module implementation is currently limited to the "xor" obfuscation/encryption.

In your shinken-specific.cfg file, just add (or uncomment):

```
::
```

#You can send check result to Shinken using NSCA #using send_nsca command define module{

module_name NSCA module_type nsca_server host * port 5667 encryption_method 0 password helloworld

}

define receiver{

```
receiver_name    receiver-1
address          localhost
port             7773
modules          NSCA

timeout          3             ; 'ping' timeout
data_timeout     120           ; 'data send' timeout
max_check_attempts       3     ;  if at least max_check_attempts ping failed, the node is DEAD

#advanced
realm    All
}
```

This daemon is totally optional.

It's main goal is to get all passive "things" (checks but why not other commands) in distant realms. It will act as a "passive receive buffer" and will then dispatch the data or commands directly to the appropriate Scheduler or Arbiter process.

Data can be received from any Realm, thus the Realm option is nonsensical.

For now there is no init.d script to launch it. .. note:: Verify that the init script has been added.

It is launched like all other daemons:

```
bin/shinken-receiver -c etc/receiverd.ini
```

Tip: Alternatively, for small installations with you can configure a modules inside your Arbiter instead of the Receiver. It will listen the TCP/5667 port for send_nsca packets.

To configure the NSCA module in your Arbiter instead of Receiver. Add the NSCA module to your Arbiter object configuration.

```
::
```

define arbiter{ arbiter_name Arbiter-Master

 # host_name node1 ;result of the hostname command under Unix address localhost ;IP or DNS adress port 7770 spare 0 modules NSCA

}

Retention troubleshooting The retention file contains the state of your host and services, so that they are kept when shinken is restarted.

Sometimes you'll want to inspect (and possibly fix) the retention file, in case you need to work-around a bug or simply better understand what is stored there.

When you use the PickleRetention module in the scheduler (cf. ''define scheduler" in ''shinken-specific.cfg''), you can simply manipulate the retention file using Python.

For this you can use the following code.

- It assumes Shinken is installed in ''/opt/shinken" with the retention file in ''/tmp/retention.dat'':
- Run and play with it interactively using ''ipython -i inspect_retention.py''.

```
#!/usr/bin/python
import pickle
import sys
sys.path.append('/opt/shinken')
import shinken

r = pickle.load(file('/tmp/retention.dat'))
h = r['hosts']

# Example:
# [(k,v) for (k,v) in h['your_host'].items() if k.find('downtime') >= 0]
#
# del h['your_host']
#
# for k,v in r['services'].items():
#     if 'your_host' in k:
#         del r['services'][k]
```

To save your changes:

- Stop Shinken: ‘’service shinken stop’‘
- Save the pickle: ‘’pickle.dump(r, open(‘/tmp/retention.dat’, ‘w’))’‘
- Start Shinken: ‘’service shinken start’‘

NRPE Module

What is it The NRPE module allows Shinken Pollers to bypass the launch of the check_nrpe process. It reads the check command and opens the connection by itself. It scales the use of NRPE for active supervision of servers hosting NRPE agents.

The command definitions should be identical to the check_nrpe calls.

How to define it The definition is very easy (and you probably just have to uncomment it):

```
define module{
     module_name       NrpeBooster
     module_type       nrpe_poller
}
```

Then you add it to your poller object:

```
define poller {
    [...]
    modules   NrpeBooster
}
```

Then just tag all your check_nrpe commands with this module:

```
define command {
   command_name   check_nrpe
   command_line   $USER1$/check_nrpe -H $HOSTADRESS$ -c $ARG1$ -a $ARG2$
   module_type    nrpe_poller
}
```

That’s it. From now on all checks that use this command will use Shinken’s NRPE module and will be launched by it.

Extending Shinken

Introduction There are a lot of “Modules” and “Addons” that are available for Shinken. Shinken can be extended by using different types of methods.

- Web interfaces from various open-source vendors can be used (Based on Livestatus API)
- Shinken itself can be extended using modules that are embedded into the various daemon processes

** (Arbiter, Poller, Receiver, Broker, Scheduler, Reactionner) * External software can provide functional enhancements for reporting, management or usability aspects

Shinken itself provides methods to extend the base functionality:

- *Broker modules* provide external access to runtime data from Shinken
- Poller modules such as *NRPE* and the *SNMP*
- Receiver modules like *NSCA* provide acquisition methods for Shinken

- Arbiter modules permit manipulating the configuration
- The webUI that permits embedding web interface elements

Independent software that works in concert with Shinken is available for:

- Monitoring remote hosts through agent software (*NIX, Windows, etc.)
- Submitting passive checks from remote hosts
- Managing the config files through a web interface
- Mobile phone UIs
- Desktop UIs and Hypervisors
- Desktop notification addons
- ...and much more

You can find many addons that are compatible with Shinken by visiting. The only caveat is that the addons should not use the status.dat file and preferably the modern API interfaces like Livestatus:

- Nagios.org
- SourceForge.net
- NagiosExchange.org
- Shinken community exchange for monitoring packs

Broker modules The broker module receives messages from the Schedulers related to host, service check results. In addition to that it receives a copy of the compiled configuration at startup. What is special about the broker, is that without modules, the broker does nothing. It makes the configuration and result data available to modules. Modules are the ones in charge of doing something with the data. This could be exporting this "raw" data into flat files, databases or exposing it as an API.

The modules are presented according to their use cases.

- Core modules
- Livestatus Module for frontends
- Exporting data to metric databases
- SQL based Modules for frontends
- Exporting data to logging management systems
- Legacy modules for migration purposes
- Modules no longer supported

Core modules

simple_log: get all logs into one file You can get a log for all your daemons in a single file. With the exception of Debug level logs which are not sent through the network as a safe guard. Shinken state messages are ONLY logged at the debug level in the local log files. These are the ALL CAPS states that some 3rd party interfaces use to mine data from the historical logs. Actual state messages are sent as objects between the various daemons.

It takes the parameters:

- module_name: name of the module called by the brokers

- module_type: simple_log
- path: path of the log file

Here is an example:

```
define module{
```

```
     module_name      Simple-log
     module_type      simple_log
     path             /usr/local/shinken/var/nagios.log
     archive_path     /usr/local/shinken/var/archives/
}
```

Syslog - Send all logs to a local syslog server Send all logs to a local syslog server. Support for remote syslog can be implemented if requested. Just lookup the syslog module, easy to modify. Use for example with Splunk, graylog2, Logstash, Elastic search, Kibana, or other log management and analysis system.

```
define module{
```

```
  module_name Syslog
  module_type syslog
}
```

Lightweight forwarder to Splunk Shinken state data from the local syslog can also be sent to a Splunk server for indexing, reports, SLA and analysis. Via syslog or better yet, the Splunk lightweight forwarder which supports, TCP, buffering and security parameters.

Livestatus API Module - Thruk, Nagvis and Multisite Web frontends There are three well known frontends and various small tools that can interface with the Livestatus API. This API is currently the most efficient method of sharing live data with external interfaces. It provides a rich query language similar to SQL, authentication, command execution, caching,connections persistence, multiple object methods (JSON, Python). All Livestatus data is kept in memory, there is no disk IO involved. It exposes configuration objects, the current state of the hosts and services as well as historical Shinken state log messages.

- MK Multisite
- Thruk
- NagVis

Have you installed the required packages to use the Livestatus module? You can look at the requirement section of the 10 minute installation guide for the requirement lists.

Livestatus Module

It takes the following parameters:

- module_name: name of the module called by the brokers
- module_type: livestatus
- host: IP interface to listen to. The default is '127.0.0.1'. '*' means 'listen on all interfaces'.
- port: TCP port to listen to.
- socket: Unix socket to listen to.

- allowed_hosts: a comma-separated list of IP-addresses which are allowed to contact the TCP port. Please keep in mind that these must be ip-addresses, NOT host names. (DNS lookups for every incoming livestatus request could hang up and therefore block the module)
- modules: a comma-separated list of modules (see below)
- pnp_path: relevant if you use the multisite gui. pnp_path points to the perfdata directory where the pnp4nagios data reside (it's the directory which contains a subdirectory for each host). Multisite needs it to display a small perfdata icon if a rrd file exists.
- To deactivate an input, the port- and socket-attributes can also take the value "none".

The Livestatus module itself can have sub-modules. In fact, it **must** have at least one submodule responsible for storing log events to a database, SQLite or MongoDB.

Livestatus module - Logstore Sqlite Stores log-broks to an sqlite database.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_sqlite
- use_aggressive_sql: Prefer the use of sql queries to pre-filter data prior to python filtering. This is required for very large installations, as the Python structures are not indexed when filtering. Optional argument set to 0 by default. To enable set the value to 1. Some erroneous output may occur, but informal testing has shown these corner cases do not occur.
- read_only: don't send any update to the database. Should be used when you run several livestatus modules : 1 instance is R/W, other are read only.
- database_file: the path to the sqlite database file which is used to store the log broks/messages. The default is 'var/livestatus.db'
- archive_path: the path to a subdirectory where database file archives will be created. Every day the data from the last day will be moved to an archive datafile. The default is 'var/archives'.
- max_logs_age: the maximum age of the log messages (before they are deleted from the database). The default is 1 year. The argument to this parameter takes the form <number>[<period of time>], where <period of time> can be d for days, w for weeks, m for months and y for years. This parameter is currently ignored. In future releases it will be used to automatically delete ancient database files.

Here is an example:

```
define module{
```

```
     module_name      Livestatus
     module_type      livestatus
     host             *       ; * = listen on all configured ip addresses
     port             50000   ; port to listen
     socket           /usr/local/shinken/var/rw/live
     modules          logsqlite
}
define module{
```

```
     module_name      logsqlite
     module_type      logstore_sqlite
     use_aggressive_sql     0 ; optional, by default set to 0. Only for large installations.
     database_file    /usr/local/shinken/var/livelogs.db
     max_logs_age     3m ; three months. Other time intervals are d=days, w=weeks, y=years
}
```

Livestatus module - Logstore MongoDB Stores historical log broks(inter daemon Shinken messages) to a MongoDB database. MongoDB is a distributed and very performant database that permits resilience and high availability. The current implementation has a few known broken pieces (some search functions are broken) and there are bugs in the implementation, so it is considered experimental until power users and developers have ironed out the bugs. It is the database of the future for Shinken.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_mongodb
- mongodb_uri: The address of the master. (Default: i_cant_write_the_uri_here_it_messes_the_wiki_up)
- replica_set: If you are running a MongoDB cluster (called a "replica set" in MongoDB), you need to specify it's name here. With this option set, you can also write the mongodb_uri as a comma-separated list of host:port items. (But one is enough, it will be used as a "seed")
- database: <undocumented>
- collection: <undocumented>
- max_logs_age: <undocumented>

The configuration looks quite similar to the sqlite one. **In a single-node installation and with decent amount of log traffic, the sqlite backend should be considered best practice, as it needs no extra software and is stable and fast (when run in-memory).**

Livestatus module - Logstore Null In case you don't need any logging (for instance, if you dedicate a livestatus module instance to nagvis), you can use this module.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_null

Network Based Modules - Graphite graphing Graphite is a graphing and data analysis tool. It is composed of a web frontend (graphite-web), fixed size databases (whisper) and data redistribution/munging daemon. (carbon) The first step is *having Graphite installed somewhere*, if you do not have Graphite installed, please do this and come back later.

Pre-requisite : Shinken 1.2.2+ is recommended for the best experience with Graphite.

graphite_perfdata: exports check result performance data to Graphite Export all performance data included in check results to Whisper databases managed by Graphite. Data is buffered, then exported once every broker time tick. (Once per second). Should a communication loss occur, it will buffer data for 5 minutes before dropping data. The tick_limit max is configurable, the only limitation is the amount of memory the buffered data can eat.

The graphite broker module (v1.2) sends data to graphite in the following format :

HOSTNAME.SERVICENAME.METRICNAME

It can be optionally enhanced to send it the following format :

_GRAPHITE_PRE.HOSTNAME.SOURCE.SERVICENAME.METRICNAME._GRAPHITE_POST

Each of the three variables are optional :

- The _GRAPHITE_PRE variable can be set per host/service to provide a more flexible naming convention. (ex. Prod.site1.Hostname.servicename)

- The _GRAPHITE_POST variable can be set per host/service to specify the more information concerning the variable being stored that graphite can use to determine the retention rule to use for the variable.
- The SOURCE variable can be set in shinken-specific.cfg for the WebUI module and the Graphite broker.

Metric names are converted from Shinken's format to a more restrictive Graphite naming. Unsupported characters are converted to "_" underscore. So do not be surprised to see that some names differ in the WebUI or directly in Graphite. Permitted characters in Graphite are "**A-Za-z_**.", the hyphen character is permitted from Shinken, though only future versions of Graphite will support it.

Performance data transfer method can be set to pickle, which is a binary format that can send data more efficiently than raw ascii.

It takes the following parameters:

- module_name: name of the module called by the brokers
- module_type: graphite_perfdata
- host: ip address of the graphite server running a carbon instance
- port: port where carbon listens for metrics (default: 2003 for raw socket, 2004 for pickle encoded data)
- use_pickle: Use a more efficient transport for sending check results to graphite instead of raw data on the socket (v1.2)
- tick_limit: Number of ticks to buffer performance data during a communication outage with Graphite. On tick limit exceeded, flush to /dev/null and start buffering again. (v1.2)
- graphite_data_source: Set the source name for all data coming from shinken sent to Graphite. This helps diferentiate between data from other sources for the same hostnames. (ex. Diamond, statsd, ganglia, shinken) (v1.2)

Here is an example:

```
define module {
```

```
module_name Graphite-Perfdata
host xx.xx.xx.xx
module_type graphite_perfdata
port 2004 ; default port 2003 for raw data on the socket, 2004 for pickled data
use_pickle 1 ; default value is 0, 1 for pickled data
tick_limit 300 ; Default value 300
graphite_data_source shinken ; default is that the variable is unset
}
```

SQL Based Modules - PNP4Nagios Graphing PNP4Nagios is a graphing tool that has a web interface for RRDTool based databases. Shinken can export performance data to an npcd database which will feed the RRD files (fixed sized round robin databases). You can *learn how to install PNP4Nagios* if you haven't done it already.

npcdmod: export perfdatas to a PNP interface Export all perfdata for PNP.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: npcdmod
- path: path to the npcd config file

Here is an example:

```
define module{
 module_name  NPCD
 module_type  npcdmod
 config_file  /usr/local/pnp4nagios/etc/npcd.cfg
}
```

SQL Based Modules - Frontend Centreon2 Centreon2 use a NDO database, so you will need the ndodb_mysql module for it.

ndodb_mysql: Export to a NDO Mysql database Export status into a NDO/Mysql database. It needs the python module MySQLdb (apt-get install python-mysqldb or easy_install MySQL-python).

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: ndodb_mysql
- database: database name (ex ndo)
- user: database user
- password: database user passworddt
- host: database host
- character_set: utf8 is a good one

Here is an example:

```
define module{
```

```
     module_name      ToNdodb_Mysql
     module_type      ndodb_mysql
     database         ndo       ; database name
     user             root      ; user of the database
     password         root      ; must be changed
     host             localhost ; host to connect to
     character_set    utf8      ;optionnal, UTF8 is the default
}
```

File based Legacy modules - perfdata export

service_perfdata: export service perfdatas to a flat file

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: service_perfdata
- path: path to the service perfdata file you want

Here is an example:

```
define module{
```

```
    module_name      Service-Perfdata
    module_type      service_perfdata
    path             /usr/local/shinken/src/var/service-perfdata
}
```

host_perfdata: export host perfdatas to a flat file

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: host_perfdata
- path: path to the host perfdata file you want

Here is an example:

```
define module{
```

```
    module_name      Host-Perfdata
    module_type      host_perfdata
    path             /usr/local/shinken/src/var/host-perfdata
}
```

Legacy File based Modules - Old CGI or VShell The Old CGI and VShell use the flat file export. If you can, avoid it! It has awful performance, all modern UIs no longer use this.

status_dat: export status into a flat file Export all status into a flat file in the old Nagios format. It's for small/medium environment because it's very slow to parse. It can be used by the Nagios CGI. It also export the objects.cache file for this interface.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: status_dat
- status_file: path of the status.dat file /usr/local/shinken/var/status.dat
- object_cache_file: path of the objects.cache file
- status_update_interval: interval in seconds to generate the status.dat file

Here is an example:

```
define module{
```

```
    module_name              Status-Dat
    module_type              status_dat
    status_file              /usr/local/shinken/var/status.data
    object_cache_file        /usr/local/shinken/var/objects.cache
    status_update_interval   15 ; update status.dat every 15s
}
```

Deprecated or unsupported modules

SQL Based MerlinDB This interface is no longer supported and is going to be completely removed from Shinken.

SQL based ndodb_oracle - Icinga web frontend using NDO Oracle This interface is no longer supported and is going to be completely removed from Shinken.

CouchDB: Export to a Couchdb database This interface is no longer supported and is going to be completely removed from Shinken.

TSCA (Thrift Service Check Acceptor) TSCA is a receiver/arbiter module to receive hosts and services check results. It provides the same functions as NSCA with additional features. High performance binary transmission, multi line output and auto generated clients for a variety of languages.

What is thrift ? Let's cut and paste the wikipedia definition from'en.wikipedia.org/wiki/Apache_Thrift'_ :

"Thrift is an interface definition language that is used to define and create services for numerous languages.[1] It is used as a remote procedure call (RPC) framework [..]. It combines a software stack with a code generation engine to build services that work efficiently to a varying degree and seamlessly between ActionScript, C#, C++ (on POSIX-compliant systems), Cappuccino, Cocoa, Erlang, Haskell, Java, OCaml, Perl, PHP, Python, Ruby, and Smalltalk."

Installation In any case, you have to install thrift with support for python (on the server side) and languages you want to use for clients.

Get it from thrift.apache.org or in your favorite distribution repository.

Server side Go to the tsca module directory and generate the python stub for the server side installation

```
cd shinken/modules/tsca
$ thrift --gen py tsca.thrift
```

Declare the module is shinken-specific.org

```
define module{
      module_name     TSCA
      module_type     tsca_server
      host            0.0.0.0
      port            9090
}
```

Samples clients There are three(3) client samples written in python, ruby and java in contrib/clients/TSCA of the Shinken distribution. You can use and extend them to send data directly in your code directly to Shinken's TSCA receiver/arbiter module.

The samples clients read a CSV file from stdin and send them the the TSCA running on localhost:9090. The CSV has the following format :

```
hostname,service description,output,rc
```

Any use of TCP in an application should take care not to block the program and to have very short timeouts. For applications that need non blocking functions, prefer a UDP based transport or a local buffer file with a separate application(send_nsca, thrift, etc) to forward your data to Shinken.

Ruby Generate the stub

```
$ thrift --gen rb ../../../shinken/modules/tsca/tsca.thrift
```

Run the client

```
$ cat file_state | ruby RubyClient.rb
```

Python Generate the stub

```
$ thrift --gen py ../../../shinken/modules/tsca/tsca.thrift
```

Run the client

```
$ cat file_state | python PythonClient.py
```

java Generate the stub

```
$ thrift --gen java ../../../shinken/modules/tsca/tsca.thrift
```

Compile the client

```
$ ant
```

Run the client

```
$ cat file_state | java JavaClientThrift
```

VMWare Arbiter module

How it works The arbiter has a module that allows the host->VM automatic host dependency creation. In fact, the module is far more generic than just this. It's a generic "host link dependencies" module.

It reads a mapping file (simple json format) with son->father links. It call an external script at a regular interval : the one I wrote is a VMWare mapping one. It used the check_esx3.pl (that all ESX admin should have) plugin and generate the mapping file. When this file is changed, the module reloads it, creates new links and deletes old ones. So when you VMotion a virtual machine, in the next pass, there will be creation of a new link and deletion of the old one in the scheduler that manages it :)

How to define it The definition is very easy :

```
define module{
     module_name       VMWare_auto_linking
     module_type       hot_dependencies
     mapping_file      /tmp/vmware_mapping_file.json
     mapping_command   /usr/local/shinken/libexec/link_vmware_host_vm.py -x '/usr/local/shinken/libex
     mapping_command_interval 60   ; optionnal
     mapping_command_timeout   300 ; optionnal
}
```

Then you add it in you arbiter object :

```
define arbiter {
    [...]
    modules   VMWare_auto_linking
}
```

So here, it will call the script /usr/local/shinken/libexec/link_vmware_host_vm.py with a listing of the vCenter vcenter.mydomain.com and generate the mapping file /tmp/vmware_mapping_file.json.

You can call : /usr/local/shinken/libexec/link_vmware_host_vm.py –help

for the full help on this script.

It looks at the file modification time each second. This command can also be launch by an external cron of course.

Note: So if you want to write a script that does this for XEN servers, all you need is to generate a json file with all the mapping. I didn't wrote the doc about this, but you can look in the test file for it, the format is very very easy :)

Here is an example of the JSON mapping file syntax:

%%:ref:*["host", "physical_host"], ["host", "virtual_machine"* <["host", "physical_host"], ["host", "virtual_machine">, "host", "physical_host"], ["host", "other_virtual_machine" <"host", "physical_host"], ["host", "other_virtual_machine">]%%

So just a list of couple 'host' string (from now only host are managed) and the host name.

Beware about it : you need the real host_name, including case.

Web Service Module The Ws_arbiter module is a Receiver or Arbiter module to receive passive check results from remote hosts via HTTP(s). This module is considered a work in progress but can be used for testing and improvement.

Configuring the Web Service Module If data is POSTed to this page, it will validate the data to determine if it is a service or host check result and submit the data to the Shinken external command queue.

The web service listens by default to TCP port 7760. The web service supports anonymous or authenticated access. Web service parameters are set in the Shinken-specific.cfg file, in the Ws_arbiter module. To enable the web service, simply add the module to your Arbiter or Receiver daemon configuration in Shinken-specific.cfg

Using the Web Service Module The web service listens for POSTs to: /push_check_result

Use curl or embed the HTTP calls in your software to submit check results.

curl -u user:password -d "time_stamp=$(date +%s)&host_name=host-checked&service_description=service-checked&return_code=0&output=Everything OK" http://shinken-srv:7760/push_check_result

Example with more readability:

```
curl
```

-u user:password -d "time_stamp=$(date +%s)

```
&host_name=host-checked
&service_description=service-checked
&return_code=0
&output=Everything OK
http://shinken-srv:7760/push_check_result
```

SNMP module This part must be splitted and sent in all module repositories

Shinken integrated SNMP Module

SnmpBooster Download Install and Configure

- *What is the SnmpBooster module*
- Install and configure the SNMP acquisition module. [You are here]
- *Reference - SnmpBooster troubleshooting*
- *Reference - SnmpBooster design specification*
- *Reference - SnmpBooster configuration dictionnary*

Downloads

The SnmpBooster module and genDevConfig are currently in public beta prior to integration within Shinken. You can consult t

- github.com/xkilian/genDevConfig
- github.com/titilambert/shinken/tree/snmp_booster/shinken/modules (snmp_booster branch) * Simply right-click and download snmp_poller.py then copy it to shinken/modules/

Requirements The SnmpBooster module requires:

- Python 2.6+
- Shinken 1.2+
- PySNMP 4.2.1+ (Python module and its dependencies)
- ConfigObj (Python module)
- python-memcached
- memcachedb or memcached package for your operating system (ex. For Ubuntu: apt-get install memcachedb) *Note*

The genDevConfig profile generator depends on:

- Perl 5.004+
- 4 perl modules available from CPAN and network repositories. genDevConfig/INSTALL has the installation details.

STRONGLY RECOMMENDED: Use the same version of Python and Pyro on all hosts running Shinken processes.

Installation SnmpBooster:

- Install the dependencies
- Copy the file snmp_poller.py from the git repository to your shinken/modules directory.
- Configuration steps are listed in the present web page.

genDevConfig:

- Download and extract the archive to your server.
- See genDevConfig/INSTALL on how to install and configure it.

Configuration

How to define the SnmpBooster module in the Shinken daemons You need to modify shinken-specific.cfg, which is located in $shinken/etc/shinken-specific.cfg

Arbiter daemon configuration Simply declare the module:

```
modules SnmpBooster</code>
```

Scheduler daemon configuration

Simply declare the module:

<code>modules SnmpBooster

Poller daemon configuration Simply declare the module:

```
modules SnmpBooster</code>
```

SnmpBooster Module declaration

Included in Shinken v1.2.1 shinken-specific.cfg.

<code>define module {

```
module_name          SnmpBooster
module_type          snmp_poller
datasource           /usr/local/shinken/etc/packs/network/SnmpBooster/   ; SET THE DIRECTORY FOR YOUR
memcached_host       x.x.x.x  ; SET THE IP ADDRESS OF YOUR memcached SERVER
memcached_port       11211  ; default port for a memcached process
```

}

If you do not know the IP adress on which your memcache is listening, check under /etc/memcached.conf. Or do a:

```
netstat -a | grep memcached</code>
If you are running a test on the local machine you can leave memcached on 127.0.0.1 (localhost), but
```

How to define a Host and Service

Step 1

Create a template for your SNMP enabled devices.

Sample template:

<code>cd shinken/etc/packs/network/ mkdir SnmpBooster

vi shinken/etc/packs/network/SnmpBooster/templates.cfg

```
define command {
```

```
command_name    check_snmp_booster
command_line    check_snmp_booster -H $HOSTNAME$ -C $SNMPCOMMUNITYREAD$ -V 2c -t $ARG1$ -i $_SERVICE
module_type     snmp_poller
```

}

```
define service {
```

```
name                    default-snmp-template
check_command           check_snmp_booster!$_SERVICEDSTEMPLATE$!$_SERVICEINST$!$_SERVICETRIGGERGROUP
_inst                   None
_triggergroup           None
max_check_attempts      3
check_interval          1
retry_interval          1
register                0
```

}

```
define host{
```

```
name                    SnmpBooster-host
alias                   SnmpBooster-host template
check_command           check_host_alive
max_check_attempts      3
check_interval          1
retry_interval          1
use                     generic-host
register                0
```

}

Step 2 Define some hosts and services. You would typically use genDevConfig or another configuration generator to create these for you.

Mandatory service arguments related to SNMP polling:

```
_dstemplate                Cisco-Generic-Router  ; Name of a DSTEMPLATE defined in the SnmpBooster co
```

```
snmpcommunityread    which is set in your resource.cfg file
```

Optional service arguments related to SNMP polling with default values:

```
_inst                   None   ; Could be numeric: 0, None or an instance mapping function like: map
```

```
_triggergroup           None   ; Name of the triggergroup defined in the SnmpBooster config.ini file
```

Sample Shinken host and service configuration:

```
# Generated by genDevConfig 3.0.0
# Args: --showunused -c publicstring 192.168.2.63
# Date: Thu Aug 30 17:47:59 2012

```

Shinken integrated SNMP Module

Overview

What is it The SnmpBooster module allows Shinken Pollers to directly manage SNMP data acquisition. This is an all Python cross-platform SNMP module. It is tightly integrated with the Shinken Poller, Scheduler and Arbiter daemons to provide the best possible user experience.

Design specification summary

- STATUS - DESIGN SPEC PERFORMANCE
- [Done] Functions as an integrated Shinken Poller module
- [Done] Necessary integration code commited to Shinken official release (Integrated starting at v1.2)
- [Done] Ability to collect thousands of SNMP metrics per second
- [Done] Be compatible with distributed data acquisition
- [Done] Collect data for a host/check_interval tuple via SNMP in a single pass
- [Done] Use all builtin Shinken scheduler logic for retries, forced checks, timeouts, dependencies, parents
- [Done] Store collected data for the duration of the check_interval in a memcached/membase
- [Done] On a restart, after the first collection, be able to pick up where the last check left and calculate derived values
- [Done] Forced check are not allowed within 30 seconds of last SNMP query to the same host/check_interval, all other requests get data from the cache.
- [Done] Only a single request to the host/check_interval via SNMP is allowed at a time, all other requests get data from the cache.
- STATUS - DESIGN SPEC USABILITY
- [Done] Usage documentation
- [xxxx] SkonfUI and Discovery usage documentation
- [xxxx] Provide sample configuration packs in Shinken
- [Done] Provide sample config.ini with examples of all types of data * SNMP OIDS, DATASOURCES, DSTEMPLATES, TRIGGERS and TRIGGERGROUPS

- [Done] Directly compatible for use with genDevConfig Shinken SNMP configuration generator
- [Done] Provide meaningful feedback for users on errors
- [Done] Capture all tracebacks and convert them to actual error or warning messages
- STATUS - DESIGN SPEC FEATURES
- [Done] Return state and performance metrics
- [Done] Performance metrics can be returned in a Weathermap compatible format
- [Done] Configuration file format is ConfigObj INI
- [Done] Load all valid INI configuration files from a directory and merge them
- [Done] Load a single INI configuration file
- [xxxx] Load a list of INI configuration files
- [Done] Configuration file describes all generic acquisition parameters (OID, DATASOURCE, DSTEMPLATE, MAP, TRIGGER, TRIGGERGROUP)
- [Done] Supports Triggers which are calculation rules to determine states
- [Done] Triggers support an RPN (Reverse Polish Notation) calculation engine which includes mathematical and logical operators
- [Done] Each TRIGGER is associated with a severity level, WARNING or CRITICAL
- [Done] Multiple TRIGGERS can be associated with a TRIGGERGROUP
- [Done] Use builtin Python Operators
- [Done] Support DERIVE, TEXT, GAUGE and COUNTER data types
- [xxxx] Support TIMETICKS data type
- [Done] Support applying RPN based calculations to received metric for scaling or conversion purposes
- [Done] Use a Python SNMP library which supports asynchronous acquisition PySNMP
- [Done] Datasources can use rule based runtime instance mapping
- [Done] Set Snmp version as a check runtime option
- [Done] Set Snmp DSTEMPLATE as a check runtime option
- [Done] Set Snmp TRIGGERGROUP as a check runtime option
- [Done] Set Snmp COMMUNITY as a check runtime option
- [Done] Use Snmp version 2c GetBulk
- [xxxx] Support Snmp version 2c GetNext if GetBulk is not supported
- [xxxx] Support Snmp version 1 GetNext
- [xxxx] Set Snmp Timeout as a check runtime option, instead of a hardcoded value at 5 seconds
- STATUS - DESIGN SPEC MAINTAINABILITY
- [xxxx] Functions documented in the source code
- [Done] Critical functions documented in the source code
- [Done] Locking sections identified in the code
- [xxxx] Unit tests with at least 80% coverage

- [xxxx] Unit tests integrated with Shinken test suite
- [Done] Code hosted on github
- [xxxx] configuration validity and integrity checking of all INI files
- [xxxx] Pep8 compliant
- [xxxx] Pylint pass

genDevConfig Plugins - Compatibility status with SnmpBooster

- STATUS - genDevConfig maintained Plugins
- [Done] Avaya ES switches
- [Done] Avaya ERS routing switches
- [Done] Cisco 29x0 switches
- [Done] MIB-II Interfaces
- [Done] Cisco PIX/ASA
- [Done] JUNOS devices
- [Done] Cisco IOS routers
- [Done] NetSNMP unix hosts ** Validation required**
- [Done] Packeteer devices ** Validation required**
- [Done] Sensatronics devices ** Validation required**
- [Done] Foundry devices ** Validation required**
- [Done] Packeteer devices ** Validation required**
- [Done] Cisco CSS ** Validation required**
- [InProgress] New Cisco Access points
- STATUS - Other maintained Plugins

Tip: [xxxx] Denotes a specification that is planned but not implemented

[InProgress] Denotes a specification that is under development

[Done] Denotes a specification that is implemented

SnmpBooster reference dictionary

- Jump back to *SnmpBooster documentation index*

SnmpBooster.ini dictionary

There are five dictionaries:

- [DATASOURCE]
- [DSTEMPLATE]
- [MAP]
- [TRIGGER]

- [TRIGGERGROUP]

DATASOURCE DICTIONARY OidVariableName refers to an actual OID that can be queries using SNMP against the device on the network.

[VariableName] refers to a Datasource and all the information required to gather and prepare the data using SNMP ds_type refers to how the data should be prepared ds_calc refers to any scaling manipulations to make the data more understandable. This is an RPN expression, where the first variable is omitted, as it is always the $OidVariable ds_oid refers to the actual $OidVariable name. An instance identifier can be appended to the name to signify that an instance is provided by the Shinken service definition. This information is passed when the check is called. ...

DSTEMPLATE DICTIONNARY [DsTemplateName] refers to the name of the DSTEMPLATE that will be referred to in the Shinken service definitions. ds refers to the list of DATASOURCES to be collected. If an instance is expected for the list of DATASOURCES, it MUST be the same instance for all Oids. If a different instance is required, use a second DSTEMPLATE.

TRIGGER DICTIONNARY

TRIGGERGROUP DICTIONNARY

MAP DICTIONNARY

SnmpBooster.ini example configuration This example definition will be used to explain each section.

[DATASOURCE]

```
OidmyOidDefinition = .1.3.6.1.45.0
[myOidDefinition] ; Use the same name as the myOidDeiniftion, but omit the leading "Oid"
    ds_type = DERIVE
    ds_calc = 8,*  ; RPN expression : Oid, 8, *  Which means Oid * 8 = Total
    ds_oid = $OidmyOidDefinition
```

[DSTEMPLATE]

```
[myCiscoRouter]
    ds = myOidDefinition
```

[TRIGGER]

```
[trigger1]
    warning = RPN expression
    critical = RPN expression
[trigger2]
    warning = RPN expression
    critical = RPN expression
```

[TRIGGERGROUP]

```
[CiscoRouterTriggers]
    triggers = trigger1, trigger2
```

SnmpBooster.ini configuring SNMP Datasources

The first location is generic data related to SNMP parameters.

- DATASOURCE information * SNMP OID * Type of data and how can it be interpreted (GAUGE, COUNTER, COUNTER64, DERIVE, DERIVE64, TEXT, TIMETICK) * Data format preparation (Scaling the data for example bits to bytes) * Is there an instance to append to the
- Instance MAP function * Mapping the instance dynamically using a function * Data or rules related to the mapping function

SnmpBooster.ini configuring SNMP DSTEMPLATES

- DSTEMPLATEs to associate DATASOURCE to actual device classes * List of DATASOURCES associated with a, for example, Cisco 1900 router. Which in turn can be applied to a Shinken service

SnmpBooster.ini setting triggers/thresholds

- TRIGGER and TRIGGERGROUPS to apply thresholding rules * Define triggers and associate them with a TRIGGERGROUP name that can be applied to a Shinken Service

Shinken integrated SNMP Module

Overview

- Jump back to *SnmpBooster documentation index*

Tip: The module is now in public beta as of 2012-10-26! Have Fun!

Nothing new to add, more to come in 2013. 2013-01-19.

What is it The SnmpBooster module allows Shinken Pollers to directly manage SNMP data acquisition. This is an all Python cross-platform SNMP module. It is tightly integrated with the Shinken Poller, Scheduler and Arbiter daemons to provide the best possible user experience.

Why use it The SnmpBooster module is designed to be very efficient and scalable. It has a very flexible configuration method to make it easy to use with Shinken Monitoring Packs and Shinken discovery runners like genDevConfig.

This acquisition module was professionally designed and developed.

It is meant to be used by the very capable discovery engine genDevConfig (**v3.0.5 and newer**) originally developed for the Cricket SNMP monitoring tool and converted for use with Shinken.

It is one of the very few serious SNMP v2c implementation making use of SnmpGetBulk type requests.

How does it work

Shinken Integration

1. The SnmpBooster Arbiter module reads the Shinken SnmpBooster configuration file(s). It reads the check commands and based on the values in the check commands that use the snmp_poller module it will creates a shared configuration cache using memcached/memcachedb. The memcache key is always the combination of the hostname. This permits to tie together Shinken Hosts and Services with the SNMP specific configuration. (MongoDB and Redis are planned to be supported in the future) The Scheduler daemon schedules Host and Service checks as it normally does.

3. The SnmpBooster module will check that a memcache host key exists for the check to be launched. Then the SnmpBooster poller module will query all services related to a host for a given acquisition frequency in one pass. (all checks done every 2 minutes will be executed in bulk, same for those every 5 minutes)

5. Check results are cached for the acquisition check_interval. The next time a check request for data from the same host is received from the Scheduler, the data will be fetched from memcache. Resulting is extremely low check latency.

2. 6. The SNMP checks still benefit from retries, timeouts, forced checks, dependencies and the powerful Scheduler daemon logic.

6. The Scheduler daemon can still force an immediate re-check by flushing the cache. This is required for the dependency model.

Performance SnmpBooster uses SNMP v2c getbulk for high efficiency, unless forced to use SNMP v2c get-next or SNMPv1 get-next. GetBulk uses a single request PDU to ask for multiple OIDs or even entire tables, instead of sending one request PDU per OID.

For example: *A typical 24 port network switch with two uplinks might use 375 OIDS (8 OIDs per interface, plus general OIDs for chassis health, memory, cpu, fans, etc.). **SnmpBooster will only require around 4 request PDUs*

*instead of 375 request PDUs**. Each PDU is a request packet which takes time to create, send get processed and return. More timeouts to manage, more connections, more impact on the remote device and more latency means much fewer checks per second.*

The SnmpBooster module supports automatic instance mapping for OIDs. (Ex. Based on the interface name it will figure out that the SNMP index(or instance) is 136. This is automatically handled by genDevConfig and SnmpBooster, no user input required. :-)

The generic SNMP configuration information is stored in the Shinken SnmpBooster INI files. There is a Defaults_unified.ini and a series of other Defaults files, one per discovery plugin for genDevConfig.

Important: genDevConfig plugins have all been converted to use the new dynamic instance mapping methods. You are now free to use most if not all Defaults*.ini files included with genDevConfig. 2012-10-28

Limitations You should have memcached instances running on each poller responsible for snmp polling. You should have your pollers with SnmpBooster in the same datacenter, as they need to be on the same machine with good connectivity to the active memcached instance. SnmpBooster is not compatible with distributed pollers in multiple datacenters, sorry, the current design of SnmpBooster uses a single centralized memcached instance for storing the timeseries data. For distributed datacenters to be supported, each poller+scheduler+memcached must be realm restrained, which is not the case today.

Design specification *SnmpBooster design specification* and current development status.

Data model The information required to define the data is split in two locations.

The first location is the host and service Shinken configuration (You need to generate or write this)

- Device specific information
  - IP addresses, host_names, device types, instance keys
  - A DSTEMPLATE must be referred to in the Service definition
  - A static SNMP instance could be referred to in the Service definition
  - An SNMP instance MAP function could be referred to in the Service definition
  - A TRIGGERGROUP could be refered to in the Service definition

The second location is SNMP Defaults.* templates. (Here you can create new devices or add new data sources)

- DATASOURCE information
  - SNMP OID
  - Type of data and how can it be interpreted (GAUGE, COUNTER, COUNTER64, DERIVE, DERIVE64, TEXT, TIMETICK)
  - Data format preparation (Scaling the data for example bits to bytes)
  - Is there an instance to append to the
- Instance MAP function * Mapping the instance dynamically using a function * Data or rules related to the mapping function
- DSTEMPLATEs to associate DATASOURCE to actual device classes * List of DATASOURCES associated with a, for example, Cisco 1900 router. Which in turn can be applied to a Shinken service
- TRIGGER and TRIGGERGROUPS to apply thresholding rules * Define triggers and associate them with a TRIGGERGROUP name that can be applied to a Shinken Service

A final location containes rules to build your Shinken configuration.

- genDevConfig plugins create Shinken configurations

Installation and configuration *SnmpBooster installation*

Reference Dictionnary *SnmpBooster reference dictionary*

Troubleshooting *SnmpBooster troubleshooting*

Graph templates These are .graph files defined in your Shinken configuration directory. Refer to the Shinken graphite templates(Not yet created) or PNP4Nagios how-to documentation. The graph templates are independent from SnmpBooster and provide templates for any collected data from Shinken.

SnmpBooster Troubleshooting

- Jump back to *SnmpBooster documentation index*

Check your config

- Have you defined the poller module name?
- Have you defined the correct path to the directory containing your Defaults*.ini files?
- Have you addded the Snmpbooster module to your arbiter, poller, scheduler?
- Have you added copied the genDevConfig templates.cfg in shinken/packs/network/SnmpBooster/
- Have you installed PySNMP, memcached and other dependencies?

Software version consistency Shinken and SnmpBooster now require **the same Python and Pyro version on all hosts running a Shinken daemon**.

If you cannot use the packaged version of Python and its modules (Pyro, memcached, etc.). Use virtualenv to declare a python version to use and install all required modules in that virtualenv.

Software version requirements Have you verified that the *requirements* are met. Python, PySNMP, Shinken, Pyro, memcached, etc.

Validate your check command arguments Use the check_plugin command and comment out the module to learn what were the exact arguments sent by the poller. This will permit you to validate all the arguments, like snmp community string, inheritance, template application, etc.

Validate connectivity

Take a packet trace using a tool like Wireshark to validate that the remote host is responding.

- Has the host responded
- **Is SnmpBooster repeating the request more often than the polling interval.**
  - If you are seeing repeated requests your device may have a compatibility issues.

- Save an snmpwalk of the device, get a packet trace using Wireshark, set the poller to debug and save the poller.log file (shinken/var/poller.log). Send all three to the SnmpBooster developers.
- Note: It is normal to see one or more bulkGet requests if you are getting large amounts of data. Ex. a 24 port switch will take 2-3 request packets.

Performance Make sure you have a low latency connection to your memcache from the Poller. Your memcache server can be replicated to all your poller hosts that should also run memcache instances. Check that memcached is running: netstat -a | grep memcached

Faulty Template A bad snmp_template file was distributed in the genDevConfig sample-config directory, there were two glaring errors.

This was fixed on 2012-10-16. Make sure you update your template, or use the data from the wiki.

Note that the template should be called: SnmpBooster-template.cfg to make it easier to troubleshoot in the logs. So when you search for SnmpBooster in your logs it will show up as well.

Log files All warnings and errors generated by the SnmpBooster module start with "[SnmpBooster] error text" and are logged using the standard Shinken logger.

The Arbiter daemon can output initial configuration, loading of host keys and intervals in memcached type error messages. The Scheduler daemon can output scheduling and alert related messages. The Poller daemon can output messages related to instance mapping, acquisition timeouts, invalid community strings, cache failures and more. These are available in the Web interface, as they are placed in the check results for the service.

You can simply do a "grep SnmpBooster *" in your shinken/var directory to see the latest messages related to the SnmpBooster module. You can also sort messages by timestamp to make it easy to find where and when errors occurred.

cd shinken/var grep SnmpBooster *

memcache persistence If you restart your memcache server or memcache crashes, your poller will no longer be able to validate that a host exists in memcache prior to writing.

You should use memcachedb to achieve persistence in case of memcache failures.

Common errors returned by SnmpBooster in the log file Errors should be fairly explicit and mean what they say, though there can be exceptions. Lets try to clear some of them.

__Arbiter log **errors__**

Missing ds_oid : This means that a variable in your OID definitions is missing, or your DATASOURCE is not named correctly or your ds_oid variable is missing. There is a typo in your ds_oid variable (ex. ds-oid, or ds_oid = $OidNameIncorrectFFFRA.%(instance)s).

Datasource not defined : Your DSTEMPLATE uses a DATASOURCE that doesn't exist check the [DataSourceName] you are referring to. Does it contain the expected OID variable, $OidName.

Missing ds_type : The DATASOURCE always needs to have a ds_type definition, GAUGE, COUNTER, DERIVE, TEXT, TIMETICK, DERIVE64, COUNTER64.

__Poller log **errors__**

Problems with calculations, repeated polling, hosts not responding, etc.

__Memcached **errors__**

memcachedb and memcached do not use the same default port. Configure the correct memcachedb port to match what is declared in your SnmpBooster module under shinken-specific.cfg.

On Ubuntu 12.04 the default installation is on port 21201 instead of 11211. This causes the error "[SnmpBooster] Memcache server (127.0.0.1:11211) is not reachable" when Shinken starts.

To change it, you must edit the file /etc/memcachedb.conf

Memcached Notes On Ubuntu 12.04 the default instalation is on port 21201 instead of 11211. This causes the error "[SnmpBooster] Memcache server (127.0.0.1:11211) is not reachable" when shinken starts.

To change it, you must edit the file /etc/memcachedb.conf

WebUI module This part must be splitted and sent in all module repositories

WebUI integration with Shinken The WebUI is an external broker module. So it's an external process launched by the broker that "eats" broks (broker messages) from the brokers. So it can get *all* broks if you place this broker in your top level realm.

The WebUI does not use a database to get data. Instead, it use a "regenerator" object that will eat each broks, and will "recreate" all Hosts/Services/Contacts objects as if the code was in the scheduler daemon. So basically, WebUI and pages always reflect the CURRENT state of hosts/services objects.

The WebUI http layer is managed by bottle.py. It's a small but powerful framework.

How does the WebUI function globally ?

There a 2 Threads running:

- the main thread is the bottle.py (http) listener. It will use the best backend it finds. We recommend using python-paste. If it does not find one, it will use the default swsgi. Paste is multi-thread, swsgi is mon-thread, so please use paste if you want to avoid locking problems.
- the 2nd thread is the regenerator one. It only gets broks and gives them to the regenerator object.

There is a lock system between the threads. You can have N Http requests in progress without problem, but during this time the renererator one will wait. During execution of the regenerator, no requests are processed. This is not considered a problem, as the regenerator is very quick, and there is only a 1s lock for a 7k service conf loading, so it's not a huge problem.

What is a WebUI User? A WebUI user is a contact. A true contact object. You must match a contact name for your user.

To create a new page? All pages are in the shinken/webui/plugins directory. Each "part" has it's own directory. A part (like the eltdetail, element detail) can have more than one "page" (like /host or /service for eltdetail).

From here we will supose you want to create a "/contact" page.

You can copy the dummy example in the plugins directory into a contact directory.

You need to change the contact/dummy.py file into a contact/contact.py file, because the webui will search for a dir/dir.py file to "load".

Templates Templates are HTML with some Python code in it in the plugins/*/views direcotry for specific templates, and the "global layout" (menu and all common part) in the webui/views directory.

Your template must call the template layout (layout.tpl in the webui/views directory) wit ha "rebase" call.

If you put the rebase call at the beginning of your template, all there is below will be place "inside" the layout that will call the common javascripts and css, make the menu adn then call your html/python code.

The rebase call can take arguments. You MUST give it:

- user: the user you give it in the return dict of your .py code

Then all is optional:

- title: title of the page
- top_right_banner_state: int, global state with clouds to put in your top right page. Look at the problem.tpl code for an example.
- js and css list: list of YOUR specific javascript or css to call AFTER the common ones.
- refresh: boolean, set the refresh to 60s or do not refresh at all

- menu_part: will put the little "^" under this part of the menu.

Example of a call, taken from the problems view:

```
rebase layout title='All problems', top_right_banner_state=top_right_banner_state, js=['problems/js/a
roblems/js/autocompleter.Request.js', 'problems/js/autocompleterObserver.js'], css=['problems/css/acc
ms/css/autocompleter.css', 'problems/css/perfometer.css'], refresh=True, menu_part='/'+page, user=use
```

Call Python objects in your templates Your templates are mainly HTML code. But of course you can call python code in it. The dict you returns in the plugin.py call will be available in this page.

For example, the my_host variable will be available in the page with the host object you find (or None if your give it a bad name of course). Then you can "call" python with for example here to show the host_name: `<span>My host name is *my_host.host_name* </span>` is a way in the templates to "call a variable or function" that will return a string, here the host_name.

If the function or property you call must return HTML code that SHOULD be output as it, without "protection", you must put a ! before your call.

Let use an example where the output value of an host is in fact an html output. If you use the code `my_host.output`, bottle.py will "protect" the html generated by escaping the string, and change <> characters with escaped value. You can change this by calling `my_host.output`. Of course, it's a security problem if the output is with a javascript code...

You can also "loop" or put "if" in your template. You just need to put your code with a % before. Like

```
%for i in xrange(1, 10):
  My valus is  {{i}}
%end
```

You must put the %end here, the indentation will NOT be enougth, sorry.

For an if it's also easy:

```
%if host.active_checks_enabled:
  The host got active checks enabled
%else:
  The host DO NOT have active check enabled
%end
```

Which javascript lib are you using? It's mootools 1.3 with all options :)

What to do?

- Finish the /mobile part
- List of current alerts
- Host info
- Host status
- Host interfaces
- Hostgroup status
- dashboard hierachique with states, and BP
- Nagvis
- add bp in nagvis auto-map

- event sources
- correlation
- pre-filtering/enrichment
- user profile
- host/srv conf

WebUI search syntax work in progress

not that we couldn't tell. ;) eh eh

beware the working men and flying tools!

WebUI SSL Certification Lets start: the goal to to have the server.pem and client.pem file in etc/certs.

Go to the etc/certs directory.

```
openssl req -new -nodes -out server.req -keyout server.key -config ./shinken_openssl_cnf
openssl ca -out server.pem -config ./shinken_openssl_cnf -infiles server.req
cp server.pem server.pem.bkp
cp server.key server.pem
cat server.pem.bkp >> server.pem
cp server.pem client.pem
```

You can try to get the validity with for the arbiter with:

```
openssl s_client -connect localhost:7770</code>
```

Amazon AWS/EC2 import

Description You can import data from Amazon AWS/EC2 **'AWS'**_ into Shinken to create hosts.

Amazon provide VM hosting with EC2. With this arbiter module, you will be able to load your EC2 hosts into Shinken.

Prerequisites

You will need the **'libcloud'**_ package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

```
define module {
 module_name      AWS
 module_type      aws_import

 # Configure your REAL key and secret for AWS
 api_key              PAAAB2CILT80I0ZA0999
 secret           GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH
 default_template generic-host        ; if the host is not tagged, use this one
 }
```

- Put in key and secret your private Landscape access. * default_template will be used if your host is not "tagged" in Landscape

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master

     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           AWS
     }
```

Restart your Arbiter and it's done :)

Generated hosts The configuration generated will look as below :

```
define host {
    host_name            i-3fc56e5a
    address              8.8.4.4
    use                  t1.micro,MyTag,EC2,generic-host
    _EC2_AVAILABILITY    us-east-1a
    _EC2_CLIENTTOKEN
    _EC2_DNS_NAME
    _EC2_GROUPS          quicklaunch-1
    _EC2_IMAGEID         ami-1b814f72
    _EC2_INSTANCEID      i-3fc56e5a
    _EC2_INSTANCETYPE    t1.micro
    _EC2_KERNELID        aki-825ea7eb
    _EC2_KEYNAME         testaws
    _EC2_LAUNCHDATETIME  2012-09-26T12:19:38.000Z
    _EC2_LAUNCHINDEX     0
    _EC2_PRIVATE_DNS
    _EC2_PRIVATE_IP
    _EC2_PRODUCTCODE
    _EC2_PUBLIC_IP       8.8.4.4
    _EC2_RAMDISKID       None
    _EC2_STATUS          stopped
    _EC2_TAGS            demo:myvalue,use:MyTag
 }
```

Here with a stopped t1.micro instance with no name. You can put your how "use" parameter by adding a EC2 tag "use" on your VM. It will be output on the host configuration so you can setup the monitoring as you want. .. _libcloud: http://libcloud.apache.org/index.html .. _AWS: https://console.aws.amazon.com

Amazon AWS/EC2 import

Description You can import data from Amazon AWS/EC3 **'AWS'**_ into Shinken to create hosts.

Amazon provide VM hosting with EC3. With this arbiter module, you will be able to load your EC2 hosts into Shinken.

Prerequisites

You will need the **'libcloud'**_ package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

```
define module {
 module_name      AWS
 module_type      aws_import

 # Configure your REAL key and secret for AWS
 api_key              PAAAB2CILT80I0ZA0999
 secret           GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH
 default_template generic-host        ; if the host is not tagged, use this one
 }
```

- Put in key and secret your private Landscape access. * default_template will be used if your host is not "tagged" in Landscape

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master

     address          localhost                  ;IP or DNS adress
     port             7770
     spare            0
     modules           AWS
     }
```

Restart your Arbiter and it's done :)

Generated hosts The configuration generated will look as below :

```
define host {
    host_name            i-3fc56e5a
    address              8.8.4.4
    use                  t1.micro,MyTag,EC2,generic-host
    _EC2_AVAILABILITY    us-east-1a
    _EC2_CLIENTTOKEN
    _EC2_DNS_NAME
    _EC2_GROUPS          quicklaunch-1
    _EC2_IMAGEID         ami-1b814f72
    _EC2_INSTANCEID      i-3fc56e5a
    _EC2_INSTANCETYPE    t1.micro
    _EC2_KERNELID        aki-825ea7eb
    _EC2_KEYNAME         testaws
    _EC2_LAUNCHDATETIME  2012-09-26T12:19:38.000Z
    _EC2_LAUNCHINDEX     0
    _EC2_PRIVATE_DNS
    _EC2_PRIVATE_IP
    _EC2_PRODUCTCODE
    _EC2_PUBLIC_IP       8.8.4.4
    _EC2_RAMDISKID       None
    _EC2_STATUS          stopped
    _EC2_TAGS            demo:myvalue,use:MyTag
 }
```

Here with a stopped t1.micro instance with no name. You can put your how "use" parameter by adding a EC2 tag "use" on your VM. It will be output on the host configuration so you can setup the monitoring as you want. .. _libcloud: http://libcloud.apache.org/index.html .. _AWS: https://console.aws.amazon.com

The distributed retention modules The high availability allow the Arbiter to send a configuration to a spare scheduler, but a spare scheduler does not have any saved states for hosts and services. It will have to recheck them all. It's better to use a distributed retention module so spares will have all the information they need to start with an accurate picture of the current states and scheduling :)

Non distributed retention modules If you are just running tests on a single server, use the pickle or memcache retention modules You can also use MongoDB if you already have it installed for use with the WebUI.

MongoDB MongoDB is a scalable, high-performance, open source NoSQL database written in C++.

Step 1: Install MongoDB:

We will use mongodb package from 10gen repository, so we start by adding it in apt sources list:

```
echo 'deb http://downloads-distro.mongodb.org/repo/debian-sysvinit dist 10gen' > /etc/apt/sources.lis
apt-get update
```

And we install it:

```
apt-get install mongodb-10gen
```

And we install pymongo, the python interface to MongoDB, with easy_install to avoid packages versions problems (like here **'forums.monitoring-fr.org/index.php?topic=5205.0'_**):

```
apt-get remove python-pymongo
easy_install pymongo
```

And finally we start MongoDB :

```
/etc/init.d/mongodb start
```

Step 2: define a mongodb_retention module in your shinken-specific.cfg file:

```
define module {
  module_name MongodbRetention
  module_type mongodb_retention
  uri mongodb://localhost/?safe=true
  database shinken
}
```

Step 3: Declare a retention module for your scheduler(s) :)

Example:

```
#The scheduler is a "Host manager". It get hosts and theirs
#services. It scheduler checks for them.
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
     port     7768                  ; tcp port of the daemon

     #optionnal: modules for things as retention
     modules    MongodbRetention
     }
```

Step 4: Restart the Arbiter, and your Scheduler will now save its state between restarts. :)

Memcached Memcached is a distributed memory resident key/value server. It's very easy to install:

```
sudo apt-get install memcached
sudo /etc/init.d/memcached start
```

The shinken module also needs the python-memcache package to talk to this server.

```
sudo apt-get install python-memcache
```

To use it,

Step 1: define a memcache_retention module in your shinken-specific.cfg file:

```
define module{
     module_name      MemcacheRetention
     module_type      memcache_retention
     server           127.0.0.1
     port             11211
}
```

Step 2: Declare a retention module for your scheduler(s) :)

Example:

```
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
     port     7768                  ; tcp port of the daemon

     #optional: modules for things as retention
     modules    MemcacheRetention
     }
```

Step 3: Restart the Arbiter, and your Scheduler will now save its state between restarts. :)

Redis Redis is a distributed key/value server (on disk and in-memory). It's very easy to install:

```
sudo apt-get install redis-server
sudo /etc/init.d/redis-server start
```

The shinken module also need the python-redis package to talk to this server.

```
sudo apt-get install python-redis
```

Step 1: define a redis_retention module in your shinken-specific.cfg file:

```
define module{
     module_name      RedisRetention
     module_type      redis_retention
     server           127.0.0.1
}
```

Step 2: Declare a retention module for your scheduler(s) :)

Example:

```
#The scheduler is a "Host manager". It get hosts and theirs
#services. It scheduler checks for them.
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
```

```
    port     7768                  ; tcp port of the daemon

    #optionnal: modules for things as retention
    modules    RedisRetention
    }
```

Step 3: Restart the Arbiter, and your Scheduler will now save its state between restarts. :) .. _forums.monitoring-fr.org/index.php?topic=5205.0: http://forums.monitoring-fr.org/index.php?topic=5205.0

How to enable and use Livestatus module

Define the Livestatus module Start by reviewing the ''/etc/shinken/shinken-specific.cfg" file for this module:

```
define module{
```

```
module_name      Livestatus
module_type      livestatus
host             *       ; * = listen on all configured IP addresses
port             50000   ; port to listen on
database_file    /var/lib/shinken/livestatus.db
```

}

With these parameters:

- module_name: name of the module called by the brokers
- module_type: livestatus
- host: IP interface to listen to. The default is *, which means "listen on all interfaces".
- port: TCP port to listen to.
- socket: Unix socket to listen to.
- database_file: the path to the sqlite database file which is used to store the log broks/messages. The default is "var/livelogs.db"
- max_logs_age: the maximum age of the log messages (before they are deleted from the database). The default is 1 year. The argument to this parameter takes the form <number>[<period of time>], where <period of time> can be d for days, w for weeks, m for months and y for years.
- allowed_hosts: a comma-separated list of IP-addresses which are allowed to contact the TCP port. Please keep in mind that these **must be IP-addresses, NOT host names**. Because DNS lookups for every incoming livestatus request could hang up and therefore block the module.

Enable the Livestatus module Still in ''/etc/shinken/shinken-specific.cfg'', find the object Broker and add "Livestatus" to its "modules":

```
define broker{
```

```
    broker_name      broker-1
[...]
```

```
    modules          Simple-log,Livestatus
}
```

Disable human readable logs In ‘’/etc/shinken/nagios.cfg’‘, verify that the option **human_timestamp_log** is set to **0**.

In version 0.6.5, you can not have at the same time a simple-log file with human readable timestamp and a Livestatus database.

Exporting data for reporting Shinken can export necessary data for reporting in 3rd party systems.

raw_socket module The raw socket module exports reporting data using a syslog format to a raw TCP socket. Theses logs can be captured, parsed and indexed by any log management system like Splunk or Logstash.

Why export reporting data Custom UIs like Thruk, Multisite, WebUI, Adagios, Nagios IX, etc. All have poor or inflexible reporting. Simply because these are not reporting engines.

This also permits to have a generic reporting method that can accept data from any Nagios, Shinken, Icinga or even Riemann.

Reporting module using Splunk Splunk was selected as the reporting platform for creating, managing and presenting reports. Though the raw_socket module does not have any Splunk specific particularities. It is notable that Splunk reports can be embedded in any 3rd party UI using its REST API.

Raw_socket log format The logs are plain-text and compliant with RFC3164. They use an intelligent date format, a configurable seperator ” “(space by default), and key=value pairs in the message data portion of the log. Should a key or value contain a space they must be double quoted. This is syslog using structured data without going to full out JSON that may not be compatible with all log management systems.

The message fields that are supplied in each status update in addition to the standard syslog header are:

- Hostname
- Servicename
- Business impact
- Host/Service status
- Host/Service previous status
- Acknowedgement status
- Maintenance status

Any time the maintenance, host, service or acknowledgement status changes, a log is sent by the Shinken raw_socket module.

Having all relevant data in each log makes it very easy to compute reports for given time periods.

The hostgroup or service group memberships, custom variables or any other configuration related data should be queried from the monitoring system using its API (Livestatus in the case of Shinken and Nagios).

Raw_socket module availability The module is available in both Shinken 1.4 and Shinken 2.0. The module will be integrated in master branches once unit tests and end-to-end testing is completed. 3rd quarter 2013.

Monitoring Linux System with Glances and checkglances.py **‘Glances‘_** is a fantastic multiplatform system monitoring tool writen by Nicolargo. Glances can run on (Linux, Windows, MacOS ...). There is a growing ecosystem around Glances and of course a Nagios/Shinken plugin : checkglances.py.

How does it work Glances can run in server mode. It provide a XML-RPC server (over http) and allow to retrieve system information throuh a restful API. The only thing to do is to install and start Glances as server on the monitored host, then install checkglances.py on the shinken server and finaly install the glances pack.

Install glances See the glances documentation to install glances on Linux.

<code bash> easy_install glances </code>

There is a debian startup script in the glances repository. And another one for centos here.

Install checkglances.py Just follow the documentation for the checkglances.py prerequisites and put it in your nagios plugins folder.

Install the glances pack Open a terminal as the shinken user and just type the following command

<code bash> shinken install glances </code>

Then just edit the configuration for a linux monitored host and tag it as **glances**

```
define host{
 name mylinuxhost
 use glances
 ...
```

Finaly restart the shinken arbiter

```
service shinken-arbiter restart
```

What will be monitored ? For the moment just the basic system (ram, cpu, load, memory, filesystem and network).

If you want to modify the default thresholds for just a host you can do it by overiding the thresholds macro in your host definition. If you want to do it for several hosts, declare a new template and just add the desired thresholds macro to be overide.

Here is a list of the macros

```
::
```

> _LOAD_WARN 2 _LOAD_CRIT 3 _CPU_WARN 80 _CPU_CRIT 90 _MEMORY_WARN 90 _MEMORY_CRIT 95 _FS /, /home _FS_WARN 90 _FS_CRIT 95 _IFACES eth0, eth1 _NET_WARN 7500000 _NET_CRIT 10000000

Note the _FS and _IFACES macros. They leverage the ability to duplicate service for a given list of things to be monitored. Here you see that / and /home partitions will be monitored. If you want to modify this then just add your own in a new template that will inherit the glances template.

Shinken GLPI integration Shinken supports importing hosts from GLPI

For people not familiar with GLPI, it is an Open-Source CMDB. Applicable to servers, routers, printers or anything you want for that matter. It is also a help-desk tool. GLPI also integrates with tools like FusionInventory for IT inventory management.

You can still have flat files AND GLPI if you want. Hosts imported from GLPI will be treated as standard hosts from flat file (inheritance, groups, etc). In fact, in this first version the module only sends the host_name to Shinken, but there should be more information extracted like network connexions for parents relations in the future. :)

Requirements

- python module MySQLdb
- Compatible version of GLPI Shinken module and GLPI version - ...
- etc..

Enabling GLPI Shinken module In your shinken-specific.cfg file, just add (or uncomment):

```
#You know GLPI? You can load all configuration from this app(
#with the webservices plugins for GLPI, in xmlrpc mode
#and with plugin monitoring for GLPI)
# =============== Work with Plugin Monitoring of GLPI ===============
#All configuration read from this will be added to the others of the
#standard flat file
define module{
     module_name      GLPI
     module_type      glpi
     uri              http://localhost/glpi/plugins/webservices/xmlrpc.php
     login_name       glpi
     login_password   glpi
}
```

And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master
#    host_name       node1       ;result of the hostname command under Unix
     address          localhost                  ;IP or DNS adress
     port             7770
     spare            0
     modules           GLPI
     }
```

It's done :)

Ip Tag module

Why tag a host based on it's IP address? We learned on the *DMZ monitoring* that you can "tag" a host with a poller_tag so it will be checked only by DMZ pollers. It can be tedious process to manually tag all these hosts. Shinken provides an automated method to do this.

This is handled by the arbiter ip_tag module.

Ip_tag module The ip_tag module is an arbiter module that looks up the host address during the configuration parsing and compares it to an predefined IP range (IPV4 or IPV6). If the range matches, it can apply or add a property, such as poller_tag. Other types of tags could be related to locations, functions, administrative groups, etc.

Method: replace or append.

replace will put the value if the property is unset. This is the default method. .. warning:: Fix me: replace, implies overriding an existing value. And will cause user issues down the line. Rename it to set. Replace should be a different method altogether, so overall there should be 3 methods(set, append, replace).

append will add with a , if a value already exist

Here is an example that will set the poller_tag property with the value DMZ of all hosts that:

- have a their hostadress ip (or name resolved) in the range 192.168.0.1/24.
- do not already have a poller_tag property set

```
define module{
```

```
     module_name     IpTag
     module_type     ip_tag
     ip_range        192.168.0.1/24
     property        poller_tag
     value           DMZ
}
```

To use the module add it in the arbiter object:

```
::
```

define arbiter { [...] modules NSCA,IpTag

}

Add value instead of setting it In the previous example we set the property poller_tag to a value. But what if we want to "add" a value, like a template name? We can change the "method" property of the module to "append" so we can add the "value" to the host property instead of replace it.

Here is an example where we want to add the "dmz" template on the hosts, while also keeping any defined templates:

```
define module{
```

```
     module_name   IpTag
     module_type   ip_tag
     ip_range      192.168.0.1/24
     property      use
     value         dmz

     # Optional method
     method append
}
```

For a host defined as:

```
define host{
```

```
     host_name   example_host1
     address     192.168.0.2
     use         linux
}
```

It will be "changed" internaly in:

```
define host{
```

```
     host_name   example_host1
     address     192.168.0.2
     use         linux,dmz
}
```

Name resolution Of course you don't need to set IP address in the address of your host. You can set a hostname, and it will be resolved, and then compared to the range. :)

Ubuntu Landscape import

Description You can import data from Ubuntu Landscape into Shinken to create hosts.

Ubuntu Landscape, is a web app to manage all your linux servers (update and co), which is provided by Canonical, Ubuntu's parent company.

This is an Arbiter import module. The Arbiter manages the configuration.

Prerequisites

You will need the landscape-api package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

define module { module_name Landscape module_type landscape_import

Configure your REAL key and secret from Landscape key PAAAB2CILT80I0ZA0999 secret GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH default_template generic-host ; if the host is not tagged, use this one

If you are using a specific certificate for landscape_api #ca /path/to.ca.cert

If you need a proxy to access https://landscape.canonical.com/api/ #https_proxy http://user:secret@myproxy.com:3128

}

- Put in key and secret your private Landscape access.
- default_template will be used if your host is not "tagged" in Landscape
- If you are using a specific certificate for connexion, give the full path in ca
- You will certainly need an https proxy to access the Landscape API. If so, configure it there.

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master
#    host_name       node1       ;result of the hostname command under Unix
     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           Landscape
     }
```

Restart your Arbiter and it's done :)

Tip: Your "tags" will be applied as templates for your hosts.

Shinken Livestatus API

Overview

- Jump back to Getting Started
- Jump back to *Livestatus module configuration*

What is it Livestatus API is the modern method of interacting with Shinken and Nagios based systems alike.

Originally developed for Nagios, MK Livetstatus, was re-implemented in Python for use with Shinken by professional developers. The access methods and query languages are the same.

Why use it It is fast.

It is network based using TCP.

It is standard for all Nagios and Shinken monitoring systems.

It uses in-memory structures for status data

It uses a back-end database for historical reporting

It uses an SQL based query language

It has a host of powerful nuts and bolts features (authentication, caching, connection persistence, multiple object methods (JSON, Python)).

What can I do with it? All programs and scripts use (or should use) this method to :

- Obtain the current state of hosts and services
- Obtain the current configuration related to hosts and services
- Send administrative commands (downtimes, comments, forcing checks)
- Filter information to display
- Obtain basic reports and event statistics

Shinken being a modern re-implementation of Nagios has additional features that are available in addition to the standard Livestatus API.

Shinken Livestatus API unique features can :

- Obtain Business Impact information
- Obtain intelligent dependency status hosts or services (combines dependency and parent information)
- Obtain Business Process states (same syntax as standard host and service queries)

How does it work Livestatus uses a powerful SQL-like query language. The standard methods and parameters are defined at :

'MK Livestatus reference methods and query language definition'_

Full list of Shinken Livestatus API methods:

'Shinken mapping.py methods'_

What software uses Livestatus to interact with Shinken

Well known Web frontends

- MK Multisite
- Thruk
- NagVis

- Splunk for Nagios

Mobile Web frontends

- get list

Scripts

- Downtime management scripts
- Debug scripts

Installing Livestatus Have you installed the required packages to use the Livestatus module? You can look at the requirement section of the *10 minute installation guide* for the *requirement lists*.

How to enable Livestatus Very simple, jump to the *Shinken Broker configuration* section to enable it. .. _Shinken mapping.py methods: https://github.com/shinken-monitoring/mod-livestatus/blob/master/module/mapping.py .. _MK Livestatus reference methods and query language definition: http://mathias-kettner.de/checkmk_livestatus.html

NSCA module The NSCA daemon module is used to receive send_nsca packets and submit them to the Shinken command pipe. The NSCA module can be loaded by the Receiver or Arbiter process. It will listen on port TCP/5667 for send_nsca packets.

Tip: Passive checks can be submitted *natively to the Shinken command pipe* or from remote hosts to modules, such as NSCA, AMQP or collectd, loaded in the Shinken Arbiter or Receiver process. AMQP is implemented for integration with the Canopsis Hypervisor, but could be re-used for generic messaging.

Note: The Shinken NSCA module implementation is currently limited to the "xor" obfuscation/encryption.

In your shinken-specific.cfg file, just add (or uncomment):

```
::
```

#You can send check result to Shinken using NSCA #using send_nsca command define module{

module_name NSCA module_type nsca_server host * port 5667 encryption_method 0 password helloworld

}

define receiver{

```
receiver_name    receiver-1
address          localhost
port             7773
modules          NSCA

timeout          3             ; 'ping' timeout
data_timeout     120           ; 'data send' timeout
max_check_attempts       3     ;  if at least max_check_attempts ping failed, the node is DEAD

#advanced
realm    All
}
```

This daemon is totally optional.

It's main goal is to get all passive "things" (checks but why not other commands) in distant realms. It will act as a "passive receive buffer" and will then dispatch the data or commands directly to the appropriate Scheduler or Arbiter process.

Data can be received from any Realm, thus the Realm option is nonsensical.

For now there is no init.d script to launch it. .. note:: Verify that the init script has been added.

It is launched like all other daemons:

```
bin/shinken-receiver -c etc/receiverd.ini
```

Tip: Alternatively, for small installations with you can configure a modules inside your Arbiter instead of the Receiver. It will listen the TCP/5667 port for send_nsca packets.

To configure the NSCA module in your Arbiter instead of Receiver. Add the NSCA module to your Arbiter object configuration.

```
::
```

define arbiter{ arbiter_name Arbiter-Master

 # host_name node1 ;result of the hostname command under Unix address localhost ;IP or DNS adress port 7770 spare 0 modules NSCA

}

Retention troubleshooting The retention file contains the state of your host and services, so that they are kept when shinken is restarted.

Sometimes you'll want to inspect (and possibly fix) the retention file, in case you need to work-around a bug or simply better understand what is stored there.

When you use the PickleRetention module in the scheduler (cf. ''define scheduler" in ''shinken-specific.cfg''), you can simply manipulate the retention file using Python.

For this you can use the following code.

- It assumes Shinken is installed in ''/opt/shinken" with the retention file in ''/tmp/retention.dat'':
- Run and play with it interactively using ''ipython -i inspect_retention.py''.

```
#!/usr/bin/python
import pickle
import sys
sys.path.append('/opt/shinken')
import shinken

r = pickle.load(file('/tmp/retention.dat'))
h = r['hosts']

# Example:
# [(k,v) for (k,v) in h['your_host'].items() if k.find('downtime') >= 0]
#
# del h['your_host']
#
# for k,v in r['services'].items():
#     if 'your_host' in k:
#         del r['services'][k]
```

To save your changes:

- Stop Shinken: ‘’service shinken stop’‘
- Save the pickle: ‘’pickle.dump(r, open(‘/tmp/retention.dat’, ‘w’))’‘
- Start Shinken: ‘’service shinken start’‘

NRPE Module

What is it The NRPE module allows Shinken Pollers to bypass the launch of the check_nrpe process. It reads the check command and opens the connection by itself. It scales the use of NRPE for active supervision of servers hosting NRPE agents.

The command definitions should be identical to the check_nrpe calls.

How to define it The definition is very easy (and you probably just have to uncomment it):

```
define module{
     module_name       NrpeBooster
     module_type       nrpe_poller
}
```

Then you add it to your poller object:

```
define poller {
    [...]
    modules   NrpeBooster
}
```

Then just tag all your check_nrpe commands with this module:

```
define command {
   command_name   check_nrpe
   command_line   $USER1$/check_nrpe -H $HOSTADRESS$ -c $ARG1$ -a $ARG2$
   module_type    nrpe_poller
}
```

That’s it. From now on all checks that use this command will use Shinken’s NRPE module and will be launched by it.

Extending Shinken

Introduction There are a lot of “Modules” and “Addons” that are available for Shinken. Shinken can be extended by using different types of methods.

- Web interfaces from various open-source vendors can be used (Based on Livestatus API)
- Shinken itself can be extended using modules that are embedded into the various daemon processes

** (Arbiter, Poller, Receiver, Broker, Scheduler, Reactionner) * External software can provide functional enhancements for reporting, management or usability aspects

Shinken itself provides methods to extend the base functionality:

- *Broker modules* provide external access to runtime data from Shinken
- Poller modules such as *NRPE* and the *SNMP*
- Receiver modules like *NSCA* provide acquisition methods for Shinken

- Arbiter modules permit manipulating the configuration
- The webUI that permits embedding web interface elements

Independent software that works in concert with Shinken is available for:

- Monitoring remote hosts through agent software (*NIX, Windows, etc.)
- Submitting passive checks from remote hosts
- Managing the config files through a web interface
- Mobile phone UIs
- Desktop UIs and Hypervisors
- Desktop notification addons
- ...and much more

You can find many addons that are compatible with Shinken by visiting. The only caveat is that the addons should not use the status.dat file and preferably the modern API interfaces like Livestatus:

- Nagios.org
- SourceForge.net
- NagiosExchange.org
- Shinken community exchange for monitoring packs

Broker modules The broker module receives messages from the Schedulers related to host, service check results. In addition to that it receives a copy of the compiled configuration at startup. What is special about the broker, is that without modules, the broker does nothing. It makes the configuration and result data available to modules. Modules are the ones in charge of doing something with the data. This could be exporting this "raw" data into flat files, databases or exposing it as an API.

The modules are presented according to their use cases.

- Core modules
- Livestatus Module for frontends
- Exporting data to metric databases
- SQL based Modules for frontends
- Exporting data to logging management systems
- Legacy modules for migration purposes
- Modules no longer supported

Core modules

simple_log: get all logs into one file You can get a log for all your daemons in a single file. With the exception of Debug level logs which are not sent through the network as a safe guard. Shinken state messages are ONLY logged at the debug level in the local log files. These are the ALL CAPS states that some 3rd party interfaces use to mine data from the historical logs. Actual state messages are sent as objects between the various daemons.

It takes the parameters:

- module_name: name of the module called by the brokers

- module_type: simple_log
- path: path of the log file

Here is an example:

```
define module{
```

```
     module_name      Simple-log
     module_type      simple_log
     path             /usr/local/shinken/var/nagios.log
     archive_path     /usr/local/shinken/var/archives/
}
```

Syslog - Send all logs to a local syslog server Send all logs to a local syslog server. Support for remote syslog can be implemented if requested. Just lookup the syslog module, easy to modify. Use for example with Splunk, graylog2, Logstash, Elastic search, Kibana, or other log management and analysis system.

```
define module{
```

```
  module_name Syslog
  module_type syslog
}
```

Lightweight forwarder to Splunk Shinken state data from the local syslog can also be sent to a Splunk server for indexing, reports, SLA and analysis. Via syslog or better yet, the Splunk lightweight forwarder which supports, TCP, buffering and security parameters.

Livestatus API Module - Thruk, Nagvis and Multisite Web frontends There are three well known frontends and various small tools that can interface with the Livestatus API. This API is currently the most efficient method of sharing live data with external interfaces. It provides a rich query language similar to SQL, authentication, command execution, caching,connections persistence, multiple object methods (JSON, Python). All Livestatus data is kept in memory, there is no disk IO involved. It exposes configuration objects, the current state of the hosts and services as well as historical Shinken state log messages.

- MK Multisite
- Thruk
- NagVis

Have you installed the required packages to use the Livestatus module? You can look at the requirement section of the 10 minute installation guide for the requirement lists.

Livestatus Module

It takes the following parameters:

- module_name: name of the module called by the brokers
- module_type: livestatus
- host: IP interface to listen to. The default is '127.0.0.1'. '*' means 'listen on all interfaces'.
- port: TCP port to listen to.
- socket: Unix socket to listen to.

- allowed_hosts: a comma-separated list of IP-addresses which are allowed to contact the TCP port. Please keep in mind that these must be ip-addresses, NOT host names. (DNS lookups for every incoming livestatus request could hang up and therefore block the module)
- modules: a comma-separated list of modules (see below)
- pnp_path: relevant if you use the multisite gui. pnp_path points to the perfdata directory where the pnp4nagios data reside (it's the directory which contains a subdirectory for each host). Multisite needs it to display a small perfdata icon if a rrd file exists.
- To deactivate an input, the port- and socket-attributes can also take the value "none".

The Livestatus module itself can have sub-modules. In fact, it **must** have at least one submodule responsible for storing log events to a database, SQLite or MongoDB.

Livestatus module - Logstore Sqlite Stores log-broks to an sqlite database.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_sqlite
- use_aggressive_sql: Prefer the use of sql queries to pre-filter data prior to python filtering. This is required for very large installations, as the Python structures are not indexed when filtering. Optional argument set to 0 by default. To enable set the value to 1. Some erroneous output may occur, but informal testing has shown these corner cases do not occur.
- read_only: don't send any update to the database. Should be used when you run several livestatus modules : 1 instance is R/W, other are read only.
- database_file: the path to the sqlite database file which is used to store the log broks/messages. The default is 'var/livestatus.db'
- archive_path: the path to a subdirectory where database file archives will be created. Every day the data from the last day will be moved to an archive datafile. The default is 'var/archives'.
- max_logs_age: the maximum age of the log messages (before they are deleted from the database). The default is 1 year. The argument to this parameter takes the form <number>[<period of time>], where <period of time> can be d for days, w for weeks, m for months and y for years. This parameter is currently ignored. In future releases it will be used to automatically delete ancient database files.

Here is an example:

```
define module{
```

```
     module_name      Livestatus
     module_type      livestatus
     host             *       ; * = listen on all configured ip addresses
     port             50000   ; port to listen
     socket           /usr/local/shinken/var/rw/live
     modules          logsqlite
}
define module{
```

```
     module_name      logsqlite
     module_type      logstore_sqlite
     use_aggressive_sql     0 ; optional, by default set to 0. Only for large installations.
     database_file    /usr/local/shinken/var/livelogs.db
     max_logs_age     3m ; three months. Other time intervals are d=days, w=weeks, y=years
}
```

Livestatus module - Logstore MongoDB Stores historical log broks(inter daemon Shinken messages) to a MongoDB database. MongoDB is a distributed and very performant database that permits resilience and high availability. The current implementation has a few known broken pieces (some search functions are broken) and there are bugs in the implementation, so it is considered experimental until power users and developers have ironed out the bugs. It is the database of the future for Shinken.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_mongodb
- mongodb_uri: The address of the master. (Default: i_cant_write_the_uri_here_it_messes_the_wiki_up)
- replica_set: If you are running a MongoDB cluster (called a "replica set" in MongoDB), you need to specify it's name here. With this option set, you can also write the mongodb_uri as a comma-separated list of host:port items. (But one is enough, it will be used as a "seed")
- database: <undocumented>
- collection: <undocumented>
- max_logs_age: <undocumented>

The configuration looks quite similar to the sqlite one. **In a single-node installation and with decent amount of log traffic, the sqlite backend should be considered best practice, as it needs no extra software and is stable and fast (when run in-memory).**

Livestatus module - Logstore Null In case you don't need any logging (for instance, if you dedicate a livestatus module instance to nagvis), you can use this module.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_null

Network Based Modules - Graphite graphing Graphite is a graphing and data analysis tool. It is composed of a web frontend (graphite-web), fixed size databases (whisper) and data redistribution/munging daemon. (carbon) The first step is *having Graphite installed somewhere*, if you do not have Graphite installed, please do this and come back later.

Pre-requisite : Shinken 1.2.2+ is recommended for the best experience with Graphite.

graphite_perfdata: exports check result performance data to Graphite Export all performance data included in check results to Whisper databases managed by Graphite. Data is buffered, then exported once every broker time tick. (Once per second). Should a communication loss occur, it will buffer data for 5 minutes before dropping data. The tick_limit max is configurable, the only limitation is the amount of memory the buffered data can eat.

The graphite broker module (v1.2) sends data to graphite in the following format :

HOSTNAME.SERVICENAME.METRICNAME

It can be optionally enhanced to send it the following format :

_GRAPHITE_PRE.HOSTNAME.SOURCE.SERVICENAME.METRICNAME._GRAPHITE_POST

Each of the three variables are optional :

- The _GRAPHITE_PRE variable can be set per host/service to provide a more flexible naming convention. (ex. Prod.site1.Hostname.servicename)

- The _GRAPHITE_POST variable can be set per host/service to specify the more information concerning the variable being stored that graphite can use to determine the retention rule to use for the variable.
- The SOURCE variable can be set in shinken-specific.cfg for the WebUI module and the Graphite broker.

Metric names are converted from Shinken's format to a more restrictive Graphite naming. Unsupported characters are converted to "_" underscore. So do not be surprised to see that some names differ in the WebUI or directly in Graphite. Permitted characters in Graphite are "**A-Za-z_**.", the hyphen character is permitted from Shinken, though only future versions of Graphite will support it.

Performance data transfer method can be set to pickle, which is a binary format that can send data more efficiently than raw ascii.

It takes the following parameters:

- module_name: name of the module called by the brokers
- module_type: graphite_perfdata
- host: ip address of the graphite server running a carbon instance
- port: port where carbon listens for metrics (default: 2003 for raw socket, 2004 for pickle encoded data)
- use_pickle: Use a more efficient transport for sending check results to graphite instead of raw data on the socket (v1.2)
- tick_limit: Number of ticks to buffer performance data during a communication outage with Graphite. On tick limit exceeded, flush to /dev/null and start buffering again. (v1.2)
- graphite_data_source: Set the source name for all data coming from shinken sent to Graphite. This helps diferentiate between data from other sources for the same hostnames. (ex. Diamond, statsd, ganglia, shinken) (v1.2)

Here is an example:

```
define module {
```

```
module_name Graphite-Perfdata
host xx.xx.xx.xx
module_type graphite_perfdata
port 2004 ; default port 2003 for raw data on the socket, 2004 for pickled data
use_pickle 1 ; default value is 0, 1 for pickled data
tick_limit 300 ; Default value 300
graphite_data_source shinken ; default is that the variable is unset
}
```

SQL Based Modules - PNP4Nagios Graphing PNP4Nagios is a graphing tool that has a web interface for RRDTool based databases. Shinken can export performance data to an npcd database which will feed the RRD files (fixed sized round robin databases). You can *learn how to install PNP4Nagios* if you haven't done it already.

npcdmod: export perfdatas to a PNP interface Export all perfdata for PNP.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: npcdmod
- path: path to the npcd config file

Here is an example:

```
define module{
 module_name  NPCD
 module_type  npcdmod
 config_file  /usr/local/pnp4nagios/etc/npcd.cfg
}
```

SQL Based Modules - Frontend Centreon2 Centreon2 use a NDO database, so you will need the ndodb_mysql module for it.

ndodb_mysql: Export to a NDO Mysql database Export status into a NDO/Mysql database. It needs the python module MySQLdb (apt-get install python-mysqldb or easy_install MySQL-python).

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: ndodb_mysql
- database: database name (ex ndo)
- user: database user
- password: database user passworddt
- host: database host
- character_set: utf8 is a good one

Here is an example:

```
define module{
```

```
     module_name      ToNdodb_Mysql
     module_type      ndodb_mysql
     database         ndo       ; database name
     user             root      ; user of the database
     password         root      ; must be changed
     host             localhost ; host to connect to
     character_set    utf8      ;optionnal, UTF8 is the default
}
```

File based Legacy modules - perfdata export

service_perfdata: export service perfdatas to a flat file

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: service_perfdata
- path: path to the service perfdata file you want

Here is an example:

```
define module{
```

```
    module_name      Service-Perfdata
    module_type      service_perfdata
    path             /usr/local/shinken/src/var/service-perfdata
}
```

host_perfdata: export host perfdatas to a flat file

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: host_perfdata
- path: path to the host perfdata file you want

Here is an example:

```
define module{
```

```
    module_name      Host-Perfdata
    module_type      host_perfdata
    path             /usr/local/shinken/src/var/host-perfdata
}
```

Legacy File based Modules - Old CGI or VShell The Old CGI and VShell use the flat file export. If you can, avoid it! It has awful performance, all modern UIs no longer use this.

status_dat: export status into a flat file Export all status into a flat file in the old Nagios format. It's for small/medium environment because it's very slow to parse. It can be used by the Nagios CGI. It also export the objects.cache file for this interface.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: status_dat
- status_file: path of the status.dat file /usr/local/shinken/var/status.dat
- object_cache_file: path of the objects.cache file
- status_update_interval: interval in seconds to generate the status.dat file

Here is an example:

```
define module{
```

```
    module_name              Status-Dat
    module_type              status_dat
    status_file              /usr/local/shinken/var/status.data
    object_cache_file        /usr/local/shinken/var/objects.cache
    status_update_interval   15 ; update status.dat every 15s
}
```

Deprecated or unsupported modules

SQL Based MerlinDB This interface is no longer supported and is going to be completely removed from Shinken.

SQL based ndodb_oracle - Icinga web frontend using NDO Oracle This interface is no longer supported and is going to be completely removed from Shinken.

CouchDB: Export to a Couchdb database This interface is no longer supported and is going to be completely removed from Shinken.

TSCA (Thrift Service Check Acceptor) TSCA is a receiver/arbiter module to receive hosts and services check results. It provides the same functions as NSCA with additional features. High performance binary transmission, multi line output and auto generated clients for a variety of languages.

What is thrift ? Let's cut and paste the wikipedia definition from'en.wikipedia.org/wiki/Apache_Thrift'_ :

"Thrift is an interface definition language that is used to define and create services for numerous languages.[1] It is used as a remote procedure call (RPC) framework [..]. It combines a software stack with a code generation engine to build services that work efficiently to a varying degree and seamlessly between ActionScript, C#, C++ (on POSIX-compliant systems), Cappuccino, Cocoa, Erlang, Haskell, Java, OCaml, Perl, PHP, Python, Ruby, and Smalltalk."

Installation In any case, you have to install thrift with support for python (on the server side) and languages you want to use for clients.

Get it from thrift.apache.org or in your favorite distribution repository.

Server side Go to the tsca module directory and generate the python stub for the server side installation

```
cd shinken/modules/tsca
$ thrift --gen py tsca.thrift
```

Declare the module is shinken-specific.org

```
define module{
      module_name     TSCA
      module_type     tsca_server
      host            0.0.0.0
      port            9090
}
```

Samples clients There are three(3) client samples written in python, ruby and java in contrib/clients/TSCA of the Shinken distribution. You can use and extend them to send data directly in your code directly to Shinken's TSCA receiver/arbiter module.

The samples clients read a CSV file from stdin and send them the the TSCA running on localhost:9090. The CSV has the following format :

```
hostname,service description,output,rc
```

Any use of TCP in an application should take care not to block the program and to have very short timeouts. For applications that need non blocking functions, prefer a UDP based transport or a local buffer file with a separate application(send_nsca, thrift, etc) to forward your data to Shinken.

Ruby Generate the stub

```
$ thrift --gen rb ../../../shinken/modules/tsca/tsca.thrift
```

Run the client

```
$ cat file_state | ruby RubyClient.rb
```

Python Generate the stub

```
$ thrift --gen py ../../../shinken/modules/tsca/tsca.thrift
```

Run the client

```
$ cat file_state | python PythonClient.py
```

java Generate the stub

```
$ thrift --gen java ../../../shinken/modules/tsca/tsca.thrift
```

Compile the client

```
$ ant
```

Run the client

```
$ cat file_state | java JavaClientThrift
```

VMWare Arbiter module

How it works The arbiter has a module that allows the host->VM automatic host dependency creation. In fact, the module is far more generic than just this. It's a generic "host link dependencies" module.

It reads a mapping file (simple json format) with son->father links. It call an external script at a regular interval : the one I wrote is a VMWare mapping one. It used the check_esx3.pl (that all ESX admin should have) plugin and generate the mapping file. When this file is changed, the module reloads it, creates new links and deletes old ones. So when you VMotion a virtual machine, in the next pass, there will be creation of a new link and deletion of the old one in the scheduler that manages it :)

How to define it The definition is very easy :

```
define module{
     module_name       VMWare_auto_linking
     module_type       hot_dependencies
     mapping_file      /tmp/vmware_mapping_file.json
     mapping_command   /usr/local/shinken/libexec/link_vmware_host_vm.py -x '/usr/local/shinken/libex
     mapping_command_interval 60   ; optionnal
     mapping_command_timeout   300 ; optionnal
}
```

Then you add it in you arbiter object :

```
define arbiter {
    [...]
    modules   VMWare_auto_linking
}
```

So here, it will call the script /usr/local/shinken/libexec/link_vmware_host_vm.py with a listing of the vCenter vcenter.mydomain.com and generate the mapping file /tmp/vmware_mapping_file.json.

You can call : /usr/local/shinken/libexec/link_vmware_host_vm.py –help

for the full help on this script.

It looks at the file modification time each second. This command can also be launch by an external cron of course.

Note: So if you want to write a script that does this for XEN servers, all you need is to generate a json file with all the mapping. I didn't wrote the doc about this, but you can look in the test file for it, the format is very very easy :)

Here is an example of the JSON mapping file syntax:

%%:ref:*["host", "physical_host"], ["host", "virtual_machine"* <["host", "physical_host"], ["host", "virtual_machine">, "host", "physical_host"], ["host", "other_virtual_machine" <"host", "physical_host"], ["host", "other_virtual_machine">]%%

So just a list of couple 'host' string (from now only host are managed) and the host name.

Beware about it : you need the real host_name, including case.

Web Service Module The Ws_arbiter module is a Receiver or Arbiter module to receive passive check results from remote hosts via HTTP(s). This module is considered a work in progress but can be used for testing and improvement.

Configuring the Web Service Module If data is POSTed to this page, it will validate the data to determine if it is a service or host check result and submit the data to the Shinken external command queue.

The web service listens by default to TCP port 7760. The web service supports anonymous or authenticated access. Web service parameters are set in the Shinken-specific.cfg file, in the Ws_arbiter module. To enable the web service, simply add the module to your Arbiter or Receiver daemon configuration in Shinken-specific.cfg

Using the Web Service Module The web service listens for POSTs to: /push_check_result

Use curl or embed the HTTP calls in your software to submit check results.

curl -u user:password -d "time_stamp=$(date +%s)&host_name=host-checked&service_description=service-checked&return_code=0&output=Everything OK" http://shinken-srv:7760/push_check_result

Example with more readability:

```
curl
```

-u user:password -d "time_stamp=$(date +%s)

```
&host_name=host-checked
&service_description=service-checked
&return_code=0
&output=Everything OK
http://shinken-srv:7760/push_check_result
```

SNMP module This part must be splitted and sent in all module repositories

Shinken integrated SNMP Module

SnmpBooster Download Install and Configure

- *What is the SnmpBooster module*
- Install and configure the SNMP acquisition module. [You are here]
- *Reference - SnmpBooster troubleshooting*
- *Reference - SnmpBooster design specification*
- *Reference - SnmpBooster configuration dictionnary*

Downloads

The SnmpBooster module and genDevConfig are currently in public beta prior to integration within Shinken. You can consult t

- github.com/xkilian/genDevConfig
- github.com/titilambert/shinken/tree/snmp_booster/shinken/modules (snmp_booster branch) * Simply right-click and download snmp_poller.py then copy it to shinken/modules/

Requirements The SnmpBooster module requires:

- Python 2.6+
- Shinken 1.2+
- PySNMP 4.2.1+ (Python module and its dependencies)
- ConfigObj (Python module)
- python-memcached
- memcachedb or memcached package for your operating system (ex. For Ubuntu: apt-get install memcachedb) *Note*

The genDevConfig profile generator depends on:

- Perl 5.004+
- 4 perl modules available from CPAN and network repositories. genDevConfig/INSTALL has the installation details.

STRONGLY RECOMMENDED: Use the same version of Python and Pyro on all hosts running Shinken processes.

Installation SnmpBooster:

- Install the dependencies
- Copy the file snmp_poller.py from the git repository to your shinken/modules directory.
- Configuration steps are listed in the present web page.

genDevConfig:

- Download and extract the archive to your server.
- See genDevConfig/INSTALL on how to install and configure it.

Configuration

How to define the SnmpBooster module in the Shinken daemons You need to modify shinken-specific.cfg, which is located in $shinken/etc/shinken-specific.cfg

Arbiter daemon configuration Simply declare the module:

```
modules SnmpBooster</code>
```

Scheduler daemon configuration

Simply declare the module:

<code>modules SnmpBooster

Poller daemon configuration Simply declare the module:

```
modules SnmpBooster</code>
```

SnmpBooster Module declaration

Included in Shinken v1.2.1 shinken-specific.cfg.

<code>define module {

```
module_name          SnmpBooster
module_type          snmp_poller
datasource           /usr/local/shinken/etc/packs/network/SnmpBooster/   ; SET THE DIRECTORY FOR YOUR
memcached_host       x.x.x.x  ; SET THE IP ADDRESS OF YOUR memcached SERVER
memcached_port       11211  ; default port for a memcached process
```

}

If you do not know the IP adress on which your memcache is listening, check under /etc/memcached.conf. Or do a:

```
netstat -a | grep memcached</code>
If you are running a test on the local machine you can leave memcached on 127.0.0.1 (localhost), but
```

How to define a Host and Service

Step 1

Create a template for your SNMP enabled devices.

Sample template:

<code>cd shinken/etc/packs/network/ mkdir SnmpBooster

vi shinken/etc/packs/network/SnmpBooster/templates.cfg

```
define command {
```

```
command_name    check_snmp_booster
command_line    check_snmp_booster -H $HOSTNAME$ -C $SNMPCOMMUNITYREAD$ -V 2c -t $ARG1$ -i $_SERVICE
module_type     snmp_poller
```

}

```
define service {
```

```
name                    default-snmp-template
check_command           check_snmp_booster!$_SERVICEDSTEMPLATE$!$_SERVICEINST$!$_SERVICETRIGGERGROUP
_inst                   None
_triggergroup           None
max_check_attempts      3
check_interval          1
retry_interval          1
register                0
```

}

```
define host{
```

```
name                    SnmpBooster-host
alias                   SnmpBooster-host template
check_command           check_host_alive
max_check_attempts      3
check_interval          1
retry_interval          1
use                     generic-host
register                0
```

}

Step 2 Define some hosts and services. You would typically use genDevConfig or another configuration generator to create these for you.

Mandatory service arguments related to SNMP polling:

```
_dstemplate                Cisco-Generic-Router  ; Name of a DSTEMPLATE defined in the SnmpBooster co
```

```
snmpcommunityread    which is set in your resource.cfg file
```

Optional service arguments related to SNMP polling with default values:

```
_inst                   None   ; Could be numeric: 0, None or an instance mapping function like: map
```

```
_triggergroup           None   ; Name of the triggergroup defined in the SnmpBooster config.ini file
```

Sample Shinken host and service configuration:

```
# Generated by genDevConfig 3.0.0
# Args: --showunused -c publicstring 192.168.2.63
# Date: Thu Aug 30 17:47:59 2012

#######################################################################
# Description: Cisco IOS Software, C2960 Software (C2960-LANBASEK9-M), Version 12.2(50)SE4, RELEASE S
#     Contact:
# System Name: SITE1-ASW-Lab04
#    Location:
#######################################################################

define host {
```

```
 host_name            192.168.2.63
 display_name         192.168.2.63
 _sys_location
 address              192.168.2.63
 hostgroups
 notes
 parents
 use                  default-snmp-host-template
 register             1
}

define service {
```

```
 host_name            192.168.2.63
 service_description  chassis
 display_name         C2960 class chassis
 _dstemplate          Cisco-Generic-Router
 _inst                0
 use                  default-snmp-template
 register             1
}

define service {
```

```
 host_name            192.168.2.63
 service_description  chassis.device-traffic
 display_name         Switch fabric statistics - Packets per Second
 _dstemplate          Device-Traffic
 use                  default-snmp-template
 register             1
}

define service {
```

```
host_name            192.168.2.63
service_description  if.FastEthernet0_1
display_name         FastEthernet0_1 Description: Link to Router-1 100.0 MBits/s ethernetCsmacd
_dstemplate          standard-interface
_inst                map(interface-name,FastEthernet0_1)
use                  default-snmp-template
register             1
```

}

Here is an example configuration of the config.ini file

```
[DATASOURCE]
```

```
  OidmyOidDefinition = .1.3.6.1.45.0
  [myOidDefinition] ; Use the same name as the myOidDeiniftion, but omit the leading "Oid"
      ds_type = DERIVE
      ds_calc = 8,*  ; RPN expression : Oid, 8, *  Which means Oid * 8 = ds_calc
      ds_oid = $OidmyOidDefinition
[DSTEMPLATE]
```

```
  [myCiscoRouter]
      ds = myOidDefinition
[TRIGGER]
```

```
  [trigger1]
      warning = RPN expression
      critical = RPN expression
  [trigger2]
      warning = RPN expression
      critical = RPN expression
[TRIGGERGROUP]
```

```
[CiscoRouterTriggers]
    triggers = trigger1, trigger2
```

Shinken integrated SNMP Module

Overview

What is it The SnmpBooster module allows Shinken Pollers to directly manage SNMP data acquisition. This is an all Python cross-platform SNMP module. It is tightly integrated with the Shinken Poller, Scheduler and Arbiter daemons to provide the best possible user experience.

Design specification summary

- STATUS - DESIGN SPEC PERFORMANCE
- [Done] Functions as an integrated Shinken Poller module
- [Done] Necessary integration code commited to Shinken official release (Integrated starting at v1.2)
- [Done] Ability to collect thousands of SNMP metrics per second
- [Done] Be compatible with distributed data acquisition
- [Done] Collect data for a host/check_interval tuple via SNMP in a single pass
- [Done] Use all builtin Shinken scheduler logic for retries, forced checks, timeouts, dependencies, parents
- [Done] Store collected data for the duration of the check_interval in a memcached/membase
- [Done] On a restart, after the first collection, be able to pick up where the last check left and calculate derived values
- [Done] Forced check are not allowed within 30 seconds of last SNMP query to the same host/check_interval, all other requests get data from the cache.
- [Done] Only a single request to the host/check_interval via SNMP is allowed at a time, all other requests get data from the cache.
- STATUS - DESIGN SPEC USABILITY
- [Done] Usage documentation
- [xxxx] SkonfUI and Discovery usage documentation
- [xxxx] Provide sample configuration packs in Shinken
- [Done] Provide sample config.ini with examples of all types of data * SNMP OIDS, DATASOURCES, DSTEMPLATES, TRIGGERS and TRIGGERGROUPS

- [Done] Directly compatible for use with genDevConfig Shinken SNMP configuration generator
- [Done] Provide meaningful feedback for users on errors
- [Done] Capture all tracebacks and convert them to actual error or warning messages
- STATUS - DESIGN SPEC FEATURES
- [Done] Return state and performance metrics
- [Done] Performance metrics can be returned in a Weathermap compatible format
- [Done] Configuration file format is ConfigObj INI
- [Done] Load all valid INI configuration files from a directory and merge them
- [Done] Load a single INI configuration file
- [xxxx] Load a list of INI configuration files
- [Done] Configuration file describes all generic acquisition parameters (OID, DATASOURCE, DSTEMPLATE, MAP, TRIGGER, TRIGGERGROUP)
- [Done] Supports Triggers which are calculation rules to determine states
- [Done] Triggers support an RPN (Reverse Polish Notation) calculation engine which includes mathematical and logical operators
- [Done] Each TRIGGER is associated with a severity level, WARNING or CRITICAL
- [Done] Multiple TRIGGERS can be associated with a TRIGGERGROUP
- [Done] Use builtin Python Operators
- [Done] Support DERIVE, TEXT, GAUGE and COUNTER data types
- [xxxx] Support TIMETICKS data type
- [Done] Support applying RPN based calculations to received metric for scaling or conversion purposes
- [Done] Use a Python SNMP library which supports asynchronous acquisition PySNMP
- [Done] Datasources can use rule based runtime instance mapping
- [Done] Set Snmp version as a check runtime option
- [Done] Set Snmp DSTEMPLATE as a check runtime option
- [Done] Set Snmp TRIGGERGROUP as a check runtime option
- [Done] Set Snmp COMMUNITY as a check runtime option
- [Done] Use Snmp version 2c GetBulk
- [xxxx] Support Snmp version 2c GetNext if GetBulk is not supported
- [xxxx] Support Snmp version 1 GetNext
- [xxxx] Set Snmp Timeout as a check runtime option, instead of a hardcoded value at 5 seconds
- STATUS - DESIGN SPEC MAINTAINABILITY
- [xxxx] Functions documented in the source code
- [Done] Critical functions documented in the source code
- [Done] Locking sections identified in the code
- [xxxx] Unit tests with at least 80% coverage

- [xxxx] Unit tests integrated with Shinken test suite
- [Done] Code hosted on github
- [xxxx] configuration validity and integrity checking of all INI files
- [xxxx] Pep8 compliant
- [xxxx] Pylint pass

genDevConfig Plugins - Compatibility status with SnmpBooster

- STATUS - genDevConfig maintained Plugins
- [Done] Avaya ES switches
- [Done] Avaya ERS routing switches
- [Done] Cisco 29x0 switches
- [Done] MIB-II Interfaces
- [Done] Cisco PIX/ASA
- [Done] JUNOS devices
- [Done] Cisco IOS routers
- [Done] NetSNMP unix hosts ** Validation required**
- [Done] Packeteer devices ** Validation required**
- [Done] Sensatronics devices ** Validation required**
- [Done] Foundry devices ** Validation required**
- [Done] Packeteer devices ** Validation required**
- [Done] Cisco CSS ** Validation required**
- [InProgress] New Cisco Access points
- STATUS - Other maintained Plugins

Tip: [xxxx] Denotes a specification that is planned but not implemented

[InProgress] Denotes a specification that is under development

[Done] Denotes a specification that is implemented

SnmpBooster reference dictionary

- Jump back to *SnmpBooster documentation index*

SnmpBooster.ini dictionary

There are five dictionaries:

- [DATASOURCE]
- [DSTEMPLATE]
- [MAP]
- [TRIGGER]

- [TRIGGERGROUP]

DATASOURCE DICTIONARY OidVariableName refers to an actual OID that can be queries using SNMP against the device on the network.

[VariableName] refers to a Datasource and all the information required to gather and prepare the data using SNMP ds_type refers to how the data should be prepared ds_calc refers to any scaling manipulations to make the data more understandable. This is an RPN expression, where the first variable is omitted, as it is always the $OidVariable ds_oid refers to the actual $OidVariable name. An instance identifier can be appended to the name to signify that an instance is provided by the Shinken service definition. This information is passed when the check is called. ...

DSTEMPLATE DICTIONNARY [DsTemplateName] refers to the name of the DSTEMPLATE that will be referred to in the Shinken service definitions. ds refers to the list of DATASOURCES to be collected. If an instance is expected for the list of DATASOURCES, it MUST be the same instance for all Oids. If a different instance is required, use a second DSTEMPLATE.

TRIGGER DICTIONNARY

TRIGGERGROUP DICTIONNARY

MAP DICTIONNARY

SnmpBooster.ini example configuration This example definition will be used to explain each section.

[DATASOURCE]

```
OidmyOidDefinition = .1.3.6.1.45.0
[myOidDefinition] ; Use the same name as the myOidDeiniftion, but omit the leading "Oid"
    ds_type = DERIVE
    ds_calc = 8,*  ; RPN expression : Oid, 8, *  Which means Oid * 8 = Total
    ds_oid = $OidmyOidDefinition
```

[DSTEMPLATE]

```
[myCiscoRouter]
    ds = myOidDefinition
```

[TRIGGER]

```
[trigger1]
    warning = RPN expression
    critical = RPN expression
[trigger2]
    warning = RPN expression
    critical = RPN expression
```

[TRIGGERGROUP]

```
[CiscoRouterTriggers]
    triggers = trigger1, trigger2
```

SnmpBooster.ini configuring SNMP Datasources

The first location is generic data related to SNMP parameters.

- DATASOURCE information * SNMP OID * Type of data and how can it be interpreted (GAUGE, COUNTER, COUNTER64, DERIVE, DERIVE64, TEXT, TIMETICK) * Data format preparation (Scaling the data for example bits to bytes) * Is there an instance to append to the
- Instance MAP function * Mapping the instance dynamically using a function * Data or rules related to the mapping function

SnmpBooster.ini configuring SNMP DSTEMPLATES

- DSTEMPLATEs to associate DATASOURCE to actual device classes * List of DATASOURCES associated with a, for example, Cisco 1900 router. Which in turn can be applied to a Shinken service

SnmpBooster.ini setting triggers/thresholds

- TRIGGER and TRIGGERGROUPS to apply thresholding rules * Define triggers and associate them with a TRIGGERGROUP name that can be applied to a Shinken Service

Shinken integrated SNMP Module

Overview

- Jump back to *SnmpBooster documentation index*

Tip: The module is now in public beta as of 2012-10-26! Have Fun!

Nothing new to add, more to come in 2013. 2013-01-19.

What is it The SnmpBooster module allows Shinken Pollers to directly manage SNMP data acquisition. This is an all Python cross-platform SNMP module. It is tightly integrated with the Shinken Poller, Scheduler and Arbiter daemons to provide the best possible user experience.

Why use it The SnmpBooster module is designed to be very efficient and scalable. It has a very flexible configuration method to make it easy to use with Shinken Monitoring Packs and Shinken discovery runners like genDevConfig.

This acquisition module was professionally designed and developed.

It is meant to be used by the very capable discovery engine genDevConfig (**v3.0.5 and newer**) originally developed for the Cricket SNMP monitoring tool and converted for use with Shinken.

It is one of the very few serious SNMP v2c implementation making use of SnmpGetBulk type requests.

How does it work

Shinken Integration

1. The SnmpBooster Arbiter module reads the Shinken SnmpBooster configuration file(s). It reads the check commands and based on the values in the check commands that use the snmp_poller module it will creates a shared configuration cache using memcached/memcachedb. The memcache key is always the combination of the hostname. This permits to tie together Shinken Hosts and Services with the SNMP specific configuration. (MongoDB and Redis are planned to be supported in the future) The Scheduler daemon schedules Host and Service checks as it normally does.

3. The SnmpBooster module will check that a memcache host key exists for the check to be launched. Then the SnmpBooster poller module will query all services related to a host for a given acquisition frequency in one pass. (all checks done every 2 minutes will be executed in bulk, same for those every 5 minutes)

5. Check results are cached for the acquisition check_interval. The next time a check request for data from the same host is received from the Scheduler, the data will be fetched from memcache. Resulting is extremely low check latency.

2. 6. The SNMP checks still benefit from retries, timeouts, forced checks, dependencies and the powerful Scheduler daemon logic.

6. The Scheduler daemon can still force an immediate re-check by flushing the cache. This is required for the dependency model.

Performance SnmpBooster uses SNMP v2c getbulk for high efficiency, unless forced to use SNMP v2c get-next or SNMPv1 get-next. GetBulk uses a single request PDU to ask for multiple OIDs or even entire tables, instead of sending one request PDU per OID.

For example: *A typical 24 port network switch with two uplinks might use 375 OIDS (8 OIDs per interface, plus general OIDs for chassis health, memory, cpu, fans, etc.). **SnmpBooster will only require around 4 request PDUs*

*instead of 375 request PDUs**. Each PDU is a request packet which takes time to create, send get processed and return. More timeouts to manage, more connections, more impact on the remote device and more latency means much fewer checks per second.*

The SnmpBooster module supports automatic instance mapping for OIDs. (Ex. Based on the interface name it will figure out that the SNMP index(or instance) is 136. This is automatically handled by genDevConfig and SnmpBooster, no user input required. :-)

The generic SNMP configuration information is stored in the Shinken SnmpBooster INI files. There is a Defaults_unified.ini and a series of other Defaults files, one per discovery plugin for genDevConfig.

Important: genDevConfig plugins have all been converted to use the new dynamic instance mapping methods. You are now free to use most if not all Defaults*.ini files included with genDevConfig. 2012-10-28

Limitations You should have memcached instances running on each poller responsible for snmp polling. You should have your pollers with SnmpBooster in the same datacenter, as they need to be on the same machine with good connectivity to the active memcached instance. SnmpBooster is not compatible with distributed pollers in multiple datacenters, sorry, the current design of SnmpBooster uses a single centralized memcached instance for storing the timeseries data. For distributed datacenters to be supported, each poller+scheduler+memcached must be realm restrained, which is not the case today.

Design specification *SnmpBooster design specification* and current development status.

Data model The information required to define the data is split in two locations.

The first location is the host and service Shinken configuration (You need to generate or write this)

- Device specific information
  - IP addresses, host_names, device types, instance keys
  - A DSTEMPLATE must be referred to in the Service definition
  - A static SNMP instance could be referred to in the Service definition
  - An SNMP instance MAP function could be referred to in the Service definition
  - A TRIGGERGROUP could be refered to in the Service definition

The second location is SNMP Defaults.* templates. (Here you can create new devices or add new data sources)

- DATASOURCE information
  - SNMP OID
  - Type of data and how can it be interpreted (GAUGE, COUNTER, COUNTER64, DERIVE, DERIVE64, TEXT, TIMETICK)
  - Data format preparation (Scaling the data for example bits to bytes)
  - Is there an instance to append to the
- Instance MAP function * Mapping the instance dynamically using a function * Data or rules related to the mapping function
- DSTEMPLATEs to associate DATASOURCE to actual device classes * List of DATASOURCES associated with a, for example, Cisco 1900 router. Which in turn can be applied to a Shinken service
- TRIGGER and TRIGGERGROUPS to apply thresholding rules * Define triggers and associate them with a TRIGGERGROUP name that can be applied to a Shinken Service

A final location containes rules to build your Shinken configuration.

- genDevConfig plugins create Shinken configurations

Installation and configuration *SnmpBooster installation*

Reference Dictionnary *SnmpBooster reference dictionary*

Troubleshooting *SnmpBooster troubleshooting*

Graph templates These are .graph files defined in your Shinken configuration directory. Refer to the Shinken graphite templates(Not yet created) or PNP4Nagios how-to documentation. The graph templates are independent from SnmpBooster and provide templates for any collected data from Shinken.

SnmpBooster Troubleshooting

- Jump back to *SnmpBooster documentation index*

Check your config

- Have you defined the poller module name?
- Have you defined the correct path to the directory containing your Defaults*.ini files?
- Have you addded the Snmpbooster module to your arbiter, poller, scheduler?
- Have you added copied the genDevConfig templates.cfg in shinken/packs/network/SnmpBooster/
- Have you installed PySNMP, memcached and other dependencies?

Software version consistency Shinken and SnmpBooster now require **the same Python and Pyro version on all hosts running a Shinken daemon**.

If you cannot use the packaged version of Python and its modules (Pyro, memcached, etc.). Use virtualenv to declare a python version to use and install all required modules in that virtualenv.

Software version requirements Have you verified that the *requirements* are met. Python, PySNMP, Shinken, Pyro, memcached, etc.

Validate your check command arguments Use the check_plugin command and comment out the module to learn what were the exact arguments sent by the poller. This will permit you to validate all the arguments, like snmp community string, inheritance, template application, etc.

Validate connectivity

Take a packet trace using a tool like Wireshark to validate that the remote host is responding.

- Has the host responded
- **Is SnmpBooster repeating the request more often than the polling interval.**
  - If you are seeing repeated requests your device may have a compatibility issues.

- Save an snmpwalk of the device, get a packet trace using Wireshark, set the poller to debug and save the poller.log file (shinken/var/poller.log). Send all three to the SnmpBooster developers.
- Note: It is normal to see one or more bulkGet requests if you are getting large amounts of data. Ex. a 24 port switch will take 2-3 request packets.

Performance Make sure you have a low latency connection to your memcache from the Poller. Your memcache server can be replicated to all your poller hosts that should also run memcache instances. Check that memcached is running: netstat -a | grep memcached

Faulty Template A bad snmp_template file was distributed in the genDevConfig sample-config directory, there were two glaring errors.

This was fixed on 2012-10-16. Make sure you update your template, or use the data from the wiki.

Note that the template should be called: SnmpBooster-template.cfg to make it easier to troubleshoot in the logs. So when you search for SnmpBooster in your logs it will show up as well.

Log files All warnings and errors generated by the SnmpBooster module start with "[SnmpBooster] error text" and are logged using the standard Shinken logger.

The Arbiter daemon can output initial configuration, loading of host keys and intervals in memcached type error messages. The Scheduler daemon can output scheduling and alert related messages. The Poller daemon can output messages related to instance mapping, acquisition timeouts, invalid community strings, cache failures and more. These are available in the Web interface, as they are placed in the check results for the service.

You can simply do a "grep SnmpBooster *" in your shinken/var directory to see the latest messages related to the SnmpBooster module. You can also sort messages by timestamp to make it easy to find where and when errors occurred.

cd shinken/var grep SnmpBooster *

memcache persistence If you restart your memcache server or memcache crashes, your poller will no longer be able to validate that a host exists in memcache prior to writing.

You should use memcachedb to achieve persistence in case of memcache failures.

Common errors returned by SnmpBooster in the log file Errors should be fairly explicit and mean what they say, though there can be exceptions. Lets try to clear some of them.

__Arbiter log **errors__**

Missing ds_oid : This means that a variable in your OID definitions is missing, or your DATASOURCE is not named correctly or your ds_oid variable is missing. There is a typo in your ds_oid variable (ex. ds-oid, or ds_oid = $OidNameIncorrectFFFRA.%(instance)s).

Datasource not defined : Your DSTEMPLATE uses a DATASOURCE that doesn't exist check the [DataSourceName] you are referring to. Does it contain the expected OID variable, $OidName.

Missing ds_type : The DATASOURCE always needs to have a ds_type definition, GAUGE, COUNTER, DERIVE, TEXT, TIMETICK, DERIVE64, COUNTER64.

__Poller log **errors__**

Problems with calculations, repeated polling, hosts not responding, etc.

__Memcached **errors__**

memcachedb and memcached do not use the same default port. Configure the correct memcachedb port to match what is declared in your SnmpBooster module under shinken-specific.cfg.

On Ubuntu 12.04 the default installation is on port 21201 instead of 11211. This causes the error "[SnmpBooster] Memcache server (127.0.0.1:11211) is not reachable" when Shinken starts.

To change it, you must edit the file /etc/memcachedb.conf

Memcached Notes On Ubuntu 12.04 the default instalation is on port 21201 instead of 11211. This causes the error "[SnmpBooster] Memcache server (127.0.0.1:11211) is not reachable" when shinken starts.

To change it, you must edit the file /etc/memcachedb.conf

WebUI module This part must be splitted and sent in all module repositories

WebUI integration with Shinken The WebUI is an external broker module. So it's an external process launched by the broker that "eats" broks (broker messages) from the brokers. So it can get *all* broks if you place this broker in your top level realm.

The WebUI does not use a database to get data. Instead, it use a "regenerator" object that will eat each broks, and will "recreate" all Hosts/Services/Contacts objects as if the code was in the scheduler daemon. So basically, WebUI and pages always reflect the CURRENT state of hosts/services objects.

The WebUI http layer is managed by bottle.py. It's a small but powerful framework.

How does the WebUI function globally ?

There a 2 Threads running:

- the main thread is the bottle.py (http) listener. It will use the best backend it finds. We recommend using python-paste. If it does not find one, it will use the default swsgi. Paste is multi-thread, swsgi is mon-thread, so please use paste if you want to avoid locking problems.
- the 2nd thread is the regenerator one. It only gets broks and gives them to the regenerator object.

There is a lock system between the threads. You can have N Http requests in progress without problem, but during this time the renererator one will wait. During execution of the regenerator, no requests are processed. This is not considered a problem, as the regenerator is very quick, and there is only a 1s lock for a 7k service conf loading, so it's not a huge problem.

What is a WebUI User? A WebUI user is a contact. A true contact object. You must match a contact name for your user.

To create a new page? All pages are in the shinken/webui/plugins directory. Each "part" has it's own directory. A part (like the eltdetail, element detail) can have more than one "page" (like /host or /service for eltdetail).

From here we will supose you want to create a "/contact" page.

You can copy the dummy example in the plugins directory into a contact directory.

You need to change the contact/dummy.py file into a contact/contact.py file, because the webui will search for a dir/dir.py file to "load".

Templates Templates are HTML with some Python code in it in the plugins/*/views direcotry for specific templates, and the "global layout" (menu and all common part) in the webui/views directory.

Your template must call the template layout (layout.tpl in the webui/views directory) wit ha "rebase" call.

If you put the rebase call at the beginning of your template, all there is below will be place "inside" the layout that will call the common javascripts and css, make the menu adn then call your html/python code.

The rebase call can take arguments. You MUST give it:

- user: the user you give it in the return dict of your .py code

Then all is optional:

- title: title of the page
- top_right_banner_state: int, global state with clouds to put in your top right page. Look at the problem.tpl code for an example.
- js and css list: list of YOUR specific javascript or css to call AFTER the common ones.
- refresh: boolean, set the refresh to 60s or do not refresh at all

- menu_part: will put the little "^" under this part of the menu.

Example of a call, taken from the problems view:

```
rebase layout title='All problems', top_right_banner_state=top_right_banner_state, js=['problems/js/a
roblems/js/autocompleter.Request.js', 'problems/js/autocompleterObserver.js'], css=['problems/css/acc
ms/css/autocompleter.css', 'problems/css/perfometer.css'], refresh=True, menu_part='/'+page, user=use
```

Call Python objects in your templates Your templates are mainly HTML code. But of course you can call python code in it. The dict you returns in the plugin.py call will be available in this page.

For example, the my_host variable will be available in the page with the host object you find (or None if your give it a bad name of course). Then you can "call" python with for example here to show the host_name: `<span>My host name is *my_host.host_name* </span>` is a way in the templates to "call a variable or function" that will return a string, here the host_name.

If the function or property you call must return HTML code that SHOULD be output as it, without "protection", you must put a ! before your call.

Let use an example where the output value of an host is in fact an html output. If you use the code `my_host.output`, bottle.py will "protect" the html generated by escaping the string, and change <> characters with escaped value. You can change this by calling `my_host.output`. Of course, it's a security problem if the output is with a javascript code...

You can also "loop" or put "if" in your template. You just need to put your code with a % before. Like

```
%for i in xrange(1, 10):
  My valus is  {{i}}
%end
```

You must put the %end here, the indentation will NOT be enougth, sorry.

For an if it's also easy:

```
%if host.active_checks_enabled:
  The host got active checks enabled
%else:
  The host DO NOT have active check enabled
%end
```

Which javascript lib are you using? It's mootools 1.3 with all options :)

What to do?

- Finish the /mobile part
- List of current alerts
- Host info
- Host status
- Host interfaces
- Hostgroup status
- dashboard hierachique with states, and BP
- Nagvis
- add bp in nagvis auto-map

- event sources
- correlation
- pre-filtering/enrichment
- user profile
- host/srv conf

WebUI search syntax work in progress

not that we couldn't tell. ;) eh eh

beware the working men and flying tools!

WebUI SSL Certification Lets start: the goal to to have the server.pem and client.pem file in etc/certs.

Go to the etc/certs directory.

```
openssl req -new -nodes -out server.req -keyout server.key -config ./shinken_openssl_cnf
openssl ca -out server.pem -config ./shinken_openssl_cnf -infiles server.req
cp server.pem server.pem.bkp
cp server.key server.pem
cat server.pem.bkp >> server.pem
cp server.pem client.pem
```

You can try to get the validity with for the arbiter with:

```
openssl s_client -connect localhost:7770</code>
```

Amazon AWS/EC2 import

Description You can import data from Amazon AWS/EC2 **'AWS'**_ into Shinken to create hosts.

Amazon provide VM hosting with EC2. With this arbiter module, you will be able to load your EC2 hosts into Shinken.

Prerequisites

You will need the **'libcloud'**_ package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

```
define module {
 module_name      AWS
 module_type      aws_import

 # Configure your REAL key and secret for AWS
 api_key              PAAAB2CILT80I0ZA0999
 secret           GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH
 default_template generic-host        ; if the host is not tagged, use this one
 }
```

- Put in key and secret your private Landscape access. * default_template will be used if your host is not "tagged" in Landscape

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master

     address          localhost                  ;IP or DNS adress
     port             7770
     spare            0
     modules           AWS
     }
```

Restart your Arbiter and it's done :)

Generated hosts The configuration generated will look as below :

```
define host {
    host_name            i-3fc56e5a
    address              8.8.4.4
    use                  t1.micro,MyTag,EC2,generic-host
    _EC2_AVAILABILITY    us-east-1a
    _EC2_CLIENTTOKEN
    _EC2_DNS_NAME
    _EC2_GROUPS          quicklaunch-1
    _EC2_IMAGEID         ami-1b814f72
    _EC2_INSTANCEID      i-3fc56e5a
    _EC2_INSTANCETYPE    t1.micro
    _EC2_KERNELID        aki-825ea7eb
    _EC2_KEYNAME         testaws
    _EC2_LAUNCHDATETIME  2012-09-26T12:19:38.000Z
    _EC2_LAUNCHINDEX     0
    _EC2_PRIVATE_DNS
    _EC2_PRIVATE_IP
    _EC2_PRODUCTCODE
    _EC2_PUBLIC_IP       8.8.4.4
    _EC2_RAMDISKID       None
    _EC2_STATUS          stopped
    _EC2_TAGS            demo:myvalue,use:MyTag
 }
```

Here with a stopped t1.micro instance with no name. You can put your how "use" parameter by adding a EC2 tag "use" on your VM. It will be output on the host configuration so you can setup the monitoring as you want. .. _libcloud: http://libcloud.apache.org/index.html .. _AWS: https://console.aws.amazon.com

Amazon AWS/EC2 import

Description You can import data from Amazon AWS/EC3 **'AWS'**_ into Shinken to create hosts.

Amazon provide VM hosting with EC3. With this arbiter module, you will be able to load your EC2 hosts into Shinken.

Prerequisites

You will need the **'libcloud'**_ package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

```
define module {
 module_name      AWS
 module_type      aws_import

 # Configure your REAL key and secret for AWS
 api_key              PAAAB2CILT80I0ZA0999
 secret           GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH
 default_template generic-host        ; if the host is not tagged, use this one
 }
```

- Put in key and secret your private Landscape access. * default_template will be used if your host is not "tagged" in Landscape

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master

     address          localhost                  ;IP or DNS adress
     port             7770
     spare            0
     modules           AWS
     }
```

Restart your Arbiter and it's done :)

Generated hosts The configuration generated will look as below :

```
define host {
    host_name            i-3fc56e5a
    address              8.8.4.4
    use                  t1.micro,MyTag,EC2,generic-host
    _EC2_AVAILABILITY    us-east-1a
    _EC2_CLIENTTOKEN
    _EC2_DNS_NAME
    _EC2_GROUPS          quicklaunch-1
    _EC2_IMAGEID         ami-1b814f72
    _EC2_INSTANCEID      i-3fc56e5a
    _EC2_INSTANCETYPE    t1.micro
    _EC2_KERNELID        aki-825ea7eb
    _EC2_KEYNAME         testaws
    _EC2_LAUNCHDATETIME  2012-09-26T12:19:38.000Z
    _EC2_LAUNCHINDEX     0
    _EC2_PRIVATE_DNS
    _EC2_PRIVATE_IP
    _EC2_PRODUCTCODE
    _EC2_PUBLIC_IP       8.8.4.4
    _EC2_RAMDISKID       None
    _EC2_STATUS          stopped
    _EC2_TAGS            demo:myvalue,use:MyTag
 }
```

Here with a stopped t1.micro instance with no name. You can put your how "use" parameter by adding a EC2 tag "use" on your VM. It will be output on the host configuration so you can setup the monitoring as you want. .. _libcloud: http://libcloud.apache.org/index.html .. _AWS: https://console.aws.amazon.com

The distributed retention modules The high availability allow the Arbiter to send a configuration to a spare scheduler, but a spare scheduler does not have any saved states for hosts and services. It will have to recheck them all. It's better to use a distributed retention module so spares will have all the information they need to start with an accurate picture of the current states and scheduling :)

Non distributed retention modules If you are just running tests on a single server, use the pickle or memcache retention modules You can also use MongoDB if you already have it installed for use with the WebUI.

MongoDB MongoDB is a scalable, high-performance, open source NoSQL database written in C++.

Step 1: Install MongoDB:

We will use mongodb package from 10gen repository, so we start by adding it in apt sources list:

```
echo 'deb http://downloads-distro.mongodb.org/repo/debian-sysvinit dist 10gen' > /etc/apt/sources.lis
apt-get update
```

And we install it:

```
apt-get install mongodb-10gen
```

And we install pymongo, the python interface to MongoDB, with easy_install to avoid packages versions problems (like here **'forums.monitoring-fr.org/index.php?topic=5205.0'_**):

```
apt-get remove python-pymongo
easy_install pymongo
```

And finally we start MongoDB :

```
/etc/init.d/mongodb start
```

Step 2: define a mongodb_retention module in your shinken-specific.cfg file:

```
define module {
  module_name MongodbRetention
  module_type mongodb_retention
  uri mongodb://localhost/?safe=true
  database shinken
}
```

Step 3: Declare a retention module for your scheduler(s) :)

Example:

```
#The scheduler is a "Host manager". It get hosts and theirs
#services. It scheduler checks for them.
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
     port     7768                  ; tcp port of the daemon

     #optionnal: modules for things as retention
     modules    MongodbRetention
     }
```

Step 4: Restart the Arbiter, and your Scheduler will now save its state between restarts. :)

Memcached Memcached is a distributed memory resident key/value server. It's very easy to install:

```
sudo apt-get install memcached
sudo /etc/init.d/memcached start
```

The shinken module also needs the python-memcache package to talk to this server.

```
sudo apt-get install python-memcache
```

To use it,

Step 1: define a memcache_retention module in your shinken-specific.cfg file:

```
define module{
     module_name      MemcacheRetention
     module_type      memcache_retention
     server           127.0.0.1
     port             11211
}
```

Step 2: Declare a retention module for your scheduler(s) :)

Example:

```
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
     port     7768                  ; tcp port of the daemon

     #optional: modules for things as retention
     modules    MemcacheRetention
     }
```

Step 3: Restart the Arbiter, and your Scheduler will now save its state between restarts. :)

Redis Redis is a distributed key/value server (on disk and in-memory). It's very easy to install:

```
sudo apt-get install redis-server
sudo /etc/init.d/redis-server start
```

The shinken module also need the python-redis package to talk to this server.

```
sudo apt-get install python-redis
```

Step 1: define a redis_retention module in your shinken-specific.cfg file:

```
define module{
     module_name      RedisRetention
     module_type      redis_retention
     server           127.0.0.1
}
```

Step 2: Declare a retention module for your scheduler(s) :)

Example:

```
#The scheduler is a "Host manager". It get hosts and theirs
#services. It scheduler checks for them.
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
```

```
    port     7768                  ; tcp port of the daemon

    #optionnal: modules for things as retention
    modules    RedisRetention
    }
```

Step 3: Restart the Arbiter, and your Scheduler will now save its state between restarts. :) .. _forums.monitoring-fr.org/index.php?topic=5205.0: http://forums.monitoring-fr.org/index.php?topic=5205.0

How to enable and use Livestatus module

Define the Livestatus module Start by reviewing the ''/etc/shinken/shinken-specific.cfg" file for this module:

```
define module{
```

```
module_name      Livestatus
module_type      livestatus
host             *       ; * = listen on all configured IP addresses
port             50000   ; port to listen on
database_file    /var/lib/shinken/livestatus.db
```

}

With these parameters:

- module_name: name of the module called by the brokers
- module_type: livestatus
- host: IP interface to listen to. The default is *, which means "listen on all interfaces".
- port: TCP port to listen to.
- socket: Unix socket to listen to.
- database_file: the path to the sqlite database file which is used to store the log broks/messages. The default is "var/livelogs.db"
- max_logs_age: the maximum age of the log messages (before they are deleted from the database). The default is 1 year. The argument to this parameter takes the form <number>[<period of time>], where <period of time> can be d for days, w for weeks, m for months and y for years.
- allowed_hosts: a comma-separated list of IP-addresses which are allowed to contact the TCP port. Please keep in mind that these **must be IP-addresses, NOT host names**. Because DNS lookups for every incoming livestatus request could hang up and therefore block the module.

Enable the Livestatus module Still in ''/etc/shinken/shinken-specific.cfg'', find the object Broker and add "Livestatus" to its "modules":

```
define broker{
```

```
    broker_name      broker-1
[...]
```

```
    modules          Simple-log,Livestatus
}
```

Disable human readable logs In ''/etc/shinken/nagios.cfg'', verify that the option **human_timestamp_log** is set to **0**.

In version 0.6.5, you can not have at the same time a simple-log file with human readable timestamp and a Livestatus database.

Exporting data for reporting Shinken can export necessary data for reporting in 3rd party systems.

raw_socket module The raw socket module exports reporting data using a syslog format to a raw TCP socket. Theses logs can be captured, parsed and indexed by any log management system like Splunk or Logstash.

Why export reporting data Custom UIs like Thruk, Multisite, WebUI, Adagios, Nagios IX, etc. All have poor or inflexible reporting. Simply because these are not reporting engines.

This also permits to have a generic reporting method that can accept data from any Nagios, Shinken, Icinga or even Riemann.

Reporting module using Splunk Splunk was selected as the reporting platform for creating, managing and presenting reports. Though the raw_socket module does not have any Splunk specific particularities. It is notable that Splunk reports can be embedded in any 3rd party UI using its REST API.

Raw_socket log format The logs are plain-text and compliant with RFC3164. They use an intelligent date format, a configurable seperator " "(space by default), and key=value pairs in the message data portion of the log. Should a key or value contain a space they must be double quoted. This is syslog using structured data without going to full out JSON that may not be compatible with all log management systems.

The message fields that are supplied in each status update in addition to the standard syslog header are:

- Hostname
- Servicename
- Business impact
- Host/Service status
- Host/Service previous status
- Acknowedgement status
- Maintenance status

Any time the maintenance, host, service or acknowledgement status changes, a log is sent by the Shinken raw_socket module.

Having all relevant data in each log makes it very easy to compute reports for given time periods.

The hostgroup or service group memberships, custom variables or any other configuration related data should be queried from the monitoring system using its API (Livestatus in the case of Shinken and Nagios).

Raw_socket module availability The module is available in both Shinken 1.4 and Shinken 2.0. The module will be integrated in master branches once unit tests and end-to-end testing is completed. 3rd quarter 2013.

Monitoring Linux System with Glances and checkglances.py **'Glances'_** is a fantastic multiplatform system monitoring tool writen by Nicolargo. Glances can run on (Linux, Windows, MacOS ...). There is a growing ecosystem around Glances and of course a Nagios/Shinken plugin : checkglances.py.

How does it work Glances can run in server mode. It provide a XML-RPC server (over http) and allow to retrieve system information throuh a restful API. The only thing to do is to install and start Glances as server on the monitored host, then install checkglances.py on the shinken server and finaly install the glances pack.

Install glances See the glances documentation to install glances on Linux.

<code bash> easy_install glances </code>

There is a debian startup script in the glances repository. And another one for centos here.

Install checkglances.py Just follow the documentation for the checkglances.py prerequisites and put it in your nagios plugins folder.

Install the glances pack Open a terminal as the shinken user and just type the following command

<code bash> shinken install glances </code>

Then just edit the configuration for a linux monitored host and tag it as **glances**

```
define host{
 name mylinuxhost
 use glances
 ...
```

Finaly restart the shinken arbiter

```
service shinken-arbiter restart
```

What will be monitored ? For the moment just the basic system (ram, cpu, load, memory, filesystem and network).

If you want to modify the default thresholds for just a host you can do it by overiding the thresholds macro in your host definition. If you want to do it for several hosts, declare a new template and just add the desired thresholds macro to be overide.

Here is a list of the macros

```
::
```

> _LOAD_WARN 2 _LOAD_CRIT 3 _CPU_WARN 80 _CPU_CRIT 90 _MEMORY_WARN 90 _MEMORY_CRIT 95 _FS /, /home _FS_WARN 90 _FS_CRIT 95 _IFACES eth0, eth1 _NET_WARN 7500000 _NET_CRIT 10000000

Note the _FS and _IFACES macros. They leverage the ability to duplicate service for a given list of things to be monitored. Here you see that / and /home partitions will be monitored. If you want to modify this then just add your own in a new template that will inherit the glances template.

Shinken GLPI integration Shinken supports importing hosts from GLPI

For people not familiar with GLPI, it is an Open-Source CMDB. Applicable to servers, routers, printers or anything you want for that matter. It is also a help-desk tool. GLPI also integrates with tools like FusionInventory for IT inventory management.

You can still have flat files AND GLPI if you want. Hosts imported from GLPI will be treated as standard hosts from flat file (inheritance, groups, etc). In fact, in this first version the module only sends the host_name to Shinken, but there should be more information extracted like network connexions for parents relations in the future. :)

Requirements

- python module MySQLdb
- Compatible version of GLPI Shinken module and GLPI version - ...
- etc..

Enabling GLPI Shinken module In your shinken-specific.cfg file, just add (or uncomment):

```
#You know GLPI? You can load all configuration from this app(
#with the webservices plugins for GLPI, in xmlrpc mode
#and with plugin monitoring for GLPI)
# =============== Work with Plugin Monitoring of GLPI ===============
#All configuration read from this will be added to the others of the
#standard flat file
define module{
     module_name      GLPI
     module_type      glpi
     uri              http://localhost/glpi/plugins/webservices/xmlrpc.php
     login_name       glpi
     login_password   glpi
}
```

And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master
#    host_name       node1       ;result of the hostname command under Unix
     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           GLPI
     }
```

It's done :)

Ip Tag module

Why tag a host based on it's IP address? We learned on the *DMZ monitoring* that you can "tag" a host with a poller_tag so it will be checked only by DMZ pollers. It can be tedious process to manually tag all these hosts. Shinken provides an automated method to do this.

This is handled by the arbiter ip_tag module.

Ip_tag module The ip_tag module is an arbiter module that looks up the host address during the configuration parsing and compares it to an predefined IP range (IPV4 or IPV6). If the range matches, it can apply or add a property, such as poller_tag. Other types of tags could be related to locations, functions, administrative groups, etc.

Method: replace or append.

replace will put the value if the property is unset. This is the default method. .. warning:: Fix me: replace, implies overriding an existing value. And will cause user issues down the line. Rename it to set. Replace should be a different method altogether, so overall there should be 3 methods(set, append, replace).

append will add with a , if a value already exist

Here is an example that will set the poller_tag property with the value DMZ of all hosts that:

- have a their hostadress ip (or name resolved) in the range 192.168.0.1/24.
- do not already have a poller_tag property set

```
define module{
```

```
     module_name     IpTag
     module_type     ip_tag
     ip_range        192.168.0.1/24
     property        poller_tag
     value           DMZ
}
```

To use the module add it in the arbiter object:

```
::
```

define arbiter { [...] modules NSCA,IpTag

}

Add value instead of setting it In the previous example we set the property poller_tag to a value. But what if we want to "add" a value, like a template name? We can change the "method" property of the module to "append" so we can add the "value" to the host property instead of replace it.

Here is an example where we want to add the "dmz" template on the hosts, while also keeping any defined templates:

```
define module{
```

```
     module_name   IpTag
     module_type   ip_tag
     ip_range      192.168.0.1/24
     property      use
     value         dmz

     # Optional method
     method append
}
```

For a host defined as:

```
define host{
```

```
     host_name   example_host1
     address     192.168.0.2
     use         linux
}
```

It will be "changed" internaly in:

```
define host{
```

```
     host_name   example_host1
     address     192.168.0.2
     use         linux,dmz
}
```

Name resolution Of course you don't need to set IP address in the address of your host. You can set a hostname, and it will be resolved, and then compared to the range. :)

Ubuntu Landscape import

Description You can import data from Ubuntu Landscape into Shinken to create hosts.

Ubuntu Landscape, is a web app to manage all your linux servers (update and co), which is provided by Canonical, Ubuntu's parent company.

This is an Arbiter import module. The Arbiter manages the configuration.

Prerequisites

You will need the landscape-api package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

define module { module_name Landscape module_type landscape_import

Configure your REAL key and secret from Landscape key PAAAB2CILT80I0ZA0999 secret GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH default_template generic-host ; if the host is not tagged, use this one

If you are using a specific certificate for landscape_api #ca /path/to.ca.cert

If you need a proxy to access https://landscape.canonical.com/api/ #https_proxy http://user:secret@myproxy.com:3128

}

- Put in key and secret your private Landscape access.
- default_template will be used if your host is not "tagged" in Landscape
- If you are using a specific certificate for connexion, give the full path in ca
- You will certainly need an https proxy to access the Landscape API. If so, configure it there.

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master
#    host_name       node1       ;result of the hostname command under Unix
     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           Landscape
     }
```

Restart your Arbiter and it's done :)

Tip: Your "tags" will be applied as templates for your hosts.

Shinken Livestatus API

Overview

- Jump back to Getting Started
- Jump back to *Livestatus module configuration*

What is it Livestatus API is the modern method of interacting with Shinken and Nagios based systems alike.

Originally developed for Nagios, MK Livetstatus, was re-implemented in Python for use with Shinken by professional developers. The access methods and query languages are the same.

Why use it It is fast.

It is network based using TCP.

It is standard for all Nagios and Shinken monitoring systems.

It uses in-memory structures for status data

It uses a back-end database for historical reporting

It uses an SQL based query language

It has a host of powerful nuts and bolts features (authentication, caching, connection persistence, multiple object methods (JSON, Python)).

What can I do with it? All programs and scripts use (or should use) this method to :

- Obtain the current state of hosts and services
- Obtain the current configuration related to hosts and services
- Send administrative commands (downtimes, comments, forcing checks)
- Filter information to display
- Obtain basic reports and event statistics

Shinken being a modern re-implementation of Nagios has additional features that are available in addition to the standard Livestatus API.

Shinken Livestatus API unique features can :

- Obtain Business Impact information
- Obtain intelligent dependency status hosts or services (combines dependency and parent information)
- Obtain Business Process states (same syntax as standard host and service queries)

How does it work Livestatus uses a powerful SQL-like query language. The standard methods and parameters are defined at :

'MK Livestatus reference methods and query language definition'_

Full list of Shinken Livestatus API methods:

'Shinken mapping.py methods'_

What software uses Livestatus to interact with Shinken

Well known Web frontends

- MK Multisite
- Thruk
- NagVis

- Splunk for Nagios

Mobile Web frontends

Scripts

- Downtime management scripts
- Debug scripts

Installing Livestatus Have you installed the required packages to use the Livestatus module? You can look at the requirement section of the *10 minute installation guide* for the *requirement lists*.

How to enable Livestatus Very simple, jump to the *Shinken Broker configuration* section to enable it. .. _Shinken mapping.py methods: https://github.com/shinken-monitoring/mod-livestatus/blob/master/module/mapping.py .. _MK Livestatus reference methods and query language definition: http://mathias-kettner.de/checkmk_livestatus.html

NSCA module The NSCA daemon module is used to receive send_nsca packets and submit them to the Shinken command pipe. The NSCA module can be loaded by the Receiver or Arbiter process. It will listen on port TCP/5667 for send_nsca packets.

Tip: Passive checks can be submitted *natively to the Shinken command pipe* or from remote hosts to modules, such as NSCA, AMQP or collectd, loaded in the Shinken Arbiter or Receiver process. AMQP is implemented for integration with the Canopsis Hypervisor, but could be re-used for generic messaging.

Note: The Shinken NSCA module implementation is currently limited to the "xor" obfuscation/encryption.

In your shinken-specific.cfg file, just add (or uncomment):

```
::
```

#You can send check result to Shinken using NSCA #using send_nsca command define module{

module_name NSCA module_type nsca_server host * port 5667 encryption_method 0 password helloworld

}

define receiver{

```
receiver_name    receiver-1
address          localhost
port             7773
modules          NSCA

timeout          3             ; 'ping' timeout
data_timeout     120           ; 'data send' timeout
max_check_attempts       3     ;  if at least max_check_attempts ping failed, the node is DEAD

#advanced
realm    All
}
```

This daemon is totally optional.

It's main goal is to get all passive "things" (checks but why not other commands) in distant realms. It will act as a "passive receive buffer" and will then dispatch the data or commands directly to the appropriate Scheduler or Arbiter process.

Data can be received from any Realm, thus the Realm option is nonsensical.

For now there is no init.d script to launch it. .. note:: Verify that the init script has been added.

It is launched like all other daemons:

```
bin/shinken-receiver -c etc/receiverd.ini
```

Tip: Alternatively, for small installations with you can configure a modules inside your Arbiter instead of the Receiver. It will listen the TCP/5667 port for send_nsca packets.

To configure the NSCA module in your Arbiter instead of Receiver. Add the NSCA module to your Arbiter object configuration.

```
::
```

define arbiter{ arbiter_name Arbiter-Master

 # host_name node1 ;result of the hostname command under Unix address localhost ;IP or DNS adress port 7770 spare 0 modules NSCA

}

Retention troubleshooting The retention file contains the state of your host and services, so that they are kept when shinken is restarted.

Sometimes you'll want to inspect (and possibly fix) the retention file, in case you need to work-around a bug or simply better understand what is stored there.

When you use the PickleRetention module in the scheduler (cf. ''define scheduler" in ''shinken-specific.cfg''), you can simply manipulate the retention file using Python.

For this you can use the following code.

- It assumes Shinken is installed in ''/opt/shinken" with the retention file in ''/tmp/retention.dat'':
- Run and play with it interactively using ''ipython -i inspect_retention.py''.

```
#!/usr/bin/python
import pickle
import sys
sys.path.append('/opt/shinken')
import shinken

r = pickle.load(file('/tmp/retention.dat'))
h = r['hosts']

# Example:
# [(k,v) for (k,v) in h['your_host'].items() if k.find('downtime') >= 0]
#
# del h['your_host']
#
# for k,v in r['services'].items():
#     if 'your_host' in k:
#         del r['services'][k]
```

To save your changes:

- Stop Shinken: ‘’service shinken stop’‘
- Save the pickle: ‘’pickle.dump(r, open(‘/tmp/retention.dat’, ‘w’))’‘
- Start Shinken: ‘’service shinken start’‘

NRPE Module

What is it The NRPE module allows Shinken Pollers to bypass the launch of the check_nrpe process. It reads the check command and opens the connection by itself. It scales the use of NRPE for active supervision of servers hosting NRPE agents.

The command definitions should be identical to the check_nrpe calls.

How to define it The definition is very easy (and you probably just have to uncomment it):

```
define module{
     module_name       NrpeBooster
     module_type       nrpe_poller
}
```

Then you add it to your poller object:

```
define poller {
    [...]
    modules   NrpeBooster
}
```

Then just tag all your check_nrpe commands with this module:

```
define command {
   command_name   check_nrpe
   command_line   $USER1$/check_nrpe -H $HOSTADRESS$ -c $ARG1$ -a $ARG2$
   module_type    nrpe_poller
}
```

That’s it. From now on all checks that use this command will use Shinken’s NRPE module and will be launched by it.

Extending Shinken

Introduction There are a lot of “Modules” and “Addons” that are available for Shinken. Shinken can be extended by using different types of methods.

- Web interfaces from various open-source vendors can be used (Based on Livestatus API)
- Shinken itself can be extended using modules that are embedded into the various daemon processes

** (Arbiter, Poller, Receiver, Broker, Scheduler, Reactionner) * External software can provide functional enhancements for reporting, management or usability aspects

Shinken itself provides methods to extend the base functionality:

- *Broker modules* provide external access to runtime data from Shinken
- Poller modules such as *NRPE* and the *SNMP*
- Receiver modules like *NSCA* provide acquisition methods for Shinken

- Arbiter modules permit manipulating the configuration
- The webUI that permits embedding web interface elements

Independent software that works in concert with Shinken is available for:

- Monitoring remote hosts through agent software (*NIX, Windows, etc.)
- Submitting passive checks from remote hosts
- Managing the config files through a web interface
- Mobile phone UIs
- Desktop UIs and Hypervisors
- Desktop notification addons
- ...and much more

You can find many addons that are compatible with Shinken by visiting. The only caveat is that the addons should not use the status.dat file and preferably the modern API interfaces like Livestatus:

- Nagios.org
- SourceForge.net
- NagiosExchange.org
- Shinken community exchange for monitoring packs

Broker modules The broker module receives messages from the Schedulers related to host, service check results. In addition to that it receives a copy of the compiled configuration at startup. What is special about the broker, is that without modules, the broker does nothing. It makes the configuration and result data available to modules. Modules are the ones in charge of doing something with the data. This could be exporting this "raw" data into flat files, databases or exposing it as an API.

The modules are presented according to their use cases.

- Core modules
- Livestatus Module for frontends
- Exporting data to metric databases
- SQL based Modules for frontends
- Exporting data to logging management systems
- Legacy modules for migration purposes
- Modules no longer supported

Core modules

simple_log: get all logs into one file You can get a log for all your daemons in a single file. With the exception of Debug level logs which are not sent through the network as a safe guard. Shinken state messages are ONLY logged at the debug level in the local log files. These are the ALL CAPS states that some 3rd party interfaces use to mine data from the historical logs. Actual state messages are sent as objects between the various daemons.

It takes the parameters:

- module_name: name of the module called by the brokers

- module_type: simple_log
- path: path of the log file

Here is an example:

```
define module{
```

```
     module_name      Simple-log
     module_type      simple_log
     path             /usr/local/shinken/var/nagios.log
     archive_path     /usr/local/shinken/var/archives/
}
```

Syslog - Send all logs to a local syslog server Send all logs to a local syslog server. Support for remote syslog can be implemented if requested. Just lookup the syslog module, easy to modify. Use for example with Splunk, graylog2, Logstash, Elastic search, Kibana, or other log management and analysis system.

```
define module{
```

```
  module_name Syslog
  module_type syslog
}
```

Lightweight forwarder to Splunk Shinken state data from the local syslog can also be sent to a Splunk server for indexing, reports, SLA and analysis. Via syslog or better yet, the Splunk lightweight forwarder which supports, TCP, buffering and security parameters.

Livestatus API Module - Thruk, Nagvis and Multisite Web frontends There are three well known frontends and various small tools that can interface with the Livestatus API. This API is currently the most efficient method of sharing live data with external interfaces. It provides a rich query language similar to SQL, authentication, command execution, caching,connections persistence, multiple object methods (JSON, Python). All Livestatus data is kept in memory, there is no disk IO involved. It exposes configuration objects, the current state of the hosts and services as well as historical Shinken state log messages.

- MK Multisite
- Thruk
- NagVis

Have you installed the required packages to use the Livestatus module? You can look at the requirement section of the 10 minute installation guide for the requirement lists.

Livestatus Module

It takes the following parameters:

- module_name: name of the module called by the brokers
- module_type: livestatus
- host: IP interface to listen to. The default is '127.0.0.1'. '*' means 'listen on all interfaces'.
- port: TCP port to listen to.
- socket: Unix socket to listen to.

- allowed_hosts: a comma-separated list of IP-addresses which are allowed to contact the TCP port. Please keep in mind that these must be ip-addresses, NOT host names. (DNS lookups for every incoming livestatus request could hang up and therefore block the module)
- modules: a comma-separated list of modules (see below)
- pnp_path: relevant if you use the multisite gui. pnp_path points to the perfdata directory where the pnp4nagios data reside (it's the directory which contains a subdirectory for each host). Multisite needs it to display a small perfdata icon if a rrd file exists.
- To deactivate an input, the port- and socket-attributes can also take the value "none".

The Livestatus module itself can have sub-modules. In fact, it **must** have at least one submodule responsible for storing log events to a database, SQLite or MongoDB.

Livestatus module - Logstore Sqlite Stores log-broks to an sqlite database.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_sqlite
- use_aggressive_sql: Prefer the use of sql queries to pre-filter data prior to python filtering. This is required for very large installations, as the Python structures are not indexed when filtering. Optional argument set to 0 by default. To enable set the value to 1. Some erroneous output may occur, but informal testing has shown these corner cases do not occur.
- read_only: don't send any update to the database. Should be used when you run several livestatus modules : 1 instance is R/W, other are read only.
- database_file: the path to the sqlite database file which is used to store the log broks/messages. The default is 'var/livestatus.db'
- archive_path: the path to a subdirectory where database file archives will be created. Every day the data from the last day will be moved to an archive datafile. The default is 'var/archives'.
- max_logs_age: the maximum age of the log messages (before they are deleted from the database). The default is 1 year. The argument to this parameter takes the form <number>[<period of time>], where <period of time> can be d for days, w for weeks, m for months and y for years. This parameter is currently ignored. In future releases it will be used to automatically delete ancient database files.

Here is an example:

```
define module{
```

```
     module_name      Livestatus
     module_type      livestatus
     host             *       ; * = listen on all configured ip addresses
     port             50000   ; port to listen
     socket           /usr/local/shinken/var/rw/live
     modules          logsqlite
}
define module{
```

```
     module_name      logsqlite
     module_type      logstore_sqlite
     use_aggressive_sql     0 ; optional, by default set to 0. Only for large installations.
     database_file    /usr/local/shinken/var/livelogs.db
     max_logs_age     3m ; three months. Other time intervals are d=days, w=weeks, y=years
}
```

Livestatus module - Logstore MongoDB Stores historical log broks(inter daemon Shinken messages) to a MongoDB database. MongoDB is a distributed and very performant database that permits resilience and high availability. The current implementation has a few known broken pieces (some search functions are broken) and there are bugs in the implementation, so it is considered experimental until power users and developers have ironed out the bugs. It is the database of the future for Shinken.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_mongodb
- mongodb_uri: The address of the master. (Default: i_cant_write_the_uri_here_it_messes_the_wiki_up)
- replica_set: If you are running a MongoDB cluster (called a "replica set" in MongoDB), you need to specify it's name here. With this option set, you can also write the mongodb_uri as a comma-separated list of host:port items. (But one is enough, it will be used as a "seed")
- database: <undocumented>
- collection: <undocumented>
- max_logs_age: <undocumented>

The configuration looks quite similar to the sqlite one. **In a single-node installation and with decent amount of log traffic, the sqlite backend should be considered best practice, as it needs no extra software and is stable and fast (when run in-memory).**

Livestatus module - Logstore Null In case you don't need any logging (for instance, if you dedicate a livestatus module instance to nagvis), you can use this module.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_null

Network Based Modules - Graphite graphing Graphite is a graphing and data analysis tool. It is composed of a web frontend (graphite-web), fixed size databases (whisper) and data redistribution/munging daemon. (carbon) The first step is *having Graphite installed somewhere*, if you do not have Graphite installed, please do this and come back later.

Pre-requisite : Shinken 1.2.2+ is recommended for the best experience with Graphite.

graphite_perfdata: exports check result performance data to Graphite Export all performance data included in check results to Whisper databases managed by Graphite. Data is buffered, then exported once every broker time tick. (Once per second). Should a communication loss occur, it will buffer data for 5 minutes before dropping data. The tick_limit max is configurable, the only limitation is the amount of memory the buffered data can eat.

The graphite broker module (v1.2) sends data to graphite in the following format :

HOSTNAME.SERVICENAME.METRICNAME

It can be optionally enhanced to send it the following format :

_GRAPHITE_PRE.HOSTNAME.SOURCE.SERVICENAME.METRICNAME._GRAPHITE_POST

Each of the three variables are optional :

- The _GRAPHITE_PRE variable can be set per host/service to provide a more flexible naming convention. (ex. Prod.site1.Hostname.servicename)

- The _GRAPHITE_POST variable can be set per host/service to specify the more information concerning the variable being stored that graphite can use to determine the retention rule to use for the variable.
- The SOURCE variable can be set in shinken-specific.cfg for the WebUI module and the Graphite broker.

Metric names are converted from Shinken's format to a more restrictive Graphite naming. Unsupported characters are converted to "_" underscore. So do not be surprised to see that some names differ in the WebUI or directly in Graphite. Permitted characters in Graphite are "**A-Za-z_**.", the hyphen character is permitted from Shinken, though only future versions of Graphite will support it.

Performance data transfer method can be set to pickle, which is a binary format that can send data more efficiently than raw ascii.

It takes the following parameters:

- module_name: name of the module called by the brokers
- module_type: graphite_perfdata
- host: ip address of the graphite server running a carbon instance
- port: port where carbon listens for metrics (default: 2003 for raw socket, 2004 for pickle encoded data)
- use_pickle: Use a more efficient transport for sending check results to graphite instead of raw data on the socket (v1.2)
- tick_limit: Number of ticks to buffer performance data during a communication outage with Graphite. On tick limit exceeded, flush to /dev/null and start buffering again. (v1.2)
- graphite_data_source: Set the source name for all data coming from shinken sent to Graphite. This helps diferentiate between data from other sources for the same hostnames. (ex. Diamond, statsd, ganglia, shinken) (v1.2)

Here is an example:

```
define module {
```

```
module_name Graphite-Perfdata
host xx.xx.xx.xx
module_type graphite_perfdata
port 2004 ; default port 2003 for raw data on the socket, 2004 for pickled data
use_pickle 1 ; default value is 0, 1 for pickled data
tick_limit 300 ; Default value 300
graphite_data_source shinken ; default is that the variable is unset
}
```

SQL Based Modules - PNP4Nagios Graphing PNP4Nagios is a graphing tool that has a web interface for RRDTool based databases. Shinken can export performance data to an npcd database which will feed the RRD files (fixed sized round robin databases). You can *learn how to install PNP4Nagios* if you haven't done it already.

npcdmod: export perfdatas to a PNP interface Export all perfdata for PNP.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: npcdmod
- path: path to the npcd config file

Here is an example:

```
define module{
 module_name  NPCD
 module_type  npcdmod
 config_file  /usr/local/pnp4nagios/etc/npcd.cfg
}
```

SQL Based Modules - Frontend Centreon2 Centreon2 use a NDO database, so you will need the ndodb_mysql module for it.

ndodb_mysql: Export to a NDO Mysql database Export status into a NDO/Mysql database. It needs the python module MySQLdb (apt-get install python-mysqldb or easy_install MySQL-python).

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: ndodb_mysql
- database: database name (ex ndo)
- user: database user
- password: database user passworddt
- host: database host
- character_set: utf8 is a good one

Here is an example:

```
define module{
```

```
     module_name      ToNdodb_Mysql
     module_type      ndodb_mysql
     database         ndo       ; database name
     user             root      ; user of the database
     password         root      ; must be changed
     host             localhost ; host to connect to
     character_set    utf8      ;optionnal, UTF8 is the default
}
```

File based Legacy modules - perfdata export

service_perfdata: export service perfdatas to a flat file

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: service_perfdata
- path: path to the service perfdata file you want

Here is an example:

```
define module{
```

```
    module_name      Service-Perfdata
    module_type      service_perfdata
    path             /usr/local/shinken/src/var/service-perfdata
}
```

host_perfdata: export host perfdatas to a flat file

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: host_perfdata
- path: path to the host perfdata file you want

Here is an example:

```
define module{
```

```
    module_name      Host-Perfdata
    module_type      host_perfdata
    path             /usr/local/shinken/src/var/host-perfdata
}
```

Legacy File based Modules - Old CGI or VShell The Old CGI and VShell use the flat file export. If you can, avoid it! It has awful performance, all modern UIs no longer use this.

status_dat: export status into a flat file Export all status into a flat file in the old Nagios format. It's for small/medium environment because it's very slow to parse. It can be used by the Nagios CGI. It also export the objects.cache file for this interface.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: status_dat
- status_file: path of the status.dat file /usr/local/shinken/var/status.dat
- object_cache_file: path of the objects.cache file
- status_update_interval: interval in seconds to generate the status.dat file

Here is an example:

```
define module{
```

```
    module_name              Status-Dat
    module_type              status_dat
    status_file              /usr/local/shinken/var/status.data
    object_cache_file        /usr/local/shinken/var/objects.cache
    status_update_interval   15 ; update status.dat every 15s
}
```

Deprecated or unsupported modules

SQL Based MerlinDB This interface is no longer supported and is going to be completely removed from Shinken.

SQL based ndodb_oracle - Icinga web frontend using NDO Oracle This interface is no longer supported and is going to be completely removed from Shinken.

CouchDB: Export to a Couchdb database This interface is no longer supported and is going to be completely removed from Shinken.

TSCA (Thrift Service Check Acceptor) TSCA is a receiver/arbiter module to receive hosts and services check results. It provides the same functions as NSCA with additional features. High performance binary transmission, multi line output and auto generated clients for a variety of languages.

What is thrift ? Let's cut and paste the wikipedia definition from'en.wikipedia.org/wiki/Apache_Thrift'_ :

"Thrift is an interface definition language that is used to define and create services for numerous languages.[1] It is used as a remote procedure call (RPC) framework [..]. It combines a software stack with a code generation engine to build services that work efficiently to a varying degree and seamlessly between ActionScript, C#, C++ (on POSIX-compliant systems), Cappuccino, Cocoa, Erlang, Haskell, Java, OCaml, Perl, PHP, Python, Ruby, and Smalltalk."

Installation In any case, you have to install thrift with support for python (on the server side) and languages you want to use for clients.

Get it from thrift.apache.org or in your favorite distribution repository.

Server side Go to the tsca module directory and generate the python stub for the server side installation

```
cd shinken/modules/tsca
$ thrift --gen py tsca.thrift
```

Declare the module is shinken-specific.org

```
define module{
      module_name     TSCA
      module_type     tsca_server
      host            0.0.0.0
      port            9090
}
```

Samples clients There are three(3) client samples written in python, ruby and java in contrib/clients/TSCA of the Shinken distribution. You can use and extend them to send data directly in your code directly to Shinken's TSCA receiver/arbiter module.

The samples clients read a CSV file from stdin and send them the the TSCA running on localhost:9090. The CSV has the following format :

```
hostname,service description,output,rc
```

Any use of TCP in an application should take care not to block the program and to have very short timeouts. For applications that need non blocking functions, prefer a UDP based transport or a local buffer file with a separate application(send_nsca, thrift, etc) to forward your data to Shinken.

Ruby Generate the stub

```
$ thrift --gen rb ../../../shinken/modules/tsca/tsca.thrift
```

Run the client

```
$ cat file_state | ruby RubyClient.rb
```

Python Generate the stub

```
$ thrift --gen py ../../../shinken/modules/tsca/tsca.thrift
```

Run the client

```
$ cat file_state | python PythonClient.py
```

java Generate the stub

```
$ thrift --gen java ../../../shinken/modules/tsca/tsca.thrift
```

Compile the client

```
$ ant
```

Run the client

```
$ cat file_state | java JavaClientThrift
```

VMWare Arbiter module

How it works The arbiter has a module that allows the host->VM automatic host dependency creation. In fact, the module is far more generic than just this. It's a generic "host link dependencies" module.

It reads a mapping file (simple json format) with son->father links. It call an external script at a regular interval : the one I wrote is a VMWare mapping one. It used the check_esx3.pl (that all ESX admin should have) plugin and generate the mapping file. When this file is changed, the module reloads it, creates new links and deletes old ones. So when you VMotion a virtual machine, in the next pass, there will be creation of a new link and deletion of the old one in the scheduler that manages it :)

How to define it The definition is very easy :

```
define module{
     module_name       VMWare_auto_linking
     module_type       hot_dependencies
     mapping_file      /tmp/vmware_mapping_file.json
     mapping_command   /usr/local/shinken/libexec/link_vmware_host_vm.py -x '/usr/local/shinken/libex
     mapping_command_interval 60   ; optionnal
     mapping_command_timeout   300 ; optionnal
}
```

Then you add it in you arbiter object :

```
define arbiter {
    [...]
    modules   VMWare_auto_linking
}
```

So here, it will call the script /usr/local/shinken/libexec/link_vmware_host_vm.py with a listing of the vCenter vcenter.mydomain.com and generate the mapping file /tmp/vmware_mapping_file.json.

You can call : /usr/local/shinken/libexec/link_vmware_host_vm.py –help

for the full help on this script.

It looks at the file modification time each second. This command can also be launch by an external cron of course.

Note: So if you want to write a script that does this for XEN servers, all you need is to generate a json file with all the mapping. I didn't wrote the doc about this, but you can look in the test file for it, the format is very very easy :)

Here is an example of the JSON mapping file syntax:

%%:ref:*["host", "physical_host"], ["host", "virtual_machine"* <["host", "physical_host"], ["host", "virtual_machine">, "host", "physical_host"], ["host", "other_virtual_machine" <"host", "physical_host"], ["host", "other_virtual_machine">]%%

So just a list of couple 'host' string (from now only host are managed) and the host name.

Beware about it : you need the real host_name, including case.

Web Service Module The Ws_arbiter module is a Receiver or Arbiter module to receive passive check results from remote hosts via HTTP(s). This module is considered a work in progress but can be used for testing and improvement.

Configuring the Web Service Module If data is POSTed to this page, it will validate the data to determine if it is a service or host check result and submit the data to the Shinken external command queue.

The web service listens by default to TCP port 7760. The web service supports anonymous or authenticated access. Web service parameters are set in the Shinken-specific.cfg file, in the Ws_arbiter module. To enable the web service, simply add the module to your Arbiter or Receiver daemon configuration in Shinken-specific.cfg

Using the Web Service Module The web service listens for POSTs to: /push_check_result

Use curl or embed the HTTP calls in your software to submit check results.

curl -u user:password -d "time_stamp=$(date +%s)&host_name=host-checked&service_description=service-checked&return_code=0&output=Everything OK" http://shinken-srv:7760/push_check_result

Example with more readability:

```
curl
```

-u user:password -d "time_stamp=$(date +%s)

```
&host_name=host-checked
&service_description=service-checked
&return_code=0
&output=Everything OK
http://shinken-srv:7760/push_check_result
```

SNMP module This part must be splitted and sent in all module repositories

Shinken integrated SNMP Module

SnmpBooster Download Install and Configure

- *What is the SnmpBooster module*
- Install and configure the SNMP acquisition module. [You are here]
- *Reference - SnmpBooster troubleshooting*
- *Reference - SnmpBooster design specification*
- *Reference - SnmpBooster configuration dictionnary*

Downloads

The SnmpBooster module and genDevConfig are currently in public beta prior to integration within Shinken. You can consult t

- github.com/xkilian/genDevConfig
- github.com/titilambert/shinken/tree/snmp_booster/shinken/modules (snmp_booster branch) * Simply right-click and download snmp_poller.py then copy it to shinken/modules/

Requirements The SnmpBooster module requires:

- Python 2.6+
- Shinken 1.2+
- PySNMP 4.2.1+ (Python module and its dependencies)
- ConfigObj (Python module)
- python-memcached
- memcachedb or memcached package for your operating system (ex. For Ubuntu: apt-get install memcachedb) *Note*

The genDevConfig profile generator depends on:

- Perl 5.004+
- 4 perl modules available from CPAN and network repositories. genDevConfig/INSTALL has the installation details.

STRONGLY RECOMMENDED: Use the same version of Python and Pyro on all hosts running Shinken processes.

Installation SnmpBooster:

- Install the dependencies
- Copy the file snmp_poller.py from the git repository to your shinken/modules directory.
- Configuration steps are listed in the present web page.

genDevConfig:

- Download and extract the archive to your server.
- See genDevConfig/INSTALL on how to install and configure it.

Configuration

How to define the SnmpBooster module in the Shinken daemons You need to modify shinken-specific.cfg, which is located in $shinken/etc/shinken-specific.cfg

Arbiter daemon configuration Simply declare the module:

```
modules SnmpBooster</code>
```

Scheduler daemon configuration

Simply declare the module:

<code>modules SnmpBooster

Poller daemon configuration Simply declare the module:

```
modules SnmpBooster</code>
```

SnmpBooster Module declaration

Included in Shinken v1.2.1 shinken-specific.cfg.

<code>define module {

```
module_name          SnmpBooster
module_type          snmp_poller
datasource           /usr/local/shinken/etc/packs/network/SnmpBooster/   ; SET THE DIRECTORY FOR YOUR
memcached_host       x.x.x.x  ; SET THE IP ADDRESS OF YOUR memcached SERVER
memcached_port       11211  ; default port for a memcached process
```

}

If you do not know the IP adress on which your memcache is listening, check under /etc/memcached.conf. Or do a:

```
netstat -a | grep memcached</code>
If you are running a test on the local machine you can leave memcached on 127.0.0.1 (localhost), but
```

How to define a Host and Service

Step 1

Create a template for your SNMP enabled devices.

Sample template:

<code>cd shinken/etc/packs/network/ mkdir SnmpBooster

vi shinken/etc/packs/network/SnmpBooster/templates.cfg

```
define command {
```

```
command_name    check_snmp_booster
command_line    check_snmp_booster -H $HOSTNAME$ -C $SNMPCOMMUNITYREAD$ -V 2c -t $ARG1$ -i $_SERVICE
module_type     snmp_poller
```

}

```
define service {
```

```
name                    default-snmp-template
check_command           check_snmp_booster!$_SERVICEDSTEMPLATE$!$_SERVICEINST$!$_SERVICETRIGGERGROUP
_inst                   None
_triggergroup           None
max_check_attempts      3
check_interval          1
retry_interval          1
register                0
```

}

```
define host{
```

```
name                    SnmpBooster-host
alias                   SnmpBooster-host template
check_command           check_host_alive
max_check_attempts      3
check_interval          1
retry_interval          1
use                     generic-host
register                0
```

}

Step 2 Define some hosts and services. You would typically use genDevConfig or another configuration generator to create these for you.

Mandatory service arguments related to SNMP polling:

```
_dstemplate                Cisco-Generic-Router  ; Name of a DSTEMPLATE defined in the SnmpBooster co
```

```
snmpcommunityread    which is set in your resource.cfg file
```

Optional service arguments related to SNMP polling with default values:

```
_inst                   None   ; Could be numeric: 0, None or an instance mapping function like: map
```

```
_triggergroup           None   ; Name of the triggergroup defined in the SnmpBooster config.ini file
```

Sample Shinken host and service configuration:

```
# Generated by genDevConfig 3.0.0
# Args: --showunused -c publicstring 192.168.2.63
# Date: Thu Aug 30 17:47:59 2012

define host {
```

```
 host_name            192.168.2.63
 display_name         192.168.2.63
 _sys_location
 address              192.168.2.63
 hostgroups
 notes
 parents
 use                  default-snmp-host-template
 register             1
}

define service {
```

```
 host_name            192.168.2.63
 service_description  chassis
 display_name         C2960 class chassis
 _dstemplate          Cisco-Generic-Router
 _inst                0
 use                  default-snmp-template
 register             1
}

define service {
```

```
 host_name            192.168.2.63
 service_description  chassis.device-traffic
 display_name         Switch fabric statistics - Packets per Second
 _dstemplate          Device-Traffic
 use                  default-snmp-template
 register             1
}

define service {
```

```
host_name            192.168.2.63
service_description  if.FastEthernet0_1
display_name         FastEthernet0_1 Description: Link to Router-1 100.0 MBits/s ethernetCsmacd
_dstemplate          standard-interface
_inst                map(interface-name,FastEthernet0_1)
use                  default-snmp-template
register             1
```

}

Here is an example configuration of the config.ini file

```
[DATASOURCE]
```

```
  OidmyOidDefinition = .1.3.6.1.45.0
  [myOidDefinition] ; Use the same name as the myOidDeiniftion, but omit the leading "Oid"
      ds_type = DERIVE
      ds_calc = 8,*  ; RPN expression : Oid, 8, *  Which means Oid * 8 = ds_calc
      ds_oid = $OidmyOidDefinition
[DSTEMPLATE]
```

```
  [myCiscoRouter]
      ds = myOidDefinition
[TRIGGER]
```

```
  [trigger1]
      warning = RPN expression
      critical = RPN expression
  [trigger2]
      warning = RPN expression
      critical = RPN expression
[TRIGGERGROUP]
```

```
[CiscoRouterTriggers]
    triggers = trigger1, trigger2
```

Shinken integrated SNMP Module

Overview

What is it The SnmpBooster module allows Shinken Pollers to directly manage SNMP data acquisition. This is an all Python cross-platform SNMP module. It is tightly integrated with the Shinken Poller, Scheduler and Arbiter daemons to provide the best possible user experience.

Design specification summary

- STATUS - DESIGN SPEC PERFORMANCE
- [Done] Functions as an integrated Shinken Poller module
- [Done] Necessary integration code commited to Shinken official release (Integrated starting at v1.2)
- [Done] Ability to collect thousands of SNMP metrics per second
- [Done] Be compatible with distributed data acquisition
- [Done] Collect data for a host/check_interval tuple via SNMP in a single pass
- [Done] Use all builtin Shinken scheduler logic for retries, forced checks, timeouts, dependencies, parents
- [Done] Store collected data for the duration of the check_interval in a memcached/membase
- [Done] On a restart, after the first collection, be able to pick up where the last check left and calculate derived values
- [Done] Forced check are not allowed within 30 seconds of last SNMP query to the same host/check_interval, all other requests get data from the cache.
- [Done] Only a single request to the host/check_interval via SNMP is allowed at a time, all other requests get data from the cache.
- STATUS - DESIGN SPEC USABILITY
- [Done] Usage documentation
- [xxxx] SkonfUI and Discovery usage documentation
- [xxxx] Provide sample configuration packs in Shinken
- [Done] Provide sample config.ini with examples of all types of data * SNMP OIDS, DATASOURCES, DSTEMPLATES, TRIGGERS and TRIGGERGROUPS

- [Done] Directly compatible for use with genDevConfig Shinken SNMP configuration generator
- [Done] Provide meaningful feedback for users on errors
- [Done] Capture all tracebacks and convert them to actual error or warning messages
- STATUS - DESIGN SPEC FEATURES
- [Done] Return state and performance metrics
- [Done] Performance metrics can be returned in a Weathermap compatible format
- [Done] Configuration file format is ConfigObj INI
- [Done] Load all valid INI configuration files from a directory and merge them
- [Done] Load a single INI configuration file
- [xxxx] Load a list of INI configuration files
- [Done] Configuration file describes all generic acquisition parameters (OID, DATASOURCE, DSTEMPLATE, MAP, TRIGGER, TRIGGERGROUP)
- [Done] Supports Triggers which are calculation rules to determine states
- [Done] Triggers support an RPN (Reverse Polish Notation) calculation engine which includes mathematical and logical operators
- [Done] Each TRIGGER is associated with a severity level, WARNING or CRITICAL
- [Done] Multiple TRIGGERS can be associated with a TRIGGERGROUP
- [Done] Use builtin Python Operators
- [Done] Support DERIVE, TEXT, GAUGE and COUNTER data types
- [xxxx] Support TIMETICKS data type
- [Done] Support applying RPN based calculations to received metric for scaling or conversion purposes
- [Done] Use a Python SNMP library which supports asynchronous acquisition PySNMP
- [Done] Datasources can use rule based runtime instance mapping
- [Done] Set Snmp version as a check runtime option
- [Done] Set Snmp DSTEMPLATE as a check runtime option
- [Done] Set Snmp TRIGGERGROUP as a check runtime option
- [Done] Set Snmp COMMUNITY as a check runtime option
- [Done] Use Snmp version 2c GetBulk
- [xxxx] Support Snmp version 2c GetNext if GetBulk is not supported
- [xxxx] Support Snmp version 1 GetNext
- [xxxx] Set Snmp Timeout as a check runtime option, instead of a hardcoded value at 5 seconds
- STATUS - DESIGN SPEC MAINTAINABILITY
- [xxxx] Functions documented in the source code
- [Done] Critical functions documented in the source code
- [Done] Locking sections identified in the code
- [xxxx] Unit tests with at least 80% coverage

- [xxxx] Unit tests integrated with Shinken test suite
- [Done] Code hosted on github
- [xxxx] configuration validity and integrity checking of all INI files
- [xxxx] Pep8 compliant
- [xxxx] Pylint pass

genDevConfig Plugins - Compatibility status with SnmpBooster

- STATUS - genDevConfig maintained Plugins
- [Done] Avaya ES switches
- [Done] Avaya ERS routing switches
- [Done] Cisco 29x0 switches
- [Done] MIB-II Interfaces
- [Done] Cisco PIX/ASA
- [Done] JUNOS devices
- [Done] Cisco IOS routers
- [Done] NetSNMP unix hosts ** Validation required**
- [Done] Packeteer devices ** Validation required**
- [Done] Sensatronics devices ** Validation required**
- [Done] Foundry devices ** Validation required**
- [Done] Packeteer devices ** Validation required**
- [Done] Cisco CSS ** Validation required**
- [InProgress] New Cisco Access points
- STATUS - Other maintained Plugins

Tip: [xxxx] Denotes a specification that is planned but not implemented

[InProgress] Denotes a specification that is under development

[Done] Denotes a specification that is implemented

SnmpBooster reference dictionary

- Jump back to *SnmpBooster documentation index*

SnmpBooster.ini dictionary

There are five dictionaries:

- [DATASOURCE]
- [DSTEMPLATE]
- [MAP]
- [TRIGGER]

- [TRIGGERGROUP]

DATASOURCE DICTIONARY OidVariableName refers to an actual OID that can be queries using SNMP against the device on the network.

[VariableName] refers to a Datasource and all the information required to gather and prepare the data using SNMP ds_type refers to how the data should be prepared ds_calc refers to any scaling manipulations to make the data more understandable. This is an RPN expression, where the first variable is omitted, as it is always the $OidVariable ds_oid refers to the actual $OidVariable name. An instance identifier can be appended to the name to signify that an instance is provided by the Shinken service definition. This information is passed when the check is called. ...

DSTEMPLATE DICTIONNARY [DsTemplateName] refers to the name of the DSTEMPLATE that will be referred to in the Shinken service definitions. ds refers to the list of DATASOURCES to be collected. If an instance is expected for the list of DATASOURCES, it MUST be the same instance for all Oids. If a different instance is required, use a second DSTEMPLATE.

TRIGGER DICTIONNARY

TRIGGERGROUP DICTIONNARY

MAP DICTIONNARY

SnmpBooster.ini example configuration This example definition will be used to explain each section.

[DATASOURCE]

```
OidmyOidDefinition = .1.3.6.1.45.0
[myOidDefinition] ; Use the same name as the myOidDeiniftion, but omit the leading "Oid"
    ds_type = DERIVE
    ds_calc = 8,*  ; RPN expression : Oid, 8, *  Which means Oid * 8 = Total
    ds_oid = $OidmyOidDefinition
```

[DSTEMPLATE]

```
[myCiscoRouter]
    ds = myOidDefinition
```

[TRIGGER]

```
[trigger1]
    warning = RPN expression
    critical = RPN expression
[trigger2]
    warning = RPN expression
    critical = RPN expression
```

[TRIGGERGROUP]

```
[CiscoRouterTriggers]
    triggers = trigger1, trigger2
```

SnmpBooster.ini configuring SNMP Datasources

The first location is generic data related to SNMP parameters.

- DATASOURCE information * SNMP OID * Type of data and how can it be interpreted (GAUGE, COUNTER, COUNTER64, DERIVE, DERIVE64, TEXT, TIMETICK) * Data format preparation (Scaling the data for example bits to bytes) * Is there an instance to append to the
- Instance MAP function * Mapping the instance dynamically using a function * Data or rules related to the mapping function

SnmpBooster.ini configuring SNMP DSTEMPLATES

- DSTEMPLATEs to associate DATASOURCE to actual device classes * List of DATASOURCES associated with a, for example, Cisco 1900 router. Which in turn can be applied to a Shinken service

SnmpBooster.ini setting triggers/thresholds

- TRIGGER and TRIGGERGROUPS to apply thresholding rules * Define triggers and associate them with a TRIGGERGROUP name that can be applied to a Shinken Service

Shinken integrated SNMP Module

Overview

- Jump back to *SnmpBooster documentation index*

Tip: The module is now in public beta as of 2012-10-26! Have Fun!

Nothing new to add, more to come in 2013. 2013-01-19.

What is it The SnmpBooster module allows Shinken Pollers to directly manage SNMP data acquisition. This is an all Python cross-platform SNMP module. It is tightly integrated with the Shinken Poller, Scheduler and Arbiter daemons to provide the best possible user experience.

Why use it The SnmpBooster module is designed to be very efficient and scalable. It has a very flexible configuration method to make it easy to use with Shinken Monitoring Packs and Shinken discovery runners like genDevConfig.

This acquisition module was professionally designed and developed.

It is meant to be used by the very capable discovery engine genDevConfig (**v3.0.5 and newer**) originally developed for the Cricket SNMP monitoring tool and converted for use with Shinken.

It is one of the very few serious SNMP v2c implementation making use of SnmpGetBulk type requests.

How does it work

Shinken Integration

1. The SnmpBooster Arbiter module reads the Shinken SnmpBooster configuration file(s). It reads the check commands and based on the values in the check commands that use the snmp_poller module it will creates a shared configuration cache using memcached/memcachedb. The memcache key is always the combination of the hostname. This permits to tie together Shinken Hosts and Services with the SNMP specific configuration. (MongoDB and Redis are planned to be supported in the future) The Scheduler daemon schedules Host and Service checks as it normally does.

3. The SnmpBooster module will check that a memcache host key exists for the check to be launched. Then the SnmpBooster poller module will query all services related to a host for a given acquisition frequency in one pass. (all checks done every 2 minutes will be executed in bulk, same for those every 5 minutes)

5. Check results are cached for the acquisition check_interval. The next time a check request for data from the same host is received from the Scheduler, the data will be fetched from memcache. Resulting is extremely low check latency.

2. 6. The SNMP checks still benefit from retries, timeouts, forced checks, dependencies and the powerful Scheduler daemon logic.

6. The Scheduler daemon can still force an immediate re-check by flushing the cache. This is required for the dependency model.

Performance SnmpBooster uses SNMP v2c getbulk for high efficiency, unless forced to use SNMP v2c get-next or SNMPv1 get-next. GetBulk uses a single request PDU to ask for multiple OIDs or even entire tables, instead of sending one request PDU per OID.

For example: *A typical 24 port network switch with two uplinks might use 375 OIDS (8 OIDs per interface, plus general OIDs for chassis health, memory, cpu, fans, etc.). **SnmpBooster will only require around 4 request PDUs*

*instead of 375 request PDUs**. Each PDU is a request packet which takes time to create, send get processed and return. More timeouts to manage, more connections, more impact on the remote device and more latency means much fewer checks per second.*

The SnmpBooster module supports automatic instance mapping for OIDs. (Ex. Based on the interface name it will figure out that the SNMP index(or instance) is 136. This is automatically handled by genDevConfig and SnmpBooster, no user input required. :-)

The generic SNMP configuration information is stored in the Shinken SnmpBooster INI files. There is a Defaults_unified.ini and a series of other Defaults files, one per discovery plugin for genDevConfig.

Important: genDevConfig plugins have all been converted to use the new dynamic instance mapping methods. You are now free to use most if not all Defaults*.ini files included with genDevConfig. 2012-10-28

Limitations You should have memcached instances running on each poller responsible for snmp polling. You should have your pollers with SnmpBooster in the same datacenter, as they need to be on the same machine with good connectivity to the active memcached instance. SnmpBooster is not compatible with distributed pollers in multiple datacenters, sorry, the current design of SnmpBooster uses a single centralized memcached instance for storing the timeseries data. For distributed datacenters to be supported, each poller+scheduler+memcached must be realm restrained, which is not the case today.

Design specification *SnmpBooster design specification* and current development status.

Data model The information required to define the data is split in two locations.

The first location is the host and service Shinken configuration (You need to generate or write this)

- Device specific information
  - IP addresses, host_names, device types, instance keys
  - A DSTEMPLATE must be referred to in the Service definition
  - A static SNMP instance could be referred to in the Service definition
  - An SNMP instance MAP function could be referred to in the Service definition
  - A TRIGGERGROUP could be refered to in the Service definition

The second location is SNMP Defaults.* templates. (Here you can create new devices or add new data sources)

- DATASOURCE information
  - SNMP OID
  - Type of data and how can it be interpreted (GAUGE, COUNTER, COUNTER64, DERIVE, DERIVE64, TEXT, TIMETICK)
  - Data format preparation (Scaling the data for example bits to bytes)
  - Is there an instance to append to the
- Instance MAP function * Mapping the instance dynamically using a function * Data or rules related to the mapping function
- DSTEMPLATEs to associate DATASOURCE to actual device classes * List of DATASOURCES associated with a, for example, Cisco 1900 router. Which in turn can be applied to a Shinken service
- TRIGGER and TRIGGERGROUPS to apply thresholding rules * Define triggers and associate them with a TRIGGERGROUP name that can be applied to a Shinken Service

A final location containes rules to build your Shinken configuration.

- genDevConfig plugins create Shinken configurations

Installation and configuration *SnmpBooster installation*

Reference Dictionnary *SnmpBooster reference dictionary*

Troubleshooting *SnmpBooster troubleshooting*

Graph templates These are .graph files defined in your Shinken configuration directory. Refer to the Shinken graphite templates(Not yet created) or PNP4Nagios how-to documentation. The graph templates are independent from SnmpBooster and provide templates for any collected data from Shinken.

SnmpBooster Troubleshooting

- Jump back to *SnmpBooster documentation index*

Check your config

- Have you defined the poller module name?
- Have you defined the correct path to the directory containing your Defaults*.ini files?
- Have you addded the Snmpbooster module to your arbiter, poller, scheduler?
- Have you added copied the genDevConfig templates.cfg in shinken/packs/network/SnmpBooster/
- Have you installed PySNMP, memcached and other dependencies?

Software version consistency Shinken and SnmpBooster now require **the same Python and Pyro version on all hosts running a Shinken daemon**.

If you cannot use the packaged version of Python and its modules (Pyro, memcached, etc.). Use virtualenv to declare a python version to use and install all required modules in that virtualenv.

Software version requirements Have you verified that the *requirements* are met. Python, PySNMP, Shinken, Pyro, memcached, etc.

Validate your check command arguments Use the check_plugin command and comment out the module to learn what were the exact arguments sent by the poller. This will permit you to validate all the arguments, like snmp community string, inheritance, template application, etc.

Validate connectivity

Take a packet trace using a tool like Wireshark to validate that the remote host is responding.

- Has the host responded
- **Is SnmpBooster repeating the request more often than the polling interval.**
  - If you are seeing repeated requests your device may have a compatibility issues.

- Save an snmpwalk of the device, get a packet trace using Wireshark, set the poller to debug and save the poller.log file (shinken/var/poller.log). Send all three to the SnmpBooster developers.
- Note: It is normal to see one or more bulkGet requests if you are getting large amounts of data. Ex. a 24 port switch will take 2-3 request packets.

Performance Make sure you have a low latency connection to your memcache from the Poller. Your memcache server can be replicated to all your poller hosts that should also run memcache instances. Check that memcached is running: netstat -a | grep memcached

Faulty Template A bad snmp_template file was distributed in the genDevConfig sample-config directory, there were two glaring errors.

This was fixed on 2012-10-16. Make sure you update your template, or use the data from the wiki.

Note that the template should be called: SnmpBooster-template.cfg to make it easier to troubleshoot in the logs. So when you search for SnmpBooster in your logs it will show up as well.

Log files All warnings and errors generated by the SnmpBooster module start with "[SnmpBooster] error text" and are logged using the standard Shinken logger.

The Arbiter daemon can output initial configuration, loading of host keys and intervals in memcached type error messages. The Scheduler daemon can output scheduling and alert related messages. The Poller daemon can output messages related to instance mapping, acquisition timeouts, invalid community strings, cache failures and more. These are available in the Web interface, as they are placed in the check results for the service.

You can simply do a "grep SnmpBooster *" in your shinken/var directory to see the latest messages related to the SnmpBooster module. You can also sort messages by timestamp to make it easy to find where and when errors occurred.

cd shinken/var grep SnmpBooster *

memcache persistence If you restart your memcache server or memcache crashes, your poller will no longer be able to validate that a host exists in memcache prior to writing.

You should use memcachedb to achieve persistence in case of memcache failures.

Common errors returned by SnmpBooster in the log file Errors should be fairly explicit and mean what they say, though there can be exceptions. Lets try to clear some of them.

__Arbiter log **errors__**

Missing ds_oid : This means that a variable in your OID definitions is missing, or your DATASOURCE is not named correctly or your ds_oid variable is missing. There is a typo in your ds_oid variable (ex. ds-oid, or ds_oid = $OidNameIncorrectFFFRA.%(instance)s).

Datasource not defined : Your DSTEMPLATE uses a DATASOURCE that doesn't exist check the [DataSourceName] you are referring to. Does it contain the expected OID variable, $OidName.

Missing ds_type : The DATASOURCE always needs to have a ds_type definition, GAUGE, COUNTER, DERIVE, TEXT, TIMETICK, DERIVE64, COUNTER64.

__Poller log **errors__**

Problems with calculations, repeated polling, hosts not responding, etc.

__Memcached **errors__**

memcachedb and memcached do not use the same default port. Configure the correct memcachedb port to match what is declared in your SnmpBooster module under shinken-specific.cfg.

On Ubuntu 12.04 the default installation is on port 21201 instead of 11211. This causes the error "[SnmpBooster] Memcache server (127.0.0.1:11211) is not reachable" when Shinken starts.

To change it, you must edit the file /etc/memcachedb.conf

Memcached Notes On Ubuntu 12.04 the default instalation is on port 21201 instead of 11211. This causes the error "[SnmpBooster] Memcache server (127.0.0.1:11211) is not reachable" when shinken starts.

To change it, you must edit the file /etc/memcachedb.conf

WebUI module This part must be splitted and sent in all module repositories

WebUI integration with Shinken The WebUI is an external broker module. So it's an external process launched by the broker that "eats" broks (broker messages) from the brokers. So it can get *all* broks if you place this broker in your top level realm.

The WebUI does not use a database to get data. Instead, it use a "regenerator" object that will eat each broks, and will "recreate" all Hosts/Services/Contacts objects as if the code was in the scheduler daemon. So basically, WebUI and pages always reflect the CURRENT state of hosts/services objects.

The WebUI http layer is managed by bottle.py. It's a small but powerful framework.

How does the WebUI function globally ?

There a 2 Threads running:

- the main thread is the bottle.py (http) listener. It will use the best backend it finds. We recommend using python-paste. If it does not find one, it will use the default swsgi. Paste is multi-thread, swsgi is mon-thread, so please use paste if you want to avoid locking problems.
- the 2nd thread is the regenerator one. It only gets broks and gives them to the regenerator object.

There is a lock system between the threads. You can have N Http requests in progress without problem, but during this time the renererator one will wait. During execution of the regenerator, no requests are processed. This is not considered a problem, as the regenerator is very quick, and there is only a 1s lock for a 7k service conf loading, so it's not a huge problem.

What is a WebUI User? A WebUI user is a contact. A true contact object. You must match a contact name for your user.

To create a new page? All pages are in the shinken/webui/plugins directory. Each "part" has it's own directory. A part (like the eltdetail, element detail) can have more than one "page" (like /host or /service for eltdetail).

From here we will supose you want to create a "/contact" page.

You can copy the dummy example in the plugins directory into a contact directory.

You need to change the contact/dummy.py file into a contact/contact.py file, because the webui will search for a dir/dir.py file to "load".

Templates Templates are HTML with some Python code in it in the plugins/*/views direcotry for specific templates, and the "global layout" (menu and all common part) in the webui/views directory.

Your template must call the template layout (layout.tpl in the webui/views directory) wit ha "rebase" call.

If you put the rebase call at the beginning of your template, all there is below will be place "inside" the layout that will call the common javascripts and css, make the menu adn then call your html/python code.

The rebase call can take arguments. You MUST give it:

- user: the user you give it in the return dict of your .py code

Then all is optional:

- title: title of the page
- top_right_banner_state: int, global state with clouds to put in your top right page. Look at the problem.tpl code for an example.
- js and css list: list of YOUR specific javascript or css to call AFTER the common ones.
- refresh: boolean, set the refresh to 60s or do not refresh at all

- menu_part: will put the little "^" under this part of the menu.

Example of a call, taken from the problems view:

```
rebase layout title='All problems', top_right_banner_state=top_right_banner_state, js=['problems/js/a
roblems/js/autocompleter.Request.js', 'problems/js/autocompleterObserver.js'], css=['problems/css/acc
ms/css/autocompleter.css', 'problems/css/perfometer.css'], refresh=True, menu_part='/'+page, user=use
```

Call Python objects in your templates Your templates are mainly HTML code. But of course you can call python code in it. The dict you returns in the plugin.py call will be available in this page.

For example, the my_host variable will be available in the page with the host object you find (or None if your give it a bad name of course). Then you can "call" python with for example here to show the host_name: `<span>My host name is *my_host.host_name* </span>` is a way in the templates to "call a variable or function" that will return a string, here the host_name.

If the function or property you call must return HTML code that SHOULD be output as it, without "protection", you must put a ! before your call.

Let use an example where the output value of an host is in fact an html output. If you use the code `my_host.output`, bottle.py will "protect" the html generated by escaping the string, and change <> characters with escaped value. You can change this by calling `my_host.output`. Of course, it's a security problem if the output is with a javascript code...

You can also "loop" or put "if" in your template. You just need to put your code with a % before. Like

```
%for i in xrange(1, 10):
  My valus is  {{i}}
%end
```

You must put the %end here, the indentation will NOT be enougth, sorry.

For an if it's also easy:

```
%if host.active_checks_enabled:
  The host got active checks enabled
%else:
  The host DO NOT have active check enabled
%end
```

Which javascript lib are you using? It's mootools 1.3 with all options :)

What to do?

- Finish the /mobile part
- List of current alerts
- Host info
- Host status
- Host interfaces
- Hostgroup status
- dashboard hierachique with states, and BP
- Nagvis
- add bp in nagvis auto-map

- event sources
- correlation
- pre-filtering/enrichment
- user profile
- host/srv conf

WebUI search syntax work in progress

not that we couldn't tell. ;) eh eh

beware the working men and flying tools!

WebUI SSL Certification Lets start: the goal to to have the server.pem and client.pem file in etc/certs.

Go to the etc/certs directory.

```
openssl req -new -nodes -out server.req -keyout server.key -config ./shinken_openssl_cnf
openssl ca -out server.pem -config ./shinken_openssl_cnf -infiles server.req
cp server.pem server.pem.bkp
cp server.key server.pem
cat server.pem.bkp >> server.pem
cp server.pem client.pem
```

You can try to get the validity with for the arbiter with:

```
openssl s_client -connect localhost:7770</code>
```

Amazon AWS/EC2 import

Description You can import data from Amazon AWS/EC2 **'AWS'**_ into Shinken to create hosts.

Amazon provide VM hosting with EC2. With this arbiter module, you will be able to load your EC2 hosts into Shinken.

Prerequisites

You will need the **'libcloud'**_ package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

```
define module {
 module_name      AWS
 module_type      aws_import

 # Configure your REAL key and secret for AWS
 api_key              PAAAB2CILT80I0ZA0999
 secret           GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH
 default_template generic-host        ; if the host is not tagged, use this one
 }
```

- Put in key and secret your private Landscape access. * default_template will be used if your host is not "tagged" in Landscape

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master

     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           AWS
     }
```

Restart your Arbiter and it's done :)

Generated hosts The configuration generated will look as below :

```
define host {
    host_name            i-3fc56e5a
    address              8.8.4.4
    use                  t1.micro,MyTag,EC2,generic-host
    _EC2_AVAILABILITY    us-east-1a
    _EC2_CLIENTTOKEN
    _EC2_DNS_NAME
    _EC2_GROUPS          quicklaunch-1
    _EC2_IMAGEID         ami-1b814f72
    _EC2_INSTANCEID      i-3fc56e5a
    _EC2_INSTANCETYPE    t1.micro
    _EC2_KERNELID        aki-825ea7eb
    _EC2_KEYNAME         testaws
    _EC2_LAUNCHDATETIME  2012-09-26T12:19:38.000Z
    _EC2_LAUNCHINDEX     0
    _EC2_PRIVATE_DNS
    _EC2_PRIVATE_IP
    _EC2_PRODUCTCODE
    _EC2_PUBLIC_IP       8.8.4.4
    _EC2_RAMDISKID       None
    _EC2_STATUS          stopped
    _EC2_TAGS            demo:myvalue,use:MyTag
 }
```

Here with a stopped t1.micro instance with no name. You can put your how "use" parameter by adding a EC2 tag "use" on your VM. It will be output on the host configuration so you can setup the monitoring as you want. .. _libcloud: http://libcloud.apache.org/index.html .. _AWS: https://console.aws.amazon.com

Amazon AWS/EC2 import

Description You can import data from Amazon AWS/EC3 **'AWS'**_ into Shinken to create hosts.

Amazon provide VM hosting with EC3. With this arbiter module, you will be able to load your EC2 hosts into Shinken.

Prerequisites

You will need the **'libcloud'**_ package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

```
define module {
 module_name      AWS
 module_type      aws_import

 # Configure your REAL key and secret for AWS
 api_key              PAAAB2CILT80I0ZA0999
 secret           GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH
 default_template generic-host        ; if the host is not tagged, use this one
 }
```

- Put in key and secret your private Landscape access. * default_template will be used if your host is not "tagged" in Landscape

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master

     address          localhost                  ;IP or DNS adress
     port             7770
     spare            0
     modules           AWS
     }
```

Restart your Arbiter and it's done :)

Generated hosts The configuration generated will look as below :

```
define host {
    host_name            i-3fc56e5a
    address              8.8.4.4
    use                  t1.micro,MyTag,EC2,generic-host
    _EC2_AVAILABILITY    us-east-1a
    _EC2_CLIENTTOKEN
    _EC2_DNS_NAME
    _EC2_GROUPS          quicklaunch-1
    _EC2_IMAGEID         ami-1b814f72
    _EC2_INSTANCEID      i-3fc56e5a
    _EC2_INSTANCETYPE    t1.micro
    _EC2_KERNELID        aki-825ea7eb
    _EC2_KEYNAME         testaws
    _EC2_LAUNCHDATETIME  2012-09-26T12:19:38.000Z
    _EC2_LAUNCHINDEX     0
    _EC2_PRIVATE_DNS
    _EC2_PRIVATE_IP
    _EC2_PRODUCTCODE
    _EC2_PUBLIC_IP       8.8.4.4
    _EC2_RAMDISKID       None
    _EC2_STATUS          stopped
    _EC2_TAGS            demo:myvalue,use:MyTag
 }
```

Here with a stopped t1.micro instance with no name. You can put your how "use" parameter by adding a EC2 tag "use" on your VM. It will be output on the host configuration so you can setup the monitoring as you want. .. _libcloud: http://libcloud.apache.org/index.html .. _AWS: https://console.aws.amazon.com

The distributed retention modules The high availability allow the Arbiter to send a configuration to a spare scheduler, but a spare scheduler does not have any saved states for hosts and services. It will have to recheck them all. It's better to use a distributed retention module so spares will have all the information they need to start with an accurate picture of the current states and scheduling :)

Non distributed retention modules If you are just running tests on a single server, use the pickle or memcache retention modules You can also use MongoDB if you already have it installed for use with the WebUI.

MongoDB MongoDB is a scalable, high-performance, open source NoSQL database written in C++.

Step 1: Install MongoDB:

We will use mongodb package from 10gen repository, so we start by adding it in apt sources list:

```
echo 'deb http://downloads-distro.mongodb.org/repo/debian-sysvinit dist 10gen' > /etc/apt/sources.lis
apt-get update
```

And we install it:

```
apt-get install mongodb-10gen
```

And we install pymongo, the python interface to MongoDB, with easy_install to avoid packages versions problems (like here **'forums.monitoring-fr.org/index.php?topic=5205.0'_**):

```
apt-get remove python-pymongo
easy_install pymongo
```

And finally we start MongoDB :

```
/etc/init.d/mongodb start
```

Step 2: define a mongodb_retention module in your shinken-specific.cfg file:

```
define module {
  module_name MongodbRetention
  module_type mongodb_retention
  uri mongodb://localhost/?safe=true
  database shinken
}
```

Step 3: Declare a retention module for your scheduler(s) :)

Example:

```
#The scheduler is a "Host manager". It get hosts and theirs
#services. It scheduler checks for them.
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
     port     7768                  ; tcp port of the daemon

     #optionnal: modules for things as retention
     modules    MongodbRetention
     }
```

Step 4: Restart the Arbiter, and your Scheduler will now save its state between restarts. :)

Memcached Memcached is a distributed memory resident key/value server. It's very easy to install:

```
sudo apt-get install memcached
sudo /etc/init.d/memcached start
```

The shinken module also needs the python-memcache package to talk to this server.

```
sudo apt-get install python-memcache
```

To use it,

Step 1: define a memcache_retention module in your shinken-specific.cfg file:

```
define module{
     module_name      MemcacheRetention
     module_type      memcache_retention
     server           127.0.0.1
     port             11211
}
```

Step 2: Declare a retention module for your scheduler(s) :)

Example:

```
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
     port     7768                  ; tcp port of the daemon

     #optional: modules for things as retention
     modules    MemcacheRetention
     }
```

Step 3: Restart the Arbiter, and your Scheduler will now save its state between restarts. :)

Redis Redis is a distributed key/value server (on disk and in-memory). It's very easy to install:

```
sudo apt-get install redis-server
sudo /etc/init.d/redis-server start
```

The shinken module also need the python-redis package to talk to this server.

```
sudo apt-get install python-redis
```

Step 1: define a redis_retention module in your shinken-specific.cfg file:

```
define module{
     module_name      RedisRetention
     module_type      redis_retention
     server           127.0.0.1
}
```

Step 2: Declare a retention module for your scheduler(s) :)

Example:

```
#The scheduler is a "Host manager". It get hosts and theirs
#services. It scheduler checks for them.
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
```

```
    port     7768                  ; tcp port of the daemon

    #optionnal: modules for things as retention
    modules    RedisRetention
    }
```

Step 3: Restart the Arbiter, and your Scheduler will now save its state between restarts. :) .. _forums.monitoring-fr.org/index.php?topic=5205.0: http://forums.monitoring-fr.org/index.php?topic=5205.0

How to enable and use Livestatus module

Define the Livestatus module Start by reviewing the ''/etc/shinken/shinken-specific.cfg" file for this module:

```
define module{
```

```
module_name      Livestatus
module_type      livestatus
host             *       ; * = listen on all configured IP addresses
port             50000   ; port to listen on
database_file    /var/lib/shinken/livestatus.db
```

}

With these parameters:

- module_name: name of the module called by the brokers
- module_type: livestatus
- host: IP interface to listen to. The default is *, which means "listen on all interfaces".
- port: TCP port to listen to.
- socket: Unix socket to listen to.
- database_file: the path to the sqlite database file which is used to store the log broks/messages. The default is "var/livelogs.db"
- max_logs_age: the maximum age of the log messages (before they are deleted from the database). The default is 1 year. The argument to this parameter takes the form <number>[<period of time>], where <period of time> can be d for days, w for weeks, m for months and y for years.
- allowed_hosts: a comma-separated list of IP-addresses which are allowed to contact the TCP port. Please keep in mind that these **must be IP-addresses, NOT host names**. Because DNS lookups for every incoming livestatus request could hang up and therefore block the module.

Enable the Livestatus module Still in ''/etc/shinken/shinken-specific.cfg'', find the object Broker and add "Livestatus" to its "modules":

```
define broker{
```

```
    broker_name      broker-1
[...]
```

```
    modules          Simple-log,Livestatus
}
```

Disable human readable logs In ‘’/etc/shinken/nagios.cfg’‘, verify that the option **human_timestamp_log** is set to **0**.

In version 0.6.5, you can not have at the same time a simple-log file with human readable timestamp and a Livestatus database.

Exporting data for reporting Shinken can export necessary data for reporting in 3rd party systems.

raw_socket module The raw socket module exports reporting data using a syslog format to a raw TCP socket. Theses logs can be captured, parsed and indexed by any log management system like Splunk or Logstash.

Why export reporting data Custom UIs like Thruk, Multisite, WebUI, Adagios, Nagios IX, etc. All have poor or inflexible reporting. Simply because these are not reporting engines.

This also permits to have a generic reporting method that can accept data from any Nagios, Shinken, Icinga or even Riemann.

Reporting module using Splunk Splunk was selected as the reporting platform for creating, managing and presenting reports. Though the raw_socket module does not have any Splunk specific particularities. It is notable that Splunk reports can be embedded in any 3rd party UI using its REST API.

Raw_socket log format The logs are plain-text and compliant with RFC3164. They use an intelligent date format, a configurable seperator ” “(space by default), and key=value pairs in the message data portion of the log. Should a key or value contain a space they must be double quoted. This is syslog using structured data without going to full out JSON that may not be compatible with all log management systems.

The message fields that are supplied in each status update in addition to the standard syslog header are:

- Hostname
- Servicename
- Business impact
- Host/Service status
- Host/Service previous status
- Acknowedgement status
- Maintenance status

Any time the maintenance, host, service or acknowledgement status changes, a log is sent by the Shinken raw_socket module.

Having all relevant data in each log makes it very easy to compute reports for given time periods.

The hostgroup or service group memberships, custom variables or any other configuration related data should be queried from the monitoring system using its API (Livestatus in the case of Shinken and Nagios).

Raw_socket module availability The module is available in both Shinken 1.4 and Shinken 2.0. The module will be integrated in master branches once unit tests and end-to-end testing is completed. 3rd quarter 2013.

Monitoring Linux System with Glances and checkglances.py **‘Glances‘_** is a fantastic multiplatform system monitoring tool writen by Nicolargo. Glances can run on (Linux, Windows, MacOS ...). There is a growing ecosystem around Glances and of course a Nagios/Shinken plugin : checkglances.py.

How does it work Glances can run in server mode. It provide a XML-RPC server (over http) and allow to retrieve system information throuh a restful API. The only thing to do is to install and start Glances as server on the monitored host, then install checkglances.py on the shinken server and finaly install the glances pack.

Install glances See the glances documentation to install glances on Linux.

<code bash> easy_install glances </code>

There is a debian startup script in the glances repository. And another one for centos here.

Install checkglances.py Just follow the documentation for the checkglances.py prerequisites and put it in your nagios plugins folder.

Install the glances pack Open a terminal as the shinken user and just type the following command

<code bash> shinken install glances </code>

Then just edit the configuration for a linux monitored host and tag it as **glances**

```
define host{
 name mylinuxhost
 use glances
 ...
```

Finaly restart the shinken arbiter

```
service shinken-arbiter restart
```

What will be monitored ? For the moment just the basic system (ram, cpu, load, memory, filesystem and network).

If you want to modify the default thresholds for just a host you can do it by overiding the thresholds macro in your host definition. If you want to do it for several hosts, declare a new template and just add the desired thresholds macro to be overide.

Here is a list of the macros

```
::
```

> _LOAD_WARN 2 _LOAD_CRIT 3 _CPU_WARN 80 _CPU_CRIT 90 _MEMORY_WARN 90 _MEMORY_CRIT 95 _FS /, /home _FS_WARN 90 _FS_CRIT 95 _IFACES eth0, eth1 _NET_WARN 7500000 _NET_CRIT 10000000

Note the _FS and _IFACES macros. They leverage the ability to duplicate service for a given list of things to be monitored. Here you see that / and /home partitions will be monitored. If you want to modify this then just add your own in a new template that will inherit the glances template.

Shinken GLPI integration Shinken supports importing hosts from GLPI

For people not familiar with GLPI, it is an Open-Source CMDB. Applicable to servers, routers, printers or anything you want for that matter. It is also a help-desk tool. GLPI also integrates with tools like FusionInventory for IT inventory management.

You can still have flat files AND GLPI if you want. Hosts imported from GLPI will be treated as standard hosts from flat file (inheritance, groups, etc). In fact, in this first version the module only sends the host_name to Shinken, but there should be more information extracted like network connexions for parents relations in the future. :)

Requirements

- python module MySQLdb
- Compatible version of GLPI Shinken module and GLPI version - ...
- etc..

Enabling GLPI Shinken module In your shinken-specific.cfg file, just add (or uncomment):

```
#You know GLPI? You can load all configuration from this app(
#with the webservices plugins for GLPI, in xmlrpc mode
#and with plugin monitoring for GLPI)
# =============== Work with Plugin Monitoring of GLPI ===============
#All configuration read from this will be added to the others of the
#standard flat file
define module{
     module_name      GLPI
     module_type      glpi
     uri              http://localhost/glpi/plugins/webservices/xmlrpc.php
     login_name       glpi
     login_password   glpi
}
```

And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master
#    host_name       node1       ;result of the hostname command under Unix
     address          localhost                  ;IP or DNS adress
     port             7770
     spare            0
     modules           GLPI
     }
```

It's done :)

Ip Tag module

Why tag a host based on it's IP address? We learned on the *DMZ monitoring* that you can "tag" a host with a poller_tag so it will be checked only by DMZ pollers. It can be tedious process to manually tag all these hosts. Shinken provides an automated method to do this.

This is handled by the arbiter ip_tag module.

Ip_tag module The ip_tag module is an arbiter module that looks up the host address during the configuration parsing and compares it to an predefined IP range (IPV4 or IPV6). If the range matches, it can apply or add a property, such as poller_tag. Other types of tags could be related to locations, functions, administrative groups, etc.

Method: replace or append.

replace will put the value if the property is unset. This is the default method. .. warning:: Fix me: replace, implies overriding an existing value. And will cause user issues down the line. Rename it to set. Replace should be a different method altogether, so overall there should be 3 methods(set, append, replace).

append will add with a , if a value already exist

Here is an example that will set the poller_tag property with the value DMZ of all hosts that:

- have a their hostadress ip (or name resolved) in the range 192.168.0.1/24.
- do not already have a poller_tag property set

```
define module{
```

```
     module_name     IpTag
     module_type     ip_tag
     ip_range        192.168.0.1/24
     property        poller_tag
     value           DMZ
}
```

To use the module add it in the arbiter object:

```
::
```

define arbiter { [...] modules NSCA,IpTag

}

Add value instead of setting it In the previous example we set the property poller_tag to a value. But what if we want to "add" a value, like a template name? We can change the "method" property of the module to "append" so we can add the "value" to the host property instead of replace it.

Here is an example where we want to add the "dmz" template on the hosts, while also keeping any defined templates:

```
define module{
```

```
     module_name   IpTag
     module_type   ip_tag
     ip_range      192.168.0.1/24
     property      use
     value         dmz

     # Optional method
     method append
}
```

For a host defined as:

```
define host{
```

```
     host_name   example_host1
     address     192.168.0.2
     use         linux
}
```

It will be "changed" internaly in:

```
define host{
```

```
     host_name   example_host1
     address     192.168.0.2
     use         linux,dmz
}
```

Name resolution Of course you don't need to set IP address in the address of your host. You can set a hostname, and it will be resolved, and then compared to the range. :)

Ubuntu Landscape import

Description You can import data from Ubuntu Landscape into Shinken to create hosts.

Ubuntu Landscape, is a web app to manage all your linux servers (update and co), which is provided by Canonical, Ubuntu's parent company.

This is an Arbiter import module. The Arbiter manages the configuration.

Prerequisites

You will need the landscape-api package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

define module { module_name Landscape module_type landscape_import

Configure your REAL key and secret from Landscape key PAAAB2CILT80I0ZA0999 secret GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH default_template generic-host ; if the host is not tagged, use this one

If you are using a specific certificate for landscape_api #ca /path/to.ca.cert

If you need a proxy to access https://landscape.canonical.com/api/ #https_proxy http://user:secret@myproxy.com:3128

}

- Put in key and secret your private Landscape access.
- default_template will be used if your host is not "tagged" in Landscape
- If you are using a specific certificate for connexion, give the full path in ca
- You will certainly need an https proxy to access the Landscape API. If so, configure it there.

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master
#    host_name       node1       ;result of the hostname command under Unix
     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           Landscape
     }
```

Restart your Arbiter and it's done :)

Tip: Your "tags" will be applied as templates for your hosts.

Shinken Livestatus API

Overview

- Jump back to Getting Started
- Jump back to *Livestatus module configuration*

What is it Livestatus API is the modern method of interacting with Shinken and Nagios based systems alike.

Originally developed for Nagios, MK Livetstatus, was re-implemented in Python for use with Shinken by professional developers. The access methods and query languages are the same.

Why use it It is fast.

It is network based using TCP.

It is standard for all Nagios and Shinken monitoring systems.

It uses in-memory structures for status data

It uses a back-end database for historical reporting

It uses an SQL based query language

It has a host of powerful nuts and bolts features (authentication, caching, connection persistence, multiple object methods (JSON, Python)).

What can I do with it? All programs and scripts use (or should use) this method to :

- Obtain the current state of hosts and services
- Obtain the current configuration related to hosts and services
- Send administrative commands (downtimes, comments, forcing checks)
- Filter information to display
- Obtain basic reports and event statistics

Shinken being a modern re-implementation of Nagios has additional features that are available in addition to the standard Livestatus API.

Shinken Livestatus API unique features can :

- Obtain Business Impact information
- Obtain intelligent dependency status hosts or services (combines dependency and parent information)
- Obtain Business Process states (same syntax as standard host and service queries)

How does it work Livestatus uses a powerful SQL-like query language. The standard methods and parameters are defined at :

'MK Livestatus reference methods and query language definition'_

Full list of Shinken Livestatus API methods:

'Shinken mapping.py methods'_

What software uses Livestatus to interact with Shinken

Well known Web frontends

- MK Multisite
- Thruk
- NagVis

- Splunk for Nagios

Mobile Web frontends

- get list

Scripts

- Downtime management scripts
- Debug scripts

Installing Livestatus Have you installed the required packages to use the Livestatus module? You can look at the requirement section of the *10 minute installation guide* for the *requirement lists*.

How to enable Livestatus Very simple, jump to the *Shinken Broker configuration* section to enable it. .. _Shinken mapping.py methods: https://github.com/shinken-monitoring/mod-livestatus/blob/master/module/mapping.py .. _MK Livestatus reference methods and query language definition: http://mathias-kettner.de/checkmk_livestatus.html

NSCA module The NSCA daemon module is used to receive send_nsca packets and submit them to the Shinken command pipe. The NSCA module can be loaded by the Receiver or Arbiter process. It will listen on port TCP/5667 for send_nsca packets.

Tip: Passive checks can be submitted *natively to the Shinken command pipe* or from remote hosts to modules, such as NSCA, AMQP or collectd, loaded in the Shinken Arbiter or Receiver process. AMQP is implemented for integration with the Canopsis Hypervisor, but could be re-used for generic messaging.

Note: The Shinken NSCA module implementation is currently limited to the "xor" obfuscation/encryption.

In your shinken-specific.cfg file, just add (or uncomment):

```
::
```

#You can send check result to Shinken using NSCA #using send_nsca command define module{

module_name NSCA module_type nsca_server host * port 5667 encryption_method 0 password helloworld

}

define receiver{

```
receiver_name    receiver-1
address          localhost
port             7773
modules          NSCA

timeout          3             ; 'ping' timeout
data_timeout     120           ; 'data send' timeout
max_check_attempts       3     ;  if at least max_check_attempts ping failed, the node is DEAD

#advanced
realm    All
}
```

This daemon is totally optional.

It's main goal is to get all passive "things" (checks but why not other commands) in distant realms. It will act as a "passive receive buffer" and will then dispatch the data or commands directly to the appropriate Scheduler or Arbiter process.

Data can be received from any Realm, thus the Realm option is nonsensical.

For now there is no init.d script to launch it. .. note:: Verify that the init script has been added.

It is launched like all other daemons:

```
bin/shinken-receiver -c etc/receiverd.ini
```

Tip: Alternatively, for small installations with you can configure a modules inside your Arbiter instead of the Receiver. It will listen the TCP/5667 port for send_nsca packets.

To configure the NSCA module in your Arbiter instead of Receiver. Add the NSCA module to your Arbiter object configuration.

```
::
```

define arbiter{ arbiter_name Arbiter-Master

 # host_name node1 ;result of the hostname command under Unix address localhost ;IP or DNS adress port 7770 spare 0 modules NSCA

}

Retention troubleshooting The retention file contains the state of your host and services, so that they are kept when shinken is restarted.

Sometimes you'll want to inspect (and possibly fix) the retention file, in case you need to work-around a bug or simply better understand what is stored there.

When you use the PickleRetention module in the scheduler (cf. ''define scheduler" in ''shinken-specific.cfg''), you can simply manipulate the retention file using Python.

For this you can use the following code.

- It assumes Shinken is installed in ''/opt/shinken" with the retention file in ''/tmp/retention.dat'':
- Run and play with it interactively using ''ipython -i inspect_retention.py''.

```
#!/usr/bin/python
import pickle
import sys
sys.path.append('/opt/shinken')
import shinken

r = pickle.load(file('/tmp/retention.dat'))
h = r['hosts']

# Example:
# [(k,v) for (k,v) in h['your_host'].items() if k.find('downtime') >= 0]
#
# del h['your_host']
#
# for k,v in r['services'].items():
#     if 'your_host' in k:
#         del r['services'][k]
```

To save your changes:

- Stop Shinken: ‘’service shinken stop’‘
- Save the pickle: ‘’pickle.dump(r, open(‘/tmp/retention.dat’, ‘w’))’‘
- Start Shinken: ‘’service shinken start’‘

NRPE Module

What is it The NRPE module allows Shinken Pollers to bypass the launch of the check_nrpe process. It reads the check command and opens the connection by itself. It scales the use of NRPE for active supervision of servers hosting NRPE agents.

The command definitions should be identical to the check_nrpe calls.

How to define it The definition is very easy (and you probably just have to uncomment it):

```
define module{
     module_name       NrpeBooster
     module_type       nrpe_poller
}
```

Then you add it to your poller object:

```
define poller {
    [...]
    modules   NrpeBooster
}
```

Then just tag all your check_nrpe commands with this module:

```
define command {
   command_name   check_nrpe
   command_line   $USER1$/check_nrpe -H $HOSTADRESS$ -c $ARG1$ -a $ARG2$
   module_type    nrpe_poller
}
```

That’s it. From now on all checks that use this command will use Shinken’s NRPE module and will be launched by it.

Extending Shinken

Introduction There are a lot of “Modules” and “Addons” that are available for Shinken. Shinken can be extended by using different types of methods.

- Web interfaces from various open-source vendors can be used (Based on Livestatus API)
- Shinken itself can be extended using modules that are embedded into the various daemon processes

** (Arbiter, Poller, Receiver, Broker, Scheduler, Reactionner) * External software can provide functional enhancements for reporting, management or usability aspects

Shinken itself provides methods to extend the base functionality:

- *Broker modules* provide external access to runtime data from Shinken
- Poller modules such as *NRPE* and the *SNMP*
- Receiver modules like *NSCA* provide acquisition methods for Shinken

- Arbiter modules permit manipulating the configuration
- The webUI that permits embedding web interface elements

Independent software that works in concert with Shinken is available for:

- Monitoring remote hosts through agent software (*NIX, Windows, etc.)
- Submitting passive checks from remote hosts
- Managing the config files through a web interface
- Mobile phone UIs
- Desktop UIs and Hypervisors
- Desktop notification addons
- ...and much more

You can find many addons that are compatible with Shinken by visiting. The only caveat is that the addons should not use the status.dat file and preferably the modern API interfaces like Livestatus:

- Nagios.org
- SourceForge.net
- NagiosExchange.org
- Shinken community exchange for monitoring packs

Broker modules The broker module receives messages from the Schedulers related to host, service check results. In addition to that it receives a copy of the compiled configuration at startup. What is special about the broker, is that without modules, the broker does nothing. It makes the configuration and result data available to modules. Modules are the ones in charge of doing something with the data. This could be exporting this "raw" data into flat files, databases or exposing it as an API.

The modules are presented according to their use cases.

- Core modules
- Livestatus Module for frontends
- Exporting data to metric databases
- SQL based Modules for frontends
- Exporting data to logging management systems
- Legacy modules for migration purposes
- Modules no longer supported

Core modules

simple_log: get all logs into one file You can get a log for all your daemons in a single file. With the exception of Debug level logs which are not sent through the network as a safe guard. Shinken state messages are ONLY logged at the debug level in the local log files. These are the ALL CAPS states that some 3rd party interfaces use to mine data from the historical logs. Actual state messages are sent as objects between the various daemons.

It takes the parameters:

- module_name: name of the module called by the brokers

- module_type: simple_log
- path: path of the log file

Here is an example:

```
define module{
```

```
     module_name      Simple-log
     module_type      simple_log
     path             /usr/local/shinken/var/nagios.log
     archive_path     /usr/local/shinken/var/archives/
}
```

Syslog - Send all logs to a local syslog server Send all logs to a local syslog server. Support for remote syslog can be implemented if requested. Just lookup the syslog module, easy to modify. Use for example with Splunk, graylog2, Logstash, Elastic search, Kibana, or other log management and analysis system.

```
define module{
```

```
  module_name Syslog
  module_type syslog
}
```

Lightweight forwarder to Splunk Shinken state data from the local syslog can also be sent to a Splunk server for indexing, reports, SLA and analysis. Via syslog or better yet, the Splunk lightweight forwarder which supports, TCP, buffering and security parameters.

Livestatus API Module - Thruk, Nagvis and Multisite Web frontends There are three well known frontends and various small tools that can interface with the Livestatus API. This API is currently the most efficient method of sharing live data with external interfaces. It provides a rich query language similar to SQL, authentication, command execution, caching,connections persistence, multiple object methods (JSON, Python). All Livestatus data is kept in memory, there is no disk IO involved. It exposes configuration objects, the current state of the hosts and services as well as historical Shinken state log messages.

- MK Multisite
- Thruk
- NagVis

Have you installed the required packages to use the Livestatus module? You can look at the requirement section of the 10 minute installation guide for the requirement lists.

Livestatus Module

It takes the following parameters:

- module_name: name of the module called by the brokers
- module_type: livestatus
- host: IP interface to listen to. The default is '127.0.0.1'. '*' means 'listen on all interfaces'.
- port: TCP port to listen to.
- socket: Unix socket to listen to.

- allowed_hosts: a comma-separated list of IP-addresses which are allowed to contact the TCP port. Please keep in mind that these must be ip-addresses, NOT host names. (DNS lookups for every incoming livestatus request could hang up and therefore block the module)
- modules: a comma-separated list of modules (see below)
- pnp_path: relevant if you use the multisite gui. pnp_path points to the perfdata directory where the pnp4nagios data reside (it's the directory which contains a subdirectory for each host). Multisite needs it to display a small perfdata icon if a rrd file exists.
- To deactivate an input, the port- and socket-attributes can also take the value "none".

The Livestatus module itself can have sub-modules. In fact, it **must** have at least one submodule responsible for storing log events to a database, SQLite or MongoDB.

Livestatus module - Logstore Sqlite Stores log-broks to an sqlite database.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_sqlite
- use_aggressive_sql: Prefer the use of sql queries to pre-filter data prior to python filtering. This is required for very large installations, as the Python structures are not indexed when filtering. Optional argument set to 0 by default. To enable set the value to 1. Some erroneous output may occur, but informal testing has shown these corner cases do not occur.
- read_only: don't send any update to the database. Should be used when you run several livestatus modules : 1 instance is R/W, other are read only.
- database_file: the path to the sqlite database file which is used to store the log broks/messages. The default is 'var/livestatus.db'
- archive_path: the path to a subdirectory where database file archives will be created. Every day the data from the last day will be moved to an archive datafile. The default is 'var/archives'.
- max_logs_age: the maximum age of the log messages (before they are deleted from the database). The default is 1 year. The argument to this parameter takes the form <number>[<period of time>], where <period of time> can be d for days, w for weeks, m for months and y for years. This parameter is currently ignored. In future releases it will be used to automatically delete ancient database files.

Here is an example:

```
define module{
```

```
     module_name      Livestatus
     module_type      livestatus
     host             *       ; * = listen on all configured ip addresses
     port             50000   ; port to listen
     socket           /usr/local/shinken/var/rw/live
     modules          logsqlite
}
define module{
```

```
     module_name      logsqlite
     module_type      logstore_sqlite
     use_aggressive_sql     0 ; optional, by default set to 0. Only for large installations.
     database_file    /usr/local/shinken/var/livelogs.db
     max_logs_age     3m ; three months. Other time intervals are d=days, w=weeks, y=years
}
```

Livestatus module - Logstore MongoDB Stores historical log broks(inter daemon Shinken messages) to a MongoDB database. MongoDB is a distributed and very performant database that permits resilience and high availability. The current implementation has a few known broken pieces (some search functions are broken) and there are bugs in the implementation, so it is considered experimental until power users and developers have ironed out the bugs. It is the database of the future for Shinken.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_mongodb
- mongodb_uri: The address of the master. (Default: i_cant_write_the_uri_here_it_messes_the_wiki_up)
- replica_set: If you are running a MongoDB cluster (called a "replica set" in MongoDB), you need to specify it's name here. With this option set, you can also write the mongodb_uri as a comma-separated list of host:port items. (But one is enough, it will be used as a "seed")
- database: <undocumented>
- collection: <undocumented>
- max_logs_age: <undocumented>

The configuration looks quite similar to the sqlite one. **In a single-node installation and with decent amount of log traffic, the sqlite backend should be considered best practice, as it needs no extra software and is stable and fast (when run in-memory).**

Livestatus module - Logstore Null In case you don't need any logging (for instance, if you dedicate a livestatus module instance to nagvis), you can use this module.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_null

Network Based Modules - Graphite graphing Graphite is a graphing and data analysis tool. It is composed of a web frontend (graphite-web), fixed size databases (whisper) and data redistribution/munging daemon. (carbon) The first step is *having Graphite installed somewhere*, if you do not have Graphite installed, please do this and come back later.

Pre-requisite : Shinken 1.2.2+ is recommended for the best experience with Graphite.

graphite_perfdata: exports check result performance data to Graphite Export all performance data included in check results to Whisper databases managed by Graphite. Data is buffered, then exported once every broker time tick. (Once per second). Should a communication loss occur, it will buffer data for 5 minutes before dropping data. The tick_limit max is configurable, the only limitation is the amount of memory the buffered data can eat.

The graphite broker module (v1.2) sends data to graphite in the following format :

HOSTNAME.SERVICENAME.METRICNAME

It can be optionally enhanced to send it the following format :

_GRAPHITE_PRE.HOSTNAME.SOURCE.SERVICENAME.METRICNAME._GRAPHITE_POST

Each of the three variables are optional :

- The _GRAPHITE_PRE variable can be set per host/service to provide a more flexible naming convention. (ex. Prod.site1.Hostname.servicename)

- The _GRAPHITE_POST variable can be set per host/service to specify the more information concerning the variable being stored that graphite can use to determine the retention rule to use for the variable.
- The SOURCE variable can be set in shinken-specific.cfg for the WebUI module and the Graphite broker.

Metric names are converted from Shinken's format to a more restrictive Graphite naming. Unsupported characters are converted to "_" underscore. So do not be surprised to see that some names differ in the WebUI or directly in Graphite. Permitted characters in Graphite are "**A-Za-z_**.", the hyphen character is permitted from Shinken, though only future versions of Graphite will support it.

Performance data transfer method can be set to pickle, which is a binary format that can send data more efficiently than raw ascii.

It takes the following parameters:

- module_name: name of the module called by the brokers
- module_type: graphite_perfdata
- host: ip address of the graphite server running a carbon instance
- port: port where carbon listens for metrics (default: 2003 for raw socket, 2004 for pickle encoded data)
- use_pickle: Use a more efficient transport for sending check results to graphite instead of raw data on the socket (v1.2)
- tick_limit: Number of ticks to buffer performance data during a communication outage with Graphite. On tick limit exceeded, flush to /dev/null and start buffering again. (v1.2)
- graphite_data_source: Set the source name for all data coming from shinken sent to Graphite. This helps diferentiate between data from other sources for the same hostnames. (ex. Diamond, statsd, ganglia, shinken) (v1.2)

Here is an example:

```
define module {
```

```
module_name Graphite-Perfdata
host xx.xx.xx.xx
module_type graphite_perfdata
port 2004 ; default port 2003 for raw data on the socket, 2004 for pickled data
use_pickle 1 ; default value is 0, 1 for pickled data
tick_limit 300 ; Default value 300
graphite_data_source shinken ; default is that the variable is unset
}
```

SQL Based Modules - PNP4Nagios Graphing PNP4Nagios is a graphing tool that has a web interface for RRDTool based databases. Shinken can export performance data to an npcd database which will feed the RRD files (fixed sized round robin databases). You can *learn how to install PNP4Nagios* if you haven't done it already.

npcdmod: export perfdatas to a PNP interface Export all perfdata for PNP.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: npcdmod
- path: path to the npcd config file

Here is an example:

```
define module{
 module_name  NPCD
 module_type  npcdmod
 config_file  /usr/local/pnp4nagios/etc/npcd.cfg
}
```

SQL Based Modules - Frontend Centreon2 Centreon2 use a NDO database, so you will need the ndodb_mysql module for it.

ndodb_mysql: Export to a NDO Mysql database Export status into a NDO/Mysql database. It needs the python module MySQLdb (apt-get install python-mysqldb or easy_install MySQL-python).

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: ndodb_mysql
- database: database name (ex ndo)
- user: database user
- password: database user passworddt
- host: database host
- character_set: utf8 is a good one

Here is an example:

```
define module{
```

```
     module_name      ToNdodb_Mysql
     module_type      ndodb_mysql
     database         ndo       ; database name
     user             root      ; user of the database
     password         root      ; must be changed
     host             localhost ; host to connect to
     character_set    utf8      ;optionnal, UTF8 is the default
}
```

File based Legacy modules - perfdata export

service_perfdata: export service perfdatas to a flat file

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: service_perfdata
- path: path to the service perfdata file you want

Here is an example:

```
define module{
```

```
    module_name      Service-Perfdata
    module_type      service_perfdata
    path             /usr/local/shinken/src/var/service-perfdata
}
```

host_perfdata: export host perfdatas to a flat file

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: host_perfdata
- path: path to the host perfdata file you want

Here is an example:

```
define module{
```

```
    module_name      Host-Perfdata
    module_type      host_perfdata
    path             /usr/local/shinken/src/var/host-perfdata
}
```

Legacy File based Modules - Old CGI or VShell The Old CGI and VShell use the flat file export. If you can, avoid it! It has awful performance, all modern UIs no longer use this.

status_dat: export status into a flat file Export all status into a flat file in the old Nagios format. It's for small/medium environment because it's very slow to parse. It can be used by the Nagios CGI. It also export the objects.cache file for this interface.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: status_dat
- status_file: path of the status.dat file /usr/local/shinken/var/status.dat
- object_cache_file: path of the objects.cache file
- status_update_interval: interval in seconds to generate the status.dat file

Here is an example:

```
define module{
```

```
    module_name              Status-Dat
    module_type              status_dat
    status_file              /usr/local/shinken/var/status.data
    object_cache_file        /usr/local/shinken/var/objects.cache
    status_update_interval   15 ; update status.dat every 15s
}
```

Deprecated or unsupported modules

SQL Based MerlinDB This interface is no longer supported and is going to be completely removed from Shinken.

SQL based ndodb_oracle - Icinga web frontend using NDO Oracle This interface is no longer supported and is going to be completely removed from Shinken.

CouchDB: Export to a Couchdb database This interface is no longer supported and is going to be completely removed from Shinken.

TSCA (Thrift Service Check Acceptor) TSCA is a receiver/arbiter module to receive hosts and services check results. It provides the same functions as NSCA with additional features. High performance binary transmission, multi line output and auto generated clients for a variety of languages.

What is thrift ? Let's cut and paste the wikipedia definition from'en.wikipedia.org/wiki/Apache_Thrift'_ :

"Thrift is an interface definition language that is used to define and create services for numerous languages.[1] It is used as a remote procedure call (RPC) framework [..]. It combines a software stack with a code generation engine to build services that work efficiently to a varying degree and seamlessly between ActionScript, C#, C++ (on POSIX-compliant systems), Cappuccino, Cocoa, Erlang, Haskell, Java, OCaml, Perl, PHP, Python, Ruby, and Smalltalk."

Installation In any case, you have to install thrift with support for python (on the server side) and languages you want to use for clients.

Get it from thrift.apache.org or in your favorite distribution repository.

Server side Go to the tsca module directory and generate the python stub for the server side installation

```
cd shinken/modules/tsca
$ thrift --gen py tsca.thrift
```

Declare the module is shinken-specific.org

```
define module{
      module_name     TSCA
      module_type     tsca_server
      host            0.0.0.0
      port            9090
}
```

Samples clients There are three(3) client samples written in python, ruby and java in contrib/clients/TSCA of the Shinken distribution. You can use and extend them to send data directly in your code directly to Shinken's TSCA receiver/arbiter module.

The samples clients read a CSV file from stdin and send them the the TSCA running on localhost:9090. The CSV has the following format :

```
hostname,service description,output,rc
```

Any use of TCP in an application should take care not to block the program and to have very short timeouts. For applications that need non blocking functions, prefer a UDP based transport or a local buffer file with a separate application(send_nsca, thrift, etc) to forward your data to Shinken.

Ruby Generate the stub

```
$ thrift --gen rb ../../../shinken/modules/tsca/tsca.thrift
```

Run the client

```
$ cat file_state | ruby RubyClient.rb
```

Python Generate the stub

```
$ thrift --gen py ../../../shinken/modules/tsca/tsca.thrift
```

Run the client

```
$ cat file_state | python PythonClient.py
```

java Generate the stub

```
$ thrift --gen java ../../../shinken/modules/tsca/tsca.thrift
```

Compile the client

```
$ ant
```

Run the client

```
$ cat file_state | java JavaClientThrift
```

VMWare Arbiter module

How it works The arbiter has a module that allows the host->VM automatic host dependency creation. In fact, the module is far more generic than just this. It's a generic "host link dependencies" module.

It reads a mapping file (simple json format) with son->father links. It call an external script at a regular interval : the one I wrote is a VMWare mapping one. It used the check_esx3.pl (that all ESX admin should have) plugin and generate the mapping file. When this file is changed, the module reloads it, creates new links and deletes old ones. So when you VMotion a virtual machine, in the next pass, there will be creation of a new link and deletion of the old one in the scheduler that manages it :)

How to define it The definition is very easy :

```
define module{
     module_name       VMWare_auto_linking
     module_type       hot_dependencies
     mapping_file      /tmp/vmware_mapping_file.json
     mapping_command   /usr/local/shinken/libexec/link_vmware_host_vm.py -x '/usr/local/shinken/libex
     mapping_command_interval 60   ; optionnal
     mapping_command_timeout   300 ; optionnal
}
```

Then you add it in you arbiter object :

```
define arbiter {
    [...]
    modules   VMWare_auto_linking
}
```

So here, it will call the script /usr/local/shinken/libexec/link_vmware_host_vm.py with a listing of the vCenter vcenter.mydomain.com and generate the mapping file /tmp/vmware_mapping_file.json.

You can call : /usr/local/shinken/libexec/link_vmware_host_vm.py –help

for the full help on this script.

It looks at the file modification time each second. This command can also be launch by an external cron of course.

Note: So if you want to write a script that does this for XEN servers, all you need is to generate a json file with all the mapping. I didn't wrote the doc about this, but you can look in the test file for it, the format is very very easy :)

Here is an example of the JSON mapping file syntax:

%%:ref:*["host", "physical_host"], ["host", "virtual_machine"* <["host", "physical_host"], ["host", "virtual_machine">, "host", "physical_host"], ["host", "other_virtual_machine" <"host", "physical_host"], ["host", "other_virtual_machine">]%%

So just a list of couple 'host' string (from now only host are managed) and the host name.

Beware about it : you need the real host_name, including case.

Web Service Module The Ws_arbiter module is a Receiver or Arbiter module to receive passive check results from remote hosts via HTTP(s). This module is considered a work in progress but can be used for testing and improvement.

Configuring the Web Service Module If data is POSTed to this page, it will validate the data to determine if it is a service or host check result and submit the data to the Shinken external command queue.

The web service listens by default to TCP port 7760. The web service supports anonymous or authenticated access. Web service parameters are set in the Shinken-specific.cfg file, in the Ws_arbiter module. To enable the web service, simply add the module to your Arbiter or Receiver daemon configuration in Shinken-specific.cfg

Using the Web Service Module The web service listens for POSTs to: /push_check_result

Use curl or embed the HTTP calls in your software to submit check results.

curl -u user:password -d "time_stamp=$(date +%s)&host_name=host-checked&service_description=service-checked&return_code=0&output=Everything OK" http://shinken-srv:7760/push_check_result

Example with more readability:

```
curl
```

-u user:password -d "time_stamp=$(date +%s)

```
&host_name=host-checked
&service_description=service-checked
&return_code=0
&output=Everything OK
http://shinken-srv:7760/push_check_result
```

SNMP module This part must be splitted and sent in all module repositories

Shinken integrated SNMP Module

SnmpBooster Download Install and Configure

- *What is the SnmpBooster module*
- Install and configure the SNMP acquisition module. [You are here]
- *Reference - SnmpBooster troubleshooting*
- *Reference - SnmpBooster design specification*
- *Reference - SnmpBooster configuration dictionnary*

Downloads

The SnmpBooster module and genDevConfig are currently in public beta prior to integration within Shinken. You can consult t

- github.com/xkilian/genDevConfig
- github.com/titilambert/shinken/tree/snmp_booster/shinken/modules (snmp_booster branch) * Simply right-click and download snmp_poller.py then copy it to shinken/modules/

Requirements The SnmpBooster module requires:

- Python 2.6+
- Shinken 1.2+
- PySNMP 4.2.1+ (Python module and its dependencies)
- ConfigObj (Python module)
- python-memcached
- memcachedb or memcached package for your operating system (ex. For Ubuntu: apt-get install memcachedb) *Note*

The genDevConfig profile generator depends on:

- Perl 5.004+
- 4 perl modules available from CPAN and network repositories. genDevConfig/INSTALL has the installation details.

STRONGLY RECOMMENDED: Use the same version of Python and Pyro on all hosts running Shinken processes.

Installation SnmpBooster:

- Install the dependencies
- Copy the file snmp_poller.py from the git repository to your shinken/modules directory.
- Configuration steps are listed in the present web page.

genDevConfig:

- Download and extract the archive to your server.
- See genDevConfig/INSTALL on how to install and configure it.

Configuration

How to define the SnmpBooster module in the Shinken daemons You need to modify shinken-specific.cfg, which is located in $shinken/etc/shinken-specific.cfg

Arbiter daemon configuration Simply declare the module:

```
modules SnmpBooster</code>
```

Scheduler daemon configuration

Simply declare the module:

<code>modules SnmpBooster

Poller daemon configuration Simply declare the module:

```
modules SnmpBooster</code>
```

SnmpBooster Module declaration

Included in Shinken v1.2.1 shinken-specific.cfg.

<code>define module {

```
module_name          SnmpBooster
module_type          snmp_poller
datasource           /usr/local/shinken/etc/packs/network/SnmpBooster/   ; SET THE DIRECTORY FOR YOUR
memcached_host       x.x.x.x  ; SET THE IP ADDRESS OF YOUR memcached SERVER
memcached_port       11211  ; default port for a memcached process
```

}

If you do not know the IP adress on which your memcache is listening, check under /etc/memcached.conf. Or do a:

```
netstat -a | grep memcached</code>
If you are running a test on the local machine you can leave memcached on 127.0.0.1 (localhost), but
```

How to define a Host and Service

Step 1

Create a template for your SNMP enabled devices.

Sample template:

<code>cd shinken/etc/packs/network/ mkdir SnmpBooster

vi shinken/etc/packs/network/SnmpBooster/templates.cfg

```
define command {
```

```
command_name    check_snmp_booster
command_line    check_snmp_booster -H $HOSTNAME$ -C $SNMPCOMMUNITYREAD$ -V 2c -t $ARG1$ -i $_SERVICE
module_type     snmp_poller
```

}

```
define service {
```

```
name                    default-snmp-template
check_command           check_snmp_booster!$_SERVICEDSTEMPLATE$!$_SERVICEINST$!$_SERVICETRIGGERGROUP
_inst                   None
_triggergroup           None
max_check_attempts      3
check_interval          1
retry_interval          1
register                0
```

}

```
define host{
```

```
name                    SnmpBooster-host
alias                   SnmpBooster-host template
check_command           check_host_alive
max_check_attempts      3
check_interval          1
retry_interval          1
use                     generic-host
register                0
```

}

Step 2 Define some hosts and services. You would typically use genDevConfig or another configuration generator to create these for you.

Mandatory service arguments related to SNMP polling:

```
_dstemplate                Cisco-Generic-Router  ; Name of a DSTEMPLATE defined in the SnmpBooster co
```

```
snmpcommunityread    which is set in your resource.cfg file
```

Optional service arguments related to SNMP polling with default values:

```
_inst                   None   ; Could be numeric: 0, None or an instance mapping function like: map
```

```
_triggergroup           None   ; Name of the triggergroup defined in the SnmpBooster config.ini file
```

Sample Shinken host and service configuration:

```
# Generated by genDevConfig 3.0.0
# Args: --showunused -c publicstring 192.168.2.63
# Date: Thu Aug 30 17:47:59 2012

define host {
```

```
 host_name            192.168.2.63
 display_name         192.168.2.63
 _sys_location
 address              192.168.2.63
 hostgroups
 notes
 parents
 use                  default-snmp-host-template
 register             1
}

define service {
```

```
 host_name            192.168.2.63
 service_description  chassis
 display_name         C2960 class chassis
 _dstemplate          Cisco-Generic-Router
 _inst                0
 use                  default-snmp-template
 register             1
}

define service {
```

```
 host_name            192.168.2.63
 service_description  chassis.device-traffic
 display_name         Switch fabric statistics - Packets per Second
 _dstemplate          Device-Traffic
 use                  default-snmp-template
 register             1
}

define service {
```

```
host_name            192.168.2.63
service_description  if.FastEthernet0_1
display_name         FastEthernet0_1 Description: Link to Router-1 100.0 MBits/s ethernetCsmacd
_dstemplate          standard-interface
_inst                map(interface-name,FastEthernet0_1)
use                  default-snmp-template
register             1
```

}

Here is an example configuration of the config.ini file

```
[DATASOURCE]
```

```
  OidmyOidDefinition = .1.3.6.1.45.0
  [myOidDefinition] ; Use the same name as the myOidDeiniftion, but omit the leading "Oid"
      ds_type = DERIVE
      ds_calc = 8,*  ; RPN expression : Oid, 8, *  Which means Oid * 8 = ds_calc
      ds_oid = $OidmyOidDefinition
[DSTEMPLATE]
```

```
  [myCiscoRouter]
      ds = myOidDefinition
[TRIGGER]
```

```
  [trigger1]
      warning = RPN expression
      critical = RPN expression
  [trigger2]
      warning = RPN expression
      critical = RPN expression
[TRIGGERGROUP]
```

```
[CiscoRouterTriggers]
    triggers = trigger1, trigger2
```

Shinken integrated SNMP Module

Overview

What is it The SnmpBooster module allows Shinken Pollers to directly manage SNMP data acquisition. This is an all Python cross-platform SNMP module. It is tightly integrated with the Shinken Poller, Scheduler and Arbiter daemons to provide the best possible user experience.

Design specification summary

- STATUS - DESIGN SPEC PERFORMANCE
- [Done] Functions as an integrated Shinken Poller module
- [Done] Necessary integration code commited to Shinken official release (Integrated starting at v1.2)
- [Done] Ability to collect thousands of SNMP metrics per second
- [Done] Be compatible with distributed data acquisition
- [Done] Collect data for a host/check_interval tuple via SNMP in a single pass
- [Done] Use all builtin Shinken scheduler logic for retries, forced checks, timeouts, dependencies, parents
- [Done] Store collected data for the duration of the check_interval in a memcached/membase
- [Done] On a restart, after the first collection, be able to pick up where the last check left and calculate derived values
- [Done] Forced check are not allowed within 30 seconds of last SNMP query to the same host/check_interval, all other requests get data from the cache.
- [Done] Only a single request to the host/check_interval via SNMP is allowed at a time, all other requests get data from the cache.
- STATUS - DESIGN SPEC USABILITY
- [Done] Usage documentation
- [xxxx] SkonfUI and Discovery usage documentation
- [xxxx] Provide sample configuration packs in Shinken
- [Done] Provide sample config.ini with examples of all types of data * SNMP OIDS, DATASOURCES, DSTEMPLATES, TRIGGERS and TRIGGERGROUPS

- [Done] Directly compatible for use with genDevConfig Shinken SNMP configuration generator
- [Done] Provide meaningful feedback for users on errors
- [Done] Capture all tracebacks and convert them to actual error or warning messages
- STATUS - DESIGN SPEC FEATURES
- [Done] Return state and performance metrics
- [Done] Performance metrics can be returned in a Weathermap compatible format
- [Done] Configuration file format is ConfigObj INI
- [Done] Load all valid INI configuration files from a directory and merge them
- [Done] Load a single INI configuration file
- [xxxx] Load a list of INI configuration files
- [Done] Configuration file describes all generic acquisition parameters (OID, DATASOURCE, DSTEMPLATE, MAP, TRIGGER, TRIGGERGROUP)
- [Done] Supports Triggers which are calculation rules to determine states
- [Done] Triggers support an RPN (Reverse Polish Notation) calculation engine which includes mathematical and logical operators
- [Done] Each TRIGGER is associated with a severity level, WARNING or CRITICAL
- [Done] Multiple TRIGGERS can be associated with a TRIGGERGROUP
- [Done] Use builtin Python Operators
- [Done] Support DERIVE, TEXT, GAUGE and COUNTER data types
- [xxxx] Support TIMETICKS data type
- [Done] Support applying RPN based calculations to received metric for scaling or conversion purposes
- [Done] Use a Python SNMP library which supports asynchronous acquisition PySNMP
- [Done] Datasources can use rule based runtime instance mapping
- [Done] Set Snmp version as a check runtime option
- [Done] Set Snmp DSTEMPLATE as a check runtime option
- [Done] Set Snmp TRIGGERGROUP as a check runtime option
- [Done] Set Snmp COMMUNITY as a check runtime option
- [Done] Use Snmp version 2c GetBulk
- [xxxx] Support Snmp version 2c GetNext if GetBulk is not supported
- [xxxx] Support Snmp version 1 GetNext
- [xxxx] Set Snmp Timeout as a check runtime option, instead of a hardcoded value at 5 seconds
- STATUS - DESIGN SPEC MAINTAINABILITY
- [xxxx] Functions documented in the source code
- [Done] Critical functions documented in the source code
- [Done] Locking sections identified in the code
- [xxxx] Unit tests with at least 80% coverage

- [xxxx] Unit tests integrated with Shinken test suite
- [Done] Code hosted on github
- [xxxx] configuration validity and integrity checking of all INI files
- [xxxx] Pep8 compliant
- [xxxx] Pylint pass

genDevConfig Plugins - Compatibility status with SnmpBooster

- STATUS - genDevConfig maintained Plugins
- [Done] Avaya ES switches
- [Done] Avaya ERS routing switches
- [Done] Cisco 29x0 switches
- [Done] MIB-II Interfaces
- [Done] Cisco PIX/ASA
- [Done] JUNOS devices
- [Done] Cisco IOS routers
- [Done] NetSNMP unix hosts ** Validation required**
- [Done] Packeteer devices ** Validation required**
- [Done] Sensatronics devices ** Validation required**
- [Done] Foundry devices ** Validation required**
- [Done] Packeteer devices ** Validation required**
- [Done] Cisco CSS ** Validation required**
- [InProgress] New Cisco Access points
- STATUS - Other maintained Plugins

Tip: [xxxx] Denotes a specification that is planned but not implemented

[InProgress] Denotes a specification that is under development

[Done] Denotes a specification that is implemented

SnmpBooster reference dictionary

- Jump back to *SnmpBooster documentation index*

SnmpBooster.ini dictionary

There are five dictionaries:

- [DATASOURCE]
- [DSTEMPLATE]
- [MAP]
- [TRIGGER]

- [TRIGGERGROUP]

DATASOURCE DICTIONARY OidVariableName refers to an actual OID that can be queries using SNMP against the device on the network.

[VariableName] refers to a Datasource and all the information required to gather and prepare the data using SNMP ds_type refers to how the data should be prepared ds_calc refers to any scaling manipulations to make the data more understandable. This is an RPN expression, where the first variable is omitted, as it is always the $OidVariable ds_oid refers to the actual $OidVariable name. An instance identifier can be appended to the name to signify that an instance is provided by the Shinken service definition. This information is passed when the check is called. ...

DSTEMPLATE DICTIONNARY [DsTemplateName] refers to the name of the DSTEMPLATE that will be referred to in the Shinken service definitions. ds refers to the list of DATASOURCES to be collected. If an instance is expected for the list of DATASOURCES, it MUST be the same instance for all Oids. If a different instance is required, use a second DSTEMPLATE.

TRIGGER DICTIONNARY

TRIGGERGROUP DICTIONNARY

MAP DICTIONNARY

SnmpBooster.ini example configuration This example definition will be used to explain each section.

[DATASOURCE]

```
OidmyOidDefinition = .1.3.6.1.45.0
[myOidDefinition] ; Use the same name as the myOidDeiniftion, but omit the leading "Oid"
    ds_type = DERIVE
    ds_calc = 8,*  ; RPN expression : Oid, 8, *  Which means Oid * 8 = Total
    ds_oid = $OidmyOidDefinition
```

[DSTEMPLATE]

```
[myCiscoRouter]
    ds = myOidDefinition
```

[TRIGGER]

```
[trigger1]
    warning = RPN expression
    critical = RPN expression
[trigger2]
    warning = RPN expression
    critical = RPN expression
```

[TRIGGERGROUP]

```
[CiscoRouterTriggers]
    triggers = trigger1, trigger2
```

SnmpBooster.ini configuring SNMP Datasources

The first location is generic data related to SNMP parameters.

- DATASOURCE information * SNMP OID * Type of data and how can it be interpreted (GAUGE, COUNTER, COUNTER64, DERIVE, DERIVE64, TEXT, TIMETICK) * Data format preparation (Scaling the data for example bits to bytes) * Is there an instance to append to the
- Instance MAP function * Mapping the instance dynamically using a function * Data or rules related to the mapping function

SnmpBooster.ini configuring SNMP DSTEMPLATES

- DSTEMPLATEs to associate DATASOURCE to actual device classes * List of DATASOURCES associated with a, for example, Cisco 1900 router. Which in turn can be applied to a Shinken service

SnmpBooster.ini setting triggers/thresholds

- TRIGGER and TRIGGERGROUPS to apply thresholding rules * Define triggers and associate them with a TRIGGERGROUP name that can be applied to a Shinken Service

Shinken integrated SNMP Module

Overview

- Jump back to *SnmpBooster documentation index*

Tip: The module is now in public beta as of 2012-10-26! Have Fun!

Nothing new to add, more to come in 2013. 2013-01-19.

What is it The SnmpBooster module allows Shinken Pollers to directly manage SNMP data acquisition. This is an all Python cross-platform SNMP module. It is tightly integrated with the Shinken Poller, Scheduler and Arbiter daemons to provide the best possible user experience.

Why use it The SnmpBooster module is designed to be very efficient and scalable. It has a very flexible configuration method to make it easy to use with Shinken Monitoring Packs and Shinken discovery runners like genDevConfig.

This acquisition module was professionally designed and developed.

It is meant to be used by the very capable discovery engine genDevConfig (**v3.0.5 and newer**) originally developed for the Cricket SNMP monitoring tool and converted for use with Shinken.

It is one of the very few serious SNMP v2c implementation making use of SnmpGetBulk type requests.

How does it work

Shinken Integration

1. The SnmpBooster Arbiter module reads the Shinken SnmpBooster configuration file(s). It reads the check commands and based on the values in the check commands that use the snmp_poller module it will creates a shared configuration cache using memcached/memcachedb. The memcache key is always the combination of the hostname. This permits to tie together Shinken Hosts and Services with the SNMP specific configuration. (MongoDB and Redis are planned to be supported in the future) The Scheduler daemon schedules Host and Service checks as it normally does.

3. The SnmpBooster module will check that a memcache host key exists for the check to be launched. Then the SnmpBooster poller module will query all services related to a host for a given acquisition frequency in one pass. (all checks done every 2 minutes will be executed in bulk, same for those every 5 minutes)

5. Check results are cached for the acquisition check_interval. The next time a check request for data from the same host is received from the Scheduler, the data will be fetched from memcache. Resulting is extremely low check latency.

2. 6. The SNMP checks still benefit from retries, timeouts, forced checks, dependencies and the powerful Scheduler daemon logic.

6. The Scheduler daemon can still force an immediate re-check by flushing the cache. This is required for the dependency model.

Performance SnmpBooster uses SNMP v2c getbulk for high efficiency, unless forced to use SNMP v2c get-next or SNMPv1 get-next. GetBulk uses a single request PDU to ask for multiple OIDs or even entire tables, instead of sending one request PDU per OID.

For example: *A typical 24 port network switch with two uplinks might use 375 OIDS (8 OIDs per interface, plus general OIDs for chassis health, memory, cpu, fans, etc.). **SnmpBooster will only require around 4 request PDUs*

*instead of 375 request PDUs**. Each PDU is a request packet which takes time to create, send get processed and return. More timeouts to manage, more connections, more impact on the remote device and more latency means much fewer checks per second.*

The SnmpBooster module supports automatic instance mapping for OIDs. (Ex. Based on the interface name it will figure out that the SNMP index(or instance) is 136. This is automatically handled by genDevConfig and SnmpBooster, no user input required. :-)

The generic SNMP configuration information is stored in the Shinken SnmpBooster INI files. There is a Defaults_unified.ini and a series of other Defaults files, one per discovery plugin for genDevConfig.

Important: genDevConfig plugins have all been converted to use the new dynamic instance mapping methods. You are now free to use most if not all Defaults*.ini files included with genDevConfig. 2012-10-28

Limitations You should have memcached instances running on each poller responsible for snmp polling. You should have your pollers with SnmpBooster in the same datacenter, as they need to be on the same machine with good connectivity to the active memcached instance. SnmpBooster is not compatible with distributed pollers in multiple datacenters, sorry, the current design of SnmpBooster uses a single centralized memcached instance for storing the timeseries data. For distributed datacenters to be supported, each poller+scheduler+memcached must be realm restrained, which is not the case today.

Design specification *SnmpBooster design specification* and current development status.

Data model The information required to define the data is split in two locations.

The first location is the host and service Shinken configuration (You need to generate or write this)

- Device specific information
  - IP addresses, host_names, device types, instance keys
  - A DSTEMPLATE must be referred to in the Service definition
  - A static SNMP instance could be referred to in the Service definition
  - An SNMP instance MAP function could be referred to in the Service definition
  - A TRIGGERGROUP could be refered to in the Service definition

The second location is SNMP Defaults.* templates. (Here you can create new devices or add new data sources)

- DATASOURCE information
  - SNMP OID
  - Type of data and how can it be interpreted (GAUGE, COUNTER, COUNTER64, DERIVE, DERIVE64, TEXT, TIMETICK)
  - Data format preparation (Scaling the data for example bits to bytes)
  - Is there an instance to append to the
- Instance MAP function * Mapping the instance dynamically using a function * Data or rules related to the mapping function
- DSTEMPLATEs to associate DATASOURCE to actual device classes * List of DATASOURCES associated with a, for example, Cisco 1900 router. Which in turn can be applied to a Shinken service
- TRIGGER and TRIGGERGROUPS to apply thresholding rules * Define triggers and associate them with a TRIGGERGROUP name that can be applied to a Shinken Service

A final location containes rules to build your Shinken configuration.

- genDevConfig plugins create Shinken configurations

Installation and configuration *SnmpBooster installation*

Reference Dictionnary *SnmpBooster reference dictionary*

Troubleshooting *SnmpBooster troubleshooting*

Graph templates These are .graph files defined in your Shinken configuration directory. Refer to the Shinken graphite templates(Not yet created) or PNP4Nagios how-to documentation. The graph templates are independent from SnmpBooster and provide templates for any collected data from Shinken.

SnmpBooster Troubleshooting

- Jump back to *SnmpBooster documentation index*

Check your config

- Have you defined the poller module name?
- Have you defined the correct path to the directory containing your Defaults*.ini files?
- Have you addded the Snmpbooster module to your arbiter, poller, scheduler?
- Have you added copied the genDevConfig templates.cfg in shinken/packs/network/SnmpBooster/
- Have you installed PySNMP, memcached and other dependencies?

Software version consistency Shinken and SnmpBooster now require **the same Python and Pyro version on all hosts running a Shinken daemon**.

If you cannot use the packaged version of Python and its modules (Pyro, memcached, etc.). Use virtualenv to declare a python version to use and install all required modules in that virtualenv.

Software version requirements Have you verified that the *requirements* are met. Python, PySNMP, Shinken, Pyro, memcached, etc.

Validate your check command arguments Use the check_plugin command and comment out the module to learn what were the exact arguments sent by the poller. This will permit you to validate all the arguments, like snmp community string, inheritance, template application, etc.

Validate connectivity

Take a packet trace using a tool like Wireshark to validate that the remote host is responding.

- Has the host responded
- **Is SnmpBooster repeating the request more often than the polling interval.**
  - If you are seeing repeated requests your device may have a compatibility issues.

- Save an snmpwalk of the device, get a packet trace using Wireshark, set the poller to debug and save the poller.log file (shinken/var/poller.log). Send all three to the SnmpBooster developers.
- Note: It is normal to see one or more bulkGet requests if you are getting large amounts of data. Ex. a 24 port switch will take 2-3 request packets.

Performance Make sure you have a low latency connection to your memcache from the Poller. Your memcache server can be replicated to all your poller hosts that should also run memcache instances. Check that memcached is running: netstat -a | grep memcached

Faulty Template A bad snmp_template file was distributed in the genDevConfig sample-config directory, there were two glaring errors.

This was fixed on 2012-10-16. Make sure you update your template, or use the data from the wiki.

Note that the template should be called: SnmpBooster-template.cfg to make it easier to troubleshoot in the logs. So when you search for SnmpBooster in your logs it will show up as well.

Log files All warnings and errors generated by the SnmpBooster module start with "[SnmpBooster] error text" and are logged using the standard Shinken logger.

The Arbiter daemon can output initial configuration, loading of host keys and intervals in memcached type error messages. The Scheduler daemon can output scheduling and alert related messages. The Poller daemon can output messages related to instance mapping, acquisition timeouts, invalid community strings, cache failures and more. These are available in the Web interface, as they are placed in the check results for the service.

You can simply do a "grep SnmpBooster *" in your shinken/var directory to see the latest messages related to the SnmpBooster module. You can also sort messages by timestamp to make it easy to find where and when errors occurred.

cd shinken/var grep SnmpBooster *

memcache persistence If you restart your memcache server or memcache crashes, your poller will no longer be able to validate that a host exists in memcache prior to writing.

You should use memcachedb to achieve persistence in case of memcache failures.

Common errors returned by SnmpBooster in the log file Errors should be fairly explicit and mean what they say, though there can be exceptions. Lets try to clear some of them.

__Arbiter log **errors__**

Missing ds_oid : This means that a variable in your OID definitions is missing, or your DATASOURCE is not named correctly or your ds_oid variable is missing. There is a typo in your ds_oid variable (ex. ds-oid, or ds_oid = $OidNameIncorrectFFFRA.%(instance)s).

Datasource not defined : Your DSTEMPLATE uses a DATASOURCE that doesn't exist check the [DataSourceName] you are referring to. Does it contain the expected OID variable, $OidName.

Missing ds_type : The DATASOURCE always needs to have a ds_type definition, GAUGE, COUNTER, DERIVE, TEXT, TIMETICK, DERIVE64, COUNTER64.

__Poller log **errors__**

Problems with calculations, repeated polling, hosts not responding, etc.

__Memcached **errors__**

memcachedb and memcached do not use the same default port. Configure the correct memcachedb port to match what is declared in your SnmpBooster module under shinken-specific.cfg.

On Ubuntu 12.04 the default installation is on port 21201 instead of 11211. This causes the error "[SnmpBooster] Memcache server (127.0.0.1:11211) is not reachable" when Shinken starts.

To change it, you must edit the file /etc/memcachedb.conf

Memcached Notes On Ubuntu 12.04 the default instalation is on port 21201 instead of 11211. This causes the error "[SnmpBooster] Memcache server (127.0.0.1:11211) is not reachable" when shinken starts.

To change it, you must edit the file /etc/memcachedb.conf

WebUI module This part must be splitted and sent in all module repositories

WebUI integration with Shinken The WebUI is an external broker module. So it's an external process launched by the broker that "eats" broks (broker messages) from the brokers. So it can get *all* broks if you place this broker in your top level realm.

The WebUI does not use a database to get data. Instead, it use a "regenerator" object that will eat each broks, and will "recreate" all Hosts/Services/Contacts objects as if the code was in the scheduler daemon. So basically, WebUI and pages always reflect the CURRENT state of hosts/services objects.

The WebUI http layer is managed by bottle.py. It's a small but powerful framework.

How does the WebUI function globally ?

There a 2 Threads running:

- the main thread is the bottle.py (http) listener. It will use the best backend it finds. We recommend using python-paste. If it does not find one, it will use the default swsgi. Paste is multi-thread, swsgi is mon-thread, so please use paste if you want to avoid locking problems.
- the 2nd thread is the regenerator one. It only gets broks and gives them to the regenerator object.

There is a lock system between the threads. You can have N Http requests in progress without problem, but during this time the renererator one will wait. During execution of the regenerator, no requests are processed. This is not considered a problem, as the regenerator is very quick, and there is only a 1s lock for a 7k service conf loading, so it's not a huge problem.

What is a WebUI User? A WebUI user is a contact. A true contact object. You must match a contact name for your user.

To create a new page? All pages are in the shinken/webui/plugins directory. Each "part" has it's own directory. A part (like the eltdetail, element detail) can have more than one "page" (like /host or /service for eltdetail).

From here we will supose you want to create a "/contact" page.

You can copy the dummy example in the plugins directory into a contact directory.

You need to change the contact/dummy.py file into a contact/contact.py file, because the webui will search for a dir/dir.py file to "load".

Templates Templates are HTML with some Python code in it in the plugins/*/views direcotry for specific templates, and the "global layout" (menu and all common part) in the webui/views directory.

Your template must call the template layout (layout.tpl in the webui/views directory) wit ha "rebase" call.

If you put the rebase call at the beginning of your template, all there is below will be place "inside" the layout that will call the common javascripts and css, make the menu adn then call your html/python code.

The rebase call can take arguments. You MUST give it:

- user: the user you give it in the return dict of your .py code

Then all is optional:

- title: title of the page
- top_right_banner_state: int, global state with clouds to put in your top right page. Look at the problem.tpl code for an example.
- js and css list: list of YOUR specific javascript or css to call AFTER the common ones.
- refresh: boolean, set the refresh to 60s or do not refresh at all

- menu_part: will put the little "^" under this part of the menu.

Example of a call, taken from the problems view:

```
rebase layout title='All problems', top_right_banner_state=top_right_banner_state, js=['problems/js/a
roblems/js/autocompleter.Request.js', 'problems/js/autocompleterObserver.js'], css=['problems/css/acc
ms/css/autocompleter.css', 'problems/css/perfometer.css'], refresh=True, menu_part='/'+page, user=use
```

Call Python objects in your templates Your templates are mainly HTML code. But of course you can call python code in it. The dict you returns in the plugin.py call will be available in this page.

For example, the my_host variable will be available in the page with the host object you find (or None if your give it a bad name of course). Then you can "call" python with for example here to show the host_name: `<span>My host name is *my_host.host_name* </span>` is a way in the templates to "call a variable or function" that will return a string, here the host_name.

If the function or property you call must return HTML code that SHOULD be output as it, without "protection", you must put a ! before your call.

Let use an example where the output value of an host is in fact an html output. If you use the code `my_host.output`, bottle.py will "protect" the html generated by escaping the string, and change <> characters with escaped value. You can change this by calling `my_host.output`. Of course, it's a security problem if the output is with a javascript code...

You can also "loop" or put "if" in your template. You just need to put your code with a % before. Like

```
%for i in xrange(1, 10):
  My valus is  {{i}}
%end
```

You must put the %end here, the indentation will NOT be enougth, sorry.

For an if it's also easy:

```
%if host.active_checks_enabled:
  The host got active checks enabled
%else:
  The host DO NOT have active check enabled
%end
```

Which javascript lib are you using? It's mootools 1.3 with all options :)

What to do?

- Finish the /mobile part
- List of current alerts
- Host info
- Host status
- Host interfaces
- Hostgroup status
- dashboard hierachique with states, and BP
- Nagvis
- add bp in nagvis auto-map

- event sources
- correlation
- pre-filtering/enrichment
- user profile
- host/srv conf

WebUI search syntax work in progress

not that we couldn't tell. ;) eh eh

beware the working men and flying tools!

WebUI SSL Certification Lets start: the goal to to have the server.pem and client.pem file in etc/certs.

Go to the etc/certs directory.

```
openssl req -new -nodes -out server.req -keyout server.key -config ./shinken_openssl_cnf
openssl ca -out server.pem -config ./shinken_openssl_cnf -infiles server.req
cp server.pem server.pem.bkp
cp server.key server.pem
cat server.pem.bkp >> server.pem
cp server.pem client.pem
```

You can try to get the validity with for the arbiter with:

```
openssl s_client -connect localhost:7770</code>
```

Amazon AWS/EC2 import

Description You can import data from Amazon AWS/EC2 **'AWS'**_ into Shinken to create hosts.

Amazon provide VM hosting with EC2. With this arbiter module, you will be able to load your EC2 hosts into Shinken.

Prerequisites

You will need the **'libcloud'**_ package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

```
define module {
 module_name      AWS
 module_type      aws_import

 # Configure your REAL key and secret for AWS
 api_key              PAAAB2CILT80I0ZA0999
 secret           GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH
 default_template generic-host        ; if the host is not tagged, use this one
 }
```

- Put in key and secret your private Landscape access. * default_template will be used if your host is not "tagged" in Landscape

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master

     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           AWS
     }
```

Restart your Arbiter and it's done :)

Generated hosts The configuration generated will look as below :

```
define host {
    host_name            i-3fc56e5a
    address              8.8.4.4
    use                  t1.micro,MyTag,EC2,generic-host
    _EC2_AVAILABILITY    us-east-1a
    _EC2_CLIENTTOKEN
    _EC2_DNS_NAME
    _EC2_GROUPS          quicklaunch-1
    _EC2_IMAGEID         ami-1b814f72
    _EC2_INSTANCEID      i-3fc56e5a
    _EC2_INSTANCETYPE    t1.micro
    _EC2_KERNELID        aki-825ea7eb
    _EC2_KEYNAME         testaws
    _EC2_LAUNCHDATETIME  2012-09-26T12:19:38.000Z
    _EC2_LAUNCHINDEX     0
    _EC2_PRIVATE_DNS
    _EC2_PRIVATE_IP
    _EC2_PRODUCTCODE
    _EC2_PUBLIC_IP       8.8.4.4
    _EC2_RAMDISKID       None
    _EC2_STATUS          stopped
    _EC2_TAGS            demo:myvalue,use:MyTag
 }
```

Here with a stopped t1.micro instance with no name. You can put your how "use" parameter by adding a EC2 tag "use" on your VM. It will be output on the host configuration so you can setup the monitoring as you want. .. _libcloud: http://libcloud.apache.org/index.html .. _AWS: https://console.aws.amazon.com

Amazon AWS/EC2 import

Description You can import data from Amazon AWS/EC3 **'AWS'**_ into Shinken to create hosts.

Amazon provide VM hosting with EC3. With this arbiter module, you will be able to load your EC2 hosts into Shinken.

Prerequisites

You will need the **'libcloud'**_ package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

```
define module {
 module_name      AWS
 module_type      aws_import

 # Configure your REAL key and secret for AWS
 api_key              PAAAB2CILT80I0ZA0999
 secret           GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH
 default_template generic-host        ; if the host is not tagged, use this one
 }
```

- Put in key and secret your private Landscape access. * default_template will be used if your host is not "tagged" in Landscape

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master

     address          localhost                  ;IP or DNS adress
     port             7770
     spare            0
     modules           AWS
     }
```

Restart your Arbiter and it's done :)

Generated hosts The configuration generated will look as below :

```
define host {
    host_name            i-3fc56e5a
    address              8.8.4.4
    use                  t1.micro,MyTag,EC2,generic-host
    _EC2_AVAILABILITY    us-east-1a
    _EC2_CLIENTTOKEN
    _EC2_DNS_NAME
    _EC2_GROUPS          quicklaunch-1
    _EC2_IMAGEID         ami-1b814f72
    _EC2_INSTANCEID      i-3fc56e5a
    _EC2_INSTANCETYPE    t1.micro
    _EC2_KERNELID        aki-825ea7eb
    _EC2_KEYNAME         testaws
    _EC2_LAUNCHDATETIME  2012-09-26T12:19:38.000Z
    _EC2_LAUNCHINDEX     0
    _EC2_PRIVATE_DNS
    _EC2_PRIVATE_IP
    _EC2_PRODUCTCODE
    _EC2_PUBLIC_IP       8.8.4.4
    _EC2_RAMDISKID       None
    _EC2_STATUS          stopped
    _EC2_TAGS            demo:myvalue,use:MyTag
 }
```

Here with a stopped t1.micro instance with no name. You can put your how "use" parameter by adding a EC2 tag "use" on your VM. It will be output on the host configuration so you can setup the monitoring as you want. .. _libcloud: http://libcloud.apache.org/index.html .. _AWS: https://console.aws.amazon.com

The distributed retention modules The high availability allow the Arbiter to send a configuration to a spare scheduler, but a spare scheduler does not have any saved states for hosts and services. It will have to recheck them all. It's better to use a distributed retention module so spares will have all the information they need to start with an accurate picture of the current states and scheduling :)

Non distributed retention modules If you are just running tests on a single server, use the pickle or memcache retention modules You can also use MongoDB if you already have it installed for use with the WebUI.

MongoDB MongoDB is a scalable, high-performance, open source NoSQL database written in C++.

Step 1: Install MongoDB:

We will use mongodb package from 10gen repository, so we start by adding it in apt sources list:

```
echo 'deb http://downloads-distro.mongodb.org/repo/debian-sysvinit dist 10gen' > /etc/apt/sources.lis
apt-get update
```

And we install it:

```
apt-get install mongodb-10gen
```

And we install pymongo, the python interface to MongoDB, with easy_install to avoid packages versions problems (like here **'forums.monitoring-fr.org/index.php?topic=5205.0'_**):

```
apt-get remove python-pymongo
easy_install pymongo
```

And finally we start MongoDB :

```
/etc/init.d/mongodb start
```

Step 2: define a mongodb_retention module in your shinken-specific.cfg file:

```
define module {
  module_name MongodbRetention
  module_type mongodb_retention
  uri mongodb://localhost/?safe=true
  database shinken
}
```

Step 3: Declare a retention module for your scheduler(s) :)

Example:

```
#The scheduler is a "Host manager". It get hosts and theirs
#services. It scheduler checks for them.
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
     port     7768                  ; tcp port of the daemon

     #optionnal: modules for things as retention
     modules    MongodbRetention
     }
```

Step 4: Restart the Arbiter, and your Scheduler will now save its state between restarts. :)

Memcached Memcached is a distributed memory resident key/value server. It's very easy to install:

```
sudo apt-get install memcached
sudo /etc/init.d/memcached start
```

The shinken module also needs the python-memcache package to talk to this server.

```
sudo apt-get install python-memcache
```

To use it,

Step 1: define a memcache_retention module in your shinken-specific.cfg file:

```
define module{
     module_name      MemcacheRetention
     module_type      memcache_retention
     server           127.0.0.1
     port             11211
}
```

Step 2: Declare a retention module for your scheduler(s) :)

Example:

```
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
     port     7768                  ; tcp port of the daemon

     #optional: modules for things as retention
     modules    MemcacheRetention
     }
```

Step 3: Restart the Arbiter, and your Scheduler will now save its state between restarts. :)

Redis Redis is a distributed key/value server (on disk and in-memory). It's very easy to install:

```
sudo apt-get install redis-server
sudo /etc/init.d/redis-server start
```

The shinken module also need the python-redis package to talk to this server.

```
sudo apt-get install python-redis
```

Step 1: define a redis_retention module in your shinken-specific.cfg file:

```
define module{
     module_name      RedisRetention
     module_type      redis_retention
     server           127.0.0.1
}
```

Step 2: Declare a retention module for your scheduler(s) :)

Example:

```
#The scheduler is a "Host manager". It get hosts and theirs
#services. It scheduler checks for them.
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
```

```
    port     7768                  ; tcp port of the daemon

    #optionnal: modules for things as retention
    modules    RedisRetention
    }
```

Step 3: Restart the Arbiter, and your Scheduler will now save its state between restarts. :) .. _forums.monitoring-fr.org/index.php?topic=5205.0: http://forums.monitoring-fr.org/index.php?topic=5205.0

How to enable and use Livestatus module

Define the Livestatus module Start by reviewing the ''/etc/shinken/shinken-specific.cfg" file for this module:

```
define module{
```

```
module_name      Livestatus
module_type      livestatus
host             *       ; * = listen on all configured IP addresses
port             50000   ; port to listen on
database_file    /var/lib/shinken/livestatus.db
```

}

With these parameters:

- module_name: name of the module called by the brokers
- module_type: livestatus
- host: IP interface to listen to. The default is *, which means "listen on all interfaces".
- port: TCP port to listen to.
- socket: Unix socket to listen to.
- database_file: the path to the sqlite database file which is used to store the log broks/messages. The default is "var/livelogs.db"
- max_logs_age: the maximum age of the log messages (before they are deleted from the database). The default is 1 year. The argument to this parameter takes the form <number>[<period of time>], where <period of time> can be d for days, w for weeks, m for months and y for years.
- allowed_hosts: a comma-separated list of IP-addresses which are allowed to contact the TCP port. Please keep in mind that these **must be IP-addresses, NOT host names**. Because DNS lookups for every incoming livestatus request could hang up and therefore block the module.

Enable the Livestatus module Still in ''/etc/shinken/shinken-specific.cfg'', find the object Broker and add "Livestatus" to its "modules":

```
define broker{
```

```
    broker_name      broker-1
[...]
```

```
    modules          Simple-log,Livestatus
}
```

Disable human readable logs In ‘’/etc/shinken/nagios.cfg’‘, verify that the option **human_timestamp_log** is set to **0**.

In version 0.6.5, you can not have at the same time a simple-log file with human readable timestamp and a Livestatus database.

Exporting data for reporting Shinken can export necessary data for reporting in 3rd party systems.

raw_socket module The raw socket module exports reporting data using a syslog format to a raw TCP socket. Theses logs can be captured, parsed and indexed by any log management system like Splunk or Logstash.

Why export reporting data Custom UIs like Thruk, Multisite, WebUI, Adagios, Nagios IX, etc. All have poor or inflexible reporting. Simply because these are not reporting engines.

This also permits to have a generic reporting method that can accept data from any Nagios, Shinken, Icinga or even Riemann.

Reporting module using Splunk Splunk was selected as the reporting platform for creating, managing and presenting reports. Though the raw_socket module does not have any Splunk specific particularities. It is notable that Splunk reports can be embedded in any 3rd party UI using its REST API.

Raw_socket log format The logs are plain-text and compliant with RFC3164. They use an intelligent date format, a configurable seperator ” “(space by default), and key=value pairs in the message data portion of the log. Should a key or value contain a space they must be double quoted. This is syslog using structured data without going to full out JSON that may not be compatible with all log management systems.

The message fields that are supplied in each status update in addition to the standard syslog header are:

- Hostname
- Servicename
- Business impact
- Host/Service status
- Host/Service previous status
- Acknowedgement status
- Maintenance status

Any time the maintenance, host, service or acknowledgement status changes, a log is sent by the Shinken raw_socket module.

Having all relevant data in each log makes it very easy to compute reports for given time periods.

The hostgroup or service group memberships, custom variables or any other configuration related data should be queried from the monitoring system using its API (Livestatus in the case of Shinken and Nagios).

Raw_socket module availability The module is available in both Shinken 1.4 and Shinken 2.0. The module will be integrated in master branches once unit tests and end-to-end testing is completed. 3rd quarter 2013.

Monitoring Linux System with Glances and checkglances.py **‘Glances‘_** is a fantastic multiplatform system monitoring tool writen by Nicolargo. Glances can run on (Linux, Windows, MacOS ...). There is a growing ecosystem around Glances and of course a Nagios/Shinken plugin : checkglances.py.

How does it work Glances can run in server mode. It provide a XML-RPC server (over http) and allow to retrieve system information throuh a restful API. The only thing to do is to install and start Glances as server on the monitored host, then install checkglances.py on the shinken server and finaly install the glances pack.

Install glances See the glances documentation to install glances on Linux.

<code bash> easy_install glances </code>

There is a debian startup script in the glances repository. And another one for centos here.

Install checkglances.py Just follow the documentation for the checkglances.py prerequisites and put it in your nagios plugins folder.

Install the glances pack Open a terminal as the shinken user and just type the following command

<code bash> shinken install glances </code>

Then just edit the configuration for a linux monitored host and tag it as **glances**

```
define host{
 name mylinuxhost
 use glances
 ...
```

Finaly restart the shinken arbiter

```
service shinken-arbiter restart
```

What will be monitored ? For the moment just the basic system (ram, cpu, load, memory, filesystem and network).

If you want to modify the default thresholds for just a host you can do it by overiding the thresholds macro in your host definition. If you want to do it for several hosts, declare a new template and just add the desired thresholds macro to be overide.

Here is a list of the macros

```
::
```

> _LOAD_WARN 2 _LOAD_CRIT 3 _CPU_WARN 80 _CPU_CRIT 90 _MEMORY_WARN 90 _MEMORY_CRIT 95 _FS /, /home _FS_WARN 90 _FS_CRIT 95 _IFACES eth0, eth1 _NET_WARN 7500000 _NET_CRIT 10000000

Note the _FS and _IFACES macros. They leverage the ability to duplicate service for a given list of things to be monitored. Here you see that / and /home partitions will be monitored. If you want to modify this then just add your own in a new template that will inherit the glances template.

Shinken GLPI integration Shinken supports importing hosts from GLPI

For people not familiar with GLPI, it is an Open-Source CMDB. Applicable to servers, routers, printers or anything you want for that matter. It is also a help-desk tool. GLPI also integrates with tools like FusionInventory for IT inventory management.

You can still have flat files AND GLPI if you want. Hosts imported from GLPI will be treated as standard hosts from flat file (inheritance, groups, etc). In fact, in this first version the module only sends the host_name to Shinken, but there should be more information extracted like network connexions for parents relations in the future. :)

Requirements

- python module MySQLdb
- Compatible version of GLPI Shinken module and GLPI version - ...
- etc..

Enabling GLPI Shinken module In your shinken-specific.cfg file, just add (or uncomment):

```
#You know GLPI? You can load all configuration from this app(
#with the webservices plugins for GLPI, in xmlrpc mode
#and with plugin monitoring for GLPI)
# =============== Work with Plugin Monitoring of GLPI ===============
#All configuration read from this will be added to the others of the
#standard flat file
define module{
     module_name      GLPI
     module_type      glpi
     uri              http://localhost/glpi/plugins/webservices/xmlrpc.php
     login_name       glpi
     login_password   glpi
}
```

And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master
#    host_name       node1       ;result of the hostname command under Unix
     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           GLPI
     }
```

It's done :)

Ip Tag module

Why tag a host based on it's IP address? We learned on the *DMZ monitoring* that you can "tag" a host with a poller_tag so it will be checked only by DMZ pollers. It can be tedious process to manually tag all these hosts. Shinken provides an automated method to do this.

This is handled by the arbiter ip_tag module.

Ip_tag module The ip_tag module is an arbiter module that looks up the host address during the configuration parsing and compares it to an predefined IP range (IPV4 or IPV6). If the range matches, it can apply or add a property, such as poller_tag. Other types of tags could be related to locations, functions, administrative groups, etc.

Method: replace or append.

replace will put the value if the property is unset. This is the default method. .. warning:: Fix me: replace, implies overriding an existing value. And will cause user issues down the line. Rename it to set. Replace should be a different method altogether, so overall there should be 3 methods(set, append, replace).

append will add with a , if a value already exist

Here is an example that will set the poller_tag property with the value DMZ of all hosts that:

- have a their hostadress ip (or name resolved) in the range 192.168.0.1/24.
- do not already have a poller_tag property set

```
define module{
```

```
     module_name     IpTag
     module_type     ip_tag
     ip_range        192.168.0.1/24
     property        poller_tag
     value           DMZ
}
```

To use the module add it in the arbiter object:

```
::
```

define arbiter { [...] modules NSCA,IpTag

}

Add value instead of setting it In the previous example we set the property poller_tag to a value. But what if we want to "add" a value, like a template name? We can change the "method" property of the module to "append" so we can add the "value" to the host property instead of replace it.

Here is an example where we want to add the "dmz" template on the hosts, while also keeping any defined templates:

```
define module{
```

```
     module_name   IpTag
     module_type   ip_tag
     ip_range      192.168.0.1/24
     property      use
     value         dmz

     # Optional method
     method append
}
```

For a host defined as:

```
define host{
```

```
     host_name   example_host1
     address     192.168.0.2
     use         linux
}
```

It will be "changed" internaly in:

```
define host{
```

```
     host_name   example_host1
     address     192.168.0.2
     use         linux,dmz
}
```

Name resolution Of course you don't need to set IP address in the address of your host. You can set a hostname, and it will be resolved, and then compared to the range. :)

Ubuntu Landscape import

Description You can import data from Ubuntu Landscape into Shinken to create hosts.

Ubuntu Landscape, is a web app to manage all your linux servers (update and co), which is provided by Canonical, Ubuntu's parent company.

This is an Arbiter import module. The Arbiter manages the configuration.

Prerequisites

You will need the landscape-api package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

define module { module_name Landscape module_type landscape_import

Configure your REAL key and secret from Landscape key PAAAB2CILT80I0ZA0999 secret GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH default_template generic-host ; if the host is not tagged, use this one

If you are using a specific certificate for landscape_api #ca /path/to.ca.cert

If you need a proxy to access https://landscape.canonical.com/api/ #https_proxy http://user:secret@myproxy.com:3128

}

- Put in key and secret your private Landscape access.
- default_template will be used if your host is not "tagged" in Landscape
- If you are using a specific certificate for connexion, give the full path in ca
- You will certainly need an https proxy to access the Landscape API. If so, configure it there.

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master
#    host_name       node1       ;result of the hostname command under Unix
     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           Landscape
     }
```

Restart your Arbiter and it's done :)

Tip: Your "tags" will be applied as templates for your hosts.

Shinken Livestatus API

Overview

- Jump back to Getting Started
- Jump back to *Livestatus module configuration*

What is it Livestatus API is the modern method of interacting with Shinken and Nagios based systems alike.

Originally developed for Nagios, MK Livetstatus, was re-implemented in Python for use with Shinken by professional developers. The access methods and query languages are the same.

Why use it It is fast.

It is network based using TCP.

It is standard for all Nagios and Shinken monitoring systems.

It uses in-memory structures for status data

It uses a back-end database for historical reporting

It uses an SQL based query language

It has a host of powerful nuts and bolts features (authentication, caching, connection persistence, multiple object methods (JSON, Python)).

What can I do with it? All programs and scripts use (or should use) this method to :

- Obtain the current state of hosts and services
- Obtain the current configuration related to hosts and services
- Send administrative commands (downtimes, comments, forcing checks)
- Filter information to display
- Obtain basic reports and event statistics

Shinken being a modern re-implementation of Nagios has additional features that are available in addition to the standard Livestatus API.

Shinken Livestatus API unique features can :

- Obtain Business Impact information
- Obtain intelligent dependency status hosts or services (combines dependency and parent information)
- Obtain Business Process states (same syntax as standard host and service queries)

How does it work Livestatus uses a powerful SQL-like query language. The standard methods and parameters are defined at :

'MK Livestatus reference methods and query language definition'_

Full list of Shinken Livestatus API methods:

'Shinken mapping.py methods'_

What software uses Livestatus to interact with Shinken

Well known Web frontends

- MK Multisite
- Thruk
- NagVis

- Splunk for Nagios

Mobile Web frontends

- get list

Scripts

- Downtime management scripts
- Debug scripts

Installing Livestatus Have you installed the required packages to use the Livestatus module? You can look at the requirement section of the *10 minute installation guide* for the *requirement lists*.

How to enable Livestatus Very simple, jump to the *Shinken Broker configuration* section to enable it. .. _Shinken mapping.py methods: https://github.com/shinken-monitoring/mod-livestatus/blob/master/module/mapping.py .. _MK Livestatus reference methods and query language definition: http://mathias-kettner.de/checkmk_livestatus.html

NSCA module The NSCA daemon module is used to receive send_nsca packets and submit them to the Shinken command pipe. The NSCA module can be loaded by the Receiver or Arbiter process. It will listen on port TCP/5667 for send_nsca packets.

Tip: Passive checks can be submitted *natively to the Shinken command pipe* or from remote hosts to modules, such as NSCA, AMQP or collectd, loaded in the Shinken Arbiter or Receiver process. AMQP is implemented for integration with the Canopsis Hypervisor, but could be re-used for generic messaging.

Note: The Shinken NSCA module implementation is currently limited to the "xor" obfuscation/encryption.

In your shinken-specific.cfg file, just add (or uncomment):

```
::
```

#You can send check result to Shinken using NSCA #using send_nsca command define module{

module_name NSCA module_type nsca_server host * port 5667 encryption_method 0 password helloworld

}

define receiver{

```
receiver_name    receiver-1
address          localhost
port             7773
modules          NSCA

timeout          3             ; 'ping' timeout
data_timeout     120           ; 'data send' timeout
max_check_attempts       3     ;  if at least max_check_attempts ping failed, the node is DEAD

#advanced
realm    All
}
```

This daemon is totally optional.

It's main goal is to get all passive "things" (checks but why not other commands) in distant realms. It will act as a "passive receive buffer" and will then dispatch the data or commands directly to the appropriate Scheduler or Arbiter process.

Data can be received from any Realm, thus the Realm option is nonsensical.

For now there is no init.d script to launch it. .. note:: Verify that the init script has been added.

It is launched like all other daemons:

```
bin/shinken-receiver -c etc/receiverd.ini
```

Tip: Alternatively, for small installations with you can configure a modules inside your Arbiter instead of the Receiver. It will listen the TCP/5667 port for send_nsca packets.

To configure the NSCA module in your Arbiter instead of Receiver. Add the NSCA module to your Arbiter object configuration.

```
::
```

define arbiter{ arbiter_name Arbiter-Master

 # host_name node1 ;result of the hostname command under Unix address localhost ;IP or DNS adress port 7770 spare 0 modules NSCA

}

Retention troubleshooting The retention file contains the state of your host and services, so that they are kept when shinken is restarted.

Sometimes you'll want to inspect (and possibly fix) the retention file, in case you need to work-around a bug or simply better understand what is stored there.

When you use the PickleRetention module in the scheduler (cf. ''define scheduler" in ''shinken-specific.cfg''), you can simply manipulate the retention file using Python.

For this you can use the following code.

- It assumes Shinken is installed in ''/opt/shinken" with the retention file in ''/tmp/retention.dat'':
- Run and play with it interactively using ''ipython -i inspect_retention.py''.

```
#!/usr/bin/python
import pickle
import sys
sys.path.append('/opt/shinken')
import shinken

r = pickle.load(file('/tmp/retention.dat'))
h = r['hosts']

# Example:
# [(k,v) for (k,v) in h['your_host'].items() if k.find('downtime') >= 0]
#
# del h['your_host']
#
# for k,v in r['services'].items():
#     if 'your_host' in k:
#         del r['services'][k]
```

To save your changes:

- Stop Shinken: ‘’service shinken stop’‘
- Save the pickle: ‘’pickle.dump(r, open(‘/tmp/retention.dat’, ‘w’))’‘
- Start Shinken: ‘’service shinken start’‘

NRPE Module

What is it The NRPE module allows Shinken Pollers to bypass the launch of the check_nrpe process. It reads the check command and opens the connection by itself. It scales the use of NRPE for active supervision of servers hosting NRPE agents.

The command definitions should be identical to the check_nrpe calls.

How to define it The definition is very easy (and you probably just have to uncomment it):

```
define module{
     module_name       NrpeBooster
     module_type       nrpe_poller
}
```

Then you add it to your poller object:

```
define poller {
    [...]
    modules   NrpeBooster
}
```

Then just tag all your check_nrpe commands with this module:

```
define command {
   command_name   check_nrpe
   command_line   $USER1$/check_nrpe -H $HOSTADRESS$ -c $ARG1$ -a $ARG2$
   module_type    nrpe_poller
}
```

That’s it. From now on all checks that use this command will use Shinken’s NRPE module and will be launched by it.

Extending Shinken

Introduction There are a lot of “Modules” and “Addons” that are available for Shinken. Shinken can be extended by using different types of methods.

- Web interfaces from various open-source vendors can be used (Based on Livestatus API)
- Shinken itself can be extended using modules that are embedded into the various daemon processes

** (Arbiter, Poller, Receiver, Broker, Scheduler, Reactionner) * External software can provide functional enhancements for reporting, management or usability aspects

Shinken itself provides methods to extend the base functionality:

- *Broker modules* provide external access to runtime data from Shinken
- Poller modules such as *NRPE* and the *SNMP*
- Receiver modules like *NSCA* provide acquisition methods for Shinken

- Arbiter modules permit manipulating the configuration
- The webUI that permits embedding web interface elements

Independent software that works in concert with Shinken is available for:

- Monitoring remote hosts through agent software (*NIX, Windows, etc.)
- Submitting passive checks from remote hosts
- Managing the config files through a web interface
- Mobile phone UIs
- Desktop UIs and Hypervisors
- Desktop notification addons
- ...and much more

You can find many addons that are compatible with Shinken by visiting. The only caveat is that the addons should not use the status.dat file and preferably the modern API interfaces like Livestatus:

- Nagios.org
- SourceForge.net
- NagiosExchange.org
- Shinken community exchange for monitoring packs

Broker modules The broker module receives messages from the Schedulers related to host, service check results. In addition to that it receives a copy of the compiled configuration at startup. What is special about the broker, is that without modules, the broker does nothing. It makes the configuration and result data available to modules. Modules are the ones in charge of doing something with the data. This could be exporting this "raw" data into flat files, databases or exposing it as an API.

The modules are presented according to their use cases.

- Core modules
- Livestatus Module for frontends
- Exporting data to metric databases
- SQL based Modules for frontends
- Exporting data to logging management systems
- Legacy modules for migration purposes
- Modules no longer supported

Core modules

simple_log: get all logs into one file You can get a log for all your daemons in a single file. With the exception of Debug level logs which are not sent through the network as a safe guard. Shinken state messages are ONLY logged at the debug level in the local log files. These are the ALL CAPS states that some 3rd party interfaces use to mine data from the historical logs. Actual state messages are sent as objects between the various daemons.

It takes the parameters:

- module_name: name of the module called by the brokers

- module_type: simple_log
- path: path of the log file

Here is an example:

```
define module{
```

```
     module_name      Simple-log
     module_type      simple_log
     path             /usr/local/shinken/var/nagios.log
     archive_path     /usr/local/shinken/var/archives/
}
```

Syslog - Send all logs to a local syslog server Send all logs to a local syslog server. Support for remote syslog can be implemented if requested. Just lookup the syslog module, easy to modify. Use for example with Splunk, graylog2, Logstash, Elastic search, Kibana, or other log management and analysis system.

```
define module{
```

```
  module_name Syslog
  module_type syslog
}
```

Lightweight forwarder to Splunk Shinken state data from the local syslog can also be sent to a Splunk server for indexing, reports, SLA and analysis. Via syslog or better yet, the Splunk lightweight forwarder which supports, TCP, buffering and security parameters.

Livestatus API Module - Thruk, Nagvis and Multisite Web frontends There are three well known frontends and various small tools that can interface with the Livestatus API. This API is currently the most efficient method of sharing live data with external interfaces. It provides a rich query language similar to SQL, authentication, command execution, caching,connections persistence, multiple object methods (JSON, Python). All Livestatus data is kept in memory, there is no disk IO involved. It exposes configuration objects, the current state of the hosts and services as well as historical Shinken state log messages.

- MK Multisite
- Thruk
- NagVis

Have you installed the required packages to use the Livestatus module? You can look at the requirement section of the 10 minute installation guide for the requirement lists.

Livestatus Module

It takes the following parameters:

- module_name: name of the module called by the brokers
- module_type: livestatus
- host: IP interface to listen to. The default is '127.0.0.1'. '*' means 'listen on all interfaces'.
- port: TCP port to listen to.
- socket: Unix socket to listen to.

- allowed_hosts: a comma-separated list of IP-addresses which are allowed to contact the TCP port. Please keep in mind that these must be ip-addresses, NOT host names. (DNS lookups for every incoming livestatus request could hang up and therefore block the module)
- modules: a comma-separated list of modules (see below)
- pnp_path: relevant if you use the multisite gui. pnp_path points to the perfdata directory where the pnp4nagios data reside (it's the directory which contains a subdirectory for each host). Multisite needs it to display a small perfdata icon if a rrd file exists.
- To deactivate an input, the port- and socket-attributes can also take the value "none".

The Livestatus module itself can have sub-modules. In fact, it **must** have at least one submodule responsible for storing log events to a database, SQLite or MongoDB.

Livestatus module - Logstore Sqlite Stores log-broks to an sqlite database.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_sqlite
- use_aggressive_sql: Prefer the use of sql queries to pre-filter data prior to python filtering. This is required for very large installations, as the Python structures are not indexed when filtering. Optional argument set to 0 by default. To enable set the value to 1. Some erroneous output may occur, but informal testing has shown these corner cases do not occur.
- read_only: don't send any update to the database. Should be used when you run several livestatus modules : 1 instance is R/W, other are read only.
- database_file: the path to the sqlite database file which is used to store the log broks/messages. The default is 'var/livestatus.db'
- archive_path: the path to a subdirectory where database file archives will be created. Every day the data from the last day will be moved to an archive datafile. The default is 'var/archives'.
- max_logs_age: the maximum age of the log messages (before they are deleted from the database). The default is 1 year. The argument to this parameter takes the form <number>[<period of time>], where <period of time> can be d for days, w for weeks, m for months and y for years. This parameter is currently ignored. In future releases it will be used to automatically delete ancient database files.

Here is an example:

```
define module{
```

```
     module_name      Livestatus
     module_type      livestatus
     host             *       ; * = listen on all configured ip addresses
     port             50000   ; port to listen
     socket           /usr/local/shinken/var/rw/live
     modules          logsqlite
}
define module{
```

```
     module_name      logsqlite
     module_type      logstore_sqlite
     use_aggressive_sql     0 ; optional, by default set to 0. Only for large installations.
     database_file    /usr/local/shinken/var/livelogs.db
     max_logs_age     3m ; three months. Other time intervals are d=days, w=weeks, y=years
}
```

Livestatus module - Logstore MongoDB Stores historical log broks(inter daemon Shinken messages) to a MongoDB database. MongoDB is a distributed and very performant database that permits resilience and high availability. The current implementation has a few known broken pieces (some search functions are broken) and there are bugs in the implementation, so it is considered experimental until power users and developers have ironed out the bugs. It is the database of the future for Shinken.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_mongodb
- mongodb_uri: The address of the master. (Default: i_cant_write_the_uri_here_it_messes_the_wiki_up)
- replica_set: If you are running a MongoDB cluster (called a "replica set" in MongoDB), you need to specify it's name here. With this option set, you can also write the mongodb_uri as a comma-separated list of host:port items. (But one is enough, it will be used as a "seed")
- database: <undocumented>
- collection: <undocumented>
- max_logs_age: <undocumented>

The configuration looks quite similar to the sqlite one. **In a single-node installation and with decent amount of log traffic, the sqlite backend should be considered best practice, as it needs no extra software and is stable and fast (when run in-memory).**

Livestatus module - Logstore Null In case you don't need any logging (for instance, if you dedicate a livestatus module instance to nagvis), you can use this module.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_null

Network Based Modules - Graphite graphing Graphite is a graphing and data analysis tool. It is composed of a web frontend (graphite-web), fixed size databases (whisper) and data redistribution/munging daemon. (carbon) The first step is *having Graphite installed somewhere*, if you do not have Graphite installed, please do this and come back later.

Pre-requisite : Shinken 1.2.2+ is recommended for the best experience with Graphite.

graphite_perfdata: exports check result performance data to Graphite Export all performance data included in check results to Whisper databases managed by Graphite. Data is buffered, then exported once every broker time tick. (Once per second). Should a communication loss occur, it will buffer data for 5 minutes before dropping data. The tick_limit max is configurable, the only limitation is the amount of memory the buffered data can eat.

The graphite broker module (v1.2) sends data to graphite in the following format :

HOSTNAME.SERVICENAME.METRICNAME

It can be optionally enhanced to send it the following format :

_GRAPHITE_PRE.HOSTNAME.SOURCE.SERVICENAME.METRICNAME._GRAPHITE_POST

Each of the three variables are optional :

- The _GRAPHITE_PRE variable can be set per host/service to provide a more flexible naming convention. (ex. Prod.site1.Hostname.servicename)

- The _GRAPHITE_POST variable can be set per host/service to specify the more information concerning the variable being stored that graphite can use to determine the retention rule to use for the variable.
- The SOURCE variable can be set in shinken-specific.cfg for the WebUI module and the Graphite broker.

Metric names are converted from Shinken's format to a more restrictive Graphite naming. Unsupported characters are converted to "_" underscore. So do not be surprised to see that some names differ in the WebUI or directly in Graphite. Permitted characters in Graphite are "**A-Za-z_**.", the hyphen character is permitted from Shinken, though only future versions of Graphite will support it.

Performance data transfer method can be set to pickle, which is a binary format that can send data more efficiently than raw ascii.

It takes the following parameters:

- module_name: name of the module called by the brokers
- module_type: graphite_perfdata
- host: ip address of the graphite server running a carbon instance
- port: port where carbon listens for metrics (default: 2003 for raw socket, 2004 for pickle encoded data)
- use_pickle: Use a more efficient transport for sending check results to graphite instead of raw data on the socket (v1.2)
- tick_limit: Number of ticks to buffer performance data during a communication outage with Graphite. On tick limit exceeded, flush to /dev/null and start buffering again. (v1.2)
- graphite_data_source: Set the source name for all data coming from shinken sent to Graphite. This helps diferentiate between data from other sources for the same hostnames. (ex. Diamond, statsd, ganglia, shinken) (v1.2)

Here is an example:

```
define module {
```

```
module_name Graphite-Perfdata
host xx.xx.xx.xx
module_type graphite_perfdata
port 2004 ; default port 2003 for raw data on the socket, 2004 for pickled data
use_pickle 1 ; default value is 0, 1 for pickled data
tick_limit 300 ; Default value 300
graphite_data_source shinken ; default is that the variable is unset
}
```

SQL Based Modules - PNP4Nagios Graphing PNP4Nagios is a graphing tool that has a web interface for RRDTool based databases. Shinken can export performance data to an npcd database which will feed the RRD files (fixed sized round robin databases). You can *learn how to install PNP4Nagios* if you haven't done it already.

npcdmod: export perfdatas to a PNP interface Export all perfdata for PNP.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: npcdmod
- path: path to the npcd config file

Here is an example:

```
define module{
 module_name  NPCD
 module_type  npcdmod
 config_file  /usr/local/pnp4nagios/etc/npcd.cfg
}
```

SQL Based Modules - Frontend Centreon2 Centreon2 use a NDO database, so you will need the ndodb_mysql module for it.

ndodb_mysql: Export to a NDO Mysql database Export status into a NDO/Mysql database. It needs the python module MySQLdb (apt-get install python-mysqldb or easy_install MySQL-python).

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: ndodb_mysql
- database: database name (ex ndo)
- user: database user
- password: database user passworddt
- host: database host
- character_set: utf8 is a good one

Here is an example:

```
define module{
```

```
     module_name      ToNdodb_Mysql
     module_type      ndodb_mysql
     database         ndo       ; database name
     user             root      ; user of the database
     password         root      ; must be changed
     host             localhost ; host to connect to
     character_set    utf8      ;optionnal, UTF8 is the default
}
```

File based Legacy modules - perfdata export

service_perfdata: export service perfdatas to a flat file

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: service_perfdata
- path: path to the service perfdata file you want

Here is an example:

```
define module{
```

```
    module_name      Service-Perfdata
    module_type      service_perfdata
    path             /usr/local/shinken/src/var/service-perfdata
}
```

host_perfdata: export host perfdatas to a flat file

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: host_perfdata
- path: path to the host perfdata file you want

Here is an example:

```
define module{
```

```
    module_name      Host-Perfdata
    module_type      host_perfdata
    path             /usr/local/shinken/src/var/host-perfdata
}
```

Legacy File based Modules - Old CGI or VShell The Old CGI and VShell use the flat file export. If you can, avoid it! It has awful performance, all modern UIs no longer use this.

status_dat: export status into a flat file Export all status into a flat file in the old Nagios format. It's for small/medium environment because it's very slow to parse. It can be used by the Nagios CGI. It also export the objects.cache file for this interface.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: status_dat
- status_file: path of the status.dat file /usr/local/shinken/var/status.dat
- object_cache_file: path of the objects.cache file
- status_update_interval: interval in seconds to generate the status.dat file

Here is an example:

```
define module{
```

```
    module_name              Status-Dat
    module_type              status_dat
    status_file              /usr/local/shinken/var/status.data
    object_cache_file        /usr/local/shinken/var/objects.cache
    status_update_interval   15 ; update status.dat every 15s
}
```

Deprecated or unsupported modules

SQL Based MerlinDB This interface is no longer supported and is going to be completely removed from Shinken.

SQL based ndodb_oracle - Icinga web frontend using NDO Oracle This interface is no longer supported and is going to be completely removed from Shinken.

CouchDB: Export to a Couchdb database This interface is no longer supported and is going to be completely removed from Shinken.

TSCA (Thrift Service Check Acceptor) TSCA is a receiver/arbiter module to receive hosts and services check results. It provides the same functions as NSCA with additional features. High performance binary transmission, multi line output and auto generated clients for a variety of languages.

What is thrift ? Let's cut and paste the wikipedia definition from'en.wikipedia.org/wiki/Apache_Thrift'_ :

"Thrift is an interface definition language that is used to define and create services for numerous languages.[1] It is used as a remote procedure call (RPC) framework [..]. It combines a software stack with a code generation engine to build services that work efficiently to a varying degree and seamlessly between ActionScript, C#, C++ (on POSIX-compliant systems), Cappuccino, Cocoa, Erlang, Haskell, Java, OCaml, Perl, PHP, Python, Ruby, and Smalltalk."

Installation In any case, you have to install thrift with support for python (on the server side) and languages you want to use for clients.

Get it from thrift.apache.org or in your favorite distribution repository.

Server side Go to the tsca module directory and generate the python stub for the server side installation

```
cd shinken/modules/tsca
$ thrift --gen py tsca.thrift
```

Declare the module is shinken-specific.org

```
define module{
      module_name     TSCA
      module_type     tsca_server
      host            0.0.0.0
      port            9090
}
```

Samples clients There are three(3) client samples written in python, ruby and java in contrib/clients/TSCA of the Shinken distribution. You can use and extend them to send data directly in your code directly to Shinken's TSCA receiver/arbiter module.

The samples clients read a CSV file from stdin and send them the the TSCA running on localhost:9090. The CSV has the following format :

```
hostname,service description,output,rc
```

Any use of TCP in an application should take care not to block the program and to have very short timeouts. For applications that need non blocking functions, prefer a UDP based transport or a local buffer file with a separate application(send_nsca, thrift, etc) to forward your data to Shinken.

Ruby Generate the stub

```
$ thrift --gen rb ../../../shinken/modules/tsca/tsca.thrift
```

Run the client

```
$ cat file_state | ruby RubyClient.rb
```

Python Generate the stub

```
$ thrift --gen py ../../../shinken/modules/tsca/tsca.thrift
```

Run the client

```
$ cat file_state | python PythonClient.py
```

java Generate the stub

```
$ thrift --gen java ../../../shinken/modules/tsca/tsca.thrift
```

Compile the client

```
$ ant
```

Run the client

```
$ cat file_state | java JavaClientThrift
```

VMWare Arbiter module

How it works The arbiter has a module that allows the host->VM automatic host dependency creation. In fact, the module is far more generic than just this. It's a generic "host link dependencies" module.

It reads a mapping file (simple json format) with son->father links. It call an external script at a regular interval : the one I wrote is a VMWare mapping one. It used the check_esx3.pl (that all ESX admin should have) plugin and generate the mapping file. When this file is changed, the module reloads it, creates new links and deletes old ones. So when you VMotion a virtual machine, in the next pass, there will be creation of a new link and deletion of the old one in the scheduler that manages it :)

How to define it The definition is very easy :

```
define module{
     module_name       VMWare_auto_linking
     module_type       hot_dependencies
     mapping_file      /tmp/vmware_mapping_file.json
     mapping_command   /usr/local/shinken/libexec/link_vmware_host_vm.py -x '/usr/local/shinken/libex
     mapping_command_interval 60   ; optionnal
     mapping_command_timeout   300 ; optionnal
}
```

Then you add it in you arbiter object :

```
define arbiter {
    [...]
    modules   VMWare_auto_linking
}
```

So here, it will call the script /usr/local/shinken/libexec/link_vmware_host_vm.py with a listing of the vCenter vcenter.mydomain.com and generate the mapping file /tmp/vmware_mapping_file.json.

You can call : /usr/local/shinken/libexec/link_vmware_host_vm.py –help

for the full help on this script.

It looks at the file modification time each second. This command can also be launch by an external cron of course.

Note: So if you want to write a script that does this for XEN servers, all you need is to generate a json file with all the mapping. I didn't wrote the doc about this, but you can look in the test file for it, the format is very very easy :)

Here is an example of the JSON mapping file syntax:

%%:ref:*["host", "physical_host"], ["host", "virtual_machine"* <["host", "physical_host"], ["host", "virtual_machine">, "host", "physical_host"], ["host", "other_virtual_machine" <"host", "physical_host"], ["host", "other_virtual_machine">]%%

So just a list of couple 'host' string (from now only host are managed) and the host name.

Beware about it : you need the real host_name, including case.

Web Service Module The Ws_arbiter module is a Receiver or Arbiter module to receive passive check results from remote hosts via HTTP(s). This module is considered a work in progress but can be used for testing and improvement.

Configuring the Web Service Module If data is POSTed to this page, it will validate the data to determine if it is a service or host check result and submit the data to the Shinken external command queue.

The web service listens by default to TCP port 7760. The web service supports anonymous or authenticated access. Web service parameters are set in the Shinken-specific.cfg file, in the Ws_arbiter module. To enable the web service, simply add the module to your Arbiter or Receiver daemon configuration in Shinken-specific.cfg

Using the Web Service Module The web service listens for POSTs to: /push_check_result

Use curl or embed the HTTP calls in your software to submit check results.

curl -u user:password -d "time_stamp=$(date +%s)&host_name=host-checked&service_description=service-checked&return_code=0&output=Everything OK" http://shinken-srv:7760/push_check_result

Example with more readability:

```
curl
```

-u user:password -d "time_stamp=$(date +%s)

```
&host_name=host-checked
&service_description=service-checked
&return_code=0
&output=Everything OK
http://shinken-srv:7760/push_check_result
```

SNMP module This part must be splitted and sent in all module repositories

Shinken integrated SNMP Module

SnmpBooster Download Install and Configure

- *What is the SnmpBooster module*
- Install and configure the SNMP acquisition module. [You are here]
- *Reference - SnmpBooster troubleshooting*
- *Reference - SnmpBooster design specification*
- *Reference - SnmpBooster configuration dictionnary*

Downloads

The SnmpBooster module and genDevConfig are currently in public beta prior to integration within Shinken. You can consult t

- github.com/xkilian/genDevConfig
- github.com/titilambert/shinken/tree/snmp_booster/shinken/modules (snmp_booster branch) * Simply right-click and download snmp_poller.py then copy it to shinken/modules/

Requirements The SnmpBooster module requires:

- Python 2.6+
- Shinken 1.2+
- PySNMP 4.2.1+ (Python module and its dependencies)
- ConfigObj (Python module)
- python-memcached
- memcachedb or memcached package for your operating system (ex. For Ubuntu: apt-get install memcachedb) *Note*

The genDevConfig profile generator depends on:

- Perl 5.004+
- 4 perl modules available from CPAN and network repositories. genDevConfig/INSTALL has the installation details.

STRONGLY RECOMMENDED: Use the same version of Python and Pyro on all hosts running Shinken processes.

Installation SnmpBooster:

- Install the dependencies
- Copy the file snmp_poller.py from the git repository to your shinken/modules directory.
- Configuration steps are listed in the present web page.

genDevConfig:

- Download and extract the archive to your server.
- See genDevConfig/INSTALL on how to install and configure it.

Configuration

How to define the SnmpBooster module in the Shinken daemons You need to modify shinken-specific.cfg, which is located in $shinken/etc/shinken-specific.cfg

Arbiter daemon configuration Simply declare the module:

```
modules SnmpBooster</code>
```

Scheduler daemon configuration

Simply declare the module:

<code>modules SnmpBooster

Poller daemon configuration Simply declare the module:

```
modules SnmpBooster</code>
```

SnmpBooster Module declaration

Included in Shinken v1.2.1 shinken-specific.cfg.

<code>define module {

```
module_name          SnmpBooster
module_type          snmp_poller
datasource           /usr/local/shinken/etc/packs/network/SnmpBooster/   ; SET THE DIRECTORY FOR YOUR
memcached_host       x.x.x.x  ; SET THE IP ADDRESS OF YOUR memcached SERVER
memcached_port       11211  ; default port for a memcached process
```

}

If you do not know the IP adress on which your memcache is listening, check under /etc/memcached.conf. Or do a:

```
netstat -a | grep memcached</code>
If you are running a test on the local machine you can leave memcached on 127.0.0.1 (localhost), but
```

How to define a Host and Service

Step 1

Create a template for your SNMP enabled devices.

Sample template:

<code>cd shinken/etc/packs/network/ mkdir SnmpBooster

vi shinken/etc/packs/network/SnmpBooster/templates.cfg

```
define command {
```

```
command_name    check_snmp_booster
command_line    check_snmp_booster -H $HOSTNAME$ -C $SNMPCOMMUNITYREAD$ -V 2c -t $ARG1$ -i $_SERVICE
module_type     snmp_poller
```

}

```
define service {
```

```
name                    default-snmp-template
check_command           check_snmp_booster!$_SERVICEDSTEMPLATE$!$_SERVICEINST$!$_SERVICETRIGGERGROUP
_inst                   None
_triggergroup           None
max_check_attempts      3
check_interval          1
retry_interval          1
register                0
```

}

```
define host{
```

```
name                    SnmpBooster-host
alias                   SnmpBooster-host template
check_command           check_host_alive
max_check_attempts      3
check_interval          1
retry_interval          1
use                     generic-host
register                0
```

}

Step 2 Define some hosts and services. You would typically use genDevConfig or another configuration generator to create these for you.

Mandatory service arguments related to SNMP polling:

```
_dstemplate                Cisco-Generic-Router  ; Name of a DSTEMPLATE defined in the SnmpBooster co
```

```
snmpcommunityread    which is set in your resource.cfg file
```

Optional service arguments related to SNMP polling with default values:

```
_inst                   None   ; Could be numeric: 0, None or an instance mapping function like: map
```

```
_triggergroup           None   ; Name of the triggergroup defined in the SnmpBooster config.ini file
```

Sample Shinken host and service configuration:

```
# Generated by genDevConfig 3.0.0
# Args: --showunused -c publicstring 192.168.2.63
# Date: Thu Aug 30 17:47:59 2012

#######################################################################
# Description: Cisco IOS Software, C2960 Software (C2960-LANBASEK9-M), Version 12.2(50)SE4, RELEASE S
#     Contact:

define host {
```

```
 host_name            192.168.2.63
 display_name         192.168.2.63
 _sys_location
 address              192.168.2.63
 hostgroups
 notes
 parents
 use                  default-snmp-host-template
 register             1
}

define service {
```

```
 host_name            192.168.2.63
 service_description  chassis
 display_name         C2960 class chassis
 _dstemplate          Cisco-Generic-Router
 _inst                0
 use                  default-snmp-template
 register             1
}

define service {
```

```
 host_name            192.168.2.63
 service_description  chassis.device-traffic
 display_name         Switch fabric statistics - Packets per Second
 _dstemplate          Device-Traffic
 use                  default-snmp-template
 register             1
}

define service {
```

```
host_name            192.168.2.63
service_description  if.FastEthernet0_1
display_name         FastEthernet0_1 Description: Link to Router-1 100.0 MBits/s ethernetCsmacd
_dstemplate          standard-interface
_inst                map(interface-name,FastEthernet0_1)
use                  default-snmp-template
register             1
```

}

Here is an example configuration of the config.ini file

```
[DATASOURCE]
```

```
  OidmyOidDefinition = .1.3.6.1.45.0
  [myOidDefinition] ; Use the same name as the myOidDeiniftion, but omit the leading "Oid"
      ds_type = DERIVE
      ds_calc = 8,*  ; RPN expression : Oid, 8, *  Which means Oid * 8 = ds_calc
      ds_oid = $OidmyOidDefinition
[DSTEMPLATE]
```

```
  [myCiscoRouter]
      ds = myOidDefinition
[TRIGGER]
```

```
  [trigger1]
      warning = RPN expression
      critical = RPN expression
  [trigger2]
      warning = RPN expression
      critical = RPN expression
[TRIGGERGROUP]
```

```
[CiscoRouterTriggers]
    triggers = trigger1, trigger2
```

Shinken integrated SNMP Module

Overview

What is it The SnmpBooster module allows Shinken Pollers to directly manage SNMP data acquisition. This is an all Python cross-platform SNMP module. It is tightly integrated with the Shinken Poller, Scheduler and Arbiter daemons to provide the best possible user experience.

Design specification summary

- STATUS - DESIGN SPEC PERFORMANCE
- [Done] Functions as an integrated Shinken Poller module
- [Done] Necessary integration code commited to Shinken official release (Integrated starting at v1.2)
- [Done] Ability to collect thousands of SNMP metrics per second
- [Done] Be compatible with distributed data acquisition
- [Done] Collect data for a host/check_interval tuple via SNMP in a single pass
- [Done] Use all builtin Shinken scheduler logic for retries, forced checks, timeouts, dependencies, parents
- [Done] Store collected data for the duration of the check_interval in a memcached/membase
- [Done] On a restart, after the first collection, be able to pick up where the last check left and calculate derived values
- [Done] Forced check are not allowed within 30 seconds of last SNMP query to the same host/check_interval, all other requests get data from the cache.
- [Done] Only a single request to the host/check_interval via SNMP is allowed at a time, all other requests get data from the cache.
- STATUS - DESIGN SPEC USABILITY
- [Done] Usage documentation
- [xxxx] SkonfUI and Discovery usage documentation
- [xxxx] Provide sample configuration packs in Shinken
- [Done] Provide sample config.ini with examples of all types of data * SNMP OIDS, DATASOURCES, DSTEMPLATES, TRIGGERS and TRIGGERGROUPS

- [Done] Directly compatible for use with genDevConfig Shinken SNMP configuration generator
- [Done] Provide meaningful feedback for users on errors
- [Done] Capture all tracebacks and convert them to actual error or warning messages
- STATUS - DESIGN SPEC FEATURES
- [Done] Return state and performance metrics
- [Done] Performance metrics can be returned in a Weathermap compatible format
- [Done] Configuration file format is ConfigObj INI
- [Done] Load all valid INI configuration files from a directory and merge them
- [Done] Load a single INI configuration file
- [xxxx] Load a list of INI configuration files
- [Done] Configuration file describes all generic acquisition parameters (OID, DATASOURCE, DSTEMPLATE, MAP, TRIGGER, TRIGGERGROUP)
- [Done] Supports Triggers which are calculation rules to determine states
- [Done] Triggers support an RPN (Reverse Polish Notation) calculation engine which includes mathematical and logical operators
- [Done] Each TRIGGER is associated with a severity level, WARNING or CRITICAL
- [Done] Multiple TRIGGERS can be associated with a TRIGGERGROUP
- [Done] Use builtin Python Operators
- [Done] Support DERIVE, TEXT, GAUGE and COUNTER data types
- [xxxx] Support TIMETICKS data type
- [Done] Support applying RPN based calculations to received metric for scaling or conversion purposes
- [Done] Use a Python SNMP library which supports asynchronous acquisition PySNMP
- [Done] Datasources can use rule based runtime instance mapping
- [Done] Set Snmp version as a check runtime option
- [Done] Set Snmp DSTEMPLATE as a check runtime option
- [Done] Set Snmp TRIGGERGROUP as a check runtime option
- [Done] Set Snmp COMMUNITY as a check runtime option
- [Done] Use Snmp version 2c GetBulk
- [xxxx] Support Snmp version 2c GetNext if GetBulk is not supported
- [xxxx] Support Snmp version 1 GetNext
- [xxxx] Set Snmp Timeout as a check runtime option, instead of a hardcoded value at 5 seconds
- STATUS - DESIGN SPEC MAINTAINABILITY
- [xxxx] Functions documented in the source code
- [Done] Critical functions documented in the source code
- [Done] Locking sections identified in the code
- [xxxx] Unit tests with at least 80% coverage

- [xxxx] Unit tests integrated with Shinken test suite
- [Done] Code hosted on github
- [xxxx] configuration validity and integrity checking of all INI files
- [xxxx] Pep8 compliant
- [xxxx] Pylint pass

genDevConfig Plugins - Compatibility status with SnmpBooster

- STATUS - genDevConfig maintained Plugins
- [Done] Avaya ES switches
- [Done] Avaya ERS routing switches
- [Done] Cisco 29x0 switches
- [Done] MIB-II Interfaces
- [Done] Cisco PIX/ASA
- [Done] JUNOS devices
- [Done] Cisco IOS routers
- [Done] NetSNMP unix hosts ** Validation required**
- [Done] Packeteer devices ** Validation required**
- [Done] Sensatronics devices ** Validation required**
- [Done] Foundry devices ** Validation required**
- [Done] Packeteer devices ** Validation required**
- [Done] Cisco CSS ** Validation required**
- [InProgress] New Cisco Access points
- STATUS - Other maintained Plugins

Tip: [xxxx] Denotes a specification that is planned but not implemented

[InProgress] Denotes a specification that is under development

[Done] Denotes a specification that is implemented

SnmpBooster reference dictionary

- Jump back to *SnmpBooster documentation index*

SnmpBooster.ini dictionary

There are five dictionaries:

- [DATASOURCE]
- [DSTEMPLATE]
- [MAP]
- [TRIGGER]

- [TRIGGERGROUP]

DATASOURCE DICTIONARY OidVariableName refers to an actual OID that can be queries using SNMP against the device on the network.

[VariableName] refers to a Datasource and all the information required to gather and prepare the data using SNMP ds_type refers to how the data should be prepared ds_calc refers to any scaling manipulations to make the data more understandable. This is an RPN expression, where the first variable is omitted, as it is always the $OidVariable ds_oid refers to the actual $OidVariable name. An instance identifier can be appended to the name to signify that an instance is provided by the Shinken service definition. This information is passed when the check is called. ...

DSTEMPLATE DICTIONNARY [DsTemplateName] refers to the name of the DSTEMPLATE that will be referred to in the Shinken service definitions. ds refers to the list of DATASOURCES to be collected. If an instance is expected for the list of DATASOURCES, it MUST be the same instance for all Oids. If a different instance is required, use a second DSTEMPLATE.

TRIGGER DICTIONNARY

TRIGGERGROUP DICTIONNARY

MAP DICTIONNARY

SnmpBooster.ini example configuration This example definition will be used to explain each section.

[DATASOURCE]

```
OidmyOidDefinition = .1.3.6.1.45.0
[myOidDefinition] ; Use the same name as the myOidDeiniftion, but omit the leading "Oid"
    ds_type = DERIVE
    ds_calc = 8,*  ; RPN expression : Oid, 8, *  Which means Oid * 8 = Total
    ds_oid = $OidmyOidDefinition
```

[DSTEMPLATE]

```
[myCiscoRouter]
    ds = myOidDefinition
```

[TRIGGER]

```
[trigger1]
    warning = RPN expression
    critical = RPN expression
[trigger2]
    warning = RPN expression
    critical = RPN expression
```

[TRIGGERGROUP]

```
[CiscoRouterTriggers]
    triggers = trigger1, trigger2
```

SnmpBooster.ini configuring SNMP Datasources

The first location is generic data related to SNMP parameters.

- DATASOURCE information * SNMP OID * Type of data and how can it be interpreted (GAUGE, COUNTER, COUNTER64, DERIVE, DERIVE64, TEXT, TIMETICK) * Data format preparation (Scaling the data for example bits to bytes) * Is there an instance to append to the
- Instance MAP function * Mapping the instance dynamically using a function * Data or rules related to the mapping function

SnmpBooster.ini configuring SNMP DSTEMPLATES

- DSTEMPLATEs to associate DATASOURCE to actual device classes * List of DATASOURCES associated with a, for example, Cisco 1900 router. Which in turn can be applied to a Shinken service

SnmpBooster.ini setting triggers/thresholds

- TRIGGER and TRIGGERGROUPS to apply thresholding rules * Define triggers and associate them with a TRIGGERGROUP name that can be applied to a Shinken Service

Shinken integrated SNMP Module

Overview

- Jump back to *SnmpBooster documentation index*

Tip: The module is now in public beta as of 2012-10-26! Have Fun!

Nothing new to add, more to come in 2013. 2013-01-19.

What is it The SnmpBooster module allows Shinken Pollers to directly manage SNMP data acquisition. This is an all Python cross-platform SNMP module. It is tightly integrated with the Shinken Poller, Scheduler and Arbiter daemons to provide the best possible user experience.

Why use it The SnmpBooster module is designed to be very efficient and scalable. It has a very flexible configuration method to make it easy to use with Shinken Monitoring Packs and Shinken discovery runners like genDevConfig.

This acquisition module was professionally designed and developed.

It is meant to be used by the very capable discovery engine genDevConfig (**v3.0.5 and newer**) originally developed for the Cricket SNMP monitoring tool and converted for use with Shinken.

It is one of the very few serious SNMP v2c implementation making use of SnmpGetBulk type requests.

How does it work

Shinken Integration

1. The SnmpBooster Arbiter module reads the Shinken SnmpBooster configuration file(s). It reads the check commands and based on the values in the check commands that use the snmp_poller module it will creates a shared configuration cache using memcached/memcachedb. The memcache key is always the combination of the hostname. This permits to tie together Shinken Hosts and Services with the SNMP specific configuration. (MongoDB and Redis are planned to be supported in the future) The Scheduler daemon schedules Host and Service checks as it normally does.

3. The SnmpBooster module will check that a memcache host key exists for the check to be launched. Then the SnmpBooster poller module will query all services related to a host for a given acquisition frequency in one pass. (all checks done every 2 minutes will be executed in bulk, same for those every 5 minutes)

5. Check results are cached for the acquisition check_interval. The next time a check request for data from the same host is received from the Scheduler, the data will be fetched from memcache. Resulting is extremely low check latency.

2. 6. The SNMP checks still benefit from retries, timeouts, forced checks, dependencies and the powerful Scheduler daemon logic.

6. The Scheduler daemon can still force an immediate re-check by flushing the cache. This is required for the dependency model.

Performance SnmpBooster uses SNMP v2c getbulk for high efficiency, unless forced to use SNMP v2c get-next or SNMPv1 get-next. GetBulk uses a single request PDU to ask for multiple OIDs or even entire tables, instead of sending one request PDU per OID.

For example: *A typical 24 port network switch with two uplinks might use 375 OIDS (8 OIDs per interface, plus general OIDs for chassis health, memory, cpu, fans, etc.). **SnmpBooster will only require around 4 request PDUs*

*instead of 375 request PDUs**. Each PDU is a request packet which takes time to create, send get processed and return. More timeouts to manage, more connections, more impact on the remote device and more latency means much fewer checks per second.*

The SnmpBooster module supports automatic instance mapping for OIDs. (Ex. Based on the interface name it will figure out that the SNMP index(or instance) is 136. This is automatically handled by genDevConfig and SnmpBooster, no user input required. :-)

The generic SNMP configuration information is stored in the Shinken SnmpBooster INI files. There is a Defaults_unified.ini and a series of other Defaults files, one per discovery plugin for genDevConfig.

Important: genDevConfig plugins have all been converted to use the new dynamic instance mapping methods. You are now free to use most if not all Defaults*.ini files included with genDevConfig. 2012-10-28

Limitations You should have memcached instances running on each poller responsible for snmp polling. You should have your pollers with SnmpBooster in the same datacenter, as they need to be on the same machine with good connectivity to the active memcached instance. SnmpBooster is not compatible with distributed pollers in multiple datacenters, sorry, the current design of SnmpBooster uses a single centralized memcached instance for storing the timeseries data. For distributed datacenters to be supported, each poller+scheduler+memcached must be realm restrained, which is not the case today.

Design specification *SnmpBooster design specification* and current development status.

Data model The information required to define the data is split in two locations.

The first location is the host and service Shinken configuration (You need to generate or write this)

- Device specific information
  - IP addresses, host_names, device types, instance keys
  - A DSTEMPLATE must be referred to in the Service definition
  - A static SNMP instance could be referred to in the Service definition
  - An SNMP instance MAP function could be referred to in the Service definition
  - A TRIGGERGROUP could be refered to in the Service definition

The second location is SNMP Defaults.* templates. (Here you can create new devices or add new data sources)

- DATASOURCE information
  - SNMP OID
  - Type of data and how can it be interpreted (GAUGE, COUNTER, COUNTER64, DERIVE, DERIVE64, TEXT, TIMETICK)
  - Data format preparation (Scaling the data for example bits to bytes)
  - Is there an instance to append to the
- Instance MAP function * Mapping the instance dynamically using a function * Data or rules related to the mapping function
- DSTEMPLATEs to associate DATASOURCE to actual device classes * List of DATASOURCES associated with a, for example, Cisco 1900 router. Which in turn can be applied to a Shinken service
- TRIGGER and TRIGGERGROUPS to apply thresholding rules * Define triggers and associate them with a TRIGGERGROUP name that can be applied to a Shinken Service

A final location containes rules to build your Shinken configuration.

- genDevConfig plugins create Shinken configurations

Installation and configuration *SnmpBooster installation*

Reference Dictionnary *SnmpBooster reference dictionary*

Troubleshooting *SnmpBooster troubleshooting*

Graph templates These are .graph files defined in your Shinken configuration directory. Refer to the Shinken graphite templates(Not yet created) or PNP4Nagios how-to documentation. The graph templates are independent from SnmpBooster and provide templates for any collected data from Shinken.

SnmpBooster Troubleshooting

Check your config

- Have you defined the poller module name?
- Have you defined the correct path to the directory containing your Defaults*.ini files?
- Have you addded the Snmpbooster module to your arbiter, poller, scheduler?
- Have you added copied the genDevConfig templates.cfg in shinken/packs/network/SnmpBooster/
- Have you installed PySNMP, memcached and other dependencies?

Software version consistency Shinken and SnmpBooster now require **the same Python and Pyro version on all hosts running a Shinken daemon**.

If you cannot use the packaged version of Python and its modules (Pyro, memcached, etc.). Use virtualenv to declare a python version to use and install all required modules in that virtualenv.

Software version requirements Have you verified that the *requirements* are met. Python, PySNMP, Shinken, Pyro, memcached, etc.

Validate your check command arguments Use the check_plugin command and comment out the module to learn what were the exact arguments sent by the poller. This will permit you to validate all the arguments, like snmp community string, inheritance, template application, etc.

Validate connectivity

Take a packet trace using a tool like Wireshark to validate that the remote host is responding.

- Has the host responded
- **Is SnmpBooster repeating the request more often than the polling interval.**
  - If you are seeing repeated requests your device may have a compatibility issues.

- Save an snmpwalk of the device, get a packet trace using Wireshark, set the poller to debug and save the poller.log file (shinken/var/poller.log). Send all three to the SnmpBooster developers.
- Note: It is normal to see one or more bulkGet requests if you are getting large amounts of data. Ex. a 24 port switch will take 2-3 request packets.

Performance Make sure you have a low latency connection to your memcache from the Poller. Your memcache server can be replicated to all your poller hosts that should also run memcache instances. Check that memcached is running: netstat -a | grep memcached

Faulty Template A bad snmp_template file was distributed in the genDevConfig sample-config directory, there were two glaring errors.

This was fixed on 2012-10-16. Make sure you update your template, or use the data from the wiki.

Note that the template should be called: SnmpBooster-template.cfg to make it easier to troubleshoot in the logs. So when you search for SnmpBooster in your logs it will show up as well.

Log files All warnings and errors generated by the SnmpBooster module start with "[SnmpBooster] error text" and are logged using the standard Shinken logger.

The Arbiter daemon can output initial configuration, loading of host keys and intervals in memcached type error messages. The Scheduler daemon can output scheduling and alert related messages. The Poller daemon can output messages related to instance mapping, acquisition timeouts, invalid community strings, cache failures and more. These are available in the Web interface, as they are placed in the check results for the service.

You can simply do a "grep SnmpBooster *" in your shinken/var directory to see the latest messages related to the SnmpBooster module. You can also sort messages by timestamp to make it easy to find where and when errors occurred.

cd shinken/var grep SnmpBooster *

memcache persistence If you restart your memcache server or memcache crashes, your poller will no longer be able to validate that a host exists in memcache prior to writing.

You should use memcachedb to achieve persistence in case of memcache failures.

Common errors returned by SnmpBooster in the log file Errors should be fairly explicit and mean what they say, though there can be exceptions. Lets try to clear some of them.

__Arbiter log **errors__**

Missing ds_oid : This means that a variable in your OID definitions is missing, or your DATASOURCE is not named correctly or your ds_oid variable is missing. There is a typo in your ds_oid variable (ex. ds-oid, or ds_oid = $OidNameIncorrectFFFRA.%(instance)s).

Datasource not defined : Your DSTEMPLATE uses a DATASOURCE that doesn't exist check the [DataSourceName] you are referring to. Does it contain the expected OID variable, $OidName.

Missing ds_type : The DATASOURCE always needs to have a ds_type definition, GAUGE, COUNTER, DERIVE, TEXT, TIMETICK, DERIVE64, COUNTER64.

__Poller log **errors__**

Problems with calculations, repeated polling, hosts not responding, etc.

__Memcached **errors__**

memcachedb and memcached do not use the same default port. Configure the correct memcachedb port to match what is declared in your SnmpBooster module under shinken-specific.cfg.

On Ubuntu 12.04 the default installation is on port 21201 instead of 11211. This causes the error "[SnmpBooster] Memcache server (127.0.0.1:11211) is not reachable" when Shinken starts.

To change it, you must edit the file /etc/memcachedb.conf

Memcached Notes On Ubuntu 12.04 the default instalation is on port 21201 instead of 11211. This causes the error "[SnmpBooster] Memcache server (127.0.0.1:11211) is not reachable" when shinken starts.

To change it, you must edit the file /etc/memcachedb.conf

WebUI module This part must be splitted and sent in all module repositories

WebUI integration with Shinken The WebUI is an external broker module. So it's an external process launched by the broker that "eats" broks (broker messages) from the brokers. So it can get *all* broks if you place this broker in your top level realm.

The WebUI does not use a database to get data. Instead, it use a "regenerator" object that will eat each broks, and will "recreate" all Hosts/Services/Contacts objects as if the code was in the scheduler daemon. So basically, WebUI and pages always reflect the CURRENT state of hosts/services objects.

The WebUI http layer is managed by bottle.py. It's a small but powerful framework.

How does the WebUI function globally ?

There a 2 Threads running:

- the main thread is the bottle.py (http) listener. It will use the best backend it finds. We recommend using python-paste. If it does not find one, it will use the default swsgi. Paste is multi-thread, swsgi is mon-thread, so please use paste if you want to avoid locking problems.
- the 2nd thread is the regenerator one. It only gets broks and gives them to the regenerator object.

There is a lock system between the threads. You can have N Http requests in progress without problem, but during this time the renererator one will wait. During execution of the regenerator, no requests are processed. This is not considered a problem, as the regenerator is very quick, and there is only a 1s lock for a 7k service conf loading, so it's not a huge problem.

What is a WebUI User? A WebUI user is a contact. A true contact object. You must match a contact name for your user.

To create a new page? All pages are in the shinken/webui/plugins directory. Each "part" has it's own directory. A part (like the eltdetail, element detail) can have more than one "page" (like /host or /service for eltdetail).

From here we will supose you want to create a "/contact" page.

You can copy the dummy example in the plugins directory into a contact directory.

You need to change the contact/dummy.py file into a contact/contact.py file, because the webui will search for a dir/dir.py file to "load".

Templates Templates are HTML with some Python code in it in the plugins/*/views direcotry for specific templates, and the "global layout" (menu and all common part) in the webui/views directory.

Your template must call the template layout (layout.tpl in the webui/views directory) wit ha "rebase" call.

If you put the rebase call at the beginning of your template, all there is below will be place "inside" the layout that will call the common javascripts and css, make the menu adn then call your html/python code.

The rebase call can take arguments. You MUST give it:

- user: the user you give it in the return dict of your .py code

Then all is optional:

- title: title of the page
- top_right_banner_state: int, global state with clouds to put in your top right page. Look at the problem.tpl code for an example.
- js and css list: list of YOUR specific javascript or css to call AFTER the common ones.
- refresh: boolean, set the refresh to 60s or do not refresh at all

- menu_part: will put the little "^" under this part of the menu.

Example of a call, taken from the problems view:

```
rebase layout title='All problems', top_right_banner_state=top_right_banner_state, js=['problems/js/a
roblems/js/autocompleter.Request.js', 'problems/js/autocompleterObserver.js'], css=['problems/css/acc
ms/css/autocompleter.css', 'problems/css/perfometer.css'], refresh=True, menu_part='/'+page, user=use
```

Call Python objects in your templates Your templates are mainly HTML code. But of course you can call python code in it. The dict you returns in the plugin.py call will be available in this page.

For example, the my_host variable will be available in the page with the host object you find (or None if your give it a bad name of course). Then you can "call" python with for example here to show the host_name: `<span>My host name is *my_host.host_name* </span>` is a way in the templates to "call a variable or function" that will return a string, here the host_name.

If the function or property you call must return HTML code that SHOULD be output as it, without "protection", you must put a ! before your call.

Let use an example where the output value of an host is in fact an html output. If you use the code `my_host.output`, bottle.py will "protect" the html generated by escaping the string, and change <> characters with escaped value. You can change this by calling `my_host.output`. Of course, it's a security problem if the output is with a javascript code...

You can also "loop" or put "if" in your template. You just need to put your code with a % before. Like

```
%for i in xrange(1, 10):
  My valus is  {{i}}
%end
```

You must put the %end here, the indentation will NOT be enougth, sorry.

For an if it's also easy:

```
%if host.active_checks_enabled:
  The host got active checks enabled
%else:
  The host DO NOT have active check enabled
%end
```

Which javascript lib are you using? It's mootools 1.3 with all options :)

What to do?

- Finish the /mobile part
- List of current alerts
- Host info
- Host status
- Host interfaces
- Hostgroup status
- dashboard hierachique with states, and BP
- Nagvis
- add bp in nagvis auto-map

- event sources
- correlation
- pre-filtering/enrichment
- user profile
- host/srv conf

WebUI search syntax work in progress

not that we couldn't tell. ;) eh eh

beware the working men and flying tools!

WebUI SSL Certification Lets start: the goal to to have the server.pem and client.pem file in etc/certs.

Go to the etc/certs directory.

```
openssl req -new -nodes -out server.req -keyout server.key -config ./shinken_openssl_cnf
openssl ca -out server.pem -config ./shinken_openssl_cnf -infiles server.req
cp server.pem server.pem.bkp
cp server.key server.pem
cat server.pem.bkp >> server.pem
cp server.pem client.pem
```

You can try to get the validity with for the arbiter with:

```
openssl s_client -connect localhost:7770</code>
```

Amazon AWS/EC2 import

Description You can import data from Amazon AWS/EC2 **'AWS'**_ into Shinken to create hosts.

Amazon provide VM hosting with EC2. With this arbiter module, you will be able to load your EC2 hosts into Shinken.

Prerequisites

You will need the **'libcloud'**_ package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

```
define module {
 module_name      AWS
 module_type      aws_import

 # Configure your REAL key and secret for AWS
 api_key              PAAAB2CILT80I0ZA0999
 secret           GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH
 default_template generic-host        ; if the host is not tagged, use this one
 }
```

- Put in key and secret your private Landscape access. * default_template will be used if your host is not "tagged" in Landscape

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master

     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           AWS
     }
```

Restart your Arbiter and it's done :)

Generated hosts The configuration generated will look as below :

```
define host {
    host_name            i-3fc56e5a
    address              8.8.4.4
    use                  t1.micro,MyTag,EC2,generic-host
    _EC2_AVAILABILITY    us-east-1a
    _EC2_CLIENTTOKEN
    _EC2_DNS_NAME
    _EC2_GROUPS          quicklaunch-1
    _EC2_IMAGEID         ami-1b814f72
    _EC2_INSTANCEID      i-3fc56e5a
    _EC2_INSTANCETYPE    t1.micro
    _EC2_KERNELID        aki-825ea7eb
    _EC2_KEYNAME         testaws
    _EC2_LAUNCHDATETIME  2012-09-26T12:19:38.000Z
    _EC2_LAUNCHINDEX     0
    _EC2_PRIVATE_DNS
    _EC2_PRIVATE_IP
    _EC2_PRODUCTCODE
    _EC2_PUBLIC_IP       8.8.4.4
    _EC2_RAMDISKID       None
    _EC2_STATUS          stopped
    _EC2_TAGS            demo:myvalue,use:MyTag
 }
```

Here with a stopped t1.micro instance with no name. You can put your how "use" parameter by adding a EC2 tag "use" on your VM. It will be output on the host configuration so you can setup the monitoring as you want. .. _libcloud: http://libcloud.apache.org/index.html .. _AWS: https://console.aws.amazon.com

Amazon AWS/EC2 import

Description You can import data from Amazon AWS/EC3 **'AWS'**_ into Shinken to create hosts.

Amazon provide VM hosting with EC3. With this arbiter module, you will be able to load your EC2 hosts into Shinken.

Prerequisites

You will need the **'libcloud'**_ package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

```
define module {
 module_name      AWS
 module_type      aws_import

 # Configure your REAL key and secret for AWS
 api_key              PAAAB2CILT80I0ZA0999
 secret           GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH
 default_template generic-host        ; if the host is not tagged, use this one
 }
```

- Put in key and secret your private Landscape access. * default_template will be used if your host is not "tagged" in Landscape

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master

     address          localhost                  ;IP or DNS adress
     port             7770
     spare            0
     modules           AWS
     }
```

Restart your Arbiter and it's done :)

Generated hosts The configuration generated will look as below :

```
define host {
    host_name            i-3fc56e5a
    address              8.8.4.4
    use                  t1.micro,MyTag,EC2,generic-host
    _EC2_AVAILABILITY    us-east-1a
    _EC2_CLIENTTOKEN
    _EC2_DNS_NAME
    _EC2_GROUPS          quicklaunch-1
    _EC2_IMAGEID         ami-1b814f72
    _EC2_INSTANCEID      i-3fc56e5a
    _EC2_INSTANCETYPE    t1.micro
    _EC2_KERNELID        aki-825ea7eb
    _EC2_KEYNAME         testaws
    _EC2_LAUNCHDATETIME  2012-09-26T12:19:38.000Z
    _EC2_LAUNCHINDEX     0
    _EC2_PRIVATE_DNS
    _EC2_PRIVATE_IP
    _EC2_PRODUCTCODE
    _EC2_PUBLIC_IP       8.8.4.4
    _EC2_RAMDISKID       None
    _EC2_STATUS          stopped
    _EC2_TAGS            demo:myvalue,use:MyTag
 }
```

Here with a stopped t1.micro instance with no name. You can put your how "use" parameter by adding a EC2 tag "use" on your VM. It will be output on the host configuration so you can setup the monitoring as you want. .. _libcloud: http://libcloud.apache.org/index.html .. _AWS: https://console.aws.amazon.com

The distributed retention modules The high availability allow the Arbiter to send a configuration to a spare scheduler, but a spare scheduler does not have any saved states for hosts and services. It will have to recheck them all. It's better to use a distributed retention module so spares will have all the information they need to start with an accurate picture of the current states and scheduling :)

Non distributed retention modules If you are just running tests on a single server, use the pickle or memcache retention modules You can also use MongoDB if you already have it installed for use with the WebUI.

MongoDB MongoDB is a scalable, high-performance, open source NoSQL database written in C++.

Step 1: Install MongoDB:

We will use mongodb package from 10gen repository, so we start by adding it in apt sources list:

```
echo 'deb http://downloads-distro.mongodb.org/repo/debian-sysvinit dist 10gen' > /etc/apt/sources.lis
apt-get update
```

And we install it:

```
apt-get install mongodb-10gen
```

And we install pymongo, the python interface to MongoDB, with easy_install to avoid packages versions problems (like here **'forums.monitoring-fr.org/index.php?topic=5205.0'_**):

```
apt-get remove python-pymongo
easy_install pymongo
```

And finally we start MongoDB :

```
/etc/init.d/mongodb start
```

Step 2: define a mongodb_retention module in your shinken-specific.cfg file:

```
define module {
  module_name MongodbRetention
  module_type mongodb_retention
  uri mongodb://localhost/?safe=true
  database shinken
}
```

Step 3: Declare a retention module for your scheduler(s) :)

Example:

```
#The scheduler is a "Host manager". It get hosts and theirs
#services. It scheduler checks for them.
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
     port     7768                  ; tcp port of the daemon

     #optionnal: modules for things as retention
     modules    MongodbRetention
     }
```

Step 4: Restart the Arbiter, and your Scheduler will now save its state between restarts. :)

Memcached Memcached is a distributed memory resident key/value server. It's very easy to install:

```
sudo apt-get install memcached
sudo /etc/init.d/memcached start
```

The shinken module also needs the python-memcache package to talk to this server.

```
sudo apt-get install python-memcache
```

To use it,

Step 1: define a memcache_retention module in your shinken-specific.cfg file:

```
define module{
     module_name      MemcacheRetention
     module_type      memcache_retention
     server           127.0.0.1
     port             11211
}
```

Step 2: Declare a retention module for your scheduler(s) :)

Example:

```
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
     port     7768                  ; tcp port of the daemon

     #optional: modules for things as retention
     modules    MemcacheRetention
     }
```

Step 3: Restart the Arbiter, and your Scheduler will now save its state between restarts. :)

Redis Redis is a distributed key/value server (on disk and in-memory). It's very easy to install:

```
sudo apt-get install redis-server
sudo /etc/init.d/redis-server start
```

The shinken module also need the python-redis package to talk to this server.

```
sudo apt-get install python-redis
```

Step 1: define a redis_retention module in your shinken-specific.cfg file:

```
define module{
     module_name      RedisRetention
     module_type      redis_retention
     server           127.0.0.1
}
```

Step 2: Declare a retention module for your scheduler(s) :)

Example:

```
#The scheduler is a "Host manager". It get hosts and theirs
#services. It scheduler checks for them.
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
```

```
    port     7768                  ; tcp port of the daemon

    #optionnal: modules for things as retention
    modules    RedisRetention
    }
```

Step 3: Restart the Arbiter, and your Scheduler will now save its state between restarts. :) .. _forums.monitoring-fr.org/index.php?topic=5205.0: http://forums.monitoring-fr.org/index.php?topic=5205.0

How to enable and use Livestatus module

Define the Livestatus module Start by reviewing the ''/etc/shinken/shinken-specific.cfg" file for this module:

```
define module{
```

```
module_name      Livestatus
module_type      livestatus
host             *       ; * = listen on all configured IP addresses
port             50000   ; port to listen on
database_file    /var/lib/shinken/livestatus.db
```

}

With these parameters:

- module_name: name of the module called by the brokers
- module_type: livestatus
- host: IP interface to listen to. The default is *, which means "listen on all interfaces".
- port: TCP port to listen to.
- socket: Unix socket to listen to.
- database_file: the path to the sqlite database file which is used to store the log broks/messages. The default is "var/livelogs.db"
- max_logs_age: the maximum age of the log messages (before they are deleted from the database). The default is 1 year. The argument to this parameter takes the form <number>[<period of time>], where <period of time> can be d for days, w for weeks, m for months and y for years.
- allowed_hosts: a comma-separated list of IP-addresses which are allowed to contact the TCP port. Please keep in mind that these **must be IP-addresses, NOT host names**. Because DNS lookups for every incoming livestatus request could hang up and therefore block the module.

Enable the Livestatus module Still in ''/etc/shinken/shinken-specific.cfg'', find the object Broker and add "Livestatus" to its "modules":

```
define broker{
```

```
    broker_name      broker-1
[...]
```

```
    modules          Simple-log,Livestatus
}
```

Disable human readable logs In ‘’/etc/shinken/nagios.cfg’‘, verify that the option **human_timestamp_log** is set to **0**.

In version 0.6.5, you can not have at the same time a simple-log file with human readable timestamp and a Livestatus database.

Exporting data for reporting Shinken can export necessary data for reporting in 3rd party systems.

raw_socket module The raw socket module exports reporting data using a syslog format to a raw TCP socket. Theses logs can be captured, parsed and indexed by any log management system like Splunk or Logstash.

Why export reporting data Custom UIs like Thruk, Multisite, WebUI, Adagios, Nagios IX, etc. All have poor or inflexible reporting. Simply because these are not reporting engines.

This also permits to have a generic reporting method that can accept data from any Nagios, Shinken, Icinga or even Riemann.

Reporting module using Splunk Splunk was selected as the reporting platform for creating, managing and presenting reports. Though the raw_socket module does not have any Splunk specific particularities. It is notable that Splunk reports can be embedded in any 3rd party UI using its REST API.

Raw_socket log format The logs are plain-text and compliant with RFC3164. They use an intelligent date format, a configurable seperator ” “(space by default), and key=value pairs in the message data portion of the log. Should a key or value contain a space they must be double quoted. This is syslog using structured data without going to full out JSON that may not be compatible with all log management systems.

The message fields that are supplied in each status update in addition to the standard syslog header are:

- Hostname
- Servicename
- Business impact
- Host/Service status
- Host/Service previous status
- Acknowedgement status
- Maintenance status

Any time the maintenance, host, service or acknowledgement status changes, a log is sent by the Shinken raw_socket module.

Having all relevant data in each log makes it very easy to compute reports for given time periods.

The hostgroup or service group memberships, custom variables or any other configuration related data should be queried from the monitoring system using its API (Livestatus in the case of Shinken and Nagios).

Raw_socket module availability The module is available in both Shinken 1.4 and Shinken 2.0. The module will be integrated in master branches once unit tests and end-to-end testing is completed. 3rd quarter 2013.

Monitoring Linux System with Glances and checkglances.py **‘Glances‘_** is a fantastic multiplatform system monitoring tool writen by Nicolargo. Glances can run on (Linux, Windows, MacOS ...). There is a growing ecosystem around Glances and of course a Nagios/Shinken plugin : checkglances.py.

How does it work Glances can run in server mode. It provide a XML-RPC server (over http) and allow to retrieve system information throuh a restful API. The only thing to do is to install and start Glances as server on the monitored host, then install checkglances.py on the shinken server and finaly install the glances pack.

Install glances See the glances documentation to install glances on Linux.

<code bash> easy_install glances </code>

There is a debian startup script in the glances repository. And another one for centos here.

Install checkglances.py Just follow the documentation for the checkglances.py prerequisites and put it in your nagios plugins folder.

Install the glances pack Open a terminal as the shinken user and just type the following command

<code bash> shinken install glances </code>

Then just edit the configuration for a linux monitored host and tag it as **glances**

```
define host{
 name mylinuxhost
 use glances
 ...
```

Finaly restart the shinken arbiter

```
service shinken-arbiter restart
```

What will be monitored ? For the moment just the basic system (ram, cpu, load, memory, filesystem and network).

If you want to modify the default thresholds for just a host you can do it by overiding the thresholds macro in your host definition. If you want to do it for several hosts, declare a new template and just add the desired thresholds macro to be overide.

Here is a list of the macros

```
::
```

> _LOAD_WARN 2 _LOAD_CRIT 3 _CPU_WARN 80 _CPU_CRIT 90 _MEMORY_WARN 90 _MEMORY_CRIT 95 _FS /, /home _FS_WARN 90 _FS_CRIT 95 _IFACES eth0, eth1 _NET_WARN 7500000 _NET_CRIT 10000000

Note the _FS and _IFACES macros. They leverage the ability to duplicate service for a given list of things to be monitored. Here you see that / and /home partitions will be monitored. If you want to modify this then just add your own in a new template that will inherit the glances template.

Shinken GLPI integration Shinken supports importing hosts from GLPI

For people not familiar with GLPI, it is an Open-Source CMDB. Applicable to servers, routers, printers or anything you want for that matter. It is also a help-desk tool. GLPI also integrates with tools like FusionInventory for IT inventory management.

You can still have flat files AND GLPI if you want. Hosts imported from GLPI will be treated as standard hosts from flat file (inheritance, groups, etc). In fact, in this first version the module only sends the host_name to Shinken, but there should be more information extracted like network connexions for parents relations in the future. :)

Requirements

- python module MySQLdb
- Compatible version of GLPI Shinken module and GLPI version - ...
- etc..

Enabling GLPI Shinken module In your shinken-specific.cfg file, just add (or uncomment):

```
#You know GLPI? You can load all configuration from this app(
#with the webservices plugins for GLPI, in xmlrpc mode
#and with plugin monitoring for GLPI)
# =============== Work with Plugin Monitoring of GLPI ===============
#All configuration read from this will be added to the others of the
#standard flat file
define module{
     module_name      GLPI
     module_type      glpi
     uri              http://localhost/glpi/plugins/webservices/xmlrpc.php
     login_name       glpi
     login_password   glpi
}
```

And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master
#    host_name       node1       ;result of the hostname command under Unix
     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           GLPI
     }
```

It's done :)

Ip Tag module

Why tag a host based on it's IP address? We learned on the *DMZ monitoring* that you can "tag" a host with a poller_tag so it will be checked only by DMZ pollers. It can be tedious process to manually tag all these hosts. Shinken provides an automated method to do this.

This is handled by the arbiter ip_tag module.

Ip_tag module The ip_tag module is an arbiter module that looks up the host address during the configuration parsing and compares it to an predefined IP range (IPV4 or IPV6). If the range matches, it can apply or add a property, such as poller_tag. Other types of tags could be related to locations, functions, administrative groups, etc.

Method: replace or append.

replace will put the value if the property is unset. This is the default method. .. warning:: Fix me: replace, implies overriding an existing value. And will cause user issues down the line. Rename it to set. Replace should be a different method altogether, so overall there should be 3 methods(set, append, replace).

append will add with a , if a value already exist

Here is an example that will set the poller_tag property with the value DMZ of all hosts that:

- have a their hostadress ip (or name resolved) in the range 192.168.0.1/24.
- do not already have a poller_tag property set

```
define module{
```

```
     module_name     IpTag
     module_type     ip_tag
     ip_range        192.168.0.1/24
     property        poller_tag
     value           DMZ
}
```

To use the module add it in the arbiter object:

```
::
```

define arbiter { [...] modules NSCA,IpTag

}

Add value instead of setting it In the previous example we set the property poller_tag to a value. But what if we want to "add" a value, like a template name? We can change the "method" property of the module to "append" so we can add the "value" to the host property instead of replace it.

Here is an example where we want to add the "dmz" template on the hosts, while also keeping any defined templates:

```
define module{
```

```
     module_name   IpTag
     module_type   ip_tag
     ip_range      192.168.0.1/24
     property      use
     value         dmz

     # Optional method
     method append
}
```

For a host defined as:

```
define host{
```

```
     host_name   example_host1
     address     192.168.0.2
     use         linux
}
```

It will be "changed" internaly in:

```
define host{
```

```
     host_name   example_host1
     address     192.168.0.2
     use         linux,dmz
}
```

Name resolution Of course you don't need to set IP address in the address of your host. You can set a hostname, and it will be resolved, and then compared to the range. :)

Ubuntu Landscape import

Description You can import data from Ubuntu Landscape into Shinken to create hosts.

Ubuntu Landscape, is a web app to manage all your linux servers (update and co), which is provided by Canonical, Ubuntu's parent company.

This is an Arbiter import module. The Arbiter manages the configuration.

Prerequisites

You will need the landscape-api package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

define module { module_name Landscape module_type landscape_import

Configure your REAL key and secret from Landscape key PAAAB2CILT80I0ZA0999 secret GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH default_template generic-host ; if the host is not tagged, use this one

If you are using a specific certificate for landscape_api #ca /path/to.ca.cert

If you need a proxy to access https://landscape.canonical.com/api/ #https_proxy http://user:secret@myproxy.com:3128

}

- Put in key and secret your private Landscape access.
- default_template will be used if your host is not "tagged" in Landscape
- If you are using a specific certificate for connexion, give the full path in ca
- You will certainly need an https proxy to access the Landscape API. If so, configure it there.

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master
#    host_name       node1       ;result of the hostname command under Unix
     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           Landscape
     }
```

Restart your Arbiter and it's done :)

Tip: Your "tags" will be applied as templates for your hosts.

Shinken Livestatus API

Overview

- Jump back to Getting Started
- Jump back to *Livestatus module configuration*

What is it Livestatus API is the modern method of interacting with Shinken and Nagios based systems alike.

Originally developed for Nagios, MK Livetstatus, was re-implemented in Python for use with Shinken by professional developers. The access methods and query languages are the same.

Why use it It is fast.

It is network based using TCP.

It is standard for all Nagios and Shinken monitoring systems.

It uses in-memory structures for status data

It uses a back-end database for historical reporting

It uses an SQL based query language

It has a host of powerful nuts and bolts features (authentication, caching, connection persistence, multiple object methods (JSON, Python)).

What can I do with it? All programs and scripts use (or should use) this method to :

- Obtain the current state of hosts and services
- Obtain the current configuration related to hosts and services
- Send administrative commands (downtimes, comments, forcing checks)
- Filter information to display
- Obtain basic reports and event statistics

Shinken being a modern re-implementation of Nagios has additional features that are available in addition to the standard Livestatus API.

Shinken Livestatus API unique features can :

- Obtain Business Impact information
- Obtain intelligent dependency status hosts or services (combines dependency and parent information)
- Obtain Business Process states (same syntax as standard host and service queries)

How does it work Livestatus uses a powerful SQL-like query language. The standard methods and parameters are defined at :

'MK Livestatus reference methods and query language definition'_

Full list of Shinken Livestatus API methods:

'Shinken mapping.py methods'_

What software uses Livestatus to interact with Shinken

Well known Web frontends

- MK Multisite
- Thruk
- NagVis

- Splunk for Nagios

Mobile Web frontends

- get list

Scripts

- Downtime management scripts
- Debug scripts

Installing Livestatus Have you installed the required packages to use the Livestatus module? You can look at the requirement section of the *10 minute installation guide* for the *requirement lists*.

How to enable Livestatus Very simple, jump to the *Shinken Broker configuration* section to enable it. .. _Shinken mapping.py methods: https://github.com/shinken-monitoring/mod-livestatus/blob/master/module/mapping.py .. _MK Livestatus reference methods and query language definition: http://mathias-kettner.de/checkmk_livestatus.html

NSCA module The NSCA daemon module is used to receive send_nsca packets and submit them to the Shinken command pipe. The NSCA module can be loaded by the Receiver or Arbiter process. It will listen on port TCP/5667 for send_nsca packets.

Tip: Passive checks can be submitted *natively to the Shinken command pipe* or from remote hosts to modules, such as NSCA, AMQP or collectd, loaded in the Shinken Arbiter or Receiver process. AMQP is implemented for integration with the Canopsis Hypervisor, but could be re-used for generic messaging.

Note: The Shinken NSCA module implementation is currently limited to the "xor" obfuscation/encryption.

In your shinken-specific.cfg file, just add (or uncomment):

```
::
```

#You can send check result to Shinken using NSCA #using send_nsca command define module{

module_name NSCA module_type nsca_server host * port 5667 encryption_method 0 password helloworld

}

define receiver{

```
receiver_name    receiver-1
address          localhost
port             7773
modules          NSCA

timeout          3             ; 'ping' timeout
data_timeout     120           ; 'data send' timeout
max_check_attempts       3     ;  if at least max_check_attempts ping failed, the node is DEAD

#advanced
realm    All
}
```

This daemon is totally optional.

It's main goal is to get all passive "things" (checks but why not other commands) in distant realms. It will act as a "passive receive buffer" and will then dispatch the data or commands directly to the appropriate Scheduler or Arbiter process.

Data can be received from any Realm, thus the Realm option is nonsensical.

For now there is no init.d script to launch it. .. note:: Verify that the init script has been added.

It is launched like all other daemons:

```
bin/shinken-receiver -c etc/receiverd.ini
```

Tip: Alternatively, for small installations with you can configure a modules inside your Arbiter instead of the Receiver. It will listen the TCP/5667 port for send_nsca packets.

To configure the NSCA module in your Arbiter instead of Receiver. Add the NSCA module to your Arbiter object configuration.

```
::
```

define arbiter{ arbiter_name Arbiter-Master

 # host_name node1 ;result of the hostname command under Unix address localhost ;IP or DNS adress port 7770 spare 0 modules NSCA

}

Retention troubleshooting The retention file contains the state of your host and services, so that they are kept when shinken is restarted.

Sometimes you'll want to inspect (and possibly fix) the retention file, in case you need to work-around a bug or simply better understand what is stored there.

When you use the PickleRetention module in the scheduler (cf. ''define scheduler" in ''shinken-specific.cfg''), you can simply manipulate the retention file using Python.

For this you can use the following code.

- It assumes Shinken is installed in ''/opt/shinken" with the retention file in ''/tmp/retention.dat'':
- Run and play with it interactively using ''ipython -i inspect_retention.py''.

```
#!/usr/bin/python
import pickle
import sys
sys.path.append('/opt/shinken')
import shinken

r = pickle.load(file('/tmp/retention.dat'))
h = r['hosts']

# Example:
# [(k,v) for (k,v) in h['your_host'].items() if k.find('downtime') >= 0]
#
# del h['your_host']
#
# for k,v in r['services'].items():
#     if 'your_host' in k:
#         del r['services'][k]
```

To save your changes:

- Stop Shinken: ‘’service shinken stop’‘
- Save the pickle: ‘’pickle.dump(r, open(‘/tmp/retention.dat’, ‘w’))’‘
- Start Shinken: ‘’service shinken start’‘

NRPE Module

What is it The NRPE module allows Shinken Pollers to bypass the launch of the check_nrpe process. It reads the check command and opens the connection by itself. It scales the use of NRPE for active supervision of servers hosting NRPE agents.

The command definitions should be identical to the check_nrpe calls.

How to define it The definition is very easy (and you probably just have to uncomment it):

```
define module{
     module_name       NrpeBooster
     module_type       nrpe_poller
}
```

Then you add it to your poller object:

```
define poller {
    [...]
    modules   NrpeBooster
}
```

Then just tag all your check_nrpe commands with this module:

```
define command {
   command_name   check_nrpe
   command_line   $USER1$/check_nrpe -H $HOSTADRESS$ -c $ARG1$ -a $ARG2$
   module_type    nrpe_poller
}
```

That’s it. From now on all checks that use this command will use Shinken’s NRPE module and will be launched by it.

Extending Shinken

Introduction There are a lot of “Modules” and “Addons” that are available for Shinken. Shinken can be extended by using different types of methods.

- Web interfaces from various open-source vendors can be used (Based on Livestatus API)
- Shinken itself can be extended using modules that are embedded into the various daemon processes

** (Arbiter, Poller, Receiver, Broker, Scheduler, Reactionner) * External software can provide functional enhancements for reporting, management or usability aspects

Shinken itself provides methods to extend the base functionality:

- *Broker modules* provide external access to runtime data from Shinken
- Poller modules such as *NRPE* and the *SNMP*
- Receiver modules like *NSCA* provide acquisition methods for Shinken

- Arbiter modules permit manipulating the configuration
- The webUI that permits embedding web interface elements

Independent software that works in concert with Shinken is available for:

- Monitoring remote hosts through agent software (*NIX, Windows, etc.)
- Submitting passive checks from remote hosts
- Managing the config files through a web interface
- Mobile phone UIs
- Desktop UIs and Hypervisors
- Desktop notification addons
- ...and much more

You can find many addons that are compatible with Shinken by visiting. The only caveat is that the addons should not use the status.dat file and preferably the modern API interfaces like Livestatus:

- Nagios.org
- SourceForge.net
- NagiosExchange.org
- Shinken community exchange for monitoring packs

Broker modules The broker module receives messages from the Schedulers related to host, service check results. In addition to that it receives a copy of the compiled configuration at startup. What is special about the broker, is that without modules, the broker does nothing. It makes the configuration and result data available to modules. Modules are the ones in charge of doing something with the data. This could be exporting this "raw" data into flat files, databases or exposing it as an API.

The modules are presented according to their use cases.

- Core modules
- Livestatus Module for frontends
- Exporting data to metric databases
- SQL based Modules for frontends
- Exporting data to logging management systems
- Legacy modules for migration purposes
- Modules no longer supported

Core modules

simple_log: get all logs into one file You can get a log for all your daemons in a single file. With the exception of Debug level logs which are not sent through the network as a safe guard. Shinken state messages are ONLY logged at the debug level in the local log files. These are the ALL CAPS states that some 3rd party interfaces use to mine data from the historical logs. Actual state messages are sent as objects between the various daemons.

It takes the parameters:

- module_name: name of the module called by the brokers

- module_type: simple_log
- path: path of the log file

Here is an example:

```
define module{
```

```
     module_name      Simple-log
     module_type      simple_log
     path             /usr/local/shinken/var/nagios.log
     archive_path     /usr/local/shinken/var/archives/
}
```

Syslog - Send all logs to a local syslog server Send all logs to a local syslog server. Support for remote syslog can be implemented if requested. Just lookup the syslog module, easy to modify. Use for example with Splunk, graylog2, Logstash, Elastic search, Kibana, or other log management and analysis system.

```
define module{
```

```
  module_name Syslog
  module_type syslog
}
```

Lightweight forwarder to Splunk Shinken state data from the local syslog can also be sent to a Splunk server for indexing, reports, SLA and analysis. Via syslog or better yet, the Splunk lightweight forwarder which supports, TCP, buffering and security parameters.

Livestatus API Module - Thruk, Nagvis and Multisite Web frontends There are three well known frontends and various small tools that can interface with the Livestatus API. This API is currently the most efficient method of sharing live data with external interfaces. It provides a rich query language similar to SQL, authentication, command execution, caching,connections persistence, multiple object methods (JSON, Python). All Livestatus data is kept in memory, there is no disk IO involved. It exposes configuration objects, the current state of the hosts and services as well as historical Shinken state log messages.

- MK Multisite
- Thruk
- NagVis

Have you installed the required packages to use the Livestatus module? You can look at the requirement section of the 10 minute installation guide for the requirement lists.

Livestatus Module

It takes the following parameters:

- module_name: name of the module called by the brokers
- module_type: livestatus
- host: IP interface to listen to. The default is '127.0.0.1'. '*' means 'listen on all interfaces'.
- port: TCP port to listen to.
- socket: Unix socket to listen to.

- allowed_hosts: a comma-separated list of IP-addresses which are allowed to contact the TCP port. Please keep in mind that these must be ip-addresses, NOT host names. (DNS lookups for every incoming livestatus request could hang up and therefore block the module)
- modules: a comma-separated list of modules (see below)
- pnp_path: relevant if you use the multisite gui. pnp_path points to the perfdata directory where the pnp4nagios data reside (it's the directory which contains a subdirectory for each host). Multisite needs it to display a small perfdata icon if a rrd file exists.
- To deactivate an input, the port- and socket-attributes can also take the value "none".

The Livestatus module itself can have sub-modules. In fact, it **must** have at least one submodule responsible for storing log events to a database, SQLite or MongoDB.

Livestatus module - Logstore Sqlite Stores log-broks to an sqlite database.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_sqlite
- use_aggressive_sql: Prefer the use of sql queries to pre-filter data prior to python filtering. This is required for very large installations, as the Python structures are not indexed when filtering. Optional argument set to 0 by default. To enable set the value to 1. Some erroneous output may occur, but informal testing has shown these corner cases do not occur.
- read_only: don't send any update to the database. Should be used when you run several livestatus modules : 1 instance is R/W, other are read only.
- database_file: the path to the sqlite database file which is used to store the log broks/messages. The default is 'var/livestatus.db'
- archive_path: the path to a subdirectory where database file archives will be created. Every day the data from the last day will be moved to an archive datafile. The default is 'var/archives'.
- max_logs_age: the maximum age of the log messages (before they are deleted from the database). The default is 1 year. The argument to this parameter takes the form <number>[<period of time>], where <period of time> can be d for days, w for weeks, m for months and y for years. This parameter is currently ignored. In future releases it will be used to automatically delete ancient database files.

Here is an example:

```
define module{
```

```
     module_name      Livestatus
     module_type      livestatus
     host             *       ; * = listen on all configured ip addresses
     port             50000   ; port to listen
     socket           /usr/local/shinken/var/rw/live
     modules          logsqlite
}
define module{
```

```
     module_name      logsqlite
     module_type      logstore_sqlite
     use_aggressive_sql     0 ; optional, by default set to 0. Only for large installations.
     database_file    /usr/local/shinken/var/livelogs.db
     max_logs_age     3m ; three months. Other time intervals are d=days, w=weeks, y=years
}
```

Livestatus module - Logstore MongoDB Stores historical log broks(inter daemon Shinken messages) to a MongoDB database. MongoDB is a distributed and very performant database that permits resilience and high availability. The current implementation has a few known broken pieces (some search functions are broken) and there are bugs in the implementation, so it is considered experimental until power users and developers have ironed out the bugs. It is the database of the future for Shinken.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_mongodb
- mongodb_uri: The address of the master. (Default: i_cant_write_the_uri_here_it_messes_the_wiki_up)
- replica_set: If you are running a MongoDB cluster (called a "replica set" in MongoDB), you need to specify it's name here. With this option set, you can also write the mongodb_uri as a comma-separated list of host:port items. (But one is enough, it will be used as a "seed")
- database: <undocumented>
- collection: <undocumented>
- max_logs_age: <undocumented>

The configuration looks quite similar to the sqlite one. **In a single-node installation and with decent amount of log traffic, the sqlite backend should be considered best practice, as it needs no extra software and is stable and fast (when run in-memory).**

Livestatus module - Logstore Null In case you don't need any logging (for instance, if you dedicate a livestatus module instance to nagvis), you can use this module.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_null

Network Based Modules - Graphite graphing Graphite is a graphing and data analysis tool. It is composed of a web frontend (graphite-web), fixed size databases (whisper) and data redistribution/munging daemon. (carbon) The first step is *having Graphite installed somewhere*, if you do not have Graphite installed, please do this and come back later.

Pre-requisite : Shinken 1.2.2+ is recommended for the best experience with Graphite.

graphite_perfdata: exports check result performance data to Graphite Export all performance data included in check results to Whisper databases managed by Graphite. Data is buffered, then exported once every broker time tick. (Once per second). Should a communication loss occur, it will buffer data for 5 minutes before dropping data. The tick_limit max is configurable, the only limitation is the amount of memory the buffered data can eat.

The graphite broker module (v1.2) sends data to graphite in the following format :

HOSTNAME.SERVICENAME.METRICNAME

It can be optionally enhanced to send it the following format :

_GRAPHITE_PRE.HOSTNAME.SOURCE.SERVICENAME.METRICNAME._GRAPHITE_POST

Each of the three variables are optional :

- The _GRAPHITE_PRE variable can be set per host/service to provide a more flexible naming convention. (ex. Prod.site1.Hostname.servicename)

- The _GRAPHITE_POST variable can be set per host/service to specify the more information concerning the variable being stored that graphite can use to determine the retention rule to use for the variable.
- The SOURCE variable can be set in shinken-specific.cfg for the WebUI module and the Graphite broker.

Metric names are converted from Shinken's format to a more restrictive Graphite naming. Unsupported characters are converted to "_" underscore. So do not be surprised to see that some names differ in the WebUI or directly in Graphite. Permitted characters in Graphite are "**A-Za-z_**.", the hyphen character is permitted from Shinken, though only future versions of Graphite will support it.

Performance data transfer method can be set to pickle, which is a binary format that can send data more efficiently than raw ascii.

It takes the following parameters:

- module_name: name of the module called by the brokers
- module_type: graphite_perfdata
- host: ip address of the graphite server running a carbon instance
- port: port where carbon listens for metrics (default: 2003 for raw socket, 2004 for pickle encoded data)
- use_pickle: Use a more efficient transport for sending check results to graphite instead of raw data on the socket (v1.2)
- tick_limit: Number of ticks to buffer performance data during a communication outage with Graphite. On tick limit exceeded, flush to /dev/null and start buffering again. (v1.2)
- graphite_data_source: Set the source name for all data coming from shinken sent to Graphite. This helps diferentiate between data from other sources for the same hostnames. (ex. Diamond, statsd, ganglia, shinken) (v1.2)

Here is an example:

```
define module {
```

```
module_name Graphite-Perfdata
host xx.xx.xx.xx
module_type graphite_perfdata
port 2004 ; default port 2003 for raw data on the socket, 2004 for pickled data
use_pickle 1 ; default value is 0, 1 for pickled data
tick_limit 300 ; Default value 300
graphite_data_source shinken ; default is that the variable is unset
}
```

SQL Based Modules - PNP4Nagios Graphing PNP4Nagios is a graphing tool that has a web interface for RRDTool based databases. Shinken can export performance data to an npcd database which will feed the RRD files (fixed sized round robin databases). You can *learn how to install PNP4Nagios* if you haven't done it already.

npcdmod: export perfdatas to a PNP interface Export all perfdata for PNP.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: npcdmod
- path: path to the npcd config file

Here is an example:

```
define module{
 module_name  NPCD
 module_type  npcdmod
 config_file  /usr/local/pnp4nagios/etc/npcd.cfg
}
```

SQL Based Modules - Frontend Centreon2 Centreon2 use a NDO database, so you will need the ndodb_mysql module for it.

ndodb_mysql: Export to a NDO Mysql database Export status into a NDO/Mysql database. It needs the python module MySQLdb (apt-get install python-mysqldb or easy_install MySQL-python).

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: ndodb_mysql
- database: database name (ex ndo)
- user: database user
- password: database user passworddt
- host: database host
- character_set: utf8 is a good one

Here is an example:

```
define module{
```

```
     module_name      ToNdodb_Mysql
     module_type      ndodb_mysql
     database         ndo       ; database name
     user             root      ; user of the database
     password         root      ; must be changed
     host             localhost ; host to connect to
     character_set    utf8      ;optionnal, UTF8 is the default
}
```

File based Legacy modules - perfdata export

service_perfdata: export service perfdatas to a flat file

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: service_perfdata
- path: path to the service perfdata file you want

Here is an example:

```
define module{
```

```
    module_name      Service-Perfdata
    module_type      service_perfdata
    path             /usr/local/shinken/src/var/service-perfdata
}
```

host_perfdata: export host perfdatas to a flat file

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: host_perfdata
- path: path to the host perfdata file you want

Here is an example:

```
define module{
```

```
    module_name      Host-Perfdata
    module_type      host_perfdata
    path             /usr/local/shinken/src/var/host-perfdata
}
```

Legacy File based Modules - Old CGI or VShell The Old CGI and VShell use the flat file export. If you can, avoid it! It has awful performance, all modern UIs no longer use this.

status_dat: export status into a flat file Export all status into a flat file in the old Nagios format. It's for small/medium environment because it's very slow to parse. It can be used by the Nagios CGI. It also export the objects.cache file for this interface.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: status_dat
- status_file: path of the status.dat file /usr/local/shinken/var/status.dat
- object_cache_file: path of the objects.cache file
- status_update_interval: interval in seconds to generate the status.dat file

Here is an example:

```
define module{
```

```
    module_name              Status-Dat
    module_type              status_dat
    status_file              /usr/local/shinken/var/status.data
    object_cache_file        /usr/local/shinken/var/objects.cache
    status_update_interval   15 ; update status.dat every 15s
}
```

Deprecated or unsupported modules

SQL Based MerlinDB This interface is no longer supported and is going to be completely removed from Shinken.

SQL based ndodb_oracle - Icinga web frontend using NDO Oracle This interface is no longer supported and is going to be completely removed from Shinken.

CouchDB: Export to a Couchdb database This interface is no longer supported and is going to be completely removed from Shinken.

TSCA (Thrift Service Check Acceptor) TSCA is a receiver/arbiter module to receive hosts and services check results. It provides the same functions as NSCA with additional features. High performance binary transmission, multi line output and auto generated clients for a variety of languages.

What is thrift ? Let's cut and paste the wikipedia definition from'en.wikipedia.org/wiki/Apache_Thrift'_ :

"Thrift is an interface definition language that is used to define and create services for numerous languages.[1] It is used as a remote procedure call (RPC) framework [..]. It combines a software stack with a code generation engine to build services that work efficiently to a varying degree and seamlessly between ActionScript, C#, C++ (on POSIX-compliant systems), Cappuccino, Cocoa, Erlang, Haskell, Java, OCaml, Perl, PHP, Python, Ruby, and Smalltalk."

Installation In any case, you have to install thrift with support for python (on the server side) and languages you want to use for clients.

Get it from thrift.apache.org or in your favorite distribution repository.

Server side Go to the tsca module directory and generate the python stub for the server side installation

```
cd shinken/modules/tsca
$ thrift --gen py tsca.thrift
```

Declare the module is shinken-specific.org

```
define module{
      module_name     TSCA
      module_type     tsca_server
      host            0.0.0.0
      port            9090
}
```

Samples clients There are three(3) client samples written in python, ruby and java in contrib/clients/TSCA of the Shinken distribution. You can use and extend them to send data directly in your code directly to Shinken's TSCA receiver/arbiter module.

The samples clients read a CSV file from stdin and send them the the TSCA running on localhost:9090. The CSV has the following format :

```
hostname,service description,output,rc
```

Any use of TCP in an application should take care not to block the program and to have very short timeouts. For applications that need non blocking functions, prefer a UDP based transport or a local buffer file with a separate application(send_nsca, thrift, etc) to forward your data to Shinken.

Ruby Generate the stub

```
$ thrift --gen rb ../../../shinken/modules/tsca/tsca.thrift
```

Run the client

```
$ cat file_state | ruby RubyClient.rb
```

Python Generate the stub

```
$ thrift --gen py ../../../shinken/modules/tsca/tsca.thrift
```

Run the client

```
$ cat file_state | python PythonClient.py
```

java Generate the stub

```
$ thrift --gen java ../../../shinken/modules/tsca/tsca.thrift
```

Compile the client

```
$ ant
```

Run the client

```
$ cat file_state | java JavaClientThrift
```

VMWare Arbiter module

How it works The arbiter has a module that allows the host->VM automatic host dependency creation. In fact, the module is far more generic than just this. It's a generic "host link dependencies" module.

It reads a mapping file (simple json format) with son->father links. It call an external script at a regular interval : the one I wrote is a VMWare mapping one. It used the check_esx3.pl (that all ESX admin should have) plugin and generate the mapping file. When this file is changed, the module reloads it, creates new links and deletes old ones. So when you VMotion a virtual machine, in the next pass, there will be creation of a new link and deletion of the old one in the scheduler that manages it :)

How to define it The definition is very easy :

```
define module{
     module_name       VMWare_auto_linking
     module_type       hot_dependencies
     mapping_file      /tmp/vmware_mapping_file.json
     mapping_command   /usr/local/shinken/libexec/link_vmware_host_vm.py -x '/usr/local/shinken/libex
     mapping_command_interval 60   ; optionnal
     mapping_command_timeout   300 ; optionnal
}
```

Then you add it in you arbiter object :

```
define arbiter {
    [...]
    modules   VMWare_auto_linking
}
```

So here, it will call the script /usr/local/shinken/libexec/link_vmware_host_vm.py with a listing of the vCenter vcenter.mydomain.com and generate the mapping file /tmp/vmware_mapping_file.json.

You can call : /usr/local/shinken/libexec/link_vmware_host_vm.py –help

for the full help on this script.

It looks at the file modification time each second. This command can also be launch by an external cron of course.

Note: So if you want to write a script that does this for XEN servers, all you need is to generate a json file with all the mapping. I didn't wrote the doc about this, but you can look in the test file for it, the format is very very easy :)

Here is an example of the JSON mapping file syntax:

%%:ref:*["host", "physical_host"], ["host", "virtual_machine"* <["host", "physical_host"], ["host", "virtual_machine">, "host", "physical_host"], ["host", "other_virtual_machine" <"host", "physical_host"], ["host", "other_virtual_machine">]%%

So just a list of couple 'host' string (from now only host are managed) and the host name.

Beware about it : you need the real host_name, including case.

Web Service Module The Ws_arbiter module is a Receiver or Arbiter module to receive passive check results from remote hosts via HTTP(s). This module is considered a work in progress but can be used for testing and improvement.

Configuring the Web Service Module If data is POSTed to this page, it will validate the data to determine if it is a service or host check result and submit the data to the Shinken external command queue.

The web service listens by default to TCP port 7760. The web service supports anonymous or authenticated access. Web service parameters are set in the Shinken-specific.cfg file, in the Ws_arbiter module. To enable the web service, simply add the module to your Arbiter or Receiver daemon configuration in Shinken-specific.cfg

Using the Web Service Module The web service listens for POSTs to: /push_check_result

Use curl or embed the HTTP calls in your software to submit check results.

curl -u user:password -d "time_stamp=$(date +%s)&host_name=host-checked&service_description=service-checked&return_code=0&output=Everything OK" http://shinken-srv:7760/push_check_result

Example with more readability:

```
curl
```

-u user:password -d "time_stamp=$(date +%s)

```
&host_name=host-checked
&service_description=service-checked
&return_code=0
&output=Everything OK
http://shinken-srv:7760/push_check_result
```

SNMP module This part must be splitted and sent in all module repositories

Shinken integrated SNMP Module

SnmpBooster Download Install and Configure

- *What is the SnmpBooster module*
- Install and configure the SNMP acquisition module. [You are here]
- *Reference - SnmpBooster troubleshooting*
- *Reference - SnmpBooster design specification*
- *Reference - SnmpBooster configuration dictionnary*

Downloads

The SnmpBooster module and genDevConfig are currently in public beta prior to integration within Shinken. You can consult t

- github.com/xkilian/genDevConfig
- github.com/titilambert/shinken/tree/snmp_booster/shinken/modules (snmp_booster branch) * Simply right-click and download snmp_poller.py then copy it to shinken/modules/

Requirements The SnmpBooster module requires:

- Python 2.6+
- Shinken 1.2+
- PySNMP 4.2.1+ (Python module and its dependencies)
- ConfigObj (Python module)
- python-memcached
- memcachedb or memcached package for your operating system (ex. For Ubuntu: apt-get install memcachedb) *Note*

The genDevConfig profile generator depends on:

- Perl 5.004+
- 4 perl modules available from CPAN and network repositories. genDevConfig/INSTALL has the installation details.

STRONGLY RECOMMENDED: Use the same version of Python and Pyro on all hosts running Shinken processes.

Installation SnmpBooster:

- Install the dependencies
- Copy the file snmp_poller.py from the git repository to your shinken/modules directory.
- Configuration steps are listed in the present web page.

genDevConfig:

- Download and extract the archive to your server.
- See genDevConfig/INSTALL on how to install and configure it.

Configuration

How to define the SnmpBooster module in the Shinken daemons You need to modify shinken-specific.cfg, which is located in $shinken/etc/shinken-specific.cfg

Arbiter daemon configuration Simply declare the module:

```
modules SnmpBooster</code>
```

Scheduler daemon configuration

Simply declare the module:

<code>modules SnmpBooster

Poller daemon configuration Simply declare the module:

```
modules SnmpBooster</code>
```

SnmpBooster Module declaration

Included in Shinken v1.2.1 shinken-specific.cfg.

<code>define module {

```
module_name          SnmpBooster
module_type          snmp_poller
datasource           /usr/local/shinken/etc/packs/network/SnmpBooster/   ; SET THE DIRECTORY FOR YOUR
memcached_host       x.x.x.x  ; SET THE IP ADDRESS OF YOUR memcached SERVER
memcached_port       11211  ; default port for a memcached process
```

}

If you do not know the IP adress on which your memcache is listening, check under /etc/memcached.conf. Or do a:

```
netstat -a | grep memcached</code>
If you are running a test on the local machine you can leave memcached on 127.0.0.1 (localhost), but
```

How to define a Host and Service

Step 1

Create a template for your SNMP enabled devices.

Sample template:

<code>cd shinken/etc/packs/network/ mkdir SnmpBooster

vi shinken/etc/packs/network/SnmpBooster/templates.cfg

```
define command {
```

```
command_name    check_snmp_booster
command_line    check_snmp_booster -H $HOSTNAME$ -C $SNMPCOMMUNITYREAD$ -V 2c -t $ARG1$ -i $_SERVICE
module_type     snmp_poller
```

}

```
define service {
```

```
name                    default-snmp-template
check_command           check_snmp_booster!$_SERVICEDSTEMPLATE$!$_SERVICEINST$!$_SERVICETRIGGERGROUP
_inst                   None
_triggergroup           None
max_check_attempts      3
check_interval          1
retry_interval          1
register                0
```

}

```
define host{
```

```
name                    SnmpBooster-host
alias                   SnmpBooster-host template
check_command           check_host_alive
max_check_attempts      3
check_interval          1
retry_interval          1
use                     generic-host
register                0
```

}

Step 2 Define some hosts and services. You would typically use genDevConfig or another configuration generator to create these for you.

Mandatory service arguments related to SNMP polling:

```
_dstemplate                Cisco-Generic-Router  ; Name of a DSTEMPLATE defined in the SnmpBooster co
```

```
snmpcommunityread    which is set in your resource.cfg file
```

Optional service arguments related to SNMP polling with default values:

```
_inst                   None   ; Could be numeric: 0, None or an instance mapping function like: map
```

```
_triggergroup           None   ; Name of the triggergroup defined in the SnmpBooster config.ini file
```

Sample Shinken host and service configuration:

```
# Generated by genDevConfig 3.0.0
# Args: --showunused -c publicstring 192.168.2.63
# Date: Thu Aug 30 17:47:59 2012

#######################################################################
# Description: Cisco IOS Software, C2960 Software (C2960-LANBASEK9-M), Version 12.2(50)SE4, RELEASE S
#     Contact:
# System Name: SITE1-ASW-Lab04
#    Location:
#######################################################################

define host {
```

```
 host_name            192.168.2.63
 display_name         192.168.2.63
 _sys_location
 address              192.168.2.63
 hostgroups
 notes
 parents
 use                  default-snmp-host-template
 register             1
}

define service {
```

```
 host_name            192.168.2.63
 service_description  chassis
 display_name         C2960 class chassis
 _dstemplate          Cisco-Generic-Router
 _inst                0
 use                  default-snmp-template
 register             1
}

define service {
```

```
 host_name            192.168.2.63
 service_description  chassis.device-traffic
 display_name         Switch fabric statistics - Packets per Second
 _dstemplate          Device-Traffic
 use                  default-snmp-template
 register             1
}

define service {
```

```
host_name            192.168.2.63
service_description  if.FastEthernet0_1
display_name         FastEthernet0_1 Description: Link to Router-1 100.0 MBits/s ethernetCsmacd
_dstemplate          standard-interface
_inst                map(interface-name,FastEthernet0_1)
use                  default-snmp-template
register             1
```

}

Here is an example configuration of the config.ini file

```
[DATASOURCE]
```

```
  OidmyOidDefinition = .1.3.6.1.45.0
  [myOidDefinition] ; Use the same name as the myOidDeiniftion, but omit the leading "Oid"
      ds_type = DERIVE
      ds_calc = 8,*  ; RPN expression : Oid, 8, *  Which means Oid * 8 = ds_calc
      ds_oid = $OidmyOidDefinition
[DSTEMPLATE]
```

```
  [myCiscoRouter]
      ds = myOidDefinition
[TRIGGER]
```

```
  [trigger1]
      warning = RPN expression
      critical = RPN expression
  [trigger2]
      warning = RPN expression
      critical = RPN expression
[TRIGGERGROUP]
```

```
[CiscoRouterTriggers]
    triggers = trigger1, trigger2
```

Shinken integrated SNMP Module

Overview

What is it The SnmpBooster module allows Shinken Pollers to directly manage SNMP data acquisition. This is an all Python cross-platform SNMP module. It is tightly integrated with the Shinken Poller, Scheduler and Arbiter daemons to provide the best possible user experience.

Design specification summary

- STATUS - DESIGN SPEC PERFORMANCE
- [Done] Functions as an integrated Shinken Poller module
- [Done] Necessary integration code commited to Shinken official release (Integrated starting at v1.2)
- [Done] Ability to collect thousands of SNMP metrics per second
- [Done] Be compatible with distributed data acquisition
- [Done] Collect data for a host/check_interval tuple via SNMP in a single pass
- [Done] Use all builtin Shinken scheduler logic for retries, forced checks, timeouts, dependencies, parents
- [Done] Store collected data for the duration of the check_interval in a memcached/membase
- [Done] On a restart, after the first collection, be able to pick up where the last check left and calculate derived values
- [Done] Forced check are not allowed within 30 seconds of last SNMP query to the same host/check_interval, all other requests get data from the cache.
- [Done] Only a single request to the host/check_interval via SNMP is allowed at a time, all other requests get data from the cache.
- STATUS - DESIGN SPEC USABILITY
- [Done] Usage documentation
- [xxxx] SkonfUI and Discovery usage documentation
- [xxxx] Provide sample configuration packs in Shinken
- [Done] Provide sample config.ini with examples of all types of data * SNMP OIDS, DATASOURCES, DSTEMPLATES, TRIGGERS and TRIGGERGROUPS

- [Done] Directly compatible for use with genDevConfig Shinken SNMP configuration generator
- [Done] Provide meaningful feedback for users on errors
- [Done] Capture all tracebacks and convert them to actual error or warning messages
- STATUS - DESIGN SPEC FEATURES
- [Done] Return state and performance metrics
- [Done] Performance metrics can be returned in a Weathermap compatible format
- [Done] Configuration file format is ConfigObj INI
- [Done] Load all valid INI configuration files from a directory and merge them
- [Done] Load a single INI configuration file
- [xxxx] Load a list of INI configuration files
- [Done] Configuration file describes all generic acquisition parameters (OID, DATASOURCE, DSTEMPLATE, MAP, TRIGGER, TRIGGERGROUP)
- [Done] Supports Triggers which are calculation rules to determine states
- [Done] Triggers support an RPN (Reverse Polish Notation) calculation engine which includes mathematical and logical operators
- [Done] Each TRIGGER is associated with a severity level, WARNING or CRITICAL
- [Done] Multiple TRIGGERS can be associated with a TRIGGERGROUP
- [Done] Use builtin Python Operators
- [Done] Support DERIVE, TEXT, GAUGE and COUNTER data types
- [xxxx] Support TIMETICKS data type
- [Done] Support applying RPN based calculations to received metric for scaling or conversion purposes
- [Done] Use a Python SNMP library which supports asynchronous acquisition PySNMP
- [Done] Datasources can use rule based runtime instance mapping
- [Done] Set Snmp version as a check runtime option
- [Done] Set Snmp DSTEMPLATE as a check runtime option
- [Done] Set Snmp TRIGGERGROUP as a check runtime option
- [Done] Set Snmp COMMUNITY as a check runtime option
- [Done] Use Snmp version 2c GetBulk
- [xxxx] Support Snmp version 2c GetNext if GetBulk is not supported
- [xxxx] Support Snmp version 1 GetNext
- [xxxx] Set Snmp Timeout as a check runtime option, instead of a hardcoded value at 5 seconds
- STATUS - DESIGN SPEC MAINTAINABILITY
- [xxxx] Functions documented in the source code
- [Done] Critical functions documented in the source code
- [Done] Locking sections identified in the code
- [xxxx] Unit tests with at least 80% coverage

- [xxxx] Unit tests integrated with Shinken test suite
- [Done] Code hosted on github
- [xxxx] configuration validity and integrity checking of all INI files
- [xxxx] Pep8 compliant
- [xxxx] Pylint pass

genDevConfig Plugins - Compatibility status with SnmpBooster

- STATUS - genDevConfig maintained Plugins
- [Done] Avaya ES switches
- [Done] Avaya ERS routing switches
- [Done] Cisco 29x0 switches
- [Done] MIB-II Interfaces
- [Done] Cisco PIX/ASA
- [Done] JUNOS devices
- [Done] Cisco IOS routers
- [Done] NetSNMP unix hosts ** Validation required**
- [Done] Packeteer devices ** Validation required**
- [Done] Sensatronics devices ** Validation required**
- [Done] Foundry devices ** Validation required**
- [Done] Packeteer devices ** Validation required**
- [Done] Cisco CSS ** Validation required**
- [InProgress] New Cisco Access points
- STATUS - Other maintained Plugins

Tip: [xxxx] Denotes a specification that is planned but not implemented

[InProgress] Denotes a specification that is under development

[Done] Denotes a specification that is implemented

SnmpBooster reference dictionary

- Jump back to *SnmpBooster documentation index*

SnmpBooster.ini dictionary

There are five dictionaries:

- [DATASOURCE]
- [DSTEMPLATE]
- [MAP]
- [TRIGGER]

- [TRIGGERGROUP]

DATASOURCE DICTIONARY OidVariableName refers to an actual OID that can be queries using SNMP against the device on the network.

[VariableName] refers to a Datasource and all the information required to gather and prepare the data using SNMP ds_type refers to how the data should be prepared ds_calc refers to any scaling manipulations to make the data more understandable. This is an RPN expression, where the first variable is omitted, as it is always the $OidVariable ds_oid refers to the actual $OidVariable name. An instance identifier can be appended to the name to signify that an instance is provided by the Shinken service definition. This information is passed when the check is called. ...

DSTEMPLATE DICTIONNARY [DsTemplateName] refers to the name of the DSTEMPLATE that will be referred to in the Shinken service definitions. ds refers to the list of DATASOURCES to be collected. If an instance is expected for the list of DATASOURCES, it MUST be the same instance for all Oids. If a different instance is required, use a second DSTEMPLATE.

TRIGGER DICTIONNARY

TRIGGERGROUP DICTIONNARY

MAP DICTIONNARY

SnmpBooster.ini example configuration This example definition will be used to explain each section.

[DATASOURCE]

```
OidmyOidDefinition = .1.3.6.1.45.0
[myOidDefinition] ; Use the same name as the myOidDeiniftion, but omit the leading "Oid"
    ds_type = DERIVE
    ds_calc = 8,*  ; RPN expression : Oid, 8, *  Which means Oid * 8 = Total
    ds_oid = $OidmyOidDefinition
```

[DSTEMPLATE]

```
[myCiscoRouter]
    ds = myOidDefinition
```

[TRIGGER]

```
[trigger1]
    warning = RPN expression
    critical = RPN expression
[trigger2]
    warning = RPN expression
    critical = RPN expression
```

[TRIGGERGROUP]

```
[CiscoRouterTriggers]
    triggers = trigger1, trigger2
```

SnmpBooster.ini configuring SNMP Datasources

The first location is generic data related to SNMP parameters.

- DATASOURCE information * SNMP OID * Type of data and how can it be interpreted (GAUGE, COUNTER, COUNTER64, DERIVE, DERIVE64, TEXT, TIMETICK) * Data format preparation (Scaling the data for example bits to bytes) * Is there an instance to append to the
- Instance MAP function * Mapping the instance dynamically using a function * Data or rules related to the mapping function

SnmpBooster.ini configuring SNMP DSTEMPLATES

- DSTEMPLATEs to associate DATASOURCE to actual device classes * List of DATASOURCES associated with a, for example, Cisco 1900 router. Which in turn can be applied to a Shinken service

SnmpBooster.ini setting triggers/thresholds

- TRIGGER and TRIGGERGROUPS to apply thresholding rules * Define triggers and associate them with a TRIGGERGROUP name that can be applied to a Shinken Service

Shinken integrated SNMP Module

Overview

- Jump back to *SnmpBooster documentation index*

Tip: The module is now in public beta as of 2012-10-26! Have Fun!

Nothing new to add, more to come in 2013. 2013-01-19.

What is it The SnmpBooster module allows Shinken Pollers to directly manage SNMP data acquisition. This is an all Python cross-platform SNMP module. It is tightly integrated with the Shinken Poller, Scheduler and Arbiter daemons to provide the best possible user experience.

Why use it The SnmpBooster module is designed to be very efficient and scalable. It has a very flexible configuration method to make it easy to use with Shinken Monitoring Packs and Shinken discovery runners like genDevConfig.

This acquisition module was professionally designed and developed.

It is meant to be used by the very capable discovery engine genDevConfig (**v3.0.5 and newer**) originally developed for the Cricket SNMP monitoring tool and converted for use with Shinken.

It is one of the very few serious SNMP v2c implementation making use of SnmpGetBulk type requests.

How does it work

Shinken Integration

1. The SnmpBooster Arbiter module reads the Shinken SnmpBooster configuration file(s). It reads the check commands and based on the values in the check commands that use the snmp_poller module it will creates a shared configuration cache using memcached/memcachedb. The memcache key is always the combination of the hostname. This permits to tie together Shinken Hosts and Services with the SNMP specific configuration. (MongoDB and Redis are planned to be supported in the future) The Scheduler daemon schedules Host and Service checks as it normally does.

3. The SnmpBooster module will check that a memcache host key exists for the check to be launched. Then the SnmpBooster poller module will query all services related to a host for a given acquisition frequency in one pass. (all checks done every 2 minutes will be executed in bulk, same for those every 5 minutes)

5. Check results are cached for the acquisition check_interval. The next time a check request for data from the same host is received from the Scheduler, the data will be fetched from memcache. Resulting is extremely low check latency.

2. 6. The SNMP checks still benefit from retries, timeouts, forced checks, dependencies and the powerful Scheduler daemon logic.

6. The Scheduler daemon can still force an immediate re-check by flushing the cache. This is required for the dependency model.

Performance SnmpBooster uses SNMP v2c getbulk for high efficiency, unless forced to use SNMP v2c get-next or SNMPv1 get-next. GetBulk uses a single request PDU to ask for multiple OIDs or even entire tables, instead of sending one request PDU per OID.

For example: *A typical 24 port network switch with two uplinks might use 375 OIDS (8 OIDs per interface, plus general OIDs for chassis health, memory, cpu, fans, etc.). **SnmpBooster will only require around 4 request PDUs*

*instead of 375 request PDUs**. Each PDU is a request packet which takes time to create, send get processed and return. More timeouts to manage, more connections, more impact on the remote device and more latency means much fewer checks per second.*

The SnmpBooster module supports automatic instance mapping for OIDs. (Ex. Based on the interface name it will figure out that the SNMP index(or instance) is 136. This is automatically handled by genDevConfig and SnmpBooster, no user input required. :-)

The generic SNMP configuration information is stored in the Shinken SnmpBooster INI files. There is a Defaults_unified.ini and a series of other Defaults files, one per discovery plugin for genDevConfig.

Important: genDevConfig plugins have all been converted to use the new dynamic instance mapping methods. You are now free to use most if not all Defaults*.ini files included with genDevConfig. 2012-10-28

Limitations You should have memcached instances running on each poller responsible for snmp polling. You should have your pollers with SnmpBooster in the same datacenter, as they need to be on the same machine with good connectivity to the active memcached instance. SnmpBooster is not compatible with distributed pollers in multiple datacenters, sorry, the current design of SnmpBooster uses a single centralized memcached instance for storing the timeseries data. For distributed datacenters to be supported, each poller+scheduler+memcached must be realm restrained, which is not the case today.

Design specification *SnmpBooster design specification* and current development status.

Data model The information required to define the data is split in two locations.

The first location is the host and service Shinken configuration (You need to generate or write this)

- Device specific information
  - IP addresses, host_names, device types, instance keys
  - A DSTEMPLATE must be referred to in the Service definition
  - A static SNMP instance could be referred to in the Service definition
  - An SNMP instance MAP function could be referred to in the Service definition
  - A TRIGGERGROUP could be refered to in the Service definition

The second location is SNMP Defaults.* templates. (Here you can create new devices or add new data sources)

- DATASOURCE information
  - SNMP OID
  - Type of data and how can it be interpreted (GAUGE, COUNTER, COUNTER64, DERIVE, DERIVE64, TEXT, TIMETICK)
  - Data format preparation (Scaling the data for example bits to bytes)
  - Is there an instance to append to the
- Instance MAP function * Mapping the instance dynamically using a function * Data or rules related to the mapping function
- DSTEMPLATEs to associate DATASOURCE to actual device classes * List of DATASOURCES associated with a, for example, Cisco 1900 router. Which in turn can be applied to a Shinken service
- TRIGGER and TRIGGERGROUPS to apply thresholding rules * Define triggers and associate them with a TRIGGERGROUP name that can be applied to a Shinken Service

A final location containes rules to build your Shinken configuration.

- genDevConfig plugins create Shinken configurations

Installation and configuration *SnmpBooster installation*

Reference Dictionnary *SnmpBooster reference dictionary*

Troubleshooting *SnmpBooster troubleshooting*

Graph templates These are .graph files defined in your Shinken configuration directory. Refer to the Shinken graphite templates(Not yet created) or PNP4Nagios how-to documentation. The graph templates are independent from SnmpBooster and provide templates for any collected data from Shinken.

SnmpBooster Troubleshooting

- Jump back to *SnmpBooster documentation index*

Check your config

- Have you defined the poller module name?
- Have you defined the correct path to the directory containing your Defaults*.ini files?
- Have you addded the Snmpbooster module to your arbiter, poller, scheduler?
- Have you added copied the genDevConfig templates.cfg in shinken/packs/network/SnmpBooster/
- Have you installed PySNMP, memcached and other dependencies?

Software version consistency Shinken and SnmpBooster now require **the same Python and Pyro version on all hosts running a Shinken daemon**.

If you cannot use the packaged version of Python and its modules (Pyro, memcached, etc.). Use virtualenv to declare a python version to use and install all required modules in that virtualenv.

Software version requirements Have you verified that the *requirements* are met. Python, PySNMP, Shinken, Pyro, memcached, etc.

Validate your check command arguments Use the check_plugin command and comment out the module to learn what were the exact arguments sent by the poller. This will permit you to validate all the arguments, like snmp community string, inheritance, template application, etc.

Validate connectivity

Take a packet trace using a tool like Wireshark to validate that the remote host is responding.

- Has the host responded
- **Is SnmpBooster repeating the request more often than the polling interval.**
  - If you are seeing repeated requests your device may have a compatibility issues.

- Save an snmpwalk of the device, get a packet trace using Wireshark, set the poller to debug and save the poller.log file (shinken/var/poller.log). Send all three to the SnmpBooster developers.
- Note: It is normal to see one or more bulkGet requests if you are getting large amounts of data. Ex. a 24 port switch will take 2-3 request packets.

Performance Make sure you have a low latency connection to your memcache from the Poller. Your memcache server can be replicated to all your poller hosts that should also run memcache instances. Check that memcached is running: netstat -a | grep memcached

Faulty Template A bad snmp_template file was distributed in the genDevConfig sample-config directory, there were two glaring errors.

This was fixed on 2012-10-16. Make sure you update your template, or use the data from the wiki.

Note that the template should be called: SnmpBooster-template.cfg to make it easier to troubleshoot in the logs. So when you search for SnmpBooster in your logs it will show up as well.

Log files All warnings and errors generated by the SnmpBooster module start with "[SnmpBooster] error text" and are logged using the standard Shinken logger.

The Arbiter daemon can output initial configuration, loading of host keys and intervals in memcached type error messages. The Scheduler daemon can output scheduling and alert related messages. The Poller daemon can output messages related to instance mapping, acquisition timeouts, invalid community strings, cache failures and more. These are available in the Web interface, as they are placed in the check results for the service.

You can simply do a "grep SnmpBooster *" in your shinken/var directory to see the latest messages related to the SnmpBooster module. You can also sort messages by timestamp to make it easy to find where and when errors occurred.

cd shinken/var grep SnmpBooster *

memcache persistence If you restart your memcache server or memcache crashes, your poller will no longer be able to validate that a host exists in memcache prior to writing.

You should use memcachedb to achieve persistence in case of memcache failures.

Common errors returned by SnmpBooster in the log file Errors should be fairly explicit and mean what they say, though there can be exceptions. Lets try to clear some of them.

__Arbiter log **errors__**

Missing ds_oid : This means that a variable in your OID definitions is missing, or your DATASOURCE is not named correctly or your ds_oid variable is missing. There is a typo in your ds_oid variable (ex. ds-oid, or ds_oid = $OidNameIncorrectFFFRA.%(instance)s).

Datasource not defined : Your DSTEMPLATE uses a DATASOURCE that doesn't exist check the [DataSourceName] you are referring to. Does it contain the expected OID variable, $OidName.

Missing ds_type : The DATASOURCE always needs to have a ds_type definition, GAUGE, COUNTER, DERIVE, TEXT, TIMETICK, DERIVE64, COUNTER64.

__Poller log **errors__**

Problems with calculations, repeated polling, hosts not responding, etc.

__Memcached **errors__**

memcachedb and memcached do not use the same default port. Configure the correct memcachedb port to match what is declared in your SnmpBooster module under shinken-specific.cfg.

On Ubuntu 12.04 the default installation is on port 21201 instead of 11211. This causes the error "[SnmpBooster] Memcache server (127.0.0.1:11211) is not reachable" when Shinken starts.

To change it, you must edit the file /etc/memcachedb.conf

Memcached Notes On Ubuntu 12.04 the default instalation is on port 21201 instead of 11211. This causes the error "[SnmpBooster] Memcache server (127.0.0.1:11211) is not reachable" when shinken starts.

To change it, you must edit the file /etc/memcachedb.conf

WebUI module This part must be splitted and sent in all module repositories

WebUI integration with Shinken The WebUI is an external broker module. So it's an external process launched by the broker that "eats" broks (broker messages) from the brokers. So it can get *all* broks if you place this broker in your top level realm.

The WebUI does not use a database to get data. Instead, it use a "regenerator" object that will eat each broks, and will "recreate" all Hosts/Services/Contacts objects as if the code was in the scheduler daemon. So basically, WebUI and pages always reflect the CURRENT state of hosts/services objects.

The WebUI http layer is managed by bottle.py. It's a small but powerful framework.

How does the WebUI function globally ?

There a 2 Threads running:

- the main thread is the bottle.py (http) listener. It will use the best backend it finds. We recommend using python-paste. If it does not find one, it will use the default swsgi. Paste is multi-thread, swsgi is mon-thread, so please use paste if you want to avoid locking problems.
- the 2nd thread is the regenerator one. It only gets broks and gives them to the regenerator object.

There is a lock system between the threads. You can have N Http requests in progress without problem, but during this time the renererator one will wait. During execution of the regenerator, no requests are processed. This is not considered a problem, as the regenerator is very quick, and there is only a 1s lock for a 7k service conf loading, so it's not a huge problem.

What is a WebUI User? A WebUI user is a contact. A true contact object. You must match a contact name for your user.

To create a new page? All pages are in the shinken/webui/plugins directory. Each "part" has it's own directory. A part (like the eltdetail, element detail) can have more than one "page" (like /host or /service for eltdetail).

From here we will supose you want to create a "/contact" page.

You can copy the dummy example in the plugins directory into a contact directory.

You need to change the contact/dummy.py file into a contact/contact.py file, because the webui will search for a dir/dir.py file to "load".

Templates Templates are HTML with some Python code in it in the plugins/*/views direcotry for specific templates, and the "global layout" (menu and all common part) in the webui/views directory.

Your template must call the template layout (layout.tpl in the webui/views directory) wit ha "rebase" call.

If you put the rebase call at the beginning of your template, all there is below will be place "inside" the layout that will call the common javascripts and css, make the menu adn then call your html/python code.

The rebase call can take arguments. You MUST give it:

- user: the user you give it in the return dict of your .py code

Then all is optional:

- title: title of the page
- top_right_banner_state: int, global state with clouds to put in your top right page. Look at the problem.tpl code for an example.
- js and css list: list of YOUR specific javascript or css to call AFTER the common ones.
- refresh: boolean, set the refresh to 60s or do not refresh at all

- menu_part: will put the little "^" under this part of the menu.

Example of a call, taken from the problems view:

```
rebase layout title='All problems', top_right_banner_state=top_right_banner_state, js=['problems/js/a
roblems/js/autocompleter.Request.js', 'problems/js/autocompleterObserver.js'], css=['problems/css/acc
ms/css/autocompleter.css', 'problems/css/perfometer.css'], refresh=True, menu_part='/'+page, user=use
```

Call Python objects in your templates Your templates are mainly HTML code. But of course you can call python code in it. The dict you returns in the plugin.py call will be available in this page.

For example, the my_host variable will be available in the page with the host object you find (or None if your give it a bad name of course). Then you can "call" python with for example here to show the host_name: `<span>My host name is *my_host.host_name* </span>` is a way in the templates to "call a variable or function" that will return a string, here the host_name.

If the function or property you call must return HTML code that SHOULD be output as it, without "protection", you must put a ! before your call.

Let use an example where the output value of an host is in fact an html output. If you use the code `my_host.output`, bottle.py will "protect" the html generated by escaping the string, and change <> characters with escaped value. You can change this by calling `my_host.output`. Of course, it's a security problem if the output is with a javascript code...

You can also "loop" or put "if" in your template. You just need to put your code with a % before. Like

```
%for i in xrange(1, 10):
  My valus is  {{i}}
%end
```

You must put the %end here, the indentation will NOT be enougth, sorry.

For an if it's also easy:

```
%if host.active_checks_enabled:
  The host got active checks enabled
%else:
  The host DO NOT have active check enabled
%end
```

Which javascript lib are you using? It's mootools 1.3 with all options :)

What to do?

- Finish the /mobile part
- List of current alerts
- Host info
- Host status
- Host interfaces
- Hostgroup status
- dashboard hierachique with states, and BP
- Nagvis
- add bp in nagvis auto-map

- event sources
- correlation
- pre-filtering/enrichment
- user profile
- host/srv conf

WebUI search syntax work in progress

not that we couldn't tell. ;) eh eh

beware the working men and flying tools!

WebUI SSL Certification Lets start: the goal to to have the server.pem and client.pem file in etc/certs.

Go to the etc/certs directory.

```
openssl req -new -nodes -out server.req -keyout server.key -config ./shinken_openssl_cnf
openssl ca -out server.pem -config ./shinken_openssl_cnf -infiles server.req
cp server.pem server.pem.bkp
cp server.key server.pem
cat server.pem.bkp >> server.pem
cp server.pem client.pem
```

You can try to get the validity with for the arbiter with:

```
openssl s_client -connect localhost:7770</code>
```

Amazon AWS/EC2 import

Description You can import data from Amazon AWS/EC2 **'AWS'**_ into Shinken to create hosts.

Amazon provide VM hosting with EC2. With this arbiter module, you will be able to load your EC2 hosts into Shinken.

Prerequisites

You will need the **'libcloud'**_ package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

```
define module {
 module_name      AWS
 module_type      aws_import

 # Configure your REAL key and secret for AWS
 api_key              PAAAB2CILT80I0ZA0999
 secret           GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH
 default_template generic-host        ; if the host is not tagged, use this one
 }
```

- Put in key and secret your private Landscape access. * default_template will be used if your host is not "tagged" in Landscape

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master

     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           AWS
     }
```

Restart your Arbiter and it's done :)

Generated hosts The configuration generated will look as below :

```
define host {
    host_name            i-3fc56e5a
    address              8.8.4.4
    use                  t1.micro,MyTag,EC2,generic-host
    _EC2_AVAILABILITY    us-east-1a
    _EC2_CLIENTTOKEN
    _EC2_DNS_NAME
    _EC2_GROUPS          quicklaunch-1
    _EC2_IMAGEID         ami-1b814f72
    _EC2_INSTANCEID      i-3fc56e5a
    _EC2_INSTANCETYPE    t1.micro
    _EC2_KERNELID        aki-825ea7eb
    _EC2_KEYNAME         testaws
    _EC2_LAUNCHDATETIME  2012-09-26T12:19:38.000Z
    _EC2_LAUNCHINDEX     0
    _EC2_PRIVATE_DNS
    _EC2_PRIVATE_IP
    _EC2_PRODUCTCODE
    _EC2_PUBLIC_IP       8.8.4.4
    _EC2_RAMDISKID       None
    _EC2_STATUS          stopped
    _EC2_TAGS            demo:myvalue,use:MyTag
 }
```

Here with a stopped t1.micro instance with no name. You can put your how "use" parameter by adding a EC2 tag "use" on your VM. It will be output on the host configuration so you can setup the monitoring as you want. .. _libcloud: http://libcloud.apache.org/index.html .. _AWS: https://console.aws.amazon.com

Amazon AWS/EC2 import

Description You can import data from Amazon AWS/EC3 **'AWS'**_ into Shinken to create hosts.

Amazon provide VM hosting with EC3. With this arbiter module, you will be able to load your EC2 hosts into Shinken.

Prerequisites

You will need the **'libcloud'**_ package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

```
define module {
 module_name      AWS
 module_type      aws_import

 # Configure your REAL key and secret for AWS
 api_key              PAAAB2CILT80I0ZA0999
 secret           GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH
 default_template generic-host        ; if the host is not tagged, use this one
 }
```

- Put in key and secret your private Landscape access. * default_template will be used if your host is not "tagged" in Landscape

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master

     address          localhost                  ;IP or DNS adress
     port             7770
     spare            0
     modules           AWS
     }
```

Restart your Arbiter and it's done :)

Generated hosts The configuration generated will look as below :

```
define host {
    host_name            i-3fc56e5a
    address              8.8.4.4
    use                  t1.micro,MyTag,EC2,generic-host
    _EC2_AVAILABILITY    us-east-1a
    _EC2_CLIENTTOKEN
    _EC2_DNS_NAME
    _EC2_GROUPS          quicklaunch-1
    _EC2_IMAGEID         ami-1b814f72
    _EC2_INSTANCEID      i-3fc56e5a
    _EC2_INSTANCETYPE    t1.micro
    _EC2_KERNELID        aki-825ea7eb
    _EC2_KEYNAME         testaws
    _EC2_LAUNCHDATETIME  2012-09-26T12:19:38.000Z
    _EC2_LAUNCHINDEX     0
    _EC2_PRIVATE_DNS
    _EC2_PRIVATE_IP
    _EC2_PRODUCTCODE
    _EC2_PUBLIC_IP       8.8.4.4
    _EC2_RAMDISKID       None
    _EC2_STATUS          stopped
    _EC2_TAGS            demo:myvalue,use:MyTag
 }
```

Here with a stopped t1.micro instance with no name. You can put your how "use" parameter by adding a EC2 tag "use" on your VM. It will be output on the host configuration so you can setup the monitoring as you want. .. _libcloud: http://libcloud.apache.org/index.html .. _AWS: https://console.aws.amazon.com

The distributed retention modules The high availability allow the Arbiter to send a configuration to a spare scheduler, but a spare scheduler does not have any saved states for hosts and services. It will have to recheck them all. It's better to use a distributed retention module so spares will have all the information they need to start with an accurate picture of the current states and scheduling :)

Non distributed retention modules If you are just running tests on a single server, use the pickle or memcache retention modules You can also use MongoDB if you already have it installed for use with the WebUI.

MongoDB MongoDB is a scalable, high-performance, open source NoSQL database written in C++.

Step 1: Install MongoDB:

We will use mongodb package from 10gen repository, so we start by adding it in apt sources list:

```
echo 'deb http://downloads-distro.mongodb.org/repo/debian-sysvinit dist 10gen' > /etc/apt/sources.lis
apt-get update
```

And we install it:

```
apt-get install mongodb-10gen
```

And we install pymongo, the python interface to MongoDB, with easy_install to avoid packages versions problems (like here **'forums.monitoring-fr.org/index.php?topic=5205.0'_**):

```
apt-get remove python-pymongo
easy_install pymongo
```

And finally we start MongoDB :

```
/etc/init.d/mongodb start
```

Step 2: define a mongodb_retention module in your shinken-specific.cfg file:

```
define module {
  module_name MongodbRetention
  module_type mongodb_retention
  uri mongodb://localhost/?safe=true
  database shinken
}
```

Step 3: Declare a retention module for your scheduler(s) :)

Example:

```
#The scheduler is a "Host manager". It get hosts and theirs
#services. It scheduler checks for them.
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
     port     7768                  ; tcp port of the daemon

     #optionnal: modules for things as retention
     modules    MongodbRetention
     }
```

Step 4: Restart the Arbiter, and your Scheduler will now save its state between restarts. :)

Memcached Memcached is a distributed memory resident key/value server. It's very easy to install:

```
sudo apt-get install memcached
sudo /etc/init.d/memcached start
```

The shinken module also needs the python-memcache package to talk to this server.

```
sudo apt-get install python-memcache
```

To use it,

Step 1: define a memcache_retention module in your shinken-specific.cfg file:

```
define module{
     module_name      MemcacheRetention
     module_type      memcache_retention
     server           127.0.0.1
     port             11211
}
```

Step 2: Declare a retention module for your scheduler(s) :)

Example:

```
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
     port     7768                  ; tcp port of the daemon

     #optional: modules for things as retention
     modules    MemcacheRetention
     }
```

Step 3: Restart the Arbiter, and your Scheduler will now save its state between restarts. :)

Redis Redis is a distributed key/value server (on disk and in-memory). It's very easy to install:

```
sudo apt-get install redis-server
sudo /etc/init.d/redis-server start
```

The shinken module also need the python-redis package to talk to this server.

```
sudo apt-get install python-redis
```

Step 1: define a redis_retention module in your shinken-specific.cfg file:

```
define module{
     module_name      RedisRetention
     module_type      redis_retention
     server           127.0.0.1
}
```

Step 2: Declare a retention module for your scheduler(s) :)

Example:

```
#The scheduler is a "Host manager". It get hosts and theirs
#services. It scheduler checks for them.
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
```

```
    port     7768                  ; tcp port of the daemon

    #optionnal: modules for things as retention
    modules    RedisRetention
    }
```

Step 3: Restart the Arbiter, and your Scheduler will now save its state between restarts. :) .. _forums.monitoring-fr.org/index.php?topic=5205.0: http://forums.monitoring-fr.org/index.php?topic=5205.0

How to enable and use Livestatus module

Define the Livestatus module Start by reviewing the ''/etc/shinken/shinken-specific.cfg" file for this module:

```
define module{
```

```
module_name      Livestatus
module_type      livestatus
host             *       ; * = listen on all configured IP addresses
port             50000   ; port to listen on
database_file    /var/lib/shinken/livestatus.db
```

}

With these parameters:

- module_name: name of the module called by the brokers
- module_type: livestatus
- host: IP interface to listen to. The default is *, which means "listen on all interfaces".
- port: TCP port to listen to.
- socket: Unix socket to listen to.
- database_file: the path to the sqlite database file which is used to store the log broks/messages. The default is "var/livelogs.db"
- max_logs_age: the maximum age of the log messages (before they are deleted from the database). The default is 1 year. The argument to this parameter takes the form <number>[<period of time>], where <period of time> can be d for days, w for weeks, m for months and y for years.
- allowed_hosts: a comma-separated list of IP-addresses which are allowed to contact the TCP port. Please keep in mind that these **must be IP-addresses, NOT host names**. Because DNS lookups for every incoming livestatus request could hang up and therefore block the module.

Enable the Livestatus module Still in ''/etc/shinken/shinken-specific.cfg'', find the object Broker and add "Livestatus" to its "modules":

```
define broker{
```

```
    broker_name      broker-1
[...]
```

```
    modules          Simple-log,Livestatus
}
```

Disable human readable logs In ''/etc/shinken/nagios.cfg'', verify that the option **human_timestamp_log** is set to **0**.

In version 0.6.5, you can not have at the same time a simple-log file with human readable timestamp and a Livestatus database.

Exporting data for reporting Shinken can export necessary data for reporting in 3rd party systems.

raw_socket module The raw socket module exports reporting data using a syslog format to a raw TCP socket. Theses logs can be captured, parsed and indexed by any log management system like Splunk or Logstash.

Why export reporting data Custom UIs like Thruk, Multisite, WebUI, Adagios, Nagios IX, etc. All have poor or inflexible reporting. Simply because these are not reporting engines.

This also permits to have a generic reporting method that can accept data from any Nagios, Shinken, Icinga or even Riemann.

Reporting module using Splunk Splunk was selected as the reporting platform for creating, managing and presenting reports. Though the raw_socket module does not have any Splunk specific particularities. It is notable that Splunk reports can be embedded in any 3rd party UI using its REST API.

Raw_socket log format The logs are plain-text and compliant with RFC3164. They use an intelligent date format, a configurable seperator " "(space by default), and key=value pairs in the message data portion of the log. Should a key or value contain a space they must be double quoted. This is syslog using structured data without going to full out JSON that may not be compatible with all log management systems.

The message fields that are supplied in each status update in addition to the standard syslog header are:

- Hostname
- Servicename
- Business impact
- Host/Service status
- Host/Service previous status
- Acknowedgement status
- Maintenance status

Any time the maintenance, host, service or acknowledgement status changes, a log is sent by the Shinken raw_socket module.

Having all relevant data in each log makes it very easy to compute reports for given time periods.

The hostgroup or service group memberships, custom variables or any other configuration related data should be queried from the monitoring system using its API (Livestatus in the case of Shinken and Nagios).

Raw_socket module availability The module is available in both Shinken 1.4 and Shinken 2.0. The module will be integrated in master branches once unit tests and end-to-end testing is completed. 3rd quarter 2013.

Monitoring Linux System with Glances and checkglances.py **'Glances'_** is a fantastic multiplatform system monitoring tool writen by Nicolargo. Glances can run on (Linux, Windows, MacOS ...). There is a growing ecosystem around Glances and of course a Nagios/Shinken plugin : checkglances.py.

How does it work Glances can run in server mode. It provide a XML-RPC server (over http) and allow to retrieve system information throuh a restful API. The only thing to do is to install and start Glances as server on the monitored host, then install checkglances.py on the shinken server and finaly install the glances pack.

Install glances See the glances documentation to install glances on Linux.

<code bash> easy_install glances </code>

There is a debian startup script in the glances repository. And another one for centos here.

Install checkglances.py Just follow the documentation for the checkglances.py prerequisites and put it in your nagios plugins folder.

Install the glances pack Open a terminal as the shinken user and just type the following command

<code bash> shinken install glances </code>

Then just edit the configuration for a linux monitored host and tag it as **glances**

```
define host{
 name mylinuxhost
 use glances
 ...
```

Finaly restart the shinken arbiter

```
service shinken-arbiter restart
```

What will be monitored ? For the moment just the basic system (ram, cpu, load, memory, filesystem and network).

If you want to modify the default thresholds for just a host you can do it by overiding the thresholds macro in your host definition. If you want to do it for several hosts, declare a new template and just add the desired thresholds macro to be overide.

Here is a list of the macros

```
::
```

> _LOAD_WARN 2 _LOAD_CRIT 3 _CPU_WARN 80 _CPU_CRIT 90 _MEMORY_WARN 90 _MEMORY_CRIT 95 _FS /, /home _FS_WARN 90 _FS_CRIT 95 _IFACES eth0, eth1 _NET_WARN 7500000 _NET_CRIT 10000000

Note the _FS and _IFACES macros. They leverage the ability to duplicate service for a given list of things to be monitored. Here you see that / and /home partitions will be monitored. If you want to modify this then just add your own in a new template that will inherit the glances template.

Shinken GLPI integration Shinken supports importing hosts from GLPI

For people not familiar with GLPI, it is an Open-Source CMDB. Applicable to servers, routers, printers or anything you want for that matter. It is also a help-desk tool. GLPI also integrates with tools like FusionInventory for IT inventory management.

You can still have flat files AND GLPI if you want. Hosts imported from GLPI will be treated as standard hosts from flat file (inheritance, groups, etc). In fact, in this first version the module only sends the host_name to Shinken, but there should be more information extracted like network connexions for parents relations in the future. :)

Requirements

- python module MySQLdb
- Compatible version of GLPI Shinken module and GLPI version - ...
- etc..

Enabling GLPI Shinken module In your shinken-specific.cfg file, just add (or uncomment):

```
#You know GLPI? You can load all configuration from this app(
#with the webservices plugins for GLPI, in xmlrpc mode
#and with plugin monitoring for GLPI)
# =============== Work with Plugin Monitoring of GLPI ===============
#All configuration read from this will be added to the others of the
#standard flat file
define module{
     module_name      GLPI
     module_type      glpi
     uri              http://localhost/glpi/plugins/webservices/xmlrpc.php
     login_name       glpi
     login_password   glpi
}
```

And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master
#    host_name       node1       ;result of the hostname command under Unix
     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           GLPI
     }
```

It's done :)

Ip Tag module

Why tag a host based on it's IP address? We learned on the *DMZ monitoring* that you can "tag" a host with a poller_tag so it will be checked only by DMZ pollers. It can be tedious process to manually tag all these hosts. Shinken provides an automated method to do this.

This is handled by the arbiter ip_tag module.

Ip_tag module The ip_tag module is an arbiter module that looks up the host address during the configuration parsing and compares it to an predefined IP range (IPV4 or IPV6). If the range matches, it can apply or add a property, such as poller_tag. Other types of tags could be related to locations, functions, administrative groups, etc.

Method: replace or append.

replace will put the value if the property is unset. This is the default method. .. warning:: Fix me: replace, implies overriding an existing value. And will cause user issues down the line. Rename it to set. Replace should be a different method altogether, so overall there should be 3 methods(set, append, replace).

append will add with a , if a value already exist

Here is an example that will set the poller_tag property with the value DMZ of all hosts that:

- have a their hostadress ip (or name resolved) in the range 192.168.0.1/24.
- do not already have a poller_tag property set

```
define module{
```

```
     module_name     IpTag
     module_type     ip_tag
     ip_range        192.168.0.1/24
     property        poller_tag
     value           DMZ
}
```

To use the module add it in the arbiter object:

```
::
```

define arbiter { [...] modules NSCA,IpTag

}

Add value instead of setting it In the previous example we set the property poller_tag to a value. But what if we want to "add" a value, like a template name? We can change the "method" property of the module to "append" so we can add the "value" to the host property instead of replace it.

Here is an example where we want to add the "dmz" template on the hosts, while also keeping any defined templates:

```
define module{
```

```
     module_name   IpTag
     module_type   ip_tag
     ip_range      192.168.0.1/24
     property      use
     value         dmz

     # Optional method
     method append
}
```

For a host defined as:

```
define host{
```

```
     host_name   example_host1
     address     192.168.0.2
     use         linux
}
```

It will be "changed" internaly in:

```
define host{
```

```
     host_name   example_host1
     address     192.168.0.2
     use         linux,dmz
}
```

Name resolution Of course you don't need to set IP address in the address of your host. You can set a hostname, and it will be resolved, and then compared to the range. :)

Ubuntu Landscape import

Description You can import data from Ubuntu Landscape into Shinken to create hosts.

Ubuntu Landscape, is a web app to manage all your linux servers (update and co), which is provided by Canonical, Ubuntu's parent company.

This is an Arbiter import module. The Arbiter manages the configuration.

Prerequisites

You will need the landscape-api package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

define module { module_name Landscape module_type landscape_import

Configure your REAL key and secret from Landscape key PAAAB2CILT80I0ZA0999 secret GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH default_template generic-host ; if the host is not tagged, use this one

If you are using a specific certificate for landscape_api #ca /path/to.ca.cert

If you need a proxy to access https://landscape.canonical.com/api/ #https_proxy http://user:secret@myproxy.com:3128

}

- Put in key and secret your private Landscape access.
- default_template will be used if your host is not "tagged" in Landscape
- If you are using a specific certificate for connexion, give the full path in ca
- You will certainly need an https proxy to access the Landscape API. If so, configure it there.

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master
#    host_name       node1       ;result of the hostname command under Unix
     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           Landscape
     }
```

Restart your Arbiter and it's done :)

Tip: Your "tags" will be applied as templates for your hosts.

Shinken Livestatus API

Overview

- Jump back to Getting Started
- Jump back to *Livestatus module configuration*

What is it Livestatus API is the modern method of interacting with Shinken and Nagios based systems alike.

Originally developed for Nagios, MK Livetstatus, was re-implemented in Python for use with Shinken by professional developers. The access methods and query languages are the same.

Why use it It is fast.

It is network based using TCP.

It is standard for all Nagios and Shinken monitoring systems.

It uses in-memory structures for status data

It uses a back-end database for historical reporting

It uses an SQL based query language

It has a host of powerful nuts and bolts features (authentication, caching, connection persistence, multiple object methods (JSON, Python)).

What can I do with it? All programs and scripts use (or should use) this method to :

- Obtain the current state of hosts and services
- Obtain the current configuration related to hosts and services
- Send administrative commands (downtimes, comments, forcing checks)
- Filter information to display
- Obtain basic reports and event statistics

Shinken being a modern re-implementation of Nagios has additional features that are available in addition to the standard Livestatus API.

Shinken Livestatus API unique features can :

- Obtain Business Impact information
- Obtain intelligent dependency status hosts or services (combines dependency and parent information)
- Obtain Business Process states (same syntax as standard host and service queries)

How does it work Livestatus uses a powerful SQL-like query language. The standard methods and parameters are defined at :

'MK Livestatus reference methods and query language definition'_

Full list of Shinken Livestatus API methods:

'Shinken mapping.py methods'_

What software uses Livestatus to interact with Shinken

Well known Web frontends

- MK Multisite
- Thruk
- NagVis

- Splunk for Nagios

Mobile Web frontends

- get list

Scripts

- Downtime management scripts
- Debug scripts

Installing Livestatus Have you installed the required packages to use the Livestatus module? You can look at the requirement section of the *10 minute installation guide* for the *requirement lists*.

How to enable Livestatus Very simple, jump to the *Shinken Broker configuration* section to enable it. .. _Shinken mapping.py methods: https://github.com/shinken-monitoring/mod-livestatus/blob/master/module/mapping.py .. _MK Livestatus reference methods and query language definition: http://mathias-kettner.de/checkmk_livestatus.html

NSCA module The NSCA daemon module is used to receive send_nsca packets and submit them to the Shinken command pipe. The NSCA module can be loaded by the Receiver or Arbiter process. It will listen on port TCP/5667 for send_nsca packets.

Tip: Passive checks can be submitted *natively to the Shinken command pipe* or from remote hosts to modules, such as NSCA, AMQP or collectd, loaded in the Shinken Arbiter or Receiver process. AMQP is implemented for integration with the Canopsis Hypervisor, but could be re-used for generic messaging.

Note: The Shinken NSCA module implementation is currently limited to the "xor" obfuscation/encryption.

In your shinken-specific.cfg file, just add (or uncomment):

```
::
```

#You can send check result to Shinken using NSCA #using send_nsca command define module{

module_name NSCA module_type nsca_server host * port 5667 encryption_method 0 password helloworld

}

define receiver{

```
receiver_name    receiver-1
address          localhost
port             7773
modules          NSCA

timeout          3             ; 'ping' timeout
data_timeout     120           ; 'data send' timeout
max_check_attempts       3     ;  if at least max_check_attempts ping failed, the node is DEAD

#advanced
realm    All
}
```

This daemon is totally optional.

It's main goal is to get all passive "things" (checks but why not other commands) in distant realms. It will act as a "passive receive buffer" and will then dispatch the data or commands directly to the appropriate Scheduler or Arbiter process.

Data can be received from any Realm, thus the Realm option is nonsensical.

For now there is no init.d script to launch it. .. note:: Verify that the init script has been added.

It is launched like all other daemons:

```
bin/shinken-receiver -c etc/receiverd.ini
```

Tip: Alternatively, for small installations with you can configure a modules inside your Arbiter instead of the Receiver. It will listen the TCP/5667 port for send_nsca packets.

To configure the NSCA module in your Arbiter instead of Receiver. Add the NSCA module to your Arbiter object configuration.

```
::
```

define arbiter{ arbiter_name Arbiter-Master

 # host_name node1 ;result of the hostname command under Unix address localhost ;IP or DNS adress port 7770 spare 0 modules NSCA

}

Retention troubleshooting The retention file contains the state of your host and services, so that they are kept when shinken is restarted.

Sometimes you'll want to inspect (and possibly fix) the retention file, in case you need to work-around a bug or simply better understand what is stored there.

When you use the PickleRetention module in the scheduler (cf. ''define scheduler" in ''shinken-specific.cfg''), you can simply manipulate the retention file using Python.

For this you can use the following code.

- It assumes Shinken is installed in ''/opt/shinken" with the retention file in ''/tmp/retention.dat'':
- Run and play with it interactively using ''ipython -i inspect_retention.py''.

```
#!/usr/bin/python
import pickle
import sys
sys.path.append('/opt/shinken')
import shinken

r = pickle.load(file('/tmp/retention.dat'))
h = r['hosts']

# Example:
# [(k,v) for (k,v) in h['your_host'].items() if k.find('downtime') >= 0]
#
# del h['your_host']
#
# for k,v in r['services'].items():
#     if 'your_host' in k:
#         del r['services'][k]
```

To save your changes:

- Stop Shinken: ‘’service shinken stop’‘
- Save the pickle: ‘’pickle.dump(r, open(‘/tmp/retention.dat’, ‘w’))’‘
- Start Shinken: ‘’service shinken start’‘

NRPE Module

What is it The NRPE module allows Shinken Pollers to bypass the launch of the check_nrpe process. It reads the check command and opens the connection by itself. It scales the use of NRPE for active supervision of servers hosting NRPE agents.

The command definitions should be identical to the check_nrpe calls.

How to define it The definition is very easy (and you probably just have to uncomment it):

```
define module{
     module_name       NrpeBooster
     module_type       nrpe_poller
}
```

Then you add it to your poller object:

```
define poller {
    [...]
    modules   NrpeBooster
}
```

Then just tag all your check_nrpe commands with this module:

```
define command {
   command_name   check_nrpe
   command_line   $USER1$/check_nrpe -H $HOSTADRESS$ -c $ARG1$ -a $ARG2$
   module_type    nrpe_poller
}
```

That’s it. From now on all checks that use this command will use Shinken’s NRPE module and will be launched by it.

Extending Shinken

Introduction There are a lot of “Modules” and “Addons” that are available for Shinken. Shinken can be extended by using different types of methods.

- Web interfaces from various open-source vendors can be used (Based on Livestatus API)
- Shinken itself can be extended using modules that are embedded into the various daemon processes

** (Arbiter, Poller, Receiver, Broker, Scheduler, Reactionner) * External software can provide functional enhancements for reporting, management or usability aspects

Shinken itself provides methods to extend the base functionality:

- *Broker modules* provide external access to runtime data from Shinken
- Poller modules such as *NRPE* and the *SNMP*
- Receiver modules like *NSCA* provide acquisition methods for Shinken

- Arbiter modules permit manipulating the configuration
- The webUI that permits embedding web interface elements

Independent software that works in concert with Shinken is available for:

- Monitoring remote hosts through agent software (*NIX, Windows, etc.)
- Submitting passive checks from remote hosts
- Managing the config files through a web interface
- Mobile phone UIs
- Desktop UIs and Hypervisors
- Desktop notification addons
- ...and much more

You can find many addons that are compatible with Shinken by visiting. The only caveat is that the addons should not use the status.dat file and preferably the modern API interfaces like Livestatus:

- Nagios.org
- SourceForge.net
- NagiosExchange.org
- Shinken community exchange for monitoring packs

Broker modules The broker module receives messages from the Schedulers related to host, service check results. In addition to that it receives a copy of the compiled configuration at startup. What is special about the broker, is that without modules, the broker does nothing. It makes the configuration and result data available to modules. Modules are the ones in charge of doing something with the data. This could be exporting this "raw" data into flat files, databases or exposing it as an API.

The modules are presented according to their use cases.

- Core modules
- Livestatus Module for frontends
- Exporting data to metric databases
- SQL based Modules for frontends
- Exporting data to logging management systems
- Legacy modules for migration purposes
- Modules no longer supported

Core modules

simple_log: get all logs into one file You can get a log for all your daemons in a single file. With the exception of Debug level logs which are not sent through the network as a safe guard. Shinken state messages are ONLY logged at the debug level in the local log files. These are the ALL CAPS states that some 3rd party interfaces use to mine data from the historical logs. Actual state messages are sent as objects between the various daemons.

It takes the parameters:

- module_name: name of the module called by the brokers

- module_type: simple_log
- path: path of the log file

Here is an example:

```
define module{
```

```
     module_name      Simple-log
     module_type      simple_log
     path             /usr/local/shinken/var/nagios.log
     archive_path     /usr/local/shinken/var/archives/
}
```

Syslog - Send all logs to a local syslog server Send all logs to a local syslog server. Support for remote syslog can be implemented if requested. Just lookup the syslog module, easy to modify. Use for example with Splunk, graylog2, Logstash, Elastic search, Kibana, or other log management and analysis system.

```
define module{
```

```
  module_name Syslog
  module_type syslog
}
```

Lightweight forwarder to Splunk Shinken state data from the local syslog can also be sent to a Splunk server for indexing, reports, SLA and analysis. Via syslog or better yet, the Splunk lightweight forwarder which supports, TCP, buffering and security parameters.

Livestatus API Module - Thruk, Nagvis and Multisite Web frontends There are three well known frontends and various small tools that can interface with the Livestatus API. This API is currently the most efficient method of sharing live data with external interfaces. It provides a rich query language similar to SQL, authentication, command execution, caching,connections persistence, multiple object methods (JSON, Python). All Livestatus data is kept in memory, there is no disk IO involved. It exposes configuration objects, the current state of the hosts and services as well as historical Shinken state log messages.

- MK Multisite
- Thruk
- NagVis

Have you installed the required packages to use the Livestatus module? You can look at the requirement section of the 10 minute installation guide for the requirement lists.

Livestatus Module

It takes the following parameters:

- module_name: name of the module called by the brokers
- module_type: livestatus
- host: IP interface to listen to. The default is '127.0.0.1'. '*' means 'listen on all interfaces'.
- port: TCP port to listen to.
- socket: Unix socket to listen to.

- allowed_hosts: a comma-separated list of IP-addresses which are allowed to contact the TCP port. Please keep in mind that these must be ip-addresses, NOT host names. (DNS lookups for every incoming livestatus request could hang up and therefore block the module)
- modules: a comma-separated list of modules (see below)
- pnp_path: relevant if you use the multisite gui. pnp_path points to the perfdata directory where the pnp4nagios data reside (it's the directory which contains a subdirectory for each host). Multisite needs it to display a small perfdata icon if a rrd file exists.
- To deactivate an input, the port- and socket-attributes can also take the value "none".

The Livestatus module itself can have sub-modules. In fact, it **must** have at least one submodule responsible for storing log events to a database, SQLite or MongoDB.

Livestatus module - Logstore Sqlite Stores log-broks to an sqlite database.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_sqlite
- use_aggressive_sql: Prefer the use of sql queries to pre-filter data prior to python filtering. This is required for very large installations, as the Python structures are not indexed when filtering. Optional argument set to 0 by default. To enable set the value to 1. Some erroneous output may occur, but informal testing has shown these corner cases do not occur.
- read_only: don't send any update to the database. Should be used when you run several livestatus modules : 1 instance is R/W, other are read only.
- database_file: the path to the sqlite database file which is used to store the log broks/messages. The default is 'var/livestatus.db'
- archive_path: the path to a subdirectory where database file archives will be created. Every day the data from the last day will be moved to an archive datafile. The default is 'var/archives'.
- max_logs_age: the maximum age of the log messages (before they are deleted from the database). The default is 1 year. The argument to this parameter takes the form <number>[<period of time>], where <period of time> can be d for days, w for weeks, m for months and y for years. This parameter is currently ignored. In future releases it will be used to automatically delete ancient database files.

Here is an example:

```
define module{
```

```
     module_name      Livestatus
     module_type      livestatus
     host             *       ; * = listen on all configured ip addresses
     port             50000   ; port to listen
     socket           /usr/local/shinken/var/rw/live
     modules          logsqlite
}
define module{
```

```
     module_name      logsqlite
     module_type      logstore_sqlite
     use_aggressive_sql     0 ; optional, by default set to 0. Only for large installations.
     database_file    /usr/local/shinken/var/livelogs.db
     max_logs_age     3m ; three months. Other time intervals are d=days, w=weeks, y=years
}
```

Livestatus module - Logstore MongoDB Stores historical log broks(inter daemon Shinken messages) to a MongoDB database. MongoDB is a distributed and very performant database that permits resilience and high availability. The current implementation has a few known broken pieces (some search functions are broken) and there are bugs in the implementation, so it is considered experimental until power users and developers have ironed out the bugs. It is the database of the future for Shinken.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_mongodb
- mongodb_uri: The address of the master. (Default: i_cant_write_the_uri_here_it_messes_the_wiki_up)
- replica_set: If you are running a MongoDB cluster (called a "replica set" in MongoDB), you need to specify it's name here. With this option set, you can also write the mongodb_uri as a comma-separated list of host:port items. (But one is enough, it will be used as a "seed")
- database: <undocumented>
- collection: <undocumented>
- max_logs_age: <undocumented>

The configuration looks quite similar to the sqlite one. **In a single-node installation and with decent amount of log traffic, the sqlite backend should be considered best practice, as it needs no extra software and is stable and fast (when run in-memory).**

Livestatus module - Logstore Null In case you don't need any logging (for instance, if you dedicate a livestatus module instance to nagvis), you can use this module.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_null

Network Based Modules - Graphite graphing Graphite is a graphing and data analysis tool. It is composed of a web frontend (graphite-web), fixed size databases (whisper) and data redistribution/munging daemon. (carbon) The first step is *having Graphite installed somewhere*, if you do not have Graphite installed, please do this and come back later.

Pre-requisite : Shinken 1.2.2+ is recommended for the best experience with Graphite.

graphite_perfdata: exports check result performance data to Graphite Export all performance data included in check results to Whisper databases managed by Graphite. Data is buffered, then exported once every broker time tick. (Once per second). Should a communication loss occur, it will buffer data for 5 minutes before dropping data. The tick_limit max is configurable, the only limitation is the amount of memory the buffered data can eat.

The graphite broker module (v1.2) sends data to graphite in the following format :

HOSTNAME.SERVICENAME.METRICNAME

It can be optionally enhanced to send it the following format :

_GRAPHITE_PRE.HOSTNAME.SOURCE.SERVICENAME.METRICNAME._GRAPHITE_POST

Each of the three variables are optional :

- The _GRAPHITE_PRE variable can be set per host/service to provide a more flexible naming convention. (ex. Prod.site1.Hostname.servicename)

- The _GRAPHITE_POST variable can be set per host/service to specify the more information concerning the variable being stored that graphite can use to determine the retention rule to use for the variable.
- The SOURCE variable can be set in shinken-specific.cfg for the WebUI module and the Graphite broker.

Metric names are converted from Shinken's format to a more restrictive Graphite naming. Unsupported characters are converted to "_" underscore. So do not be surprised to see that some names differ in the WebUI or directly in Graphite. Permitted characters in Graphite are "**A-Za-z_**.", the hyphen character is permitted from Shinken, though only future versions of Graphite will support it.

Performance data transfer method can be set to pickle, which is a binary format that can send data more efficiently than raw ascii.

It takes the following parameters:

- module_name: name of the module called by the brokers
- module_type: graphite_perfdata
- host: ip address of the graphite server running a carbon instance
- port: port where carbon listens for metrics (default: 2003 for raw socket, 2004 for pickle encoded data)
- use_pickle: Use a more efficient transport for sending check results to graphite instead of raw data on the socket (v1.2)
- tick_limit: Number of ticks to buffer performance data during a communication outage with Graphite. On tick limit exceeded, flush to /dev/null and start buffering again. (v1.2)
- graphite_data_source: Set the source name for all data coming from shinken sent to Graphite. This helps diferentiate between data from other sources for the same hostnames. (ex. Diamond, statsd, ganglia, shinken) (v1.2)

Here is an example:

```
define module {
```

```
module_name Graphite-Perfdata
host xx.xx.xx.xx
module_type graphite_perfdata
port 2004 ; default port 2003 for raw data on the socket, 2004 for pickled data
use_pickle 1 ; default value is 0, 1 for pickled data
tick_limit 300 ; Default value 300
graphite_data_source shinken ; default is that the variable is unset
}
```

SQL Based Modules - PNP4Nagios Graphing PNP4Nagios is a graphing tool that has a web interface for RRDTool based databases. Shinken can export performance data to an npcd database which will feed the RRD files (fixed sized round robin databases). You can *learn how to install PNP4Nagios* if you haven't done it already.

npcdmod: export perfdatas to a PNP interface Export all perfdata for PNP.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: npcdmod
- path: path to the npcd config file

Here is an example:

```
define module{
 module_name  NPCD
 module_type  npcdmod
 config_file  /usr/local/pnp4nagios/etc/npcd.cfg
}
```

SQL Based Modules - Frontend Centreon2 Centreon2 use a NDO database, so you will need the ndodb_mysql module for it.

ndodb_mysql: Export to a NDO Mysql database Export status into a NDO/Mysql database. It needs the python module MySQLdb (apt-get install python-mysqldb or easy_install MySQL-python).

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: ndodb_mysql
- database: database name (ex ndo)
- user: database user
- password: database user passworddt
- host: database host
- character_set: utf8 is a good one

Here is an example:

```
define module{
```

```
     module_name      ToNdodb_Mysql
     module_type      ndodb_mysql
     database         ndo       ; database name
     user             root      ; user of the database
     password         root      ; must be changed
     host             localhost ; host to connect to
     character_set    utf8      ;optionnal, UTF8 is the default
}
```

File based Legacy modules - perfdata export

service_perfdata: export service perfdatas to a flat file

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: service_perfdata
- path: path to the service perfdata file you want

Here is an example:

```
define module{
```

```
    module_name      Service-Perfdata
    module_type      service_perfdata
    path             /usr/local/shinken/src/var/service-perfdata
}
```

host_perfdata: export host perfdatas to a flat file

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: host_perfdata
- path: path to the host perfdata file you want

Here is an example:

```
define module{
```

```
    module_name      Host-Perfdata
    module_type      host_perfdata
    path             /usr/local/shinken/src/var/host-perfdata
}
```

Legacy File based Modules - Old CGI or VShell The Old CGI and VShell use the flat file export. If you can, avoid it! It has awful performance, all modern UIs no longer use this.

status_dat: export status into a flat file Export all status into a flat file in the old Nagios format. It's for small/medium environment because it's very slow to parse. It can be used by the Nagios CGI. It also export the objects.cache file for this interface.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: status_dat
- status_file: path of the status.dat file /usr/local/shinken/var/status.dat
- object_cache_file: path of the objects.cache file
- status_update_interval: interval in seconds to generate the status.dat file

Here is an example:

```
define module{
```

```
    module_name              Status-Dat
    module_type              status_dat
    status_file              /usr/local/shinken/var/status.data
    object_cache_file        /usr/local/shinken/var/objects.cache
    status_update_interval   15 ; update status.dat every 15s
}
```

Deprecated or unsupported modules

SQL Based MerlinDB This interface is no longer supported and is going to be completely removed from Shinken.

SQL based ndodb_oracle - Icinga web frontend using NDO Oracle This interface is no longer supported and is going to be completely removed from Shinken.

CouchDB: Export to a Couchdb database This interface is no longer supported and is going to be completely removed from Shinken.

TSCA (Thrift Service Check Acceptor) TSCA is a receiver/arbiter module to receive hosts and services check results. It provides the same functions as NSCA with additional features. High performance binary transmission, multi line output and auto generated clients for a variety of languages.

What is thrift ? Let's cut and paste the wikipedia definition from'en.wikipedia.org/wiki/Apache_Thrift'_ :

"Thrift is an interface definition language that is used to define and create services for numerous languages.[1] It is used as a remote procedure call (RPC) framework [..]. It combines a software stack with a code generation engine to build services that work efficiently to a varying degree and seamlessly between ActionScript, C#, C++ (on POSIX-compliant systems), Cappuccino, Cocoa, Erlang, Haskell, Java, OCaml, Perl, PHP, Python, Ruby, and Smalltalk."

Installation In any case, you have to install thrift with support for python (on the server side) and languages you want to use for clients.

Get it from thrift.apache.org or in your favorite distribution repository.

Server side Go to the tsca module directory and generate the python stub for the server side installation

```
cd shinken/modules/tsca
$ thrift --gen py tsca.thrift
```

Declare the module is shinken-specific.org

```
define module{
      module_name     TSCA
      module_type     tsca_server
      host            0.0.0.0
      port            9090
}
```

Samples clients There are three(3) client samples written in python, ruby and java in contrib/clients/TSCA of the Shinken distribution. You can use and extend them to send data directly in your code directly to Shinken's TSCA receiver/arbiter module.

The samples clients read a CSV file from stdin and send them the the TSCA running on localhost:9090. The CSV has the following format :

```
hostname,service description,output,rc
```

Any use of TCP in an application should take care not to block the program and to have very short timeouts. For applications that need non blocking functions, prefer a UDP based transport or a local buffer file with a separate application(send_nsca, thrift, etc) to forward your data to Shinken.

Ruby Generate the stub

```
$ thrift --gen rb ../../../shinken/modules/tsca/tsca.thrift
```

Run the client

```
$ cat file_state | ruby RubyClient.rb
```

Python Generate the stub

```
$ thrift --gen py ../../../shinken/modules/tsca/tsca.thrift
```

Run the client

```
$ cat file_state | python PythonClient.py
```

java Generate the stub

```
$ thrift --gen java ../../../shinken/modules/tsca/tsca.thrift
```

Compile the client

```
$ ant
```

Run the client

```
$ cat file_state | java JavaClientThrift
```

VMWare Arbiter module

How it works The arbiter has a module that allows the host->VM automatic host dependency creation. In fact, the module is far more generic than just this. It's a generic "host link dependencies" module.

It reads a mapping file (simple json format) with son->father links. It call an external script at a regular interval : the one I wrote is a VMWare mapping one. It used the check_esx3.pl (that all ESX admin should have) plugin and generate the mapping file. When this file is changed, the module reloads it, creates new links and deletes old ones. So when you VMotion a virtual machine, in the next pass, there will be creation of a new link and deletion of the old one in the scheduler that manages it :)

How to define it The definition is very easy :

```
define module{
     module_name       VMWare_auto_linking
     module_type       hot_dependencies
     mapping_file      /tmp/vmware_mapping_file.json
     mapping_command   /usr/local/shinken/libexec/link_vmware_host_vm.py -x '/usr/local/shinken/libex
     mapping_command_interval 60   ; optionnal
     mapping_command_timeout   300 ; optionnal
}
```

Then you add it in you arbiter object :

```
define arbiter {
    [...]
    modules   VMWare_auto_linking
}
```

So here, it will call the script /usr/local/shinken/libexec/link_vmware_host_vm.py with a listing of the vCenter vcenter.mydomain.com and generate the mapping file /tmp/vmware_mapping_file.json.

You can call : /usr/local/shinken/libexec/link_vmware_host_vm.py –help

for the full help on this script.

It looks at the file modification time each second. This command can also be launch by an external cron of course.

Note: So if you want to write a script that does this for XEN servers, all you need is to generate a json file with all the mapping. I didn't wrote the doc about this, but you can look in the test file for it, the format is very very easy :)

Here is an example of the JSON mapping file syntax:

%%:ref:*["host", "physical_host"], ["host", "virtual_machine"* <["host", "physical_host"], ["host", "virtual_machine">, "host", "physical_host"], ["host", "other_virtual_machine" <"host", "physical_host"], ["host", "other_virtual_machine">]%%

So just a list of couple 'host' string (from now only host are managed) and the host name.

Beware about it : you need the real host_name, including case.

Web Service Module The Ws_arbiter module is a Receiver or Arbiter module to receive passive check results from remote hosts via HTTP(s). This module is considered a work in progress but can be used for testing and improvement.

Configuring the Web Service Module If data is POSTed to this page, it will validate the data to determine if it is a service or host check result and submit the data to the Shinken external command queue.

The web service listens by default to TCP port 7760. The web service supports anonymous or authenticated access. Web service parameters are set in the Shinken-specific.cfg file, in the Ws_arbiter module. To enable the web service, simply add the module to your Arbiter or Receiver daemon configuration in Shinken-specific.cfg

Using the Web Service Module The web service listens for POSTs to: /push_check_result

Use curl or embed the HTTP calls in your software to submit check results.

curl -u user:password -d "time_stamp=$(date +%s)&host_name=host-checked&service_description=service-checked&return_code=0&output=Everything OK" http://shinken-srv:7760/push_check_result

Example with more readability:

```
curl
```

-u user:password -d "time_stamp=$(date +%s)

```
&host_name=host-checked
&service_description=service-checked
&return_code=0
&output=Everything OK
http://shinken-srv:7760/push_check_result
```

SNMP module This part must be splitted and sent in all module repositories

Shinken integrated SNMP Module

SnmpBooster Download Install and Configure

- *What is the SnmpBooster module*
- Install and configure the SNMP acquisition module. [You are here]
- *Reference - SnmpBooster troubleshooting*
- *Reference - SnmpBooster design specification*
- *Reference - SnmpBooster configuration dictionnary*

Downloads

The SnmpBooster module and genDevConfig are currently in public beta prior to integration within Shinken. You can consult t

- github.com/xkilian/genDevConfig
- github.com/titilambert/shinken/tree/snmp_booster/shinken/modules (snmp_booster branch) * Simply right-click and download snmp_poller.py then copy it to shinken/modules/

Requirements The SnmpBooster module requires:

- Python 2.6+
- Shinken 1.2+
- PySNMP 4.2.1+ (Python module and its dependencies)
- ConfigObj (Python module)
- python-memcached
- memcachedb or memcached package for your operating system (ex. For Ubuntu: apt-get install memcachedb) *Note*

The genDevConfig profile generator depends on:

- Perl 5.004+
- 4 perl modules available from CPAN and network repositories. genDevConfig/INSTALL has the installation details.

STRONGLY RECOMMENDED: Use the same version of Python and Pyro on all hosts running Shinken processes.

Installation SnmpBooster:

- Install the dependencies
- Copy the file snmp_poller.py from the git repository to your shinken/modules directory.
- Configuration steps are listed in the present web page.

genDevConfig:

- Download and extract the archive to your server.
- See genDevConfig/INSTALL on how to install and configure it.

Configuration

How to define the SnmpBooster module in the Shinken daemons You need to modify shinken-specific.cfg, which is located in $shinken/etc/shinken-specific.cfg

Arbiter daemon configuration Simply declare the module:

```
modules SnmpBooster</code>
```

Scheduler daemon configuration

Simply declare the module:

<code>modules SnmpBooster

Poller daemon configuration Simply declare the module:

```
modules SnmpBooster</code>
```

SnmpBooster Module declaration

Included in Shinken v1.2.1 shinken-specific.cfg.

<code>define module {

```
module_name          SnmpBooster
module_type          snmp_poller
datasource           /usr/local/shinken/etc/packs/network/SnmpBooster/   ; SET THE DIRECTORY FOR YOUR
memcached_host       x.x.x.x  ; SET THE IP ADDRESS OF YOUR memcached SERVER
memcached_port       11211  ; default port for a memcached process
```

}

If you do not know the IP adress on which your memcache is listening, check under /etc/memcached.conf. Or do a:

```
netstat -a | grep memcached</code>
If you are running a test on the local machine you can leave memcached on 127.0.0.1 (localhost), but
```

How to define a Host and Service

Step 1

Create a template for your SNMP enabled devices.

Sample template:

<code>cd shinken/etc/packs/network/ mkdir SnmpBooster

vi shinken/etc/packs/network/SnmpBooster/templates.cfg

```
define command {
```

```
command_name    check_snmp_booster
command_line    check_snmp_booster -H $HOSTNAME$ -C $SNMPCOMMUNITYREAD$ -V 2c -t $ARG1$ -i $_SERVICE
module_type     snmp_poller
```

}

```
define service {
```

```
name                    default-snmp-template
check_command           check_snmp_booster!$_SERVICEDSTEMPLATE$!$_SERVICEINST$!$_SERVICETRIGGERGROUP
_inst                   None
_triggergroup           None
max_check_attempts      3
check_interval          1
retry_interval          1
register                0
```

}

```
define host{
```

```
name                    SnmpBooster-host
alias                   SnmpBooster-host template
check_command           check_host_alive
max_check_attempts      3
check_interval          1
retry_interval          1
use                     generic-host
register                0
```

}

Step 2 Define some hosts and services. You would typically use genDevConfig or another configuration generator to create these for you.

Mandatory service arguments related to SNMP polling:

```
_dstemplate                Cisco-Generic-Router  ; Name of a DSTEMPLATE defined in the SnmpBooster co
```

```
snmpcommunityread    which is set in your resource.cfg file
```

Optional service arguments related to SNMP polling with default values:

```
_inst                   None   ; Could be numeric: 0, None or an instance mapping function like: map
```

```
_triggergroup           None   ; Name of the triggergroup defined in the SnmpBooster config.ini file
```

Sample Shinken host and service configuration:

```
# Generated by genDevConfig 3.0.0
# Args: --showunused -c publicstring 192.168.2.63
# Date: Thu Aug 30 17:47:59 2012

######################################################################
# Description: Cisco IOS Software, C2960 Software (C2960-LANBASEK9-M), Version 12.2(50)SE4, RELEASE S
#     Contact:
# System Name: SITE1-ASW-Lab04
#    Location:
#######################################################################

define host {
```

```
 host_name            192.168.2.63
 display_name         192.168.2.63
 _sys_location
 address              192.168.2.63
 hostgroups
 notes
 parents
 use                  default-snmp-host-template
 register             1
}

define service {
```

```
 host_name            192.168.2.63
 service_description  chassis
 display_name         C2960 class chassis
 _dstemplate          Cisco-Generic-Router
 _inst                0
 use                  default-snmp-template
 register             1
}

define service {
```

```
 host_name            192.168.2.63
 service_description  chassis.device-traffic
 display_name         Switch fabric statistics - Packets per Second
 _dstemplate          Device-Traffic
 use                  default-snmp-template
 register             1
}

define service {
```

```
host_name            192.168.2.63
service_description  if.FastEthernet0_1
display_name         FastEthernet0_1 Description: Link to Router-1 100.0 MBits/s ethernetCsmacd
_dstemplate          standard-interface
_inst                map(interface-name,FastEthernet0_1)
use                  default-snmp-template
register             1
```

}

Here is an example configuration of the config.ini file

```
[DATASOURCE]
```

```
  OidmyOidDefinition = .1.3.6.1.45.0
  [myOidDefinition] ; Use the same name as the myOidDeiniftion, but omit the leading "Oid"
      ds_type = DERIVE
      ds_calc = 8,*  ; RPN expression : Oid, 8, *  Which means Oid * 8 = ds_calc
      ds_oid = $OidmyOidDefinition
[DSTEMPLATE]
```

```
  [myCiscoRouter]
      ds = myOidDefinition
[TRIGGER]
```

```
  [trigger1]
      warning = RPN expression
      critical = RPN expression
  [trigger2]
      warning = RPN expression
      critical = RPN expression
[TRIGGERGROUP]
```

```
[CiscoRouterTriggers]
    triggers = trigger1, trigger2
```

Shinken integrated SNMP Module

Overview

What is it The SnmpBooster module allows Shinken Pollers to directly manage SNMP data acquisition. This is an all Python cross-platform SNMP module. It is tightly integrated with the Shinken Poller, Scheduler and Arbiter daemons to provide the best possible user experience.

- Jump back to *SnmpBooster documentation index*

Design specification summary

- STATUS - DESIGN SPEC PERFORMANCE
- [Done] Functions as an integrated Shinken Poller module
- [Done] Necessary integration code commited to Shinken official release (Integrated starting at v1.2)
- [Done] Ability to collect thousands of SNMP metrics per second
- [Done] Be compatible with distributed data acquisition
- [Done] Collect data for a host/check_interval tuple via SNMP in a single pass
- [Done] Use all builtin Shinken scheduler logic for retries, forced checks, timeouts, dependencies, parents
- [Done] Store collected data for the duration of the check_interval in a memcached/membase
- [Done] On a restart, after the first collection, be able to pick up where the last check left and calculate derived values
- [Done] Forced check are not allowed within 30 seconds of last SNMP query to the same host/check_interval, all other requests get data from the cache.
- [Done] Only a single request to the host/check_interval via SNMP is allowed at a time, all other requests get data from the cache.
- STATUS - DESIGN SPEC USABILITY
- [Done] Usage documentation
- [xxxx] SkonfUI and Discovery usage documentation
- [xxxx] Provide sample configuration packs in Shinken
- [Done] Provide sample config.ini with examples of all types of data * SNMP OIDS, DATASOURCES, DSTEMPLATES, TRIGGERS and TRIGGERGROUPS

- [Done] Directly compatible for use with genDevConfig Shinken SNMP configuration generator
- [Done] Provide meaningful feedback for users on errors
- [Done] Capture all tracebacks and convert them to actual error or warning messages
- STATUS - DESIGN SPEC FEATURES
- [Done] Return state and performance metrics
- [Done] Performance metrics can be returned in a Weathermap compatible format
- [Done] Configuration file format is ConfigObj INI
- [Done] Load all valid INI configuration files from a directory and merge them
- [Done] Load a single INI configuration file
- [xxxx] Load a list of INI configuration files
- [Done] Configuration file describes all generic acquisition parameters (OID, DATASOURCE, DSTEMPLATE, MAP, TRIGGER, TRIGGERGROUP)
- [Done] Supports Triggers which are calculation rules to determine states
- [Done] Triggers support an RPN (Reverse Polish Notation) calculation engine which includes mathematical and logical operators
- [Done] Each TRIGGER is associated with a severity level, WARNING or CRITICAL
- [Done] Multiple TRIGGERS can be associated with a TRIGGERGROUP
- [Done] Use builtin Python Operators
- [Done] Support DERIVE, TEXT, GAUGE and COUNTER data types
- [xxxx] Support TIMETICKS data type
- [Done] Support applying RPN based calculations to received metric for scaling or conversion purposes
- [Done] Use a Python SNMP library which supports asynchronous acquisition PySNMP
- [Done] Datasources can use rule based runtime instance mapping
- [Done] Set Snmp version as a check runtime option
- [Done] Set Snmp DSTEMPLATE as a check runtime option
- [Done] Set Snmp TRIGGERGROUP as a check runtime option
- [Done] Set Snmp COMMUNITY as a check runtime option
- [Done] Use Snmp version 2c GetBulk
- [xxxx] Support Snmp version 2c GetNext if GetBulk is not supported
- [xxxx] Support Snmp version 1 GetNext
- [xxxx] Set Snmp Timeout as a check runtime option, instead of a hardcoded value at 5 seconds
- STATUS - DESIGN SPEC MAINTAINABILITY
- [xxxx] Functions documented in the source code
- [Done] Critical functions documented in the source code
- [Done] Locking sections identified in the code
- [xxxx] Unit tests with at least 80% coverage

- [xxxx] Unit tests integrated with Shinken test suite
- [Done] Code hosted on github
- [xxxx] configuration validity and integrity checking of all INI files
- [xxxx] Pep8 compliant
- [xxxx] Pylint pass

genDevConfig Plugins - Compatibility status with SnmpBooster

- STATUS - genDevConfig maintained Plugins
- [Done] Avaya ES switches
- [Done] Avaya ERS routing switches
- [Done] Cisco 29x0 switches
- [Done] MIB-II Interfaces
- [Done] Cisco PIX/ASA
- [Done] JUNOS devices
- [Done] Cisco IOS routers
- [Done] NetSNMP unix hosts ** Validation required**
- [Done] Packeteer devices ** Validation required**
- [Done] Sensatronics devices ** Validation required**
- [Done] Foundry devices ** Validation required**
- [Done] Packeteer devices ** Validation required**
- [Done] Cisco CSS ** Validation required**
- [InProgress] New Cisco Access points
- STATUS - Other maintained Plugins

Tip: [xxxx] Denotes a specification that is planned but not implemented

[InProgress] Denotes a specification that is under development

[Done] Denotes a specification that is implemented

SnmpBooster reference dictionary

- Jump back to *SnmpBooster documentation index*

SnmpBooster.ini dictionary

There are five dictionaries:

- [DATASOURCE]
- [DSTEMPLATE]
- [MAP]
- [TRIGGER]

- [TRIGGERGROUP]

DATASOURCE DICTIONARY OidVariableName refers to an actual OID that can be queries using SNMP against the device on the network.

[VariableName] refers to a Datasource and all the information required to gather and prepare the data using SNMP ds_type refers to how the data should be prepared ds_calc refers to any scaling manipulations to make the data more understandable. This is an RPN expression, where the first variable is omitted, as it is always the $OidVariable ds_oid refers to the actual $OidVariable name. An instance identifier can be appended to the name to signify that an instance is provided by the Shinken service definition. This information is passed when the check is called. ...

DSTEMPLATE DICTIONNARY [DsTemplateName] refers to the name of the DSTEMPLATE that will be referred to in the Shinken service definitions. ds refers to the list of DATASOURCES to be collected. If an instance is expected for the list of DATASOURCES, it MUST be the same instance for all Oids. If a different instance is required, use a second DSTEMPLATE.

TRIGGER DICTIONNARY

TRIGGERGROUP DICTIONNARY

MAP DICTIONNARY

SnmpBooster.ini example configuration This example definition will be used to explain each section.

[DATASOURCE]

```
OidmyOidDefinition = .1.3.6.1.45.0
[myOidDefinition] ; Use the same name as the myOidDeiniftion, but omit the leading "Oid"
    ds_type = DERIVE
    ds_calc = 8,*  ; RPN expression : Oid, 8, *  Which means Oid * 8 = Total
    ds_oid = $OidmyOidDefinition
```

[DSTEMPLATE]

```
[myCiscoRouter]
    ds = myOidDefinition
```

[TRIGGER]

```
[trigger1]
    warning = RPN expression
    critical = RPN expression
[trigger2]
    warning = RPN expression
    critical = RPN expression
```

[TRIGGERGROUP]

```
[CiscoRouterTriggers]
    triggers = trigger1, trigger2
```

SnmpBooster.ini configuring SNMP Datasources

The first location is generic data related to SNMP parameters.

- DATASOURCE information * SNMP OID * Type of data and how can it be interpreted (GAUGE, COUNTER, COUNTER64, DERIVE, DERIVE64, TEXT, TIMETICK) * Data format preparation (Scaling the data for example bits to bytes) * Is there an instance to append to the
- Instance MAP function * Mapping the instance dynamically using a function * Data or rules related to the mapping function

SnmpBooster.ini configuring SNMP DSTEMPLATES

- DSTEMPLATEs to associate DATASOURCE to actual device classes * List of DATASOURCES associated with a, for example, Cisco 1900 router. Which in turn can be applied to a Shinken service

SnmpBooster.ini setting triggers/thresholds

- TRIGGER and TRIGGERGROUPS to apply thresholding rules * Define triggers and associate them with a TRIGGERGROUP name that can be applied to a Shinken Service

Shinken integrated SNMP Module

Overview

- Jump back to *SnmpBooster documentation index*

Tip: The module is now in public beta as of 2012-10-26! Have Fun!

Nothing new to add, more to come in 2013. 2013-01-19.

What is it The SnmpBooster module allows Shinken Pollers to directly manage SNMP data acquisition. This is an all Python cross-platform SNMP module. It is tightly integrated with the Shinken Poller, Scheduler and Arbiter daemons to provide the best possible user experience.

Why use it The SnmpBooster module is designed to be very efficient and scalable. It has a very flexible configuration method to make it easy to use with Shinken Monitoring Packs and Shinken discovery runners like genDevConfig.

This acquisition module was professionally designed and developed.

It is meant to be used by the very capable discovery engine genDevConfig (**v3.0.5 and newer**) originally developed for the Cricket SNMP monitoring tool and converted for use with Shinken.

It is one of the very few serious SNMP v2c implementation making use of SnmpGetBulk type requests.

How does it work

Shinken Integration

1. The SnmpBooster Arbiter module reads the Shinken SnmpBooster configuration file(s). It reads the check commands and based on the values in the check commands that use the snmp_poller module it will creates a shared configuration cache using memcached/memcachedb. The memcache key is always the combination of the hostname. This permits to tie together Shinken Hosts and Services with the SNMP specific configuration. (MongoDB and Redis are planned to be supported in the future) The Scheduler daemon schedules Host and Service checks as it normally does.

3. The SnmpBooster module will check that a memcache host key exists for the check to be launched. Then the SnmpBooster poller module will query all services related to a host for a given acquisition frequency in one pass. (all checks done every 2 minutes will be executed in bulk, same for those every 5 minutes)

5. Check results are cached for the acquisition check_interval. The next time a check request for data from the same host is received from the Scheduler, the data will be fetched from memcache. Resulting is extremely low check latency.

2. 6. The SNMP checks still benefit from retries, timeouts, forced checks, dependencies and the powerful Scheduler daemon logic.

6. The Scheduler daemon can still force an immediate re-check by flushing the cache. This is required for the dependency model.

Performance SnmpBooster uses SNMP v2c getbulk for high efficiency, unless forced to use SNMP v2c get-next or SNMPv1 get-next. GetBulk uses a single request PDU to ask for multiple OIDs or even entire tables, instead of sending one request PDU per OID.

For example: *A typical 24 port network switch with two uplinks might use 375 OIDS (8 OIDs per interface, plus general OIDs for chassis health, memory, cpu, fans, etc.). **SnmpBooster will only require around 4 request PDUs*

*instead of 375 request PDUs**. Each PDU is a request packet which takes time to create, send get processed and return. More timeouts to manage, more connections, more impact on the remote device and more latency means much fewer checks per second.*

The SnmpBooster module supports automatic instance mapping for OIDs. (Ex. Based on the interface name it will figure out that the SNMP index(or instance) is 136. This is automatically handled by genDevConfig and SnmpBooster, no user input required. :-)

The generic SNMP configuration information is stored in the Shinken SnmpBooster INI files. There is a Defaults_unified.ini and a series of other Defaults files, one per discovery plugin for genDevConfig.

Important: genDevConfig plugins have all been converted to use the new dynamic instance mapping methods. You are now free to use most if not all Defaults*.ini files included with genDevConfig. 2012-10-28

Limitations You should have memcached instances running on each poller responsible for snmp polling. You should have your pollers with SnmpBooster in the same datacenter, as they need to be on the same machine with good connectivity to the active memcached instance. SnmpBooster is not compatible with distributed pollers in multiple datacenters, sorry, the current design of SnmpBooster uses a single centralized memcached instance for storing the timeseries data. For distributed datacenters to be supported, each poller+scheduler+memcached must be realm restrained, which is not the case today.

Design specification *SnmpBooster design specification* and current development status.

Data model The information required to define the data is split in two locations.

The first location is the host and service Shinken configuration (You need to generate or write this)

- Device specific information
  - IP addresses, host_names, device types, instance keys
  - A DSTEMPLATE must be referred to in the Service definition
  - A static SNMP instance could be referred to in the Service definition
  - An SNMP instance MAP function could be referred to in the Service definition
  - A TRIGGERGROUP could be refered to in the Service definition

The second location is SNMP Defaults.* templates. (Here you can create new devices or add new data sources)

- DATASOURCE information
  - SNMP OID
  - Type of data and how can it be interpreted (GAUGE, COUNTER, COUNTER64, DERIVE, DERIVE64, TEXT, TIMETICK)
  - Data format preparation (Scaling the data for example bits to bytes)
  - Is there an instance to append to the
- Instance MAP function * Mapping the instance dynamically using a function * Data or rules related to the mapping function
- DSTEMPLATEs to associate DATASOURCE to actual device classes * List of DATASOURCES associated with a, for example, Cisco 1900 router. Which in turn can be applied to a Shinken service
- TRIGGER and TRIGGERGROUPS to apply thresholding rules * Define triggers and associate them with a TRIGGERGROUP name that can be applied to a Shinken Service

A final location containes rules to build your Shinken configuration.

- genDevConfig plugins create Shinken configurations

Installation and configuration *SnmpBooster installation*

Reference Dictionnary *SnmpBooster reference dictionary*

Troubleshooting *SnmpBooster troubleshooting*

Graph templates These are .graph files defined in your Shinken configuration directory. Refer to the Shinken graphite templates(Not yet created) or PNP4Nagios how-to documentation. The graph templates are independent from SnmpBooster and provide templates for any collected data from Shinken.

SnmpBooster Troubleshooting

- Jump back to *SnmpBooster documentation index*

Check your config

- Have you defined the poller module name?
- Have you defined the correct path to the directory containing your Defaults*.ini files?
- Have you addded the Snmpbooster module to your arbiter, poller, scheduler?
- Have you added copied the genDevConfig templates.cfg in shinken/packs/network/SnmpBooster/
- Have you installed PySNMP, memcached and other dependencies?

Software version consistency Shinken and SnmpBooster now require **the same Python and Pyro version on all hosts running a Shinken daemon**.

If you cannot use the packaged version of Python and its modules (Pyro, memcached, etc.). Use virtualenv to declare a python version to use and install all required modules in that virtualenv.

Software version requirements Have you verified that the *requirements* are met. Python, PySNMP, Shinken, Pyro, memcached, etc.

Validate your check command arguments Use the check_plugin command and comment out the module to learn what were the exact arguments sent by the poller. This will permit you to validate all the arguments, like snmp community string, inheritance, template application, etc.

Validate connectivity

Take a packet trace using a tool like Wireshark to validate that the remote host is responding.

- Has the host responded
- **Is SnmpBooster repeating the request more often than the polling interval.**
  - If you are seeing repeated requests your device may have a compatibility issues.

- Save an snmpwalk of the device, get a packet trace using Wireshark, set the poller to debug and save the poller.log file (shinken/var/poller.log). Send all three to the SnmpBooster developers.
- Note: It is normal to see one or more bulkGet requests if you are getting large amounts of data. Ex. a 24 port switch will take 2-3 request packets.

Performance Make sure you have a low latency connection to your memcache from the Poller. Your memcache server can be replicated to all your poller hosts that should also run memcache instances. Check that memcached is running: netstat -a | grep memcached

Faulty Template A bad snmp_template file was distributed in the genDevConfig sample-config directory, there were two glaring errors.

This was fixed on 2012-10-16. Make sure you update your template, or use the data from the wiki.

Note that the template should be called: SnmpBooster-template.cfg to make it easier to troubleshoot in the logs. So when you search for SnmpBooster in your logs it will show up as well.

Log files All warnings and errors generated by the SnmpBooster module start with "[SnmpBooster] error text" and are logged using the standard Shinken logger.

The Arbiter daemon can output initial configuration, loading of host keys and intervals in memcached type error messages. The Scheduler daemon can output scheduling and alert related messages. The Poller daemon can output messages related to instance mapping, acquisition timeouts, invalid community strings, cache failures and more. These are available in the Web interface, as they are placed in the check results for the service.

You can simply do a "grep SnmpBooster *" in your shinken/var directory to see the latest messages related to the SnmpBooster module. You can also sort messages by timestamp to make it easy to find where and when errors occurred.

cd shinken/var grep SnmpBooster *

memcache persistence If you restart your memcache server or memcache crashes, your poller will no longer be able to validate that a host exists in memcache prior to writing.

You should use memcachedb to achieve persistence in case of memcache failures.

Common errors returned by SnmpBooster in the log file Errors should be fairly explicit and mean what they say, though there can be exceptions. Lets try to clear some of them.

__Arbiter log **errors__**

Missing ds_oid : This means that a variable in your OID definitions is missing, or your DATASOURCE is not named correctly or your ds_oid variable is missing. There is a typo in your ds_oid variable (ex. ds-oid, or ds_oid = $OidNameIncorrectFFFRA.%(instance)s).

Datasource not defined : Your DSTEMPLATE uses a DATASOURCE that doesn't exist check the [DataSourceName] you are referring to. Does it contain the expected OID variable, $OidName.

Missing ds_type : The DATASOURCE always needs to have a ds_type definition, GAUGE, COUNTER, DERIVE, TEXT, TIMETICK, DERIVE64, COUNTER64.

__Poller log **errors__**

Problems with calculations, repeated polling, hosts not responding, etc.

__Memcached **errors__**

memcachedb and memcached do not use the same default port. Configure the correct memcachedb port to match what is declared in your SnmpBooster module under shinken-specific.cfg.

On Ubuntu 12.04 the default installation is on port 21201 instead of 11211. This causes the error "[SnmpBooster] Memcache server (127.0.0.1:11211) is not reachable" when Shinken starts.

To change it, you must edit the file /etc/memcachedb.conf

Memcached Notes On Ubuntu 12.04 the default instalation is on port 21201 instead of 11211. This causes the error "[SnmpBooster] Memcache server (127.0.0.1:11211) is not reachable" when shinken starts.

To change it, you must edit the file /etc/memcachedb.conf

WebUI module This part must be splitted and sent in all module repositories

WebUI integration with Shinken The WebUI is an external broker module. So it's an external process launched by the broker that "eats" broks (broker messages) from the brokers. So it can get *all* broks if you place this broker in your top level realm.

The WebUI does not use a database to get data. Instead, it use a "regenerator" object that will eat each broks, and will "recreate" all Hosts/Services/Contacts objects as if the code was in the scheduler daemon. So basically, WebUI and pages always reflect the CURRENT state of hosts/services objects.

The WebUI http layer is managed by bottle.py. It's a small but powerful framework.

How does the WebUI function globally ?

There a 2 Threads running:

- the main thread is the bottle.py (http) listener. It will use the best backend it finds. We recommend using python-paste. If it does not find one, it will use the default swsgi. Paste is multi-thread, swsgi is mon-thread, so please use paste if you want to avoid locking problems.
- the 2nd thread is the regenerator one. It only gets broks and gives them to the regenerator object.

There is a lock system between the threads. You can have N Http requests in progress without problem, but during this time the renererator one will wait. During execution of the regenerator, no requests are processed. This is not considered a problem, as the regenerator is very quick, and there is only a 1s lock for a 7k service conf loading, so it's not a huge problem.

What is a WebUI User? A WebUI user is a contact. A true contact object. You must match a contact name for your user.

To create a new page? All pages are in the shinken/webui/plugins directory. Each "part" has it's own directory. A part (like the eltdetail, element detail) can have more than one "page" (like /host or /service for eltdetail).

From here we will supose you want to create a "/contact" page.

You can copy the dummy example in the plugins directory into a contact directory.

You need to change the contact/dummy.py file into a contact/contact.py file, because the webui will search for a dir/dir.py file to "load".

Templates Templates are HTML with some Python code in it in the plugins/*/views direcotry for specific templates, and the "global layout" (menu and all common part) in the webui/views directory.

Your template must call the template layout (layout.tpl in the webui/views directory) wit ha "rebase" call.

If you put the rebase call at the beginning of your template, all there is below will be place "inside" the layout that will call the common javascripts and css, make the menu adn then call your html/python code.

The rebase call can take arguments. You MUST give it:

- user: the user you give it in the return dict of your .py code

Then all is optional:

- title: title of the page
- top_right_banner_state: int, global state with clouds to put in your top right page. Look at the problem.tpl code for an example.
- js and css list: list of YOUR specific javascript or css to call AFTER the common ones.
- refresh: boolean, set the refresh to 60s or do not refresh at all

- menu_part: will put the little "^" under this part of the menu.

Example of a call, taken from the problems view:

```
rebase layout title='All problems', top_right_banner_state=top_right_banner_state, js=['problems/js/a
roblems/js/autocompleter.Request.js', 'problems/js/autocompleterObserver.js'], css=['problems/css/acc
ms/css/autocompleter.css', 'problems/css/perfometer.css'], refresh=True, menu_part='/'+page, user=use
```

Call Python objects in your templates Your templates are mainly HTML code. But of course you can call python code in it. The dict you returns in the plugin.py call will be available in this page.

For example, the my_host variable will be available in the page with the host object you find (or None if your give it a bad name of course). Then you can "call" python with for example here to show the host_name: `<span>My host name is *my_host.host_name* </span>` is a way in the templates to "call a variable or function" that will return a string, here the host_name.

If the function or property you call must return HTML code that SHOULD be output as it, without "protection", you must put a ! before your call.

Let use an example where the output value of an host is in fact an html output. If you use the code `my_host.output`, bottle.py will "protect" the html generated by escaping the string, and change <> characters with escaped value. You can change this by calling `my_host.output`. Of course, it's a security problem if the output is with a javascript code...

You can also "loop" or put "if" in your template. You just need to put your code with a % before. Like

```
%for i in xrange(1, 10):
  My valus is  {{i}}
%end
```

You must put the %end here, the indentation will NOT be enougth, sorry.

For an if it's also easy:

```
%if host.active_checks_enabled:
  The host got active checks enabled
%else:
  The host DO NOT have active check enabled
%end
```

Which javascript lib are you using? It's mootools 1.3 with all options :)

What to do?

- Finish the /mobile part
- List of current alerts
- Host info
- Host status
- Host interfaces
- Hostgroup status
- dashboard hierachique with states, and BP
- Nagvis
- add bp in nagvis auto-map

- event sources
- correlation
- pre-filtering/enrichment
- user profile
- host/srv conf

WebUI search syntax work in progress

not that we couldn't tell. ;) eh eh

beware the working men and flying tools!

WebUI SSL Certification Lets start: the goal to to have the server.pem and client.pem file in etc/certs.

Go to the etc/certs directory.

```
openssl req -new -nodes -out server.req -keyout server.key -config ./shinken_openssl_cnf
openssl ca -out server.pem -config ./shinken_openssl_cnf -infiles server.req
cp server.pem server.pem.bkp
cp server.key server.pem
cat server.pem.bkp >> server.pem
cp server.pem client.pem
```

You can try to get the validity with for the arbiter with:

```
openssl s_client -connect localhost:7770</code>
```

Amazon AWS/EC2 import

Description You can import data from Amazon AWS/EC2 **'AWS'**_ into Shinken to create hosts.

Amazon provide VM hosting with EC2. With this arbiter module, you will be able to load your EC2 hosts into Shinken.

Prerequisites

You will need the **'libcloud'**_ package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

```
define module {
 module_name      AWS
 module_type      aws_import

 # Configure your REAL key and secret for AWS
 api_key              PAAAB2CILT80I0ZA0999
 secret           GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH
 default_template generic-host        ; if the host is not tagged, use this one
 }
```

- Put in key and secret your private Landscape access. * default_template will be used if your host is not "tagged" in Landscape

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master

     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           AWS
     }
```

Restart your Arbiter and it's done :)

Generated hosts The configuration generated will look as below :

```
define host {
    host_name            i-3fc56e5a
    address              8.8.4.4
    use                  t1.micro,MyTag,EC2,generic-host
    _EC2_AVAILABILITY    us-east-1a
    _EC2_CLIENTTOKEN
    _EC2_DNS_NAME
    _EC2_GROUPS          quicklaunch-1
    _EC2_IMAGEID         ami-1b814f72
    _EC2_INSTANCEID      i-3fc56e5a
    _EC2_INSTANCETYPE    t1.micro
    _EC2_KERNELID        aki-825ea7eb
    _EC2_KEYNAME         testaws
    _EC2_LAUNCHDATETIME  2012-09-26T12:19:38.000Z
    _EC2_LAUNCHINDEX     0
    _EC2_PRIVATE_DNS
    _EC2_PRIVATE_IP
    _EC2_PRODUCTCODE
    _EC2_PUBLIC_IP       8.8.4.4
    _EC2_RAMDISKID       None
    _EC2_STATUS          stopped
    _EC2_TAGS            demo:myvalue,use:MyTag
 }
```

Here with a stopped t1.micro instance with no name. You can put your how "use" parameter by adding a EC2 tag "use" on your VM. It will be output on the host configuration so you can setup the monitoring as you want. .. _libcloud: http://libcloud.apache.org/index.html .. _AWS: https://console.aws.amazon.com

Amazon AWS/EC2 import

Description You can import data from Amazon AWS/EC3 **'AWS'**_ into Shinken to create hosts.

Amazon provide VM hosting with EC3. With this arbiter module, you will be able to load your EC2 hosts into Shinken.

Prerequisites

You will need the **'libcloud'**_ package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

```
define module {
 module_name      AWS
 module_type      aws_import

 # Configure your REAL key and secret for AWS
 api_key              PAAAB2CILT80I0ZA0999
 secret           GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH
 default_template generic-host        ; if the host is not tagged, use this one
 }
```

- Put in key and secret your private Landscape access. * default_template will be used if your host is not "tagged" in Landscape

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master

     address          localhost                  ;IP or DNS adress
     port             7770
     spare            0
     modules           AWS
     }
```

Restart your Arbiter and it's done :)

Generated hosts The configuration generated will look as below :

```
define host {
    host_name            i-3fc56e5a
    address              8.8.4.4
    use                  t1.micro,MyTag,EC2,generic-host
    _EC2_AVAILABILITY    us-east-1a
    _EC2_CLIENTTOKEN
    _EC2_DNS_NAME
    _EC2_GROUPS          quicklaunch-1
    _EC2_IMAGEID         ami-1b814f72
    _EC2_INSTANCEID      i-3fc56e5a
    _EC2_INSTANCETYPE    t1.micro
    _EC2_KERNELID        aki-825ea7eb
    _EC2_KEYNAME         testaws
    _EC2_LAUNCHDATETIME  2012-09-26T12:19:38.000Z
    _EC2_LAUNCHINDEX     0
    _EC2_PRIVATE_DNS
    _EC2_PRIVATE_IP
    _EC2_PRODUCTCODE
    _EC2_PUBLIC_IP       8.8.4.4
    _EC2_RAMDISKID       None
    _EC2_STATUS          stopped
    _EC2_TAGS            demo:myvalue,use:MyTag
 }
```

Here with a stopped t1.micro instance with no name. You can put your how "use" parameter by adding a EC2 tag "use" on your VM. It will be output on the host configuration so you can setup the monitoring as you want. .. _libcloud: http://libcloud.apache.org/index.html .. _AWS: https://console.aws.amazon.com

The distributed retention modules The high availability allow the Arbiter to send a configuration to a spare scheduler, but a spare scheduler does not have any saved states for hosts and services. It will have to recheck them all. It's better to use a distributed retention module so spares will have all the information they need to start with an accurate picture of the current states and scheduling :)

Non distributed retention modules If you are just running tests on a single server, use the pickle or memcache retention modules You can also use MongoDB if you already have it installed for use with the WebUI.

MongoDB MongoDB is a scalable, high-performance, open source NoSQL database written in C++.

Step 1: Install MongoDB:

We will use mongodb package from 10gen repository, so we start by adding it in apt sources list:

```
echo 'deb http://downloads-distro.mongodb.org/repo/debian-sysvinit dist 10gen' > /etc/apt/sources.lis
apt-get update
```

And we install it:

```
apt-get install mongodb-10gen
```

And we install pymongo, the python interface to MongoDB, with easy_install to avoid packages versions problems (like here **'forums.monitoring-fr.org/index.php?topic=5205.0'_**):

```
apt-get remove python-pymongo
easy_install pymongo
```

And finally we start MongoDB :

```
/etc/init.d/mongodb start
```

Step 2: define a mongodb_retention module in your shinken-specific.cfg file:

```
define module {
  module_name MongodbRetention
  module_type mongodb_retention
  uri mongodb://localhost/?safe=true
  database shinken
}
```

Step 3: Declare a retention module for your scheduler(s) :)

Example:

```
#The scheduler is a "Host manager". It get hosts and theirs
#services. It scheduler checks for them.
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
     port     7768                  ; tcp port of the daemon

     #optionnal: modules for things as retention
     modules    MongodbRetention
     }
```

Step 4: Restart the Arbiter, and your Scheduler will now save its state between restarts. :)

Memcached Memcached is a distributed memory resident key/value server. It's very easy to install:

```
sudo apt-get install memcached
sudo /etc/init.d/memcached start
```

The shinken module also needs the python-memcache package to talk to this server.

```
sudo apt-get install python-memcache
```

To use it,

Step 1: define a memcache_retention module in your shinken-specific.cfg file:

```
define module{
     module_name      MemcacheRetention
     module_type      memcache_retention
     server           127.0.0.1
     port             11211
}
```

Step 2: Declare a retention module for your scheduler(s) :)

Example:

```
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
     port     7768                  ; tcp port of the daemon

     #optional: modules for things as retention
     modules    MemcacheRetention
     }
```

Step 3: Restart the Arbiter, and your Scheduler will now save its state between restarts. :)

Redis Redis is a distributed key/value server (on disk and in-memory). It's very easy to install:

```
sudo apt-get install redis-server
sudo /etc/init.d/redis-server start
```

The shinken module also need the python-redis package to talk to this server.

```
sudo apt-get install python-redis
```

Step 1: define a redis_retention module in your shinken-specific.cfg file:

```
define module{
     module_name      RedisRetention
     module_type      redis_retention
     server           127.0.0.1
}
```

Step 2: Declare a retention module for your scheduler(s) :)

Example:

```
#The scheduler is a "Host manager". It get hosts and theirs
#services. It scheduler checks for them.
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
```

```
    port     7768                  ; tcp port of the daemon

    #optionnal: modules for things as retention
    modules    RedisRetention
    }
```

Step 3: Restart the Arbiter, and your Scheduler will now save its state between restarts. :) .. _forums.monitoring-fr.org/index.php?topic=5205.0: http://forums.monitoring-fr.org/index.php?topic=5205.0

How to enable and use Livestatus module

Define the Livestatus module Start by reviewing the ''/etc/shinken/shinken-specific.cfg" file for this module:

```
define module{
```

```
module_name      Livestatus
module_type      livestatus
host             *       ; * = listen on all configured IP addresses
port             50000   ; port to listen on
database_file    /var/lib/shinken/livestatus.db
```

}

With these parameters:

- module_name: name of the module called by the brokers
- module_type: livestatus
- host: IP interface to listen to. The default is *, which means "listen on all interfaces".
- port: TCP port to listen to.
- socket: Unix socket to listen to.
- database_file: the path to the sqlite database file which is used to store the log broks/messages. The default is "var/livelogs.db"
- max_logs_age: the maximum age of the log messages (before they are deleted from the database). The default is 1 year. The argument to this parameter takes the form <number>[<period of time>], where <period of time> can be d for days, w for weeks, m for months and y for years.
- allowed_hosts: a comma-separated list of IP-addresses which are allowed to contact the TCP port. Please keep in mind that these **must be IP-addresses, NOT host names**. Because DNS lookups for every incoming livestatus request could hang up and therefore block the module.

Enable the Livestatus module Still in ''/etc/shinken/shinken-specific.cfg'', find the object Broker and add "Livestatus" to its "modules":

```
define broker{
```

```
    broker_name      broker-1
[...]
```

```
    modules          Simple-log,Livestatus
}
```

Disable human readable logs In ''/etc/shinken/nagios.cfg'', verify that the option **human_timestamp_log** is set to **0**.

In version 0.6.5, you can not have at the same time a simple-log file with human readable timestamp and a Livestatus database.

Exporting data for reporting Shinken can export necessary data for reporting in 3rd party systems.

raw_socket module The raw socket module exports reporting data using a syslog format to a raw TCP socket. Theses logs can be captured, parsed and indexed by any log management system like Splunk or Logstash.

Why export reporting data Custom UIs like Thruk, Multisite, WebUI, Adagios, Nagios IX, etc. All have poor or inflexible reporting. Simply because these are not reporting engines.

This also permits to have a generic reporting method that can accept data from any Nagios, Shinken, Icinga or even Riemann.

Reporting module using Splunk Splunk was selected as the reporting platform for creating, managing and presenting reports. Though the raw_socket module does not have any Splunk specific particularities. It is notable that Splunk reports can be embedded in any 3rd party UI using its REST API.

Raw_socket log format The logs are plain-text and compliant with RFC3164. They use an intelligent date format, a configurable seperator " "(space by default), and key=value pairs in the message data portion of the log. Should a key or value contain a space they must be double quoted. This is syslog using structured data without going to full out JSON that may not be compatible with all log management systems.

The message fields that are supplied in each status update in addition to the standard syslog header are:

- Hostname
- Servicename
- Business impact
- Host/Service status
- Host/Service previous status
- Acknowedgement status
- Maintenance status

Any time the maintenance, host, service or acknowledgement status changes, a log is sent by the Shinken raw_socket module.

Having all relevant data in each log makes it very easy to compute reports for given time periods.

The hostgroup or service group memberships, custom variables or any other configuration related data should be queried from the monitoring system using its API (Livestatus in the case of Shinken and Nagios).

Raw_socket module availability The module is available in both Shinken 1.4 and Shinken 2.0. The module will be integrated in master branches once unit tests and end-to-end testing is completed. 3rd quarter 2013.

Monitoring Linux System with Glances and checkglances.py **'Glances'_** is a fantastic multiplatform system monitoring tool writen by Nicolargo. Glances can run on (Linux, Windows, MacOS ...). There is a growing ecosystem around Glances and of course a Nagios/Shinken plugin : checkglances.py.

How does it work Glances can run in server mode. It provide a XML-RPC server (over http) and allow to retrieve system information throuh a restful API. The only thing to do is to install and start Glances as server on the monitored host, then install checkglances.py on the shinken server and finaly install the glances pack.

Install glances See the glances documentation to install glances on Linux.

<code bash> easy_install glances </code>

There is a debian startup script in the glances repository. And another one for centos here.

Install checkglances.py Just follow the documentation for the checkglances.py prerequisites and put it in your nagios plugins folder.

Install the glances pack Open a terminal as the shinken user and just type the following command

<code bash> shinken install glances </code>

Then just edit the configuration for a linux monitored host and tag it as **glances**

```
define host{
 name mylinuxhost
 use glances
 ...
```

Finaly restart the shinken arbiter

```
service shinken-arbiter restart
```

What will be monitored ? For the moment just the basic system (ram, cpu, load, memory, filesystem and network).

If you want to modify the default thresholds for just a host you can do it by overiding the thresholds macro in your host definition. If you want to do it for several hosts, declare a new template and just add the desired thresholds macro to be overide.

Here is a list of the macros

```
::
```

> _LOAD_WARN 2 _LOAD_CRIT 3 _CPU_WARN 80 _CPU_CRIT 90 _MEMORY_WARN 90 _MEMORY_CRIT 95 _FS /, /home _FS_WARN 90 _FS_CRIT 95 _IFACES eth0, eth1 _NET_WARN 7500000 _NET_CRIT 10000000

Note the _FS and _IFACES macros. They leverage the ability to duplicate service for a given list of things to be monitored. Here you see that / and /home partitions will be monitored. If you want to modify this then just add your own in a new template that will inherit the glances template.

Shinken GLPI integration Shinken supports importing hosts from GLPI

For people not familiar with GLPI, it is an Open-Source CMDB. Applicable to servers, routers, printers or anything you want for that matter. It is also a help-desk tool. GLPI also integrates with tools like FusionInventory for IT inventory management.

You can still have flat files AND GLPI if you want. Hosts imported from GLPI will be treated as standard hosts from flat file (inheritance, groups, etc). In fact, in this first version the module only sends the host_name to Shinken, but there should be more information extracted like network connexions for parents relations in the future. :)

Requirements

- python module MySQLdb
- Compatible version of GLPI Shinken module and GLPI version - ...
- etc..

Enabling GLPI Shinken module In your shinken-specific.cfg file, just add (or uncomment):

```
#You know GLPI? You can load all configuration from this app(
#with the webservices plugins for GLPI, in xmlrpc mode
#and with plugin monitoring for GLPI)
# =============== Work with Plugin Monitoring of GLPI ===============
#All configuration read from this will be added to the others of the
#standard flat file
define module{
     module_name      GLPI
     module_type      glpi
     uri              http://localhost/glpi/plugins/webservices/xmlrpc.php
     login_name       glpi
     login_password   glpi
}
```

And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master
#    host_name       node1       ;result of the hostname command under Unix
     address          localhost                  ;IP or DNS adress
     port             7770
     spare            0
     modules           GLPI
     }
```

It's done :)

Ip Tag module

Why tag a host based on it's IP address? We learned on the *DMZ monitoring* that you can "tag" a host with a poller_tag so it will be checked only by DMZ pollers. It can be tedious process to manually tag all these hosts. Shinken provides an automated method to do this.

This is handled by the arbiter ip_tag module.

Ip_tag module The ip_tag module is an arbiter module that looks up the host address during the configuration parsing and compares it to an predefined IP range (IPV4 or IPV6). If the range matches, it can apply or add a property, such as poller_tag. Other types of tags could be related to locations, functions, administrative groups, etc.

Method: replace or append.

replace will put the value if the property is unset. This is the default method. .. warning:: Fix me: replace, implies overriding an existing value. And will cause user issues down the line. Rename it to set. Replace should be a different method altogether, so overall there should be 3 methods(set, append, replace).

append will add with a , if a value already exist

Here is an example that will set the poller_tag property with the value DMZ of all hosts that:

- have a their hostadress ip (or name resolved) in the range 192.168.0.1/24.
- do not already have a poller_tag property set

```
define module{
```

```
     module_name     IpTag
     module_type     ip_tag
     ip_range        192.168.0.1/24
     property        poller_tag
     value           DMZ
}
```

To use the module add it in the arbiter object:

```
::
```

define arbiter { [...] modules NSCA,IpTag

}

Add value instead of setting it In the previous example we set the property poller_tag to a value. But what if we want to "add" a value, like a template name? We can change the "method" property of the module to "append" so we can add the "value" to the host property instead of replace it.

Here is an example where we want to add the "dmz" template on the hosts, while also keeping any defined templates:

```
define module{
```

```
     module_name   IpTag
     module_type   ip_tag
     ip_range      192.168.0.1/24
     property      use
     value         dmz

     # Optional method
     method append
}
```

For a host defined as:

```
define host{
```

```
     host_name   example_host1
     address     192.168.0.2
     use         linux
}
```

It will be "changed" internaly in:

```
define host{
```

```
     host_name   example_host1
     address     192.168.0.2
     use         linux,dmz
}
```

Name resolution Of course you don't need to set IP address in the address of your host. You can set a hostname, and it will be resolved, and then compared to the range. :)

Ubuntu Landscape import

Description You can import data from Ubuntu Landscape into Shinken to create hosts.

Ubuntu Landscape, is a web app to manage all your linux servers (update and co), which is provided by Canonical, Ubuntu's parent company.

This is an Arbiter import module. The Arbiter manages the configuration.

Prerequisites

You will need the landscape-api package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

define module { module_name Landscape module_type landscape_import

Configure your REAL key and secret from Landscape key PAAAB2CILT80I0ZA0999 secret GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH default_template generic-host ; if the host is not tagged, use this one

If you are using a specific certificate for landscape_api #ca /path/to.ca.cert

If you need a proxy to access https://landscape.canonical.com/api/ #https_proxy http://user:secret@myproxy.com:3128

}

- Put in key and secret your private Landscape access.
- default_template will be used if your host is not "tagged" in Landscape
- If you are using a specific certificate for connexion, give the full path in ca
- You will certainly need an https proxy to access the Landscape API. If so, configure it there.

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master
#    host_name       node1       ;result of the hostname command under Unix
     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           Landscape
     }
```

Restart your Arbiter and it's done :)

Tip: Your "tags" will be applied as templates for your hosts.

Shinken Livestatus API

Overview

- Jump back to Getting Started
- Jump back to *Livestatus module configuration*

What is it Livestatus API is the modern method of interacting with Shinken and Nagios based systems alike.

Originally developed for Nagios, MK Livetstatus, was re-implemented in Python for use with Shinken by professional developers. The access methods and query languages are the same.

Why use it It is fast.

It is network based using TCP.

It is standard for all Nagios and Shinken monitoring systems.

It uses in-memory structures for status data

It uses a back-end database for historical reporting

It uses an SQL based query language

It has a host of powerful nuts and bolts features (authentication, caching, connection persistence, multiple object methods (JSON, Python)).

What can I do with it? All programs and scripts use (or should use) this method to :

- Obtain the current state of hosts and services
- Obtain the current configuration related to hosts and services
- Send administrative commands (downtimes, comments, forcing checks)
- Filter information to display
- Obtain basic reports and event statistics

Shinken being a modern re-implementation of Nagios has additional features that are available in addition to the standard Livestatus API.

Shinken Livestatus API unique features can :

- Obtain Business Impact information
- Obtain intelligent dependency status hosts or services (combines dependency and parent information)
- Obtain Business Process states (same syntax as standard host and service queries)

How does it work Livestatus uses a powerful SQL-like query language. The standard methods and parameters are defined at :

'MK Livestatus reference methods and query language definition'_

Full list of Shinken Livestatus API methods:

'Shinken mapping.py methods'_

What software uses Livestatus to interact with Shinken

Well known Web frontends

- MK Multisite
- Thruk
- NagVis

- Splunk for Nagios

Mobile Web frontends

- get list

Scripts

- Downtime management scripts
- Debug scripts

Installing Livestatus Have you installed the required packages to use the Livestatus module? You can look at the requirement section of the *10 minute installation guide* for the *requirement lists*.

How to enable Livestatus Very simple, jump to the *Shinken Broker configuration* section to enable it. .. _Shinken mapping.py methods: https://github.com/shinken-monitoring/mod-livestatus/blob/master/module/mapping.py .. _MK Livestatus reference methods and query language definition: http://mathias-kettner.de/checkmk_livestatus.html

NSCA module The NSCA daemon module is used to receive send_nsca packets and submit them to the Shinken command pipe. The NSCA module can be loaded by the Receiver or Arbiter process. It will listen on port TCP/5667 for send_nsca packets.

Tip: Passive checks can be submitted *natively to the Shinken command pipe* or from remote hosts to modules, such as NSCA, AMQP or collectd, loaded in the Shinken Arbiter or Receiver process. AMQP is implemented for integration with the Canopsis Hypervisor, but could be re-used for generic messaging.

Note: The Shinken NSCA module implementation is currently limited to the "xor" obfuscation/encryption.

In your shinken-specific.cfg file, just add (or uncomment):

```
::
```

#You can send check result to Shinken using NSCA #using send_nsca command define module{

module_name NSCA module_type nsca_server host * port 5667 encryption_method 0 password helloworld

}

define receiver{

```
receiver_name    receiver-1
address          localhost
port             7773
modules          NSCA

timeout          3             ; 'ping' timeout
data_timeout     120           ; 'data send' timeout
max_check_attempts       3     ;  if at least max_check_attempts ping failed, the node is DEAD

#advanced
realm    All
}
```

This daemon is totally optional.

It's main goal is to get all passive "things" (checks but why not other commands) in distant realms. It will act as a "passive receive buffer" and will then dispatch the data or commands directly to the appropriate Scheduler or Arbiter process.

Data can be received from any Realm, thus the Realm option is nonsensical.

For now there is no init.d script to launch it. .. note:: Verify that the init script has been added.

It is launched like all other daemons:

```
bin/shinken-receiver -c etc/receiverd.ini
```

Tip: Alternatively, for small installations with you can configure a modules inside your Arbiter instead of the Receiver. It will listen the TCP/5667 port for send_nsca packets.

To configure the NSCA module in your Arbiter instead of Receiver. Add the NSCA module to your Arbiter object configuration.

```
::
```

define arbiter{ arbiter_name Arbiter-Master

 # host_name node1 ;result of the hostname command under Unix address localhost ;IP or DNS adress port 7770 spare 0 modules NSCA

}

Retention troubleshooting The retention file contains the state of your host and services, so that they are kept when shinken is restarted.

Sometimes you'll want to inspect (and possibly fix) the retention file, in case you need to work-around a bug or simply better understand what is stored there.

When you use the PickleRetention module in the scheduler (cf. ''define scheduler" in ''shinken-specific.cfg''), you can simply manipulate the retention file using Python.

For this you can use the following code.

- It assumes Shinken is installed in ''/opt/shinken" with the retention file in ''/tmp/retention.dat'':
- Run and play with it interactively using ''ipython -i inspect_retention.py''.

```
#!/usr/bin/python
import pickle
import sys
sys.path.append('/opt/shinken')
import shinken

r = pickle.load(file('/tmp/retention.dat'))
h = r['hosts']

# Example:
# [(k,v) for (k,v) in h['your_host'].items() if k.find('downtime') >= 0]
#
# del h['your_host']
#
# for k,v in r['services'].items():
#     if 'your_host' in k:
#         del r['services'][k]
```

To save your changes:

- Stop Shinken: ‘’service shinken stop’‘
- Save the pickle: ‘’pickle.dump(r, open(‘/tmp/retention.dat’, ‘w’))’‘
- Start Shinken: ‘’service shinken start’‘

NRPE Module

What is it The NRPE module allows Shinken Pollers to bypass the launch of the check_nrpe process. It reads the check command and opens the connection by itself. It scales the use of NRPE for active supervision of servers hosting NRPE agents.

The command definitions should be identical to the check_nrpe calls.

How to define it The definition is very easy (and you probably just have to uncomment it):

```
define module{
     module_name       NrpeBooster
     module_type       nrpe_poller
}
```

Then you add it to your poller object:

```
define poller {
    [...]
    modules   NrpeBooster
}
```

Then just tag all your check_nrpe commands with this module:

```
define command {
   command_name   check_nrpe
   command_line   $USER1$/check_nrpe -H $HOSTADRESS$ -c $ARG1$ -a $ARG2$
   module_type    nrpe_poller
}
```

That’s it. From now on all checks that use this command will use Shinken’s NRPE module and will be launched by it.

Extending Shinken

Introduction There are a lot of “Modules” and “Addons” that are available for Shinken. Shinken can be extended by using different types of methods.

- Web interfaces from various open-source vendors can be used (Based on Livestatus API)
- Shinken itself can be extended using modules that are embedded into the various daemon processes

** (Arbiter, Poller, Receiver, Broker, Scheduler, Reactionner) * External software can provide functional enhancements for reporting, management or usability aspects

Shinken itself provides methods to extend the base functionality:

- *Broker modules* provide external access to runtime data from Shinken
- Poller modules such as *NRPE* and the *SNMP*
- Receiver modules like *NSCA* provide acquisition methods for Shinken

- Arbiter modules permit manipulating the configuration
- The webUI that permits embedding web interface elements

Independent software that works in concert with Shinken is available for:

- Monitoring remote hosts through agent software (*NIX, Windows, etc.)
- Submitting passive checks from remote hosts
- Managing the config files through a web interface
- Mobile phone UIs
- Desktop UIs and Hypervisors
- Desktop notification addons
- ...and much more

You can find many addons that are compatible with Shinken by visiting. The only caveat is that the addons should not use the status.dat file and preferably the modern API interfaces like Livestatus:

- Nagios.org
- SourceForge.net
- NagiosExchange.org
- Shinken community exchange for monitoring packs

Broker modules The broker module receives messages from the Schedulers related to host, service check results. In addition to that it receives a copy of the compiled configuration at startup. What is special about the broker, is that without modules, the broker does nothing. It makes the configuration and result data available to modules. Modules are the ones in charge of doing something with the data. This could be exporting this "raw" data into flat files, databases or exposing it as an API.

The modules are presented according to their use cases.

- Core modules
- Livestatus Module for frontends
- Exporting data to metric databases
- SQL based Modules for frontends
- Exporting data to logging management systems
- Legacy modules for migration purposes
- Modules no longer supported

Core modules

simple_log: get all logs into one file You can get a log for all your daemons in a single file. With the exception of Debug level logs which are not sent through the network as a safe guard. Shinken state messages are ONLY logged at the debug level in the local log files. These are the ALL CAPS states that some 3rd party interfaces use to mine data from the historical logs. Actual state messages are sent as objects between the various daemons.

It takes the parameters:

- module_name: name of the module called by the brokers

- module_type: simple_log
- path: path of the log file

Here is an example:

```
define module{
```

```
     module_name      Simple-log
     module_type      simple_log
     path             /usr/local/shinken/var/nagios.log
     archive_path     /usr/local/shinken/var/archives/
}
```

Syslog - Send all logs to a local syslog server Send all logs to a local syslog server. Support for remote syslog can be implemented if requested. Just lookup the syslog module, easy to modify. Use for example with Splunk, graylog2, Logstash, Elastic search, Kibana, or other log management and analysis system.

```
define module{
```

```
  module_name Syslog
  module_type syslog
}
```

Lightweight forwarder to Splunk Shinken state data from the local syslog can also be sent to a Splunk server for indexing, reports, SLA and analysis. Via syslog or better yet, the Splunk lightweight forwarder which supports, TCP, buffering and security parameters.

Livestatus API Module - Thruk, Nagvis and Multisite Web frontends There are three well known frontends and various small tools that can interface with the Livestatus API. This API is currently the most efficient method of sharing live data with external interfaces. It provides a rich query language similar to SQL, authentication, command execution, caching,connections persistence, multiple object methods (JSON, Python). All Livestatus data is kept in memory, there is no disk IO involved. It exposes configuration objects, the current state of the hosts and services as well as historical Shinken state log messages.

- MK Multisite
- Thruk
- NagVis

Have you installed the required packages to use the Livestatus module? You can look at the requirement section of the 10 minute installation guide for the requirement lists.

Livestatus Module

It takes the following parameters:

- module_name: name of the module called by the brokers
- module_type: livestatus
- host: IP interface to listen to. The default is '127.0.0.1'. '*' means 'listen on all interfaces'.
- port: TCP port to listen to.
- socket: Unix socket to listen to.

- allowed_hosts: a comma-separated list of IP-addresses which are allowed to contact the TCP port. Please keep in mind that these must be ip-addresses, NOT host names. (DNS lookups for every incoming livestatus request could hang up and therefore block the module)
- modules: a comma-separated list of modules (see below)
- pnp_path: relevant if you use the multisite gui. pnp_path points to the perfdata directory where the pnp4nagios data reside (it's the directory which contains a subdirectory for each host). Multisite needs it to display a small perfdata icon if a rrd file exists.
- To deactivate an input, the port- and socket-attributes can also take the value "none".

The Livestatus module itself can have sub-modules. In fact, it **must** have at least one submodule responsible for storing log events to a database, SQLite or MongoDB.

Livestatus module - Logstore Sqlite Stores log-broks to an sqlite database.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_sqlite
- use_aggressive_sql: Prefer the use of sql queries to pre-filter data prior to python filtering. This is required for very large installations, as the Python structures are not indexed when filtering. Optional argument set to 0 by default. To enable set the value to 1. Some erroneous output may occur, but informal testing has shown these corner cases do not occur.
- read_only: don't send any update to the database. Should be used when you run several livestatus modules : 1 instance is R/W, other are read only.
- database_file: the path to the sqlite database file which is used to store the log broks/messages. The default is 'var/livestatus.db'
- archive_path: the path to a subdirectory where database file archives will be created. Every day the data from the last day will be moved to an archive datafile. The default is 'var/archives'.
- max_logs_age: the maximum age of the log messages (before they are deleted from the database). The default is 1 year. The argument to this parameter takes the form <number>[<period of time>], where <period of time> can be d for days, w for weeks, m for months and y for years. This parameter is currently ignored. In future releases it will be used to automatically delete ancient database files.

Here is an example:

```
define module{
```

```
     module_name      Livestatus
     module_type      livestatus
     host             *       ; * = listen on all configured ip addresses
     port             50000   ; port to listen
     socket           /usr/local/shinken/var/rw/live
     modules          logsqlite
}
define module{
```

```
     module_name      logsqlite
     module_type      logstore_sqlite
     use_aggressive_sql     0 ; optional, by default set to 0. Only for large installations.
     database_file    /usr/local/shinken/var/livelogs.db
     max_logs_age     3m ; three months. Other time intervals are d=days, w=weeks, y=years
}
```

Livestatus module - Logstore MongoDB Stores historical log broks(inter daemon Shinken messages) to a MongoDB database. MongoDB is a distributed and very performant database that permits resilience and high availability. The current implementation has a few known broken pieces (some search functions are broken) and there are bugs in the implementation, so it is considered experimental until power users and developers have ironed out the bugs. It is the database of the future for Shinken.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_mongodb
- mongodb_uri: The address of the master. (Default: i_cant_write_the_uri_here_it_messes_the_wiki_up)
- replica_set: If you are running a MongoDB cluster (called a "replica set" in MongoDB), you need to specify it's name here. With this option set, you can also write the mongodb_uri as a comma-separated list of host:port items. (But one is enough, it will be used as a "seed")
- database: <undocumented>
- collection: <undocumented>
- max_logs_age: <undocumented>

The configuration looks quite similar to the sqlite one. **In a single-node installation and with decent amount of log traffic, the sqlite backend should be considered best practice, as it needs no extra software and is stable and fast (when run in-memory).**

Livestatus module - Logstore Null In case you don't need any logging (for instance, if you dedicate a livestatus module instance to nagvis), you can use this module.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_null

Network Based Modules - Graphite graphing Graphite is a graphing and data analysis tool. It is composed of a web frontend (graphite-web), fixed size databases (whisper) and data redistribution/munging daemon. (carbon) The first step is *having Graphite installed somewhere*, if you do not have Graphite installed, please do this and come back later.

Pre-requisite : Shinken 1.2.2+ is recommended for the best experience with Graphite.

graphite_perfdata: exports check result performance data to Graphite Export all performance data included in check results to Whisper databases managed by Graphite. Data is buffered, then exported once every broker time tick. (Once per second). Should a communication loss occur, it will buffer data for 5 minutes before dropping data. The tick_limit max is configurable, the only limitation is the amount of memory the buffered data can eat.

The graphite broker module (v1.2) sends data to graphite in the following format :

HOSTNAME.SERVICENAME.METRICNAME

It can be optionally enhanced to send it the following format :

_GRAPHITE_PRE.HOSTNAME.SOURCE.SERVICENAME.METRICNAME._GRAPHITE_POST

Each of the three variables are optional :

- The _GRAPHITE_PRE variable can be set per host/service to provide a more flexible naming convention. (ex. Prod.site1.Hostname.servicename)

- The _GRAPHITE_POST variable can be set per host/service to specify the more information concerning the variable being stored that graphite can use to determine the retention rule to use for the variable.
- The SOURCE variable can be set in shinken-specific.cfg for the WebUI module and the Graphite broker.

Metric names are converted from Shinken's format to a more restrictive Graphite naming. Unsupported characters are converted to "_" underscore. So do not be surprised to see that some names differ in the WebUI or directly in Graphite. Permitted characters in Graphite are "**A-Za-z_**.", the hyphen character is permitted from Shinken, though only future versions of Graphite will support it.

Performance data transfer method can be set to pickle, which is a binary format that can send data more efficiently than raw ascii.

It takes the following parameters:

- module_name: name of the module called by the brokers
- module_type: graphite_perfdata
- host: ip address of the graphite server running a carbon instance
- port: port where carbon listens for metrics (default: 2003 for raw socket, 2004 for pickle encoded data)
- use_pickle: Use a more efficient transport for sending check results to graphite instead of raw data on the socket (v1.2)
- tick_limit: Number of ticks to buffer performance data during a communication outage with Graphite. On tick limit exceeded, flush to /dev/null and start buffering again. (v1.2)
- graphite_data_source: Set the source name for all data coming from shinken sent to Graphite. This helps diferentiate between data from other sources for the same hostnames. (ex. Diamond, statsd, ganglia, shinken) (v1.2)

Here is an example:

```
define module {
```

```
module_name Graphite-Perfdata
host xx.xx.xx.xx
module_type graphite_perfdata
port 2004 ; default port 2003 for raw data on the socket, 2004 for pickled data
use_pickle 1 ; default value is 0, 1 for pickled data
tick_limit 300 ; Default value 300
graphite_data_source shinken ; default is that the variable is unset
}
```

SQL Based Modules - PNP4Nagios Graphing PNP4Nagios is a graphing tool that has a web interface for RRDTool based databases. Shinken can export performance data to an npcd database which will feed the RRD files (fixed sized round robin databases). You can *learn how to install PNP4Nagios* if you haven't done it already.

npcdmod: export perfdatas to a PNP interface Export all perfdata for PNP.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: npcdmod
- path: path to the npcd config file

Here is an example:

```
define module{
 module_name  NPCD
 module_type  npcdmod
 config_file  /usr/local/pnp4nagios/etc/npcd.cfg
}
```

SQL Based Modules - Frontend Centreon2 Centreon2 use a NDO database, so you will need the ndodb_mysql module for it.

ndodb_mysql: Export to a NDO Mysql database Export status into a NDO/Mysql database. It needs the python module MySQLdb (apt-get install python-mysqldb or easy_install MySQL-python).

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: ndodb_mysql
- database: database name (ex ndo)
- user: database user
- password: database user passworddt
- host: database host
- character_set: utf8 is a good one

Here is an example:

```
define module{
```

```
     module_name      ToNdodb_Mysql
     module_type      ndodb_mysql
     database         ndo       ; database name
     user             root      ; user of the database
     password         root      ; must be changed
     host             localhost ; host to connect to
     character_set    utf8      ;optionnal, UTF8 is the default
}
```

File based Legacy modules - perfdata export

service_perfdata: export service perfdatas to a flat file

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: service_perfdata
- path: path to the service perfdata file you want

Here is an example:

```
define module{
```

```
    module_name      Service-Perfdata
    module_type      service_perfdata
    path             /usr/local/shinken/src/var/service-perfdata
}
```

host_perfdata: export host perfdatas to a flat file

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: host_perfdata
- path: path to the host perfdata file you want

Here is an example:

```
define module{
```

```
    module_name      Host-Perfdata
    module_type      host_perfdata
    path             /usr/local/shinken/src/var/host-perfdata
}
```

Legacy File based Modules - Old CGI or VShell The Old CGI and VShell use the flat file export. If you can, avoid it! It has awful performance, all modern UIs no longer use this.

status_dat: export status into a flat file Export all status into a flat file in the old Nagios format. It's for small/medium environment because it's very slow to parse. It can be used by the Nagios CGI. It also export the objects.cache file for this interface.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: status_dat
- status_file: path of the status.dat file /usr/local/shinken/var/status.dat
- object_cache_file: path of the objects.cache file
- status_update_interval: interval in seconds to generate the status.dat file

Here is an example:

```
define module{
```

```
    module_name              Status-Dat
    module_type              status_dat
    status_file              /usr/local/shinken/var/status.data
    object_cache_file        /usr/local/shinken/var/objects.cache
    status_update_interval   15 ; update status.dat every 15s
}
```

Deprecated or unsupported modules

SQL Based MerlinDB This interface is no longer supported and is going to be completely removed from Shinken.

SQL based ndodb_oracle - Icinga web frontend using NDO Oracle This interface is no longer supported and is going to be completely removed from Shinken.

CouchDB: Export to a Couchdb database This interface is no longer supported and is going to be completely removed from Shinken.

TSCA (Thrift Service Check Acceptor) TSCA is a receiver/arbiter module to receive hosts and services check results. It provides the same functions as NSCA with additional features. High performance binary transmission, multi line output and auto generated clients for a variety of languages.

What is thrift ? Let's cut and paste the wikipedia definition from'en.wikipedia.org/wiki/Apache_Thrift'_ :

"Thrift is an interface definition language that is used to define and create services for numerous languages.[1] It is used as a remote procedure call (RPC) framework [..]. It combines a software stack with a code generation engine to build services that work efficiently to a varying degree and seamlessly between ActionScript, C#, C++ (on POSIX-compliant systems), Cappuccino, Cocoa, Erlang, Haskell, Java, OCaml, Perl, PHP, Python, Ruby, and Smalltalk."

Installation In any case, you have to install thrift with support for python (on the server side) and languages you want to use for clients.

Get it from thrift.apache.org or in your favorite distribution repository.

Server side Go to the tsca module directory and generate the python stub for the server side installation

```
cd shinken/modules/tsca
$ thrift --gen py tsca.thrift
```

Declare the module is shinken-specific.org

```
define module{
      module_name     TSCA
      module_type     tsca_server
      host            0.0.0.0
      port            9090
}
```

Samples clients There are three(3) client samples written in python, ruby and java in contrib/clients/TSCA of the Shinken distribution. You can use and extend them to send data directly in your code directly to Shinken's TSCA receiver/arbiter module.

The samples clients read a CSV file from stdin and send them the the TSCA running on localhost:9090. The CSV has the following format :

```
hostname,service description,output,rc
```

Any use of TCP in an application should take care not to block the program and to have very short timeouts. For applications that need non blocking functions, prefer a UDP based transport or a local buffer file with a separate application(send_nsca, thrift, etc) to forward your data to Shinken.

Ruby Generate the stub

```
$ thrift --gen rb ../../../shinken/modules/tsca/tsca.thrift
```

Run the client

```
$ cat file_state | ruby RubyClient.rb
```

Python Generate the stub

```
$ thrift --gen py ../../../shinken/modules/tsca/tsca.thrift
```

Run the client

```
$ cat file_state | python PythonClient.py
```

java Generate the stub

```
$ thrift --gen java ../../../shinken/modules/tsca/tsca.thrift
```

Compile the client

```
$ ant
```

Run the client

```
$ cat file_state | java JavaClientThrift
```

VMWare Arbiter module

How it works The arbiter has a module that allows the host->VM automatic host dependency creation. In fact, the module is far more generic than just this. It's a generic "host link dependencies" module.

It reads a mapping file (simple json format) with son->father links. It call an external script at a regular interval : the one I wrote is a VMWare mapping one. It used the check_esx3.pl (that all ESX admin should have) plugin and generate the mapping file. When this file is changed, the module reloads it, creates new links and deletes old ones. So when you VMotion a virtual machine, in the next pass, there will be creation of a new link and deletion of the old one in the scheduler that manages it :)

How to define it The definition is very easy :

```
define module{
     module_name       VMWare_auto_linking
     module_type       hot_dependencies
     mapping_file      /tmp/vmware_mapping_file.json
     mapping_command   /usr/local/shinken/libexec/link_vmware_host_vm.py -x '/usr/local/shinken/libex
     mapping_command_interval 60   ; optionnal
     mapping_command_timeout   300 ; optionnal
}
```

Then you add it in you arbiter object :

```
define arbiter {
    [...]
    modules   VMWare_auto_linking
}
```

So here, it will call the script /usr/local/shinken/libexec/link_vmware_host_vm.py with a listing of the vCenter vcenter.mydomain.com and generate the mapping file /tmp/vmware_mapping_file.json.

You can call : /usr/local/shinken/libexec/link_vmware_host_vm.py –help

for the full help on this script.

It looks at the file modification time each second. This command can also be launch by an external cron of course.

Note: So if you want to write a script that does this for XEN servers, all you need is to generate a json file with all the mapping. I didn't wrote the doc about this, but you can look in the test file for it, the format is very very easy :)

Here is an example of the JSON mapping file syntax:

%%:ref:*["host", "physical_host"], ["host", "virtual_machine"* <["host", "physical_host"], ["host", "virtual_machine">, "host", "physical_host"], ["host", "other_virtual_machine" <"host", "physical_host"], ["host", "other_virtual_machine">]%%

So just a list of couple 'host' string (from now only host are managed) and the host name.

Beware about it : you need the real host_name, including case.

Web Service Module The Ws_arbiter module is a Receiver or Arbiter module to receive passive check results from remote hosts via HTTP(s). This module is considered a work in progress but can be used for testing and improvement.

Configuring the Web Service Module If data is POSTed to this page, it will validate the data to determine if it is a service or host check result and submit the data to the Shinken external command queue.

The web service listens by default to TCP port 7760. The web service supports anonymous or authenticated access. Web service parameters are set in the Shinken-specific.cfg file, in the Ws_arbiter module. To enable the web service, simply add the module to your Arbiter or Receiver daemon configuration in Shinken-specific.cfg

Using the Web Service Module The web service listens for POSTs to: /push_check_result

Use curl or embed the HTTP calls in your software to submit check results.

curl -u user:password -d "time_stamp=$(date +%s)&host_name=host-checked&service_description=service-checked&return_code=0&output=Everything OK" http://shinken-srv:7760/push_check_result

Example with more readability:

```
curl
```

-u user:password -d "time_stamp=$(date +%s)

```
&host_name=host-checked
&service_description=service-checked
&return_code=0
&output=Everything OK
http://shinken-srv:7760/push_check_result
```

SNMP module This part must be splitted and sent in all module repositories

Shinken integrated SNMP Module

SnmpBooster Download Install and Configure

- *What is the SnmpBooster module*
- Install and configure the SNMP acquisition module. [You are here]
- *Reference - SnmpBooster troubleshooting*
- *Reference - SnmpBooster design specification*
- *Reference - SnmpBooster configuration dictionnary*

Downloads

The SnmpBooster module and genDevConfig are currently in public beta prior to integration within Shinken. You can consult t

- github.com/xkilian/genDevConfig
- github.com/titilambert/shinken/tree/snmp_booster/shinken/modules (snmp_booster branch) * Simply right-click and download snmp_poller.py then copy it to shinken/modules/

Requirements The SnmpBooster module requires:

- Python 2.6+
- Shinken 1.2+
- PySNMP 4.2.1+ (Python module and its dependencies)
- ConfigObj (Python module)
- python-memcached
- memcachedb or memcached package for your operating system (ex. For Ubuntu: apt-get install memcachedb) *Note*

The genDevConfig profile generator depends on:

- Perl 5.004+
- 4 perl modules available from CPAN and network repositories. genDevConfig/INSTALL has the installation details.

STRONGLY RECOMMENDED: Use the same version of Python and Pyro on all hosts running Shinken processes.

Installation SnmpBooster:

- Install the dependencies
- Copy the file snmp_poller.py from the git repository to your shinken/modules directory.
- Configuration steps are listed in the present web page.

genDevConfig:

- Download and extract the archive to your server.
- See genDevConfig/INSTALL on how to install and configure it.

Configuration

How to define the SnmpBooster module in the Shinken daemons You need to modify shinken-specific.cfg, which is located in $shinken/etc/shinken-specific.cfg

Arbiter daemon configuration Simply declare the module:

```
modules SnmpBooster</code>
```

Scheduler daemon configuration

Simply declare the module:

<code>modules SnmpBooster

Poller daemon configuration Simply declare the module:

```
modules SnmpBooster</code>
```

SnmpBooster Module declaration

Included in Shinken v1.2.1 shinken-specific.cfg.

<code>define module {

```
module_name          SnmpBooster
module_type          snmp_poller
datasource           /usr/local/shinken/etc/packs/network/SnmpBooster/   ; SET THE DIRECTORY FOR YOUR
memcached_host       x.x.x.x  ; SET THE IP ADDRESS OF YOUR memcached SERVER
memcached_port       11211  ; default port for a memcached process
```

}

If you do not know the IP adress on which your memcache is listening, check under /etc/memcached.conf. Or do a:

```
netstat -a | grep memcached</code>
If you are running a test on the local machine you can leave memcached on 127.0.0.1 (localhost), but
```

How to define a Host and Service

Step 1

Create a template for your SNMP enabled devices.

Sample template:

<code>cd shinken/etc/packs/network/ mkdir SnmpBooster

vi shinken/etc/packs/network/SnmpBooster/templates.cfg

```
define command {
```

```
command_name    check_snmp_booster
command_line    check_snmp_booster -H $HOSTNAME$ -C $SNMPCOMMUNITYREAD$ -V 2c -t $ARG1$ -i $_SERVICE
module_type     snmp_poller
```

}

```
define service {
```

```
name                    default-snmp-template
check_command           check_snmp_booster!$_SERVICEDSTEMPLATE$!$_SERVICEINST$!$_SERVICETRIGGERGROUP
_inst                   None
_triggergroup           None
max_check_attempts      3
check_interval          1
retry_interval          1
register                0
```

}

```
define host{
```

```
name                    SnmpBooster-host
alias                   SnmpBooster-host template
check_command           check_host_alive
max_check_attempts      3
check_interval          1
retry_interval          1
use                     generic-host
register                0
```

}

Step 2 Define some hosts and services. You would typically use genDevConfig or another configuration generator to create these for you.

Mandatory service arguments related to SNMP polling:

```
_dstemplate                Cisco-Generic-Router  ; Name of a DSTEMPLATE defined in the SnmpBooster co
```

```
snmpcommunityread    which is set in your resource.cfg file
```

Optional service arguments related to SNMP polling with default values:

```
_inst                   None   ; Could be numeric: 0, None or an instance mapping function like: map
```

```
_triggergroup           None   ; Name of the triggergroup defined in the SnmpBooster config.ini file
```

Sample Shinken host and service configuration:

```
# Generated by genDevConfig 3.0.0
# Args: --showunused -c publicstring 192.168.2.63
# Date: Thu Aug 30 17:47:59 2012

#######################################################################
# Description: Cisco IOS Software, C2960 Software (C2960-LANBASEK9-M), Version 12.2(50)SE4, RELEASE S
#     Contact:
# System Name: SITE1-ASW-Lab04
#    Location:
#######################################################################

define host {
```

```
 host_name            192.168.2.63
 display_name         192.168.2.63
 _sys_location
 address              192.168.2.63
 hostgroups
 notes
 parents
 use                  default-snmp-host-template
 register             1
}

define service {
```

```
 host_name            192.168.2.63
 service_description  chassis
 display_name         C2960 class chassis
 _dstemplate          Cisco-Generic-Router
 _inst                0
 use                  default-snmp-template
 register             1
}

define service {
```

```
 host_name            192.168.2.63
 service_description  chassis.device-traffic
 display_name         Switch fabric statistics - Packets per Second
 _dstemplate          Device-Traffic
 use                  default-snmp-template
 register             1
}

define service {
```

```
host_name            192.168.2.63
service_description  if.FastEthernet0_1
display_name         FastEthernet0_1 Description: Link to Router-1 100.0 MBits/s ethernetCsmacd
_dstemplate          standard-interface
_inst                map(interface-name,FastEthernet0_1)
use                  default-snmp-template
register             1
```

}

Here is an example configuration of the config.ini file

```
[DATASOURCE]
```

```
  OidmyOidDefinition = .1.3.6.1.45.0
  [myOidDefinition] ; Use the same name as the myOidDeiniftion, but omit the leading "Oid"
      ds_type = DERIVE
      ds_calc = 8,*  ; RPN expression : Oid, 8, *  Which means Oid * 8 = ds_calc
      ds_oid = $OidmyOidDefinition
[DSTEMPLATE]
```

```
  [myCiscoRouter]
      ds = myOidDefinition
[TRIGGER]
```

```
  [trigger1]
      warning = RPN expression
      critical = RPN expression
  [trigger2]
      warning = RPN expression
      critical = RPN expression
[TRIGGERGROUP]
```

```
[CiscoRouterTriggers]
    triggers = trigger1, trigger2
```

Shinken integrated SNMP Module

Overview

What is it The SnmpBooster module allows Shinken Pollers to directly manage SNMP data acquisition. This is an all Python cross-platform SNMP module. It is tightly integrated with the Shinken Poller, Scheduler and Arbiter daemons to provide the best possible user experience.

- Jump back to *SnmpBooster documentation index*

Design specification summary

- STATUS - DESIGN SPEC PERFORMANCE
- [Done] Functions as an integrated Shinken Poller module
- [Done] Necessary integration code commited to Shinken official release (Integrated starting at v1.2)
- [Done] Ability to collect thousands of SNMP metrics per second
- [Done] Be compatible with distributed data acquisition
- [Done] Collect data for a host/check_interval tuple via SNMP in a single pass
- [Done] Use all builtin Shinken scheduler logic for retries, forced checks, timeouts, dependencies, parents
- [Done] Store collected data for the duration of the check_interval in a memcached/membase
- [Done] On a restart, after the first collection, be able to pick up where the last check left and calculate derived values
- [Done] Forced check are not allowed within 30 seconds of last SNMP query to the same host/check_interval, all other requests get data from the cache.
- [Done] Only a single request to the host/check_interval via SNMP is allowed at a time, all other requests get data from the cache.
- STATUS - DESIGN SPEC USABILITY
- [Done] Usage documentation
- [xxxx] SkonfUI and Discovery usage documentation
- [xxxx] Provide sample configuration packs in Shinken
- [Done] Provide sample config.ini with examples of all types of data * SNMP OIDS, DATASOURCES, DSTEMPLATES, TRIGGERS and TRIGGERGROUPS

- [Done] Directly compatible for use with genDevConfig Shinken SNMP configuration generator
- [Done] Provide meaningful feedback for users on errors
- [Done] Capture all tracebacks and convert them to actual error or warning messages
- STATUS - DESIGN SPEC FEATURES
- [Done] Return state and performance metrics
- [Done] Performance metrics can be returned in a Weathermap compatible format
- [Done] Configuration file format is ConfigObj INI
- [Done] Load all valid INI configuration files from a directory and merge them
- [Done] Load a single INI configuration file
- [xxxx] Load a list of INI configuration files
- [Done] Configuration file describes all generic acquisition parameters (OID, DATASOURCE, DSTEMPLATE, MAP, TRIGGER, TRIGGERGROUP)
- [Done] Supports Triggers which are calculation rules to determine states
- [Done] Triggers support an RPN (Reverse Polish Notation) calculation engine which includes mathematical and logical operators
- [Done] Each TRIGGER is associated with a severity level, WARNING or CRITICAL
- [Done] Multiple TRIGGERS can be associated with a TRIGGERGROUP
- [Done] Use builtin Python Operators
- [Done] Support DERIVE, TEXT, GAUGE and COUNTER data types
- [xxxx] Support TIMETICKS data type
- [Done] Support applying RPN based calculations to received metric for scaling or conversion purposes
- [Done] Use a Python SNMP library which supports asynchronous acquisition PySNMP
- [Done] Datasources can use rule based runtime instance mapping
- [Done] Set Snmp version as a check runtime option
- [Done] Set Snmp DSTEMPLATE as a check runtime option
- [Done] Set Snmp TRIGGERGROUP as a check runtime option
- [Done] Set Snmp COMMUNITY as a check runtime option
- [Done] Use Snmp version 2c GetBulk
- [xxxx] Support Snmp version 2c GetNext if GetBulk is not supported
- [xxxx] Support Snmp version 1 GetNext
- [xxxx] Set Snmp Timeout as a check runtime option, instead of a hardcoded value at 5 seconds
- STATUS - DESIGN SPEC MAINTAINABILITY
- [xxxx] Functions documented in the source code
- [Done] Critical functions documented in the source code
- [Done] Locking sections identified in the code
- [xxxx] Unit tests with at least 80% coverage

- [xxxx] Unit tests integrated with Shinken test suite
- [Done] Code hosted on github
- [xxxx] configuration validity and integrity checking of all INI files
- [xxxx] Pep8 compliant
- [xxxx] Pylint pass

genDevConfig Plugins - Compatibility status with SnmpBooster

- STATUS - genDevConfig maintained Plugins
- [Done] Avaya ES switches
- [Done] Avaya ERS routing switches
- [Done] Cisco 29x0 switches
- [Done] MIB-II Interfaces
- [Done] Cisco PIX/ASA
- [Done] JUNOS devices
- [Done] Cisco IOS routers
- [Done] NetSNMP unix hosts ** Validation required**
- [Done] Packeteer devices ** Validation required**
- [Done] Sensatronics devices ** Validation required**
- [Done] Foundry devices ** Validation required**
- [Done] Packeteer devices ** Validation required**
- [Done] Cisco CSS ** Validation required**

SnmpBooster reference dictionary

- Jump back to *SnmpBooster documentation index*

SnmpBooster.ini dictionary

There are five dictionaries:

- [DATASOURCE]
- [DSTEMPLATE]
- [MAP]
- [TRIGGER]

- [TRIGGERGROUP]

DATASOURCE DICTIONARY OidVariableName refers to an actual OID that can be queries using SNMP against the device on the network.

[VariableName] refers to a Datasource and all the information required to gather and prepare the data using SNMP ds_type refers to how the data should be prepared ds_calc refers to any scaling manipulations to make the data more understandable. This is an RPN expression, where the first variable is omitted, as it is always the $OidVariable ds_oid refers to the actual $OidVariable name. An instance identifier can be appended to the name to signify that an instance is provided by the Shinken service definition. This information is passed when the check is called. ...

DSTEMPLATE DICTIONNARY [DsTemplateName] refers to the name of the DSTEMPLATE that will be referred to in the Shinken service definitions. ds refers to the list of DATASOURCES to be collected. If an instance is expected for the list of DATASOURCES, it MUST be the same instance for all Oids. If a different instance is required, use a second DSTEMPLATE.

TRIGGER DICTIONNARY

TRIGGERGROUP DICTIONNARY

MAP DICTIONNARY

SnmpBooster.ini example configuration This example definition will be used to explain each section.

[DATASOURCE]

```
OidmyOidDefinition = .1.3.6.1.45.0
[myOidDefinition] ; Use the same name as the myOidDeiniftion, but omit the leading "Oid"
    ds_type = DERIVE
    ds_calc = 8,*  ; RPN expression : Oid, 8, *  Which means Oid * 8 = Total
    ds_oid = $OidmyOidDefinition
```

[DSTEMPLATE]

```
[myCiscoRouter]
    ds = myOidDefinition
```

[TRIGGER]

```
[trigger1]
    warning = RPN expression
    critical = RPN expression
[trigger2]
    warning = RPN expression
    critical = RPN expression
```

[TRIGGERGROUP]

```
[CiscoRouterTriggers]
    triggers = trigger1, trigger2
```

SnmpBooster.ini configuring SNMP Datasources

The first location is generic data related to SNMP parameters.

- DATASOURCE information * SNMP OID * Type of data and how can it be interpreted (GAUGE, COUNTER, COUNTER64, DERIVE, DERIVE64, TEXT, TIMETICK) * Data format preparation (Scaling the data for example bits to bytes) * Is there an instance to append to the
- Instance MAP function * Mapping the instance dynamically using a function * Data or rules related to the mapping function

SnmpBooster.ini configuring SNMP DSTEMPLATES

- DSTEMPLATEs to associate DATASOURCE to actual device classes * List of DATASOURCES associated with a, for example, Cisco 1900 router. Which in turn can be applied to a Shinken service

SnmpBooster.ini setting triggers/thresholds

- TRIGGER and TRIGGERGROUPS to apply thresholding rules * Define triggers and associate them with a TRIGGERGROUP name that can be applied to a Shinken Service

Shinken integrated SNMP Module

Overview

- Jump back to *SnmpBooster documentation index*

Tip: The module is now in public beta as of 2012-10-26! Have Fun!

Nothing new to add, more to come in 2013. 2013-01-19.

What is it The SnmpBooster module allows Shinken Pollers to directly manage SNMP data acquisition. This is an all Python cross-platform SNMP module. It is tightly integrated with the Shinken Poller, Scheduler and Arbiter daemons to provide the best possible user experience.

Why use it The SnmpBooster module is designed to be very efficient and scalable. It has a very flexible configuration method to make it easy to use with Shinken Monitoring Packs and Shinken discovery runners like genDevConfig.

This acquisition module was professionally designed and developed.

It is meant to be used by the very capable discovery engine genDevConfig (**v3.0.5 and newer**) originally developed for the Cricket SNMP monitoring tool and converted for use with Shinken.

It is one of the very few serious SNMP v2c implementation making use of SnmpGetBulk type requests.

How does it work

Shinken Integration

1. The SnmpBooster Arbiter module reads the Shinken SnmpBooster configuration file(s). It reads the check commands and based on the values in the check commands that use the snmp_poller module it will creates a shared configuration cache using memcached/memcachedb. The memcache key is always the combination of the hostname. This permits to tie together Shinken Hosts and Services with the SNMP specific configuration. (MongoDB and Redis are planned to be supported in the future) The Scheduler daemon schedules Host and Service checks as it normally does.

3. The SnmpBooster module will check that a memcache host key exists for the check to be launched. Then the SnmpBooster poller module will query all services related to a host for a given acquisition frequency in one pass. (all checks done every 2 minutes will be executed in bulk, same for those every 5 minutes)

5. Check results are cached for the acquisition check_interval. The next time a check request for data from the same host is received from the Scheduler, the data will be fetched from memcache. Resulting is extremely low check latency.

2. 6. The SNMP checks still benefit from retries, timeouts, forced checks, dependencies and the powerful Scheduler daemon logic.

6. The Scheduler daemon can still force an immediate re-check by flushing the cache. This is required for the dependency model.

Performance SnmpBooster uses SNMP v2c getbulk for high efficiency, unless forced to use SNMP v2c get-next or SNMPv1 get-next. GetBulk uses a single request PDU to ask for multiple OIDs or even entire tables, instead of sending one request PDU per OID.

For example: *A typical 24 port network switch with two uplinks might use 375 OIDS (8 OIDs per interface, plus general OIDs for chassis health, memory, cpu, fans, etc.). **SnmpBooster will only require around 4 request PDUs*

*instead of 375 request PDUs**. Each PDU is a request packet which takes time to create, send get processed and return. More timeouts to manage, more connections, more impact on the remote device and more latency means much fewer checks per second.*

The SnmpBooster module supports automatic instance mapping for OIDs. (Ex. Based on the interface name it will figure out that the SNMP index(or instance) is 136. This is automatically handled by genDevConfig and SnmpBooster, no user input required. :-)

The generic SNMP configuration information is stored in the Shinken SnmpBooster INI files. There is a Defaults_unified.ini and a series of other Defaults files, one per discovery plugin for genDevConfig.

Important: genDevConfig plugins have all been converted to use the new dynamic instance mapping methods. You are now free to use most if not all Defaults*.ini files included with genDevConfig. 2012-10-28

Limitations You should have memcached instances running on each poller responsible for snmp polling. You should have your pollers with SnmpBooster in the same datacenter, as they need to be on the same machine with good connectivity to the active memcached instance. SnmpBooster is not compatible with distributed pollers in multiple datacenters, sorry, the current design of SnmpBooster uses a single centralized memcached instance for storing the timeseries data. For distributed datacenters to be supported, each poller+scheduler+memcached must be realm restrained, which is not the case today.

Design specification *SnmpBooster design specification* and current development status.

Data model The information required to define the data is split in two locations.

The first location is the host and service Shinken configuration (You need to generate or write this)

- Device specific information
  - IP addresses, host_names, device types, instance keys
  - A DSTEMPLATE must be referred to in the Service definition
  - A static SNMP instance could be referred to in the Service definition
  - An SNMP instance MAP function could be referred to in the Service definition
  - A TRIGGERGROUP could be refered to in the Service definition

The second location is SNMP Defaults.* templates. (Here you can create new devices or add new data sources)

- DATASOURCE information
  - SNMP OID
  - Type of data and how can it be interpreted (GAUGE, COUNTER, COUNTER64, DERIVE, DERIVE64, TEXT, TIMETICK)
  - Data format preparation (Scaling the data for example bits to bytes)
  - Is there an instance to append to the
- Instance MAP function * Mapping the instance dynamically using a function * Data or rules related to the mapping function
- DSTEMPLATEs to associate DATASOURCE to actual device classes * List of DATASOURCES associated with a, for example, Cisco 1900 router. Which in turn can be applied to a Shinken service
- TRIGGER and TRIGGERGROUPS to apply thresholding rules * Define triggers and associate them with a TRIGGERGROUP name that can be applied to a Shinken Service

A final location containes rules to build your Shinken configuration.

- genDevConfig plugins create Shinken configurations

Installation and configuration *SnmpBooster installation*

Reference Dictionnary *SnmpBooster reference dictionary*

Troubleshooting *SnmpBooster troubleshooting*

Graph templates These are .graph files defined in your Shinken configuration directory. Refer to the Shinken graphite templates(Not yet created) or PNP4Nagios how-to documentation. The graph templates are independent from SnmpBooster and provide templates for any collected data from Shinken.

SnmpBooster Troubleshooting

- Jump back to *SnmpBooster documentation index*

Check your config

- Have you defined the poller module name?
- Have you defined the correct path to the directory containing your Defaults*.ini files?
- Have you addded the Snmpbooster module to your arbiter, poller, scheduler?
- Have you added copied the genDevConfig templates.cfg in shinken/packs/network/SnmpBooster/
- Have you installed PySNMP, memcached and other dependencies?

Software version consistency Shinken and SnmpBooster now require **the same Python and Pyro version on all hosts running a Shinken daemon**.

If you cannot use the packaged version of Python and its modules (Pyro, memcached, etc.). Use virtualenv to declare a python version to use and install all required modules in that virtualenv.

Software version requirements Have you verified that the *requirements* are met. Python, PySNMP, Shinken, Pyro, memcached, etc.

Validate your check command arguments Use the check_plugin command and comment out the module to learn what were the exact arguments sent by the poller. This will permit you to validate all the arguments, like snmp community string, inheritance, template application, etc.

Validate connectivity

Take a packet trace using a tool like Wireshark to validate that the remote host is responding.

- Has the host responded
- **Is SnmpBooster repeating the request more often than the polling interval.**
  - If you are seeing repeated requests your device may have a compatibility issues.

- Save an snmpwalk of the device, get a packet trace using Wireshark, set the poller to debug and save the poller.log file (shinken/var/poller.log). Send all three to the SnmpBooster developers.
- Note: It is normal to see one or more bulkGet requests if you are getting large amounts of data. Ex. a 24 port switch will take 2-3 request packets.

Performance Make sure you have a low latency connection to your memcache from the Poller. Your memcache server can be replicated to all your poller hosts that should also run memcache instances. Check that memcached is running: netstat -a | grep memcached

Faulty Template A bad snmp_template file was distributed in the genDevConfig sample-config directory, there were two glaring errors.

This was fixed on 2012-10-16. Make sure you update your template, or use the data from the wiki.

Note that the template should be called: SnmpBooster-template.cfg to make it easier to troubleshoot in the logs. So when you search for SnmpBooster in your logs it will show up as well.

Log files All warnings and errors generated by the SnmpBooster module start with "[SnmpBooster] error text" and are logged using the standard Shinken logger.

The Arbiter daemon can output initial configuration, loading of host keys and intervals in memcached type error messages. The Scheduler daemon can output scheduling and alert related messages. The Poller daemon can output messages related to instance mapping, acquisition timeouts, invalid community strings, cache failures and more. These are available in the Web interface, as they are placed in the check results for the service.

You can simply do a "grep SnmpBooster *" in your shinken/var directory to see the latest messages related to the SnmpBooster module. You can also sort messages by timestamp to make it easy to find where and when errors occurred.

cd shinken/var grep SnmpBooster *

memcache persistence If you restart your memcache server or memcache crashes, your poller will no longer be able to validate that a host exists in memcache prior to writing.

You should use memcachedb to achieve persistence in case of memcache failures.

Common errors returned by SnmpBooster in the log file Errors should be fairly explicit and mean what they say, though there can be exceptions. Lets try to clear some of them.

__Arbiter log **errors__**

Missing ds_oid : This means that a variable in your OID definitions is missing, or your DATASOURCE is not named correctly or your ds_oid variable is missing. There is a typo in your ds_oid variable (ex. ds-oid, or ds_oid = $OidNameIncorrectFFFRA.%(instance)s).

Datasource not defined : Your DSTEMPLATE uses a DATASOURCE that doesn't exist check the [DataSourceName] you are referring to. Does it contain the expected OID variable, $OidName.

Missing ds_type : The DATASOURCE always needs to have a ds_type definition, GAUGE, COUNTER, DERIVE, TEXT, TIMETICK, DERIVE64, COUNTER64.

__Poller log **errors__**

Problems with calculations, repeated polling, hosts not responding, etc.

__Memcached **errors__**

memcachedb and memcached do not use the same default port. Configure the correct memcachedb port to match what is declared in your SnmpBooster module under shinken-specific.cfg.

On Ubuntu 12.04 the default installation is on port 21201 instead of 11211. This causes the error "[SnmpBooster] Memcache server (127.0.0.1:11211) is not reachable" when Shinken starts.

To change it, you must edit the file /etc/memcachedb.conf

Memcached Notes On Ubuntu 12.04 the default instalation is on port 21201 instead of 11211. This causes the error "[SnmpBooster] Memcache server (127.0.0.1:11211) is not reachable" when shinken starts.

To change it, you must edit the file /etc/memcachedb.conf

WebUI module This part must be splitted and sent in all module repositories

WebUI integration with Shinken The WebUI is an external broker module. So it's an external process launched by the broker that "eats" broks (broker messages) from the brokers. So it can get *all* broks if you place this broker in your top level realm.

The WebUI does not use a database to get data. Instead, it use a "regenerator" object that will eat each broks, and will "recreate" all Hosts/Services/Contacts objects as if the code was in the scheduler daemon. So basically, WebUI and pages always reflect the CURRENT state of hosts/services objects.

The WebUI http layer is managed by bottle.py. It's a small but powerful framework.

How does the WebUI function globally ?

There a 2 Threads running:

- the main thread is the bottle.py (http) listener. It will use the best backend it finds. We recommend using python-paste. If it does not find one, it will use the default swsgi. Paste is multi-thread, swsgi is mon-thread, so please use paste if you want to avoid locking problems.
- the 2nd thread is the regenerator one. It only gets broks and gives them to the regenerator object.

There is a lock system between the threads. You can have N Http requests in progress without problem, but during this time the renererator one will wait. During execution of the regenerator, no requests are processed. This is not considered a problem, as the regenerator is very quick, and there is only a 1s lock for a 7k service conf loading, so it's not a huge problem.

What is a WebUI User? A WebUI user is a contact. A true contact object. You must match a contact name for your user.

To create a new page? All pages are in the shinken/webui/plugins directory. Each "part" has it's own directory. A part (like the eltdetail, element detail) can have more than one "page" (like /host or /service for eltdetail).

From here we will supose you want to create a "/contact" page.

You can copy the dummy example in the plugins directory into a contact directory.

You need to change the contact/dummy.py file into a contact/contact.py file, because the webui will search for a dir/dir.py file to "load".

Templates Templates are HTML with some Python code in it in the plugins/*/views direcotry for specific templates, and the "global layout" (menu and all common part) in the webui/views directory.

Your template must call the template layout (layout.tpl in the webui/views directory) wit ha "rebase" call.

If you put the rebase call at the beginning of your template, all there is below will be place "inside" the layout that will call the common javascripts and css, make the menu adn then call your html/python code.

The rebase call can take arguments. You MUST give it:

- user: the user you give it in the return dict of your .py code

Then all is optional:

- title: title of the page
- top_right_banner_state: int, global state with clouds to put in your top right page. Look at the problem.tpl code for an example.
- js and css list: list of YOUR specific javascript or css to call AFTER the common ones.
- refresh: boolean, set the refresh to 60s or do not refresh at all

- menu_part: will put the little "^" under this part of the menu.

Example of a call, taken from the problems view:

```
rebase layout title='All problems', top_right_banner_state=top_right_banner_state, js=['problems/js/a
roblems/js/autocompleter.Request.js', 'problems/js/autocompleterObserver.js'], css=['problems/css/acc
ms/css/autocompleter.css', 'problems/css/perfometer.css'], refresh=True, menu_part='/'+page, user=use
```

Call Python objects in your templates Your templates are mainly HTML code. But of course you can call python code in it. The dict you returns in the plugin.py call will be available in this page.

For example, the my_host variable will be available in the page with the host object you find (or None if your give it a bad name of course). Then you can "call" python with for example here to show the host_name: `<span>My host name is *my_host.host_name* </span>` is a way in the templates to "call a variable or function" that will return a string, here the host_name.

If the function or property you call must return HTML code that SHOULD be output as it, without "protection", you must put a ! before your call.

Let use an example where the output value of an host is in fact an html output. If you use the code `my_host.output`, bottle.py will "protect" the html generated by escaping the string, and change <> characters with escaped value. You can change this by calling `my_host.output`. Of course, it's a security problem if the output is with a javascript code...

You can also "loop" or put "if" in your template. You just need to put your code with a % before. Like

```
%for i in xrange(1, 10):
  My valus is  {{i}}
%end
```

You must put the %end here, the indentation will NOT be enougth, sorry.

For an if it's also easy:

```
%if host.active_checks_enabled:
  The host got active checks enabled
%else:
  The host DO NOT have active check enabled
%end
```

Which javascript lib are you using? It's mootools 1.3 with all options :)

What to do?

- Finish the /mobile part
- List of current alerts
- Host info
- Host status
- Host interfaces
- Hostgroup status
- dashboard hierachique with states, and BP
- Nagvis
- add bp in nagvis auto-map

- event sources
- correlation
- pre-filtering/enrichment
- user profile
- host/srv conf

WebUI search syntax work in progress

not that we couldn't tell. ;) eh eh

beware the working men and flying tools!

WebUI SSL Certification Lets start: the goal to to have the server.pem and client.pem file in etc/certs.

Go to the etc/certs directory.

```
openssl req -new -nodes -out server.req -keyout server.key -config ./shinken_openssl_cnf
openssl ca -out server.pem -config ./shinken_openssl_cnf -infiles server.req
cp server.pem server.pem.bkp
cp server.key server.pem
cat server.pem.bkp >> server.pem
cp server.pem client.pem
```

You can try to get the validity with for the arbiter with:

```
openssl s_client -connect localhost:7770</code>
```

Amazon AWS/EC2 import

Description You can import data from Amazon AWS/EC2 **'AWS'**_ into Shinken to create hosts.

Amazon provide VM hosting with EC2. With this arbiter module, you will be able to load your EC2 hosts into Shinken.

Prerequisites

You will need the **'libcloud'**_ package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

```
define module {
 module_name      AWS
 module_type      aws_import

 # Configure your REAL key and secret for AWS
 api_key              PAAAB2CILT80I0ZA0999
 secret           GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH
 default_template generic-host        ; if the host is not tagged, use this one
 }
```

- Put in key and secret your private Landscape access. * default_template will be used if your host is not "tagged" in Landscape

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master

     address          localhost                  ;IP or DNS adress
     port             7770
     spare            0
     modules           AWS
     }
```

Restart your Arbiter and it's done :)

Generated hosts The configuration generated will look as below :

```
define host {
    host_name            i-3fc56e5a
    address              8.8.4.4
    use                  t1.micro,MyTag,EC2,generic-host
    _EC2_AVAILABILITY    us-east-1a
    _EC2_CLIENTTOKEN
    _EC2_DNS_NAME
    _EC2_GROUPS          quicklaunch-1
    _EC2_IMAGEID         ami-1b814f72
    _EC2_INSTANCEID      i-3fc56e5a
    _EC2_INSTANCETYPE    t1.micro
    _EC2_KERNELID        aki-825ea7eb
    _EC2_KEYNAME         testaws
    _EC2_LAUNCHDATETIME  2012-09-26T12:19:38.000Z
    _EC2_LAUNCHINDEX     0
    _EC2_PRIVATE_DNS
    _EC2_PRIVATE_IP
    _EC2_PRODUCTCODE
    _EC2_PUBLIC_IP       8.8.4.4
    _EC2_RAMDISKID       None
    _EC2_STATUS          stopped
    _EC2_TAGS            demo:myvalue,use:MyTag
 }
```

Here with a stopped t1.micro instance with no name. You can put your how "use" parameter by adding a EC2 tag "use" on your VM. It will be output on the host configuration so you can setup the monitoring as you want. .. _libcloud: http://libcloud.apache.org/index.html .. _AWS: https://console.aws.amazon.com

Amazon AWS/EC2 import

Description You can import data from Amazon AWS/EC3 **'AWS'**_ into Shinken to create hosts.

Amazon provide VM hosting with EC3. With this arbiter module, you will be able to load your EC2 hosts into Shinken.

Prerequisites

You will need the **'libcloud'**_ package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

```
define module {
 module_name      AWS
 module_type      aws_import

 # Configure your REAL key and secret for AWS
 api_key              PAAAB2CILT80I0ZA0999
 secret           GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH
 default_template generic-host        ; if the host is not tagged, use this one
 }
```

- Put in key and secret your private Landscape access. * default_template will be used if your host is not "tagged" in Landscape

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master

     address          localhost                  ;IP or DNS adress
     port             7770
     spare            0
     modules           AWS
     }
```

Restart your Arbiter and it's done :)

Generated hosts The configuration generated will look as below :

```
define host {
    host_name            i-3fc56e5a
    address              8.8.4.4
    use                  t1.micro,MyTag,EC2,generic-host
    _EC2_AVAILABILITY    us-east-1a
    _EC2_CLIENTTOKEN
    _EC2_DNS_NAME
    _EC2_GROUPS          quicklaunch-1
    _EC2_IMAGEID         ami-1b814f72
    _EC2_INSTANCEID      i-3fc56e5a
    _EC2_INSTANCETYPE    t1.micro
    _EC2_KERNELID        aki-825ea7eb
    _EC2_KEYNAME         testaws
    _EC2_LAUNCHDATETIME  2012-09-26T12:19:38.000Z
    _EC2_LAUNCHINDEX     0
    _EC2_PRIVATE_DNS
    _EC2_PRIVATE_IP
    _EC2_PRODUCTCODE
    _EC2_PUBLIC_IP       8.8.4.4
    _EC2_RAMDISKID       None
    _EC2_STATUS          stopped
    _EC2_TAGS            demo:myvalue,use:MyTag
 }
```

Here with a stopped t1.micro instance with no name. You can put your how "use" parameter by adding a EC2 tag "use" on your VM. It will be output on the host configuration so you can setup the monitoring as you want. .. _libcloud: http://libcloud.apache.org/index.html .. _AWS: https://console.aws.amazon.com

The distributed retention modules The high availability allow the Arbiter to send a configuration to a spare scheduler, but a spare scheduler does not have any saved states for hosts and services. It will have to recheck them all. It's better to use a distributed retention module so spares will have all the information they need to start with an accurate picture of the current states and scheduling :)

Non distributed retention modules If you are just running tests on a single server, use the pickle or memcache retention modules You can also use MongoDB if you already have it installed for use with the WebUI.

MongoDB MongoDB is a scalable, high-performance, open source NoSQL database written in C++.

Step 1: Install MongoDB:

We will use mongodb package from 10gen repository, so we start by adding it in apt sources list:

```
echo 'deb http://downloads-distro.mongodb.org/repo/debian-sysvinit dist 10gen' > /etc/apt/sources.lis
apt-get update
```

And we install it:

```
apt-get install mongodb-10gen
```

And we install pymongo, the python interface to MongoDB, with easy_install to avoid packages versions problems (like here **'forums.monitoring-fr.org/index.php?topic=5205.0'_**):

```
apt-get remove python-pymongo
easy_install pymongo
```

And finally we start MongoDB :

```
/etc/init.d/mongodb start
```

Step 2: define a mongodb_retention module in your shinken-specific.cfg file:

```
define module {
  module_name MongodbRetention
  module_type mongodb_retention
  uri mongodb://localhost/?safe=true
  database shinken
}
```

Step 3: Declare a retention module for your scheduler(s) :)

Example:

```
#The scheduler is a "Host manager". It get hosts and theirs
#services. It scheduler checks for them.
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
     port     7768                  ; tcp port of the daemon

     #optionnal: modules for things as retention
     modules    MongodbRetention
     }
```

Step 4: Restart the Arbiter, and your Scheduler will now save its state between restarts. :)

Memcached Memcached is a distributed memory resident key/value server. It's very easy to install:

```
sudo apt-get install memcached
sudo /etc/init.d/memcached start
```

The shinken module also needs the python-memcache package to talk to this server.

```
sudo apt-get install python-memcache
```

To use it,

Step 1: define a memcache_retention module in your shinken-specific.cfg file:

```
define module{
     module_name      MemcacheRetention
     module_type      memcache_retention
     server           127.0.0.1
     port             11211
}
```

Step 2: Declare a retention module for your scheduler(s) :)

Example:

```
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
     port     7768                  ; tcp port of the daemon

     #optional: modules for things as retention
     modules    MemcacheRetention
     }
```

Step 3: Restart the Arbiter, and your Scheduler will now save its state between restarts. :)

Redis Redis is a distributed key/value server (on disk and in-memory). It's very easy to install:

```
sudo apt-get install redis-server
sudo /etc/init.d/redis-server start
```

The shinken module also need the python-redis package to talk to this server.

```
sudo apt-get install python-redis
```

Step 1: define a redis_retention module in your shinken-specific.cfg file:

```
define module{
     module_name      RedisRetention
     module_type      redis_retention
     server           127.0.0.1
}
```

Step 2: Declare a retention module for your scheduler(s) :)

Example:

```
#The scheduler is a "Host manager". It get hosts and theirs
#services. It scheduler checks for them.
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
```

```
    port     7768                  ; tcp port of the daemon

    #optionnal: modules for things as retention
    modules    RedisRetention
    }
```

Step 3: Restart the Arbiter, and your Scheduler will now save its state between restarts. :) .. _forums.monitoring-fr.org/index.php?topic=5205.0: http://forums.monitoring-fr.org/index.php?topic=5205.0

How to enable and use Livestatus module

Define the Livestatus module Start by reviewing the ''/etc/shinken/shinken-specific.cfg" file for this module:

```
define module{
```

```
module_name      Livestatus
module_type      livestatus
host             *       ; * = listen on all configured IP addresses
port             50000   ; port to listen on
database_file    /var/lib/shinken/livestatus.db
```

}

With these parameters:

- module_name: name of the module called by the brokers
- module_type: livestatus
- host: IP interface to listen to. The default is *, which means "listen on all interfaces".
- port: TCP port to listen to.
- socket: Unix socket to listen to.
- database_file: the path to the sqlite database file which is used to store the log broks/messages. The default is "var/livelogs.db"
- max_logs_age: the maximum age of the log messages (before they are deleted from the database). The default is 1 year. The argument to this parameter takes the form <number>[<period of time>], where <period of time> can be d for days, w for weeks, m for months and y for years.
- allowed_hosts: a comma-separated list of IP-addresses which are allowed to contact the TCP port. Please keep in mind that these **must be IP-addresses, NOT host names**. Because DNS lookups for every incoming livestatus request could hang up and therefore block the module.

Enable the Livestatus module Still in ''/etc/shinken/shinken-specific.cfg'', find the object Broker and add "Livestatus" to its "modules":

```
define broker{
```

```
    broker_name      broker-1
[...]
```

```
    modules          Simple-log,Livestatus
}
```

Disable human readable logs In ‘’/etc/shinken/nagios.cfg’‘, verify that the option **human_timestamp_log** is set to **0**.

In version 0.6.5, you can not have at the same time a simple-log file with human readable timestamp and a Livestatus database.

Exporting data for reporting Shinken can export necessary data for reporting in 3rd party systems.

raw_socket module The raw socket module exports reporting data using a syslog format to a raw TCP socket. Theses logs can be captured, parsed and indexed by any log management system like Splunk or Logstash.

Why export reporting data Custom UIs like Thruk, Multisite, WebUI, Adagios, Nagios IX, etc. All have poor or inflexible reporting. Simply because these are not reporting engines.

This also permits to have a generic reporting method that can accept data from any Nagios, Shinken, Icinga or even Riemann.

Reporting module using Splunk Splunk was selected as the reporting platform for creating, managing and presenting reports. Though the raw_socket module does not have any Splunk specific particularities. It is notable that Splunk reports can be embedded in any 3rd party UI using its REST API.

Raw_socket log format The logs are plain-text and compliant with RFC3164. They use an intelligent date format, a configurable seperator ” “(space by default), and key=value pairs in the message data portion of the log. Should a key or value contain a space they must be double quoted. This is syslog using structured data without going to full out JSON that may not be compatible with all log management systems.

The message fields that are supplied in each status update in addition to the standard syslog header are:

- Hostname
- Servicename
- Business impact
- Host/Service status
- Host/Service previous status
- Acknowedgement status
- Maintenance status

Any time the maintenance, host, service or acknowledgement status changes, a log is sent by the Shinken raw_socket module.

Having all relevant data in each log makes it very easy to compute reports for given time periods.

The hostgroup or service group memberships, custom variables or any other configuration related data should be queried from the monitoring system using its API (Livestatus in the case of Shinken and Nagios).

Raw_socket module availability The module is available in both Shinken 1.4 and Shinken 2.0. The module will be integrated in master branches once unit tests and end-to-end testing is completed. 3rd quarter 2013.

Monitoring Linux System with Glances and checkglances.py **‘Glances‘_** is a fantastic multiplatform system monitoring tool writen by Nicolargo. Glances can run on (Linux, Windows, MacOS ...). There is a growing ecosystem around Glances and of course a Nagios/Shinken plugin : checkglances.py.

How does it work Glances can run in server mode. It provide a XML-RPC server (over http) and allow to retrieve system information throuh a restful API. The only thing to do is to install and start Glances as server on the monitored host, then install checkglances.py on the shinken server and finaly install the glances pack.

Install glances See the glances documentation to install glances on Linux.

<code bash> easy_install glances </code>

There is a debian startup script in the glances repository. And another one for centos here.

Install checkglances.py Just follow the documentation for the checkglances.py prerequisites and put it in your nagios plugins folder.

Install the glances pack Open a terminal as the shinken user and just type the following command

<code bash> shinken install glances </code>

Then just edit the configuration for a linux monitored host and tag it as **glances**

```
define host{
 name mylinuxhost
 use glances
 ...
```

Finaly restart the shinken arbiter

```
service shinken-arbiter restart
```

What will be monitored ? For the moment just the basic system (ram, cpu, load, memory, filesystem and network).

If you want to modify the default thresholds for just a host you can do it by overiding the thresholds macro in your host definition. If you want to do it for several hosts, declare a new template and just add the desired thresholds macro to be overide.

Here is a list of the macros

```
::
```

> _LOAD_WARN 2 _LOAD_CRIT 3 _CPU_WARN 80 _CPU_CRIT 90 _MEMORY_WARN 90 _MEMORY_CRIT 95 _FS /, /home _FS_WARN 90 _FS_CRIT 95 _IFACES eth0, eth1 _NET_WARN 7500000 _NET_CRIT 10000000

Note the _FS and _IFACES macros. They leverage the ability to duplicate service for a given list of things to be monitored. Here you see that / and /home partitions will be monitored. If you want to modify this then just add your own in a new template that will inherit the glances template.

Shinken GLPI integration Shinken supports importing hosts from GLPI

For people not familiar with GLPI, it is an Open-Source CMDB. Applicable to servers, routers, printers or anything you want for that matter. It is also a help-desk tool. GLPI also integrates with tools like FusionInventory for IT inventory management.

You can still have flat files AND GLPI if you want. Hosts imported from GLPI will be treated as standard hosts from flat file (inheritance, groups, etc). In fact, in this first version the module only sends the host_name to Shinken, but there should be more information extracted like network connexions for parents relations in the future. :)

Requirements

- python module MySQLdb
- Compatible version of GLPI Shinken module and GLPI version - ...
- etc..

Enabling GLPI Shinken module In your shinken-specific.cfg file, just add (or uncomment):

```
#You know GLPI? You can load all configuration from this app(
#with the webservices plugins for GLPI, in xmlrpc mode
#and with plugin monitoring for GLPI)
# =============== Work with Plugin Monitoring of GLPI ===============
#All configuration read from this will be added to the others of the
#standard flat file
define module{
     module_name      GLPI
     module_type      glpi
     uri              http://localhost/glpi/plugins/webservices/xmlrpc.php
     login_name       glpi
     login_password   glpi
}
```

And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master
#    host_name       node1       ;result of the hostname command under Unix
     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           GLPI
     }
```

It's done :)

Ip Tag module

Why tag a host based on it's IP address? We learned on the *DMZ monitoring* that you can "tag" a host with a poller_tag so it will be checked only by DMZ pollers. It can be tedious process to manually tag all these hosts. Shinken provides an automated method to do this.

This is handled by the arbiter ip_tag module.

Ip_tag module The ip_tag module is an arbiter module that looks up the host address during the configuration parsing and compares it to an predefined IP range (IPV4 or IPV6). If the range matches, it can apply or add a property, such as poller_tag. Other types of tags could be related to locations, functions, administrative groups, etc.

Method: replace or append.

replace will put the value if the property is unset. This is the default method. .. warning:: Fix me: replace, implies overriding an existing value. And will cause user issues down the line. Rename it to set. Replace should be a different method altogether, so overall there should be 3 methods(set, append, replace).

append will add with a , if a value already exist

Here is an example that will set the poller_tag property with the value DMZ of all hosts that:

- have a their hostadress ip (or name resolved) in the range 192.168.0.1/24.
- do not already have a poller_tag property set

```
define module{
```

```
     module_name     IpTag
     module_type     ip_tag
     ip_range        192.168.0.1/24
     property        poller_tag
     value           DMZ
}
```

To use the module add it in the arbiter object:

```
::
```

define arbiter { [...] modules NSCA,IpTag

}

Add value instead of setting it In the previous example we set the property poller_tag to a value. But what if we want to "add" a value, like a template name? We can change the "method" property of the module to "append" so we can add the "value" to the host property instead of replace it.

Here is an example where we want to add the "dmz" template on the hosts, while also keeping any defined templates:

```
define module{
```

```
     module_name   IpTag
     module_type   ip_tag
     ip_range      192.168.0.1/24
     property      use
     value         dmz

     # Optional method
     method append
}
```

For a host defined as:

```
define host{
```

```
     host_name   example_host1
     address     192.168.0.2
     use         linux
}
```

It will be "changed" internaly in:

```
define host{
```

```
     host_name   example_host1
     address     192.168.0.2
     use         linux,dmz
}
```

Name resolution Of course you don't need to set IP address in the address of your host. You can set a hostname, and it will be resolved, and then compared to the range. :)

Ubuntu Landscape import

Description You can import data from Ubuntu Landscape into Shinken to create hosts.

Ubuntu Landscape, is a web app to manage all your linux servers (update and co), which is provided by Canonical, Ubuntu's parent company.

This is an Arbiter import module. The Arbiter manages the configuration.

Prerequisites

You will need the landscape-api package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

define module { module_name Landscape module_type landscape_import

Configure your REAL key and secret from Landscape key PAAAB2CILT80I0ZA0999 secret GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH default_template generic-host ; if the host is not tagged, use this one

If you are using a specific certificate for landscape_api #ca /path/to.ca.cert

If you need a proxy to access https://landscape.canonical.com/api/ #https_proxy http://user:secret@myproxy.com:3128

}

- Put in key and secret your private Landscape access.
- default_template will be used if your host is not "tagged" in Landscape
- If you are using a specific certificate for connexion, give the full path in ca
- You will certainly need an https proxy to access the Landscape API. If so, configure it there.

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master
#    host_name       node1       ;result of the hostname command under Unix
     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           Landscape
     }
```

Restart your Arbiter and it's done :)

Tip: Your "tags" will be applied as templates for your hosts.

Shinken Livestatus API

Overview

- Jump back to Getting Started
- Jump back to *Livestatus module configuration*

What is it Livestatus API is the modern method of interacting with Shinken and Nagios based systems alike.

Originally developed for Nagios, MK Livetstatus, was re-implemented in Python for use with Shinken by professional developers. The access methods and query languages are the same.

Why use it It is fast.

It is network based using TCP.

It is standard for all Nagios and Shinken monitoring systems.

It uses in-memory structures for status data

It uses a back-end database for historical reporting

It uses an SQL based query language

It has a host of powerful nuts and bolts features (authentication, caching, connection persistence, multiple object methods (JSON, Python)).

What can I do with it? All programs and scripts use (or should use) this method to :

- Obtain the current state of hosts and services
- Obtain the current configuration related to hosts and services
- Send administrative commands (downtimes, comments, forcing checks)
- Filter information to display
- Obtain basic reports and event statistics

Shinken being a modern re-implementation of Nagios has additional features that are available in addition to the standard Livestatus API.

Shinken Livestatus API unique features can :

- Obtain Business Impact information
- Obtain intelligent dependency status hosts or services (combines dependency and parent information)
- Obtain Business Process states (same syntax as standard host and service queries)

How does it work Livestatus uses a powerful SQL-like query language. The standard methods and parameters are defined at :

'MK Livestatus reference methods and query language definition'_

Full list of Shinken Livestatus API methods:

'Shinken mapping.py methods'_

What software uses Livestatus to interact with Shinken

Well known Web frontends

- MK Multisite
- Thruk
- NagVis

- Splunk for Nagios

Mobile Web frontends

- get list

Scripts

- Downtime management scripts
- Debug scripts

Installing Livestatus Have you installed the required packages to use the Livestatus module? You can look at the requirement section of the *10 minute installation guide* for the *requirement lists*.

How to enable Livestatus Very simple, jump to the *Shinken Broker configuration* section to enable it. .. _Shinken mapping.py methods: https://github.com/shinken-monitoring/mod-livestatus/blob/master/module/mapping.py .. _MK Livestatus reference methods and query language definition: http://mathias-kettner.de/checkmk_livestatus.html

NSCA module The NSCA daemon module is used to receive send_nsca packets and submit them to the Shinken command pipe. The NSCA module can be loaded by the Receiver or Arbiter process. It will listen on port TCP/5667 for send_nsca packets.

Tip: Passive checks can be submitted *natively to the Shinken command pipe* or from remote hosts to modules, such as NSCA, AMQP or collectd, loaded in the Shinken Arbiter or Receiver process. AMQP is implemented for integration with the Canopsis Hypervisor, but could be re-used for generic messaging.

Note: The Shinken NSCA module implementation is currently limited to the "xor" obfuscation/encryption.

In your shinken-specific.cfg file, just add (or uncomment):

```
::
```

#You can send check result to Shinken using NSCA #using send_nsca command define module{

module_name NSCA module_type nsca_server host * port 5667 encryption_method 0 password helloworld

}

define receiver{

```
receiver_name    receiver-1
address          localhost
port             7773
modules          NSCA

timeout          3             ; 'ping' timeout
data_timeout     120           ; 'data send' timeout
max_check_attempts       3     ;  if at least max_check_attempts ping failed, the node is DEAD

#advanced
realm    All
}
```

This daemon is totally optional.

It's main goal is to get all passive "things" (checks but why not other commands) in distant realms. It will act as a "passive receive buffer" and will then dispatch the data or commands directly to the appropriate Scheduler or Arbiter process.

Data can be received from any Realm, thus the Realm option is nonsensical.

For now there is no init.d script to launch it. .. note:: Verify that the init script has been added.

It is launched like all other daemons:

```
bin/shinken-receiver -c etc/receiverd.ini
```

Tip: Alternatively, for small installations with you can configure a modules inside your Arbiter instead of the Receiver. It will listen the TCP/5667 port for send_nsca packets.

To configure the NSCA module in your Arbiter instead of Receiver. Add the NSCA module to your Arbiter object configuration.

```
::
```

define arbiter{ arbiter_name Arbiter-Master

 # host_name node1 ;result of the hostname command under Unix address localhost ;IP or DNS adress port 7770 spare 0 modules NSCA

}

Retention troubleshooting The retention file contains the state of your host and services, so that they are kept when shinken is restarted.

Sometimes you'll want to inspect (and possibly fix) the retention file, in case you need to work-around a bug or simply better understand what is stored there.

When you use the PickleRetention module in the scheduler (cf. ''define scheduler" in ''shinken-specific.cfg''), you can simply manipulate the retention file using Python.

For this you can use the following code.

- It assumes Shinken is installed in ''/opt/shinken" with the retention file in ''/tmp/retention.dat'':
- Run and play with it interactively using ''ipython -i inspect_retention.py''.

```
#!/usr/bin/python
import pickle
import sys
sys.path.append('/opt/shinken')
import shinken

r = pickle.load(file('/tmp/retention.dat'))
h = r['hosts']

# Example:
# [(k,v) for (k,v) in h['your_host'].items() if k.find('downtime') >= 0]
#
# del h['your_host']
#
# for k,v in r['services'].items():
#     if 'your_host' in k:
#         del r['services'][k]
```

To save your changes:

- Stop Shinken: ‘’service shinken stop’‘
- Save the pickle: ‘’pickle.dump(r, open(‘/tmp/retention.dat’, ‘w’))’‘
- Start Shinken: ‘’service shinken start’‘

NRPE Module

What is it The NRPE module allows Shinken Pollers to bypass the launch of the check_nrpe process. It reads the check command and opens the connection by itself. It scales the use of NRPE for active supervision of servers hosting NRPE agents.

The command definitions should be identical to the check_nrpe calls.

How to define it The definition is very easy (and you probably just have to uncomment it):

```
define module{
     module_name       NrpeBooster
     module_type       nrpe_poller
}
```

Then you add it to your poller object:

```
define poller {
    [...]
    modules   NrpeBooster
}
```

Then just tag all your check_nrpe commands with this module:

```
define command {
   command_name   check_nrpe
   command_line   $USER1$/check_nrpe -H $HOSTADRESS$ -c $ARG1$ -a $ARG2$
   module_type    nrpe_poller
}
```

That’s it. From now on all checks that use this command will use Shinken’s NRPE module and will be launched by it.

Extending Shinken

Introduction There are a lot of “Modules” and “Addons” that are available for Shinken. Shinken can be extended by using different types of methods.

- Web interfaces from various open-source vendors can be used (Based on Livestatus API)
- Shinken itself can be extended using modules that are embedded into the various daemon processes

** (Arbiter, Poller, Receiver, Broker, Scheduler, Reactionner) * External software can provide functional enhancements for reporting, management or usability aspects

Shinken itself provides methods to extend the base functionality:

- *Broker modules* provide external access to runtime data from Shinken
- Poller modules such as *NRPE* and the *SNMP*
- Receiver modules like *NSCA* provide acquisition methods for Shinken

- Arbiter modules permit manipulating the configuration
- The webUI that permits embedding web interface elements

Independent software that works in concert with Shinken is available for:

- Monitoring remote hosts through agent software (*NIX, Windows, etc.)
- Submitting passive checks from remote hosts
- Managing the config files through a web interface
- Mobile phone UIs
- Desktop UIs and Hypervisors
- Desktop notification addons
- ...and much more

You can find many addons that are compatible with Shinken by visiting. The only caveat is that the addons should not use the status.dat file and preferably the modern API interfaces like Livestatus:

- Nagios.org
- SourceForge.net
- NagiosExchange.org
- Shinken community exchange for monitoring packs

Broker modules The broker module receives messages from the Schedulers related to host, service check results. In addition to that it receives a copy of the compiled configuration at startup. What is special about the broker, is that without modules, the broker does nothing. It makes the configuration and result data available to modules. Modules are the ones in charge of doing something with the data. This could be exporting this "raw" data into flat files, databases or exposing it as an API.

The modules are presented according to their use cases.

- Core modules
- Livestatus Module for frontends
- Exporting data to metric databases
- SQL based Modules for frontends
- Exporting data to logging management systems
- Legacy modules for migration purposes
- Modules no longer supported

Core modules

simple_log: get all logs into one file You can get a log for all your daemons in a single file. With the exception of Debug level logs which are not sent through the network as a safe guard. Shinken state messages are ONLY logged at the debug level in the local log files. These are the ALL CAPS states that some 3rd party interfaces use to mine data from the historical logs. Actual state messages are sent as objects between the various daemons.

It takes the parameters:

- module_name: name of the module called by the brokers

- module_type: simple_log
- path: path of the log file

Here is an example:

```
define module{
```

```
     module_name      Simple-log
     module_type      simple_log
     path             /usr/local/shinken/var/nagios.log
     archive_path     /usr/local/shinken/var/archives/
}
```

Syslog - Send all logs to a local syslog server Send all logs to a local syslog server. Support for remote syslog can be implemented if requested. Just lookup the syslog module, easy to modify. Use for example with Splunk, graylog2, Logstash, Elastic search, Kibana, or other log management and analysis system.

```
define module{
```

```
  module_name Syslog
  module_type syslog
}
```

Lightweight forwarder to Splunk Shinken state data from the local syslog can also be sent to a Splunk server for indexing, reports, SLA and analysis. Via syslog or better yet, the Splunk lightweight forwarder which supports, TCP, buffering and security parameters.

Livestatus API Module - Thruk, Nagvis and Multisite Web frontends There are three well known frontends and various small tools that can interface with the Livestatus API. This API is currently the most efficient method of sharing live data with external interfaces. It provides a rich query language similar to SQL, authentication, command execution, caching,connections persistence, multiple object methods (JSON, Python). All Livestatus data is kept in memory, there is no disk IO involved. It exposes configuration objects, the current state of the hosts and services as well as historical Shinken state log messages.

- MK Multisite
- Thruk
- NagVis

Have you installed the required packages to use the Livestatus module? You can look at the requirement section of the 10 minute installation guide for the requirement lists.

Livestatus Module

It takes the following parameters:

- module_name: name of the module called by the brokers
- module_type: livestatus
- host: IP interface to listen to. The default is '127.0.0.1'. '*' means 'listen on all interfaces'.
- port: TCP port to listen to.
- socket: Unix socket to listen to.

- allowed_hosts: a comma-separated list of IP-addresses which are allowed to contact the TCP port. Please keep in mind that these must be ip-addresses, NOT host names. (DNS lookups for every incoming livestatus request could hang up and therefore block the module)
- modules: a comma-separated list of modules (see below)
- pnp_path: relevant if you use the multisite gui. pnp_path points to the perfdata directory where the pnp4nagios data reside (it's the directory which contains a subdirectory for each host). Multisite needs it to display a small perfdata icon if a rrd file exists.
- To deactivate an input, the port- and socket-attributes can also take the value "none".

The Livestatus module itself can have sub-modules. In fact, it **must** have at least one submodule responsible for storing log events to a database, SQLite or MongoDB.

Livestatus module - Logstore Sqlite Stores log-broks to an sqlite database.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_sqlite
- use_aggressive_sql: Prefer the use of sql queries to pre-filter data prior to python filtering. This is required for very large installations, as the Python structures are not indexed when filtering. Optional argument set to 0 by default. To enable set the value to 1. Some erroneous output may occur, but informal testing has shown these corner cases do not occur.
- read_only: don't send any update to the database. Should be used when you run several livestatus modules : 1 instance is R/W, other are read only.
- database_file: the path to the sqlite database file which is used to store the log broks/messages. The default is 'var/livestatus.db'
- archive_path: the path to a subdirectory where database file archives will be created. Every day the data from the last day will be moved to an archive datafile. The default is 'var/archives'.
- max_logs_age: the maximum age of the log messages (before they are deleted from the database). The default is 1 year. The argument to this parameter takes the form <number>[<period of time>], where <period of time> can be d for days, w for weeks, m for months and y for years. This parameter is currently ignored. In future releases it will be used to automatically delete ancient database files.

Here is an example:

```
define module{
```

```
     module_name      Livestatus
     module_type      livestatus
     host             *       ; * = listen on all configured ip addresses
     port             50000   ; port to listen
     socket           /usr/local/shinken/var/rw/live
     modules          logsqlite
}
define module{
```

```
     module_name      logsqlite
     module_type      logstore_sqlite
     use_aggressive_sql     0 ; optional, by default set to 0. Only for large installations.
     database_file    /usr/local/shinken/var/livelogs.db
     max_logs_age     3m ; three months. Other time intervals are d=days, w=weeks, y=years
}
```

Livestatus module - Logstore MongoDB Stores historical log broks(inter daemon Shinken messages) to a MongoDB database. MongoDB is a distributed and very performant database that permits resilience and high availability. The current implementation has a few known broken pieces (some search functions are broken) and there are bugs in the implementation, so it is considered experimental until power users and developers have ironed out the bugs. It is the database of the future for Shinken.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_mongodb
- mongodb_uri: The address of the master. (Default: i_cant_write_the_uri_here_it_messes_the_wiki_up)
- replica_set: If you are running a MongoDB cluster (called a "replica set" in MongoDB), you need to specify it's name here. With this option set, you can also write the mongodb_uri as a comma-separated list of host:port items. (But one is enough, it will be used as a "seed")
- database: <undocumented>
- collection: <undocumented>
- max_logs_age: <undocumented>

The configuration looks quite similar to the sqlite one. **In a single-node installation and with decent amount of log traffic, the sqlite backend should be considered best practice, as it needs no extra software and is stable and fast (when run in-memory).**

Livestatus module - Logstore Null In case you don't need any logging (for instance, if you dedicate a livestatus module instance to nagvis), you can use this module.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_null

Network Based Modules - Graphite graphing Graphite is a graphing and data analysis tool. It is composed of a web frontend (graphite-web), fixed size databases (whisper) and data redistribution/munging daemon. (carbon) The first step is *having Graphite installed somewhere*, if you do not have Graphite installed, please do this and come back later.

Pre-requisite : Shinken 1.2.2+ is recommended for the best experience with Graphite.

graphite_perfdata: exports check result performance data to Graphite Export all performance data included in check results to Whisper databases managed by Graphite. Data is buffered, then exported once every broker time tick. (Once per second). Should a communication loss occur, it will buffer data for 5 minutes before dropping data. The tick_limit max is configurable, the only limitation is the amount of memory the buffered data can eat.

The graphite broker module (v1.2) sends data to graphite in the following format :

HOSTNAME.SERVICENAME.METRICNAME

It can be optionally enhanced to send it the following format :

_GRAPHITE_PRE.HOSTNAME.SOURCE.SERVICENAME.METRICNAME._GRAPHITE_POST

Each of the three variables are optional :

- The _GRAPHITE_PRE variable can be set per host/service to provide a more flexible naming convention. (ex. Prod.site1.Hostname.servicename)

- The _GRAPHITE_POST variable can be set per host/service to specify the more information concerning the variable being stored that graphite can use to determine the retention rule to use for the variable.
- The SOURCE variable can be set in shinken-specific.cfg for the WebUI module and the Graphite broker.

Metric names are converted from Shinken's format to a more restrictive Graphite naming. Unsupported characters are converted to "_" underscore. So do not be surprised to see that some names differ in the WebUI or directly in Graphite. Permitted characters in Graphite are "**A-Za-z_**.", the hyphen character is permitted from Shinken, though only future versions of Graphite will support it.

Performance data transfer method can be set to pickle, which is a binary format that can send data more efficiently than raw ascii.

It takes the following parameters:

- module_name: name of the module called by the brokers
- module_type: graphite_perfdata
- host: ip address of the graphite server running a carbon instance
- port: port where carbon listens for metrics (default: 2003 for raw socket, 2004 for pickle encoded data)
- use_pickle: Use a more efficient transport for sending check results to graphite instead of raw data on the socket (v1.2)
- tick_limit: Number of ticks to buffer performance data during a communication outage with Graphite. On tick limit exceeded, flush to /dev/null and start buffering again. (v1.2)
- graphite_data_source: Set the source name for all data coming from shinken sent to Graphite. This helps diferentiate between data from other sources for the same hostnames. (ex. Diamond, statsd, ganglia, shinken) (v1.2)

Here is an example:

```
define module {
```

```
module_name Graphite-Perfdata
host xx.xx.xx.xx
module_type graphite_perfdata
port 2004 ; default port 2003 for raw data on the socket, 2004 for pickled data
use_pickle 1 ; default value is 0, 1 for pickled data
tick_limit 300 ; Default value 300
graphite_data_source shinken ; default is that the variable is unset
}
```

SQL Based Modules - PNP4Nagios Graphing PNP4Nagios is a graphing tool that has a web interface for RRDTool based databases. Shinken can export performance data to an npcd database which will feed the RRD files (fixed sized round robin databases). You can *learn how to install PNP4Nagios* if you haven't done it already.

npcdmod: export perfdatas to a PNP interface Export all perfdata for PNP.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: npcdmod
- path: path to the npcd config file

Here is an example:

```
define module{
 module_name  NPCD
 module_type  npcdmod
 config_file  /usr/local/pnp4nagios/etc/npcd.cfg
}
```

SQL Based Modules - Frontend Centreon2 Centreon2 use a NDO database, so you will need the ndodb_mysql module for it.

ndodb_mysql: Export to a NDO Mysql database Export status into a NDO/Mysql database. It needs the python module MySQLdb (apt-get install python-mysqldb or easy_install MySQL-python).

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: ndodb_mysql
- database: database name (ex ndo)
- user: database user
- password: database user passworddt
- host: database host
- character_set: utf8 is a good one

Here is an example:

```
define module{
```

```
     module_name      ToNdodb_Mysql
     module_type      ndodb_mysql
     database         ndo       ; database name
     user             root      ; user of the database
     password         root      ; must be changed
     host             localhost ; host to connect to
     character_set    utf8      ;optionnal, UTF8 is the default
}
```

File based Legacy modules - perfdata export

service_perfdata: export service perfdatas to a flat file

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: service_perfdata
- path: path to the service perfdata file you want

Here is an example:

```
define module{
```

```
    module_name      Service-Perfdata
    module_type      service_perfdata
    path             /usr/local/shinken/src/var/service-perfdata
}
```

host_perfdata: export host perfdatas to a flat file

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: host_perfdata
- path: path to the host perfdata file you want

Here is an example:

```
define module{
```

```
    module_name      Host-Perfdata
    module_type      host_perfdata
    path             /usr/local/shinken/src/var/host-perfdata
}
```

Legacy File based Modules - Old CGI or VShell The Old CGI and VShell use the flat file export. If you can, avoid it! It has awful performance, all modern UIs no longer use this.

status_dat: export status into a flat file Export all status into a flat file in the old Nagios format. It's for small/medium environment because it's very slow to parse. It can be used by the Nagios CGI. It also export the objects.cache file for this interface.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: status_dat
- status_file: path of the status.dat file /usr/local/shinken/var/status.dat
- object_cache_file: path of the objects.cache file
- status_update_interval: interval in seconds to generate the status.dat file

Here is an example:

```
define module{
```

```
    module_name              Status-Dat
    module_type              status_dat
    status_file              /usr/local/shinken/var/status.data
    object_cache_file        /usr/local/shinken/var/objects.cache
    status_update_interval   15 ; update status.dat every 15s
}
```

Deprecated or unsupported modules

SQL Based MerlinDB This interface is no longer supported and is going to be completely removed from Shinken.

SQL based ndodb_oracle - Icinga web frontend using NDO Oracle This interface is no longer supported and is going to be completely removed from Shinken.

CouchDB: Export to a Couchdb database This interface is no longer supported and is going to be completely removed from Shinken.

TSCA (Thrift Service Check Acceptor) TSCA is a receiver/arbiter module to receive hosts and services check results. It provides the same functions as NSCA with additional features. High performance binary transmission, multi line output and auto generated clients for a variety of languages.

What is thrift ? Let's cut and paste the wikipedia definition from'en.wikipedia.org/wiki/Apache_Thrift'_ :

"Thrift is an interface definition language that is used to define and create services for numerous languages.[1] It is used as a remote procedure call (RPC) framework [..]. It combines a software stack with a code generation engine to build services that work efficiently to a varying degree and seamlessly between ActionScript, C#, C++ (on POSIX-compliant systems), Cappuccino, Cocoa, Erlang, Haskell, Java, OCaml, Perl, PHP, Python, Ruby, and Smalltalk."

Installation In any case, you have to install thrift with support for python (on the server side) and languages you want to use for clients.

Get it from thrift.apache.org or in your favorite distribution repository.

Server side Go to the tsca module directory and generate the python stub for the server side installation

```
cd shinken/modules/tsca
$ thrift --gen py tsca.thrift
```

Declare the module is shinken-specific.org

```
define module{
      module_name     TSCA
      module_type     tsca_server
      host            0.0.0.0
      port            9090
}
```

Samples clients There are three(3) client samples written in python, ruby and java in contrib/clients/TSCA of the Shinken distribution. You can use and extend them to send data directly in your code directly to Shinken's TSCA receiver/arbiter module.

The samples clients read a CSV file from stdin and send them the the TSCA running on localhost:9090. The CSV has the following format :

```
hostname,service description,output,rc
```

Any use of TCP in an application should take care not to block the program and to have very short timeouts. For applications that need non blocking functions, prefer a UDP based transport or a local buffer file with a separate application(send_nsca, thrift, etc) to forward your data to Shinken.

Ruby Generate the stub

```
$ thrift --gen rb ../../../shinken/modules/tsca/tsca.thrift
```

Run the client

```
$ cat file_state | ruby RubyClient.rb
```

Python Generate the stub

```
$ thrift --gen py ../../../shinken/modules/tsca/tsca.thrift
```

Run the client

```
$ cat file_state | python PythonClient.py
```

java Generate the stub

```
$ thrift --gen java ../../../shinken/modules/tsca/tsca.thrift
```

Compile the client

```
$ ant
```

Run the client

```
$ cat file_state | java JavaClientThrift
```

VMWare Arbiter module

How it works The arbiter has a module that allows the host->VM automatic host dependency creation. In fact, the module is far more generic than just this. It's a generic "host link dependencies" module.

It reads a mapping file (simple json format) with son->father links. It call an external script at a regular interval : the one I wrote is a VMWare mapping one. It used the check_esx3.pl (that all ESX admin should have) plugin and generate the mapping file. When this file is changed, the module reloads it, creates new links and deletes old ones. So when you VMotion a virtual machine, in the next pass, there will be creation of a new link and deletion of the old one in the scheduler that manages it :)

How to define it The definition is very easy :

```
define module{
     module_name       VMWare_auto_linking
     module_type       hot_dependencies
     mapping_file      /tmp/vmware_mapping_file.json
     mapping_command   /usr/local/shinken/libexec/link_vmware_host_vm.py -x '/usr/local/shinken/libex
     mapping_command_interval 60   ; optionnal
     mapping_command_timeout   300 ; optionnal
}
```

Then you add it in you arbiter object :

```
define arbiter {
    [...]
    modules   VMWare_auto_linking
}
```

So here, it will call the script /usr/local/shinken/libexec/link_vmware_host_vm.py with a listing of the vCenter vcenter.mydomain.com and generate the mapping file /tmp/vmware_mapping_file.json.

You can call : /usr/local/shinken/libexec/link_vmware_host_vm.py –help

for the full help on this script.

It looks at the file modification time each second. This command can also be launch by an external cron of course.

Note: So if you want to write a script that does this for XEN servers, all you need is to generate a json file with all the mapping. I didn't wrote the doc about this, but you can look in the test file for it, the format is very very easy :)

Here is an example of the JSON mapping file syntax:

%%:ref:*["host", "physical_host"], ["host", "virtual_machine"* <["host", "physical_host"], ["host", "virtual_machine">, "host", "physical_host"], ["host", "other_virtual_machine" <"host", "physical_host"], ["host", "other_virtual_machine">]%%

So just a list of couple 'host' string (from now only host are managed) and the host name.

Beware about it : you need the real host_name, including case.

Web Service Module The Ws_arbiter module is a Receiver or Arbiter module to receive passive check results from remote hosts via HTTP(s). This module is considered a work in progress but can be used for testing and improvement.

Configuring the Web Service Module If data is POSTed to this page, it will validate the data to determine if it is a service or host check result and submit the data to the Shinken external command queue.

The web service listens by default to TCP port 7760. The web service supports anonymous or authenticated access. Web service parameters are set in the Shinken-specific.cfg file, in the Ws_arbiter module. To enable the web service, simply add the module to your Arbiter or Receiver daemon configuration in Shinken-specific.cfg

Using the Web Service Module The web service listens for POSTs to: /push_check_result

Use curl or embed the HTTP calls in your software to submit check results.

curl -u user:password -d "time_stamp=$(date +%s)&host_name=host-checked&service_description=service-checked&return_code=0&output=Everything OK" http://shinken-srv:7760/push_check_result

Example with more readability:

```
curl
```

-u user:password -d "time_stamp=$(date +%s)

```
&host_name=host-checked
&service_description=service-checked
&return_code=0
&output=Everything OK
http://shinken-srv:7760/push_check_result
```

SNMP module This part must be splitted and sent in all module repositories

Shinken integrated SNMP Module

SnmpBooster Download Install and Configure

- *What is the SnmpBooster module*
- Install and configure the SNMP acquisition module. [You are here]
- *Reference - SnmpBooster troubleshooting*
- *Reference - SnmpBooster design specification*
- *Reference - SnmpBooster configuration dictionnary*

Downloads

The SnmpBooster module and genDevConfig are currently in public beta prior to integration within Shinken. You can consult t

- github.com/xkilian/genDevConfig
- github.com/titilambert/shinken/tree/snmp_booster/shinken/modules (snmp_booster branch) * Simply right-click and download snmp_poller.py then copy it to shinken/modules/

Requirements The SnmpBooster module requires:

- Python 2.6+
- Shinken 1.2+
- PySNMP 4.2.1+ (Python module and its dependencies)
- ConfigObj (Python module)
- python-memcached
- memcachedb or memcached package for your operating system (ex. For Ubuntu: apt-get install memcachedb) *Note*

The genDevConfig profile generator depends on:

- Perl 5.004+
- 4 perl modules available from CPAN and network repositories. genDevConfig/INSTALL has the installation details.

STRONGLY RECOMMENDED: Use the same version of Python and Pyro on all hosts running Shinken processes.

Installation SnmpBooster:

- Install the dependencies
- Copy the file snmp_poller.py from the git repository to your shinken/modules directory.
- Configuration steps are listed in the present web page.

genDevConfig:

- Download and extract the archive to your server.
- See genDevConfig/INSTALL on how to install and configure it.

Configuration

How to define the SnmpBooster module in the Shinken daemons You need to modify shinken-specific.cfg, which is located in $shinken/etc/shinken-specific.cfg

Arbiter daemon configuration Simply declare the module:

```
modules SnmpBooster</code>
```

Scheduler daemon configuration

Simply declare the module:

<code>modules SnmpBooster

Poller daemon configuration Simply declare the module:

```
modules SnmpBooster</code>
```

SnmpBooster Module declaration

Included in Shinken v1.2.1 shinken-specific.cfg.

<code>define module {

```
module_name          SnmpBooster
module_type          snmp_poller
datasource           /usr/local/shinken/etc/packs/network/SnmpBooster/   ; SET THE DIRECTORY FOR YOUR
memcached_host       x.x.x.x  ; SET THE IP ADDRESS OF YOUR memcached SERVER
memcached_port       11211  ; default port for a memcached process
```

}

If you do not know the IP adress on which your memcache is listening, check under /etc/memcached.conf. Or do a:

```
netstat -a | grep memcached</code>
If you are running a test on the local machine you can leave memcached on 127.0.0.1 (localhost), but
```

How to define a Host and Service

Step 1

Create a template for your SNMP enabled devices.

Sample template:

<code>cd shinken/etc/packs/network/ mkdir SnmpBooster

vi shinken/etc/packs/network/SnmpBooster/templates.cfg

```
define command {
```

```
command_name    check_snmp_booster
command_line    check_snmp_booster -H $HOSTNAME$ -C $SNMPCOMMUNITYREAD$ -V 2c -t $ARG1$ -i $_SERVICE
module_type     snmp_poller
```

}

```
define service {
```

```
name                    default-snmp-template
check_command           check_snmp_booster!$_SERVICEDSTEMPLATE$!$_SERVICEINST$!$_SERVICETRIGGERGROUP
_inst                   None
_triggergroup           None
max_check_attempts      3
check_interval          1
retry_interval          1
register                0
```

}

```
define host{
```

```
name                    SnmpBooster-host
alias                   SnmpBooster-host template
check_command           check_host_alive
max_check_attempts      3
check_interval          1
retry_interval          1
use                     generic-host
register                0
```

}

Step 2 Define some hosts and services. You would typically use genDevConfig or another configuration generator to create these for you.

Mandatory service arguments related to SNMP polling:

```
_dstemplate                Cisco-Generic-Router  ; Name of a DSTEMPLATE defined in the SnmpBooster co
```

```
snmpcommunityread    which is set in your resource.cfg file
```

Optional service arguments related to SNMP polling with default values:

```
_inst                   None   ; Could be numeric: 0, None or an instance mapping function like: map
```

```
_triggergroup           None   ; Name of the triggergroup defined in the SnmpBooster config.ini file
```

Sample Shinken host and service configuration:

```
# Generated by genDevConfig 3.0.0
# Args: --showunused -c publicstring 192.168.2.63
# Date: Thu Aug 30 17:47:59 2012

#######################################################################
# Description: Cisco IOS Software, C2960 Software (C2960-LANBASEK9-M), Version 12.2(50)SE4, RELEASE S
#     Contact:
# System Name: SITE1-ASW-Lab04
#    Location:
#######################################################################

define host {
```

```
 host_name            192.168.2.63
 display_name         192.168.2.63
 _sys_location
 address              192.168.2.63
 hostgroups
 notes
 parents
 use                  default-snmp-host-template
 register             1
}

define service {
```

```
 host_name            192.168.2.63
 service_description  chassis
 display_name         C2960 class chassis
 _dstemplate          Cisco-Generic-Router
 _inst                0
 use                  default-snmp-template
 register             1
}

define service {
```

```
 host_name            192.168.2.63
 service_description  chassis.device-traffic
 display_name         Switch fabric statistics - Packets per Second
 _dstemplate          Device-Traffic
 use                  default-snmp-template
 register             1
}

define service {
```

```
host_name            192.168.2.63
service_description  if.FastEthernet0_1
display_name         FastEthernet0_1 Description: Link to Router-1 100.0 MBits/s ethernetCsmacd
_dstemplate          standard-interface
_inst                map(interface-name,FastEthernet0_1)
use                  default-snmp-template
register             1
```

}

Here is an example configuration of the config.ini file

```
[DATASOURCE]
```

```
  OidmyOidDefinition = .1.3.6.1.45.0
  [myOidDefinition] ; Use the same name as the myOidDeiniftion, but omit the leading "Oid"
      ds_type = DERIVE
      ds_calc = 8,*  ; RPN expression : Oid, 8, *  Which means Oid * 8 = ds_calc
      ds_oid = $OidmyOidDefinition
[DSTEMPLATE]
```

```
  [myCiscoRouter]
      ds = myOidDefinition
[TRIGGER]
```

```
  [trigger1]
      warning = RPN expression
      critical = RPN expression
  [trigger2]
      warning = RPN expression
      critical = RPN expression
[TRIGGERGROUP]
```

```
[CiscoRouterTriggers]
    triggers = trigger1, trigger2
```

Shinken integrated SNMP Module

Overview

What is it The SnmpBooster module allows Shinken Pollers to directly manage SNMP data acquisition. This is an all Python cross-platform SNMP module. It is tightly integrated with the Shinken Poller, Scheduler and Arbiter daemons to provide the best possible user experience.

- Jump back to *SnmpBooster documentation index*

Design specification summary

- STATUS - DESIGN SPEC PERFORMANCE
- [Done] Functions as an integrated Shinken Poller module
- [Done] Necessary integration code commited to Shinken official release (Integrated starting at v1.2)
- [Done] Ability to collect thousands of SNMP metrics per second
- [Done] Be compatible with distributed data acquisition
- [Done] Collect data for a host/check_interval tuple via SNMP in a single pass
- [Done] Use all builtin Shinken scheduler logic for retries, forced checks, timeouts, dependencies, parents
- [Done] Store collected data for the duration of the check_interval in a memcached/membase
- [Done] On a restart, after the first collection, be able to pick up where the last check left and calculate derived values
- [Done] Forced check are not allowed within 30 seconds of last SNMP query to the same host/check_interval, all other requests get data from the cache.
- [Done] Only a single request to the host/check_interval via SNMP is allowed at a time, all other requests get data from the cache.
- STATUS - DESIGN SPEC USABILITY
- [Done] Usage documentation
- [xxxx] SkonfUI and Discovery usage documentation
- [xxxx] Provide sample configuration packs in Shinken
- [Done] Provide sample config.ini with examples of all types of data * SNMP OIDS, DATASOURCES, DSTEMPLATES, TRIGGERS and TRIGGERGROUPS

- [Done] Directly compatible for use with genDevConfig Shinken SNMP configuration generator
- [Done] Provide meaningful feedback for users on errors
- [Done] Capture all tracebacks and convert them to actual error or warning messages
- STATUS - DESIGN SPEC FEATURES
- [Done] Return state and performance metrics
- [Done] Performance metrics can be returned in a Weathermap compatible format
- [Done] Configuration file format is ConfigObj INI
- [Done] Load all valid INI configuration files from a directory and merge them

SnmpBooster reference dictionary

- Jump back to *SnmpBooster documentation index*

SnmpBooster.ini dictionary

There are five dictionaries:

- [DATASOURCE]
- [DSTEMPLATE]
- [MAP]
- [TRIGGER]

- [TRIGGERGROUP]

DATASOURCE DICTIONARY OidVariableName refers to an actual OID that can be queries using SNMP against the device on the network.

[VariableName] refers to a Datasource and all the information required to gather and prepare the data using SNMP ds_type refers to how the data should be prepared ds_calc refers to any scaling manipulations to make the data more understandable. This is an RPN expression, where the first variable is omitted, as it is always the $OidVariable ds_oid refers to the actual $OidVariable name. An instance identifier can be appended to the name to signify that an instance is provided by the Shinken service definition. This information is passed when the check is called. ...

DSTEMPLATE DICTIONNARY [DsTemplateName] refers to the name of the DSTEMPLATE that will be referred to in the Shinken service definitions. ds refers to the list of DATASOURCES to be collected. If an instance is expected for the list of DATASOURCES, it MUST be the same instance for all Oids. If a different instance is required, use a second DSTEMPLATE.

TRIGGER DICTIONNARY

TRIGGERGROUP DICTIONNARY

MAP DICTIONNARY

SnmpBooster.ini example configuration This example definition will be used to explain each section.

[DATASOURCE]

```
OidmyOidDefinition = .1.3.6.1.45.0
[myOidDefinition] ; Use the same name as the myOidDeiniftion, but omit the leading "Oid"
    ds_type = DERIVE
    ds_calc = 8,*  ; RPN expression : Oid, 8, *  Which means Oid * 8 = Total
    ds_oid = $OidmyOidDefinition
```

[DSTEMPLATE]

```
[myCiscoRouter]
    ds = myOidDefinition
```

[TRIGGER]

```
[trigger1]
    warning = RPN expression
    critical = RPN expression
[trigger2]
    warning = RPN expression
    critical = RPN expression
```

[TRIGGERGROUP]

```
[CiscoRouterTriggers]
    triggers = trigger1, trigger2
```

SnmpBooster.ini configuring SNMP Datasources

The first location is generic data related to SNMP parameters.

- DATASOURCE information * SNMP OID * Type of data and how can it be interpreted (GAUGE, COUNTER, COUNTER64, DERIVE, DERIVE64, TEXT, TIMETICK) * Data format preparation (Scaling the data for example bits to bytes) * Is there an instance to append to the
- Instance MAP function * Mapping the instance dynamically using a function * Data or rules related to the mapping function

SnmpBooster.ini configuring SNMP DSTEMPLATES

- DSTEMPLATEs to associate DATASOURCE to actual device classes * List of DATASOURCES associated with a, for example, Cisco 1900 router. Which in turn can be applied to a Shinken service

SnmpBooster.ini setting triggers/thresholds

- TRIGGER and TRIGGERGROUPS to apply thresholding rules * Define triggers and associate them with a TRIGGERGROUP name that can be applied to a Shinken Service

Shinken integrated SNMP Module

Overview

- Jump back to *SnmpBooster documentation index*

Tip: The module is now in public beta as of 2012-10-26! Have Fun!

Nothing new to add, more to come in 2013. 2013-01-19.

What is it The SnmpBooster module allows Shinken Pollers to directly manage SNMP data acquisition. This is an all Python cross-platform SNMP module. It is tightly integrated with the Shinken Poller, Scheduler and Arbiter daemons to provide the best possible user experience.

Why use it The SnmpBooster module is designed to be very efficient and scalable. It has a very flexible configuration method to make it easy to use with Shinken Monitoring Packs and Shinken discovery runners like genDevConfig.

This acquisition module was professionally designed and developed.

It is meant to be used by the very capable discovery engine genDevConfig (**v3.0.5 and newer**) originally developed for the Cricket SNMP monitoring tool and converted for use with Shinken.

It is one of the very few serious SNMP v2c implementation making use of SnmpGetBulk type requests.

How does it work

Shinken Integration

1. The SnmpBooster Arbiter module reads the Shinken SnmpBooster configuration file(s). It reads the check commands and based on the values in the check commands that use the snmp_poller module it will creates a shared configuration cache using memcached/memcachedb. The memcache key is always the combination of the hostname. This permits to tie together Shinken Hosts and Services with the SNMP specific configuration. (MongoDB and Redis are planned to be supported in the future) The Scheduler daemon schedules Host and Service checks as it normally does.

3. The SnmpBooster module will check that a memcache host key exists for the check to be launched. Then the SnmpBooster poller module will query all services related to a host for a given acquisition frequency in one pass. (all checks done every 2 minutes will be executed in bulk, same for those every 5 minutes)

5. Check results are cached for the acquisition check_interval. The next time a check request for data from the same host is received from the Scheduler, the data will be fetched from memcache. Resulting is extremely low check latency.

2. 6. The SNMP checks still benefit from retries, timeouts, forced checks, dependencies and the powerful Scheduler daemon logic.

6. The Scheduler daemon can still force an immediate re-check by flushing the cache. This is required for the dependency model.

Performance SnmpBooster uses SNMP v2c getbulk for high efficiency, unless forced to use SNMP v2c get-next or SNMPv1 get-next. GetBulk uses a single request PDU to ask for multiple OIDs or even entire tables, instead of sending one request PDU per OID.

For example: *A typical 24 port network switch with two uplinks might use 375 OIDS (8 OIDs per interface, plus general OIDs for chassis health, memory, cpu, fans, etc.). **SnmpBooster will only require around 4 request PDUs*

*instead of 375 request PDUs**. Each PDU is a request packet which takes time to create, send get processed and return. More timeouts to manage, more connections, more impact on the remote device and more latency means much fewer checks per second.*

The SnmpBooster module supports automatic instance mapping for OIDs. (Ex. Based on the interface name it will figure out that the SNMP index(or instance) is 136. This is automatically handled by genDevConfig and SnmpBooster, no user input required. :-)

The generic SNMP configuration information is stored in the Shinken SnmpBooster INI files. There is a Defaults_unified.ini and a series of other Defaults files, one per discovery plugin for genDevConfig.

Important: genDevConfig plugins have all been converted to use the new dynamic instance mapping methods. You are now free to use most if not all Defaults*.ini files included with genDevConfig. 2012-10-28

Limitations You should have memcached instances running on each poller responsible for snmp polling. You should have your pollers with SnmpBooster in the same datacenter, as they need to be on the same machine with good connectivity to the active memcached instance. SnmpBooster is not compatible with distributed pollers in multiple datacenters, sorry, the current design of SnmpBooster uses a single centralized memcached instance for storing the timeseries data. For distributed datacenters to be supported, each poller+scheduler+memcached must be realm restrained, which is not the case today.

Design specification *SnmpBooster design specification* and current development status.

Data model The information required to define the data is split in two locations.

The first location is the host and service Shinken configuration (You need to generate or write this)

- Device specific information
  - IP addresses, host_names, device types, instance keys
  - A DSTEMPLATE must be referred to in the Service definition
  - A static SNMP instance could be referred to in the Service definition
  - An SNMP instance MAP function could be referred to in the Service definition
  - A TRIGGERGROUP could be refered to in the Service definition

The second location is SNMP Defaults.* templates. (Here you can create new devices or add new data sources)

- DATASOURCE information
  - SNMP OID
  - Type of data and how can it be interpreted (GAUGE, COUNTER, COUNTER64, DERIVE, DERIVE64, TEXT, TIMETICK)
  - Data format preparation (Scaling the data for example bits to bytes)
  - Is there an instance to append to the
- Instance MAP function * Mapping the instance dynamically using a function * Data or rules related to the mapping function
- DSTEMPLATEs to associate DATASOURCE to actual device classes * List of DATASOURCES associated with a, for example, Cisco 1900 router. Which in turn can be applied to a Shinken service
- TRIGGER and TRIGGERGROUPS to apply thresholding rules * Define triggers and associate them with a TRIGGERGROUP name that can be applied to a Shinken Service

A final location containes rules to build your Shinken configuration.

- genDevConfig plugins create Shinken configurations

Installation and configuration *SnmpBooster installation*

Reference Dictionnary *SnmpBooster reference dictionary*

Troubleshooting *SnmpBooster troubleshooting*

Graph templates These are .graph files defined in your Shinken configuration directory. Refer to the Shinken graphite templates(Not yet created) or PNP4Nagios how-to documentation. The graph templates are independent from SnmpBooster and provide templates for any collected data from Shinken.

SnmpBooster Troubleshooting

- Jump back to *SnmpBooster documentation index*

Check your config

- Have you defined the poller module name?
- Have you defined the correct path to the directory containing your Defaults*.ini files?
- Have you addded the Snmpbooster module to your arbiter, poller, scheduler?
- Have you added copied the genDevConfig templates.cfg in shinken/packs/network/SnmpBooster/
- Have you installed PySNMP, memcached and other dependencies?

Software version consistency Shinken and SnmpBooster now require **the same Python and Pyro version on all hosts running a Shinken daemon**.

If you cannot use the packaged version of Python and its modules (Pyro, memcached, etc.). Use virtualenv to declare a python version to use and install all required modules in that virtualenv.

Software version requirements Have you verified that the *requirements* are met. Python, PySNMP, Shinken, Pyro, memcached, etc.

Validate your check command arguments Use the check_plugin command and comment out the module to learn what were the exact arguments sent by the poller. This will permit you to validate all the arguments, like snmp community string, inheritance, template application, etc.

Validate connectivity

Take a packet trace using a tool like Wireshark to validate that the remote host is responding.

- Has the host responded
- **Is SnmpBooster repeating the request more often than the polling interval.**
  - If you are seeing repeated requests your device may have a compatibility issues.

- Save an snmpwalk of the device, get a packet trace using Wireshark, set the poller to debug and save the poller.log file (shinken/var/poller.log). Send all three to the SnmpBooster developers.
- Note: It is normal to see one or more bulkGet requests if you are getting large amounts of data. Ex. a 24 port switch will take 2-3 request packets.

Performance Make sure you have a low latency connection to your memcache from the Poller. Your memcache server can be replicated to all your poller hosts that should also run memcache instances. Check that memcached is running: netstat -a | grep memcached

Faulty Template A bad snmp_template file was distributed in the genDevConfig sample-config directory, there were two glaring errors.

This was fixed on 2012-10-16. Make sure you update your template, or use the data from the wiki.

Note that the template should be called: SnmpBooster-template.cfg to make it easier to troubleshoot in the logs. So when you search for SnmpBooster in your logs it will show up as well.

Log files All warnings and errors generated by the SnmpBooster module start with "[SnmpBooster] error text" and are logged using the standard Shinken logger.

The Arbiter daemon can output initial configuration, loading of host keys and intervals in memcached type error messages. The Scheduler daemon can output scheduling and alert related messages. The Poller daemon can output messages related to instance mapping, acquisition timeouts, invalid community strings, cache failures and more. These are available in the Web interface, as they are placed in the check results for the service.

You can simply do a "grep SnmpBooster *" in your shinken/var directory to see the latest messages related to the SnmpBooster module. You can also sort messages by timestamp to make it easy to find where and when errors occurred.

cd shinken/var grep SnmpBooster *

memcache persistence If you restart your memcache server or memcache crashes, your poller will no longer be able to validate that a host exists in memcache prior to writing.

You should use memcachedb to achieve persistence in case of memcache failures.

Common errors returned by SnmpBooster in the log file Errors should be fairly explicit and mean what they say, though there can be exceptions. Lets try to clear some of them.

__Arbiter log **errors__**

Missing ds_oid : This means that a variable in your OID definitions is missing, or your DATASOURCE is not named correctly or your ds_oid variable is missing. There is a typo in your ds_oid variable (ex. ds-oid, or ds_oid = $OidNameIncorrectFFFRA.%(instance)s).

Datasource not defined : Your DSTEMPLATE uses a DATASOURCE that doesn't exist check the [DataSourceName] you are referring to. Does it contain the expected OID variable, $OidName.

Missing ds_type : The DATASOURCE always needs to have a ds_type definition, GAUGE, COUNTER, DERIVE, TEXT, TIMETICK, DERIVE64, COUNTER64.

__Poller log **errors__**

Problems with calculations, repeated polling, hosts not responding, etc.

__Memcached **errors__**

memcachedb and memcached do not use the same default port. Configure the correct memcachedb port to match what is declared in your SnmpBooster module under shinken-specific.cfg.

On Ubuntu 12.04 the default installation is on port 21201 instead of 11211. This causes the error "[SnmpBooster] Memcache server (127.0.0.1:11211) is not reachable" when Shinken starts.

To change it, you must edit the file /etc/memcachedb.conf

Memcached Notes On Ubuntu 12.04 the default instalation is on port 21201 instead of 11211. This causes the error "[SnmpBooster] Memcache server (127.0.0.1:11211) is not reachable" when shinken starts.

To change it, you must edit the file /etc/memcachedb.conf

WebUI module This part must be splitted and sent in all module repositories

WebUI integration with Shinken The WebUI is an external broker module. So it's an external process launched by the broker that "eats" broks (broker messages) from the brokers. So it can get *all* broks if you place this broker in your top level realm.

The WebUI does not use a database to get data. Instead, it use a "regenerator" object that will eat each broks, and will "recreate" all Hosts/Services/Contacts objects as if the code was in the scheduler daemon. So basically, WebUI and pages always reflect the CURRENT state of hosts/services objects.

The WebUI http layer is managed by bottle.py. It's a small but powerful framework.

How does the WebUI function globally ?

There a 2 Threads running:

- the main thread is the bottle.py (http) listener. It will use the best backend it finds. We recommend using python-paste. If it does not find one, it will use the default swsgi. Paste is multi-thread, swsgi is mon-thread, so please use paste if you want to avoid locking problems.
- the 2nd thread is the regenerator one. It only gets broks and gives them to the regenerator object.

There is a lock system between the threads. You can have N Http requests in progress without problem, but during this time the renererator one will wait. During execution of the regenerator, no requests are processed. This is not considered a problem, as the regenerator is very quick, and there is only a 1s lock for a 7k service conf loading, so it's not a huge problem.

What is a WebUI User? A WebUI user is a contact. A true contact object. You must match a contact name for your user.

To create a new page? All pages are in the shinken/webui/plugins directory. Each "part" has it's own directory. A part (like the eltdetail, element detail) can have more than one "page" (like /host or /service for eltdetail).

From here we will supose you want to create a "/contact" page.

You can copy the dummy example in the plugins directory into a contact directory.

You need to change the contact/dummy.py file into a contact/contact.py file, because the webui will search for a dir/dir.py file to "load".

Templates Templates are HTML with some Python code in it in the plugins/*/views direcotry for specific templates, and the "global layout" (menu and all common part) in the webui/views directory.

Your template must call the template layout (layout.tpl in the webui/views directory) wit ha "rebase" call.

If you put the rebase call at the beginning of your template, all there is below will be place "inside" the layout that will call the common javascripts and css, make the menu adn then call your html/python code.

The rebase call can take arguments. You MUST give it:

- user: the user you give it in the return dict of your .py code

Then all is optional:

- title: title of the page
- top_right_banner_state: int, global state with clouds to put in your top right page. Look at the problem.tpl code for an example.
- js and css list: list of YOUR specific javascript or css to call AFTER the common ones.
- refresh: boolean, set the refresh to 60s or do not refresh at all

- menu_part: will put the little "^" under this part of the menu.

Example of a call, taken from the problems view:

```
rebase layout title='All problems', top_right_banner_state=top_right_banner_state, js=['problems/js/a
roblems/js/autocompleter.Request.js', 'problems/js/autocompleterObserver.js'], css=['problems/css/acc
ms/css/autocompleter.css', 'problems/css/perfometer.css'], refresh=True, menu_part='/'+page, user=use
```

Call Python objects in your templates Your templates are mainly HTML code. But of course you can call python code in it. The dict you returns in the plugin.py call will be available in this page.

For example, the my_host variable will be available in the page with the host object you find (or None if your give it a bad name of course). Then you can "call" python with for example here to show the host_name: `<span>My host name is *my_host.host_name* </span>` is a way in the templates to "call a variable or function" that will return a string, here the host_name.

If the function or property you call must return HTML code that SHOULD be output as it, without "protection", you must put a ! before your call.

Let use an example where the output value of an host is in fact an html output. If you use the code `my_host.output`, bottle.py will "protect" the html generated by escaping the string, and change <> characters with escaped value. You can change this by calling `my_host.output`. Of course, it's a security problem if the output is with a javascript code...

You can also "loop" or put "if" in your template. You just need to put your code with a % before. Like

```
%for i in xrange(1, 10):
  My valus is  {{i}}
%end
```

You must put the %end here, the indentation will NOT be enougth, sorry.

For an if it's also easy:

```
%if host.active_checks_enabled:
  The host got active checks enabled
%else:
  The host DO NOT have active check enabled
%end
```

Which javascript lib are you using? It's mootools 1.3 with all options :)

What to do?

- Finish the /mobile part
- List of current alerts
- Host info
- Host status
- Host interfaces
- Hostgroup status
- dashboard hierachique with states, and BP
- Nagvis
- add bp in nagvis auto-map

- event sources
- correlation
- pre-filtering/enrichment
- user profile
- host/srv conf

WebUI search syntax work in progress

not that we couldn't tell. ;) eh eh

beware the working men and flying tools!

WebUI SSL Certification Lets start: the goal to to have the server.pem and client.pem file in etc/certs.

Go to the etc/certs directory.

```
openssl req -new -nodes -out server.req -keyout server.key -config ./shinken_openssl_cnf
openssl ca -out server.pem -config ./shinken_openssl_cnf -infiles server.req
cp server.pem server.pem.bkp
cp server.key server.pem
cat server.pem.bkp >> server.pem
cp server.pem client.pem
```

You can try to get the validity with for the arbiter with:

```
openssl s_client -connect localhost:7770</code>
```

Amazon AWS/EC2 import

Description You can import data from Amazon AWS/EC2 **'AWS'_** into Shinken to create hosts.

Amazon provide VM hosting with EC2. With this arbiter module, you will be able to load your EC2 hosts into Shinken.

Prerequisites

You will need the **'libcloud'_** package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

```
define module {
 module_name      AWS
 module_type      aws_import

 # Configure your REAL key and secret for AWS
 api_key              PAAAB2CILT80I0ZA0999
 secret           GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH
 default_template generic-host        ; if the host is not tagged, use this one
 }
```

- Put in key and secret your private Landscape access. * default_template will be used if your host is not "tagged" in Landscape

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master

     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           AWS
     }
```

Restart your Arbiter and it's done :)

Generated hosts The configuration generated will look as below :

```
define host {
    host_name            i-3fc56e5a
    address              8.8.4.4
    use                  t1.micro,MyTag,EC2,generic-host
    _EC2_AVAILABILITY    us-east-1a
    _EC2_CLIENTTOKEN
    _EC2_DNS_NAME
    _EC2_GROUPS          quicklaunch-1
    _EC2_IMAGEID         ami-1b814f72
    _EC2_INSTANCEID      i-3fc56e5a
    _EC2_INSTANCETYPE    t1.micro
    _EC2_KERNELID        aki-825ea7eb
    _EC2_KEYNAME         testaws
    _EC2_LAUNCHDATETIME  2012-09-26T12:19:38.000Z
    _EC2_LAUNCHINDEX     0
    _EC2_PRIVATE_DNS
    _EC2_PRIVATE_IP
    _EC2_PRODUCTCODE
    _EC2_PUBLIC_IP       8.8.4.4
    _EC2_RAMDISKID       None
    _EC2_STATUS          stopped
    _EC2_TAGS            demo:myvalue,use:MyTag
 }
```

Here with a stopped t1.micro instance with no name. You can put your how "use" parameter by adding a EC2 tag "use" on your VM. It will be output on the host configuration so you can setup the monitoring as you want. .. _libcloud: http://libcloud.apache.org/index.html .. _AWS: https://console.aws.amazon.com

Amazon AWS/EC2 import

Description You can import data from Amazon AWS/EC3 **'AWS'**_ into Shinken to create hosts.

Amazon provide VM hosting with EC3. With this arbiter module, you will be able to load your EC2 hosts into Shinken.

Prerequisites

You will need the **'libcloud'**_ package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

```
define module {
 module_name      AWS
 module_type      aws_import

 # Configure your REAL key and secret for AWS
 api_key              PAAAB2CILT80I0ZA0999
 secret           GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH
 default_template generic-host        ; if the host is not tagged, use this one
 }
```

- Put in key and secret your private Landscape access. * default_template will be used if your host is not "tagged" in Landscape

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master

     address          localhost                  ;IP or DNS adress
     port             7770
     spare            0
     modules           AWS
     }
```

Restart your Arbiter and it's done :)

Generated hosts The configuration generated will look as below :

```
define host {
    host_name            i-3fc56e5a
    address              8.8.4.4
    use                  t1.micro,MyTag,EC2,generic-host
    _EC2_AVAILABILITY    us-east-1a
    _EC2_CLIENTTOKEN
    _EC2_DNS_NAME
    _EC2_GROUPS          quicklaunch-1
    _EC2_IMAGEID         ami-1b814f72
    _EC2_INSTANCEID      i-3fc56e5a
    _EC2_INSTANCETYPE    t1.micro
    _EC2_KERNELID        aki-825ea7eb
    _EC2_KEYNAME         testaws
    _EC2_LAUNCHDATETIME  2012-09-26T12:19:38.000Z
    _EC2_LAUNCHINDEX     0
    _EC2_PRIVATE_DNS
    _EC2_PRIVATE_IP
    _EC2_PRODUCTCODE
    _EC2_PUBLIC_IP       8.8.4.4
    _EC2_RAMDISKID       None
    _EC2_STATUS          stopped
    _EC2_TAGS            demo:myvalue,use:MyTag
 }
```

Here with a stopped t1.micro instance with no name. You can put your how "use" parameter by adding a EC2 tag "use" on your VM. It will be output on the host configuration so you can setup the monitoring as you want. .. _libcloud: http://libcloud.apache.org/index.html .. _AWS: https://console.aws.amazon.com

The distributed retention modules The high availability allow the Arbiter to send a configuration to a spare scheduler, but a spare scheduler does not have any saved states for hosts and services. It will have to recheck them all. It's better to use a distributed retention module so spares will have all the information they need to start with an accurate picture of the current states and scheduling :)

Non distributed retention modules If you are just running tests on a single server, use the pickle or memcache retention modules You can also use MongoDB if you already have it installed for use with the WebUI.

MongoDB MongoDB is a scalable, high-performance, open source NoSQL database written in C++.

Step 1: Install MongoDB:

We will use mongodb package from 10gen repository, so we start by adding it in apt sources list:

```
echo 'deb http://downloads-distro.mongodb.org/repo/debian-sysvinit dist 10gen' > /etc/apt/sources.lis
apt-get update
```

And we install it:

```
apt-get install mongodb-10gen
```

And we install pymongo, the python interface to MongoDB, with easy_install to avoid packages versions problems (like here **'forums.monitoring-fr.org/index.php?topic=5205.0'_**):

```
apt-get remove python-pymongo
easy_install pymongo
```

And finally we start MongoDB :

```
/etc/init.d/mongodb start
```

Step 2: define a mongodb_retention module in your shinken-specific.cfg file:

```
define module {
  module_name MongodbRetention
  module_type mongodb_retention
  uri mongodb://localhost/?safe=true
  database shinken
}
```

Step 3: Declare a retention module for your scheduler(s) :)

Example:

```
#The scheduler is a "Host manager". It get hosts and theirs
#services. It scheduler checks for them.
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
     port     7768                  ; tcp port of the daemon

     #optionnal: modules for things as retention
     modules    MongodbRetention
     }
```

Step 4: Restart the Arbiter, and your Scheduler will now save its state between restarts. :)

Memcached Memcached is a distributed memory resident key/value server. It's very easy to install:

```
sudo apt-get install memcached
sudo /etc/init.d/memcached start
```

The shinken module also needs the python-memcache package to talk to this server.

```
sudo apt-get install python-memcache
```

To use it,

Step 1: define a memcache_retention module in your shinken-specific.cfg file:

```
define module{
     module_name      MemcacheRetention
     module_type      memcache_retention
     server           127.0.0.1
     port             11211
}
```

Step 2: Declare a retention module for your scheduler(s) :)

Example:

```
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
     port     7768                  ; tcp port of the daemon

     #optional: modules for things as retention
     modules    MemcacheRetention
     }
```

Step 3: Restart the Arbiter, and your Scheduler will now save its state between restarts. :)

Redis Redis is a distributed key/value server (on disk and in-memory). It's very easy to install:

```
sudo apt-get install redis-server
sudo /etc/init.d/redis-server start
```

The shinken module also need the python-redis package to talk to this server.

```
sudo apt-get install python-redis
```

Step 1: define a redis_retention module in your shinken-specific.cfg file:

```
define module{
     module_name      RedisRetention
     module_type      redis_retention
     server           127.0.0.1
}
```

Step 2: Declare a retention module for your scheduler(s) :)

Example:

```
#The scheduler is a "Host manager". It get hosts and theirs
#services. It scheduler checks for them.
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
```

```
    port     7768                  ; tcp port of the daemon

    #optionnal: modules for things as retention
    modules    RedisRetention
    }
```

Step 3: Restart the Arbiter, and your Scheduler will now save its state between restarts. :) .. _forums.monitoring-fr.org/index.php?topic=5205.0: http://forums.monitoring-fr.org/index.php?topic=5205.0

How to enable and use Livestatus module

Define the Livestatus module Start by reviewing the ''/etc/shinken/shinken-specific.cfg" file for this module:

```
define module{
```

```
module_name      Livestatus
module_type      livestatus
host             *       ; * = listen on all configured IP addresses
port             50000   ; port to listen on
database_file    /var/lib/shinken/livestatus.db
```

}

With these parameters:

- module_name: name of the module called by the brokers
- module_type: livestatus
- host: IP interface to listen to. The default is *, which means "listen on all interfaces".
- port: TCP port to listen to.
- socket: Unix socket to listen to.
- database_file: the path to the sqlite database file which is used to store the log broks/messages. The default is "var/livelogs.db"
- max_logs_age: the maximum age of the log messages (before they are deleted from the database). The default is 1 year. The argument to this parameter takes the form <number>[<period of time>], where <period of time> can be d for days, w for weeks, m for months and y for years.
- allowed_hosts: a comma-separated list of IP-addresses which are allowed to contact the TCP port. Please keep in mind that these **must be IP-addresses, NOT host names**. Because DNS lookups for every incoming livestatus request could hang up and therefore block the module.

Enable the Livestatus module Still in ''/etc/shinken/shinken-specific.cfg'', find the object Broker and add "Livestatus" to its "modules":

```
define broker{
```

```
    broker_name      broker-1
[...]
```

```
    modules          Simple-log,Livestatus
}
```

Disable human readable logs In ''/etc/shinken/nagios.cfg'', verify that the option **human_timestamp_log** is set to **0**.

In version 0.6.5, you can not have at the same time a simple-log file with human readable timestamp and a Livestatus database.

Exporting data for reporting Shinken can export necessary data for reporting in 3rd party systems.

raw_socket module The raw socket module exports reporting data using a syslog format to a raw TCP socket. Theses logs can be captured, parsed and indexed by any log management system like Splunk or Logstash.

Why export reporting data Custom UIs like Thruk, Multisite, WebUI, Adagios, Nagios IX, etc. All have poor or inflexible reporting. Simply because these are not reporting engines.

This also permits to have a generic reporting method that can accept data from any Nagios, Shinken, Icinga or even Riemann.

Reporting module using Splunk Splunk was selected as the reporting platform for creating, managing and presenting reports. Though the raw_socket module does not have any Splunk specific particularities. It is notable that Splunk reports can be embedded in any 3rd party UI using its REST API.

Raw_socket log format The logs are plain-text and compliant with RFC3164. They use an intelligent date format, a configurable seperator " "(space by default), and key=value pairs in the message data portion of the log. Should a key or value contain a space they must be double quoted. This is syslog using structured data without going to full out JSON that may not be compatible with all log management systems.

The message fields that are supplied in each status update in addition to the standard syslog header are:

- Hostname
- Servicename
- Business impact
- Host/Service status
- Host/Service previous status
- Acknowedgement status
- Maintenance status

Any time the maintenance, host, service or acknowledgement status changes, a log is sent by the Shinken raw_socket module.

Having all relevant data in each log makes it very easy to compute reports for given time periods.

The hostgroup or service group memberships, custom variables or any other configuration related data should be queried from the monitoring system using its API (Livestatus in the case of Shinken and Nagios).

Raw_socket module availability The module is available in both Shinken 1.4 and Shinken 2.0. The module will be integrated in master branches once unit tests and end-to-end testing is completed. 3rd quarter 2013.

Monitoring Linux System with Glances and checkglances.py **'Glances'_** is a fantastic multiplatform system monitoring tool writen by Nicolargo. Glances can run on (Linux, Windows, MacOS ...). There is a growing ecosystem around Glances and of course a Nagios/Shinken plugin : checkglances.py.

How does it work Glances can run in server mode. It provide a XML-RPC server (over http) and allow to retrieve system information throuh a restful API. The only thing to do is to install and start Glances as server on the monitored host, then install checkglances.py on the shinken server and finaly install the glances pack.

Install glances See the glances documentation to install glances on Linux.

<code bash> easy_install glances </code>

There is a debian startup script in the glances repository. And another one for centos here.

Install checkglances.py Just follow the documentation for the checkglances.py prerequisites and put it in your nagios plugins folder.

Install the glances pack Open a terminal as the shinken user and just type the following command

<code bash> shinken install glances </code>

Then just edit the configuration for a linux monitored host and tag it as **glances**

```
define host{
 name mylinuxhost
 use glances
 ...
```

Finaly restart the shinken arbiter

```
service shinken-arbiter restart
```

What will be monitored ? For the moment just the basic system (ram, cpu, load, memory, filesystem and network).

If you want to modify the default thresholds for just a host you can do it by overiding the thresholds macro in your host definition. If you want to do it for several hosts, declare a new template and just add the desired thresholds macro to be overide.

Here is a list of the macros

```
::
```

> _LOAD_WARN 2 _LOAD_CRIT 3 _CPU_WARN 80 _CPU_CRIT 90 _MEMORY_WARN 90 _MEMORY_CRIT 95 _FS /, /home _FS_WARN 90 _FS_CRIT 95 _IFACES eth0, eth1 _NET_WARN 7500000 _NET_CRIT 10000000

Note the _FS and _IFACES macros. They leverage the ability to duplicate service for a given list of things to be monitored. Here you see that / and /home partitions will be monitored. If you want to modify this then just add your own in a new template that will inherit the glances template.

Shinken GLPI integration Shinken supports importing hosts from GLPI

For people not familiar with GLPI, it is an Open-Source CMDB. Applicable to servers, routers, printers or anything you want for that matter. It is also a help-desk tool. GLPI also integrates with tools like FusionInventory for IT inventory management.

You can still have flat files AND GLPI if you want. Hosts imported from GLPI will be treated as standard hosts from flat file (inheritance, groups, etc). In fact, in this first version the module only sends the host_name to Shinken, but there should be more information extracted like network connexions for parents relations in the future. :)

Requirements

- python module MySQLdb
- Compatible version of GLPI Shinken module and GLPI version - ...
- etc..

Enabling GLPI Shinken module In your shinken-specific.cfg file, just add (or uncomment):

```
#You know GLPI? You can load all configuration from this app(
#with the webservices plugins for GLPI, in xmlrpc mode
#and with plugin monitoring for GLPI)
# =============== Work with Plugin Monitoring of GLPI ===============
#All configuration read from this will be added to the others of the
#standard flat file
define module{
     module_name      GLPI
     module_type      glpi
     uri              http://localhost/glpi/plugins/webservices/xmlrpc.php
     login_name       glpi
     login_password   glpi
}
```

And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master
#    host_name       node1       ;result of the hostname command under Unix
     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           GLPI
     }
```

It's done :)

Ip Tag module

Why tag a host based on it's IP address? We learned on the *DMZ monitoring* that you can "tag" a host with a poller_tag so it will be checked only by DMZ pollers. It can be tedious process to manually tag all these hosts. Shinken provides an automated method to do this.

This is handled by the arbiter ip_tag module.

Ip_tag module The ip_tag module is an arbiter module that looks up the host address during the configuration parsing and compares it to an predefined IP range (IPV4 or IPV6). If the range matches, it can apply or add a property, such as poller_tag. Other types of tags could be related to locations, functions, administrative groups, etc.

Method: replace or append.

replace will put the value if the property is unset. This is the default method. .. warning:: Fix me: replace, implies overriding an existing value. And will cause user issues down the line. Rename it to set. Replace should be a different method altogether, so overall there should be 3 methods(set, append, replace).

append will add with a , if a value already exist

Here is an example that will set the poller_tag property with the value DMZ of all hosts that:

- have a their hostadress ip (or name resolved) in the range 192.168.0.1/24.
- do not already have a poller_tag property set

```
define module{
```

```
     module_name     IpTag
     module_type     ip_tag
     ip_range        192.168.0.1/24
     property        poller_tag
     value           DMZ
}
```

To use the module add it in the arbiter object:

```
::
```

define arbiter { [...] modules NSCA,IpTag

}

Add value instead of setting it In the previous example we set the property poller_tag to a value. But what if we want to "add" a value, like a template name? We can change the "method" property of the module to "append" so we can add the "value" to the host property instead of replace it.

Here is an example where we want to add the "dmz" template on the hosts, while also keeping any defined templates:

```
define module{
```

```
     module_name   IpTag
     module_type   ip_tag
     ip_range      192.168.0.1/24
     property      use
     value         dmz

     # Optional method
     method append
}
```

For a host defined as:

```
define host{
```

```
     host_name   example_host1
     address     192.168.0.2
     use         linux
}
```

It will be "changed" internaly in:

```
define host{
```

```
     host_name   example_host1
     address     192.168.0.2
     use         linux,dmz
}
```

Name resolution Of course you don't need to set IP address in the address of your host. You can set a hostname, and it will be resolved, and then compared to the range. :)

Ubuntu Landscape import

Description You can import data from Ubuntu Landscape into Shinken to create hosts.

Ubuntu Landscape, is a web app to manage all your linux servers (update and co), which is provided by Canonical, Ubuntu's parent company.

This is an Arbiter import module. The Arbiter manages the configuration.

Prerequisites

You will need the landscape-api package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

define module { module_name Landscape module_type landscape_import

Configure your REAL key and secret from Landscape key PAAAB2CILT80I0ZA0999 secret GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH default_template generic-host ; if the host is not tagged, use this one

If you are using a specific certificate for landscape_api #ca /path/to.ca.cert

If you need a proxy to access https://landscape.canonical.com/api/ #https_proxy http://user:secret@myproxy.com:3128

}

- Put in key and secret your private Landscape access.
- default_template will be used if your host is not "tagged" in Landscape
- If you are using a specific certificate for connexion, give the full path in ca
- You will certainly need an https proxy to access the Landscape API. If so, configure it there.

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master
#    host_name       node1       ;result of the hostname command under Unix
     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           Landscape
     }
```

Restart your Arbiter and it's done :)

Tip: Your "tags" will be applied as templates for your hosts.

Shinken Livestatus API

Overview

- Jump back to Getting Started
- Jump back to *Livestatus module configuration*

What is it Livestatus API is the modern method of interacting with Shinken and Nagios based systems alike.

Originally developed for Nagios, MK Livetstatus, was re-implemented in Python for use with Shinken by professional developers. The access methods and query languages are the same.

Why use it It is fast.

It is network based using TCP.

It is standard for all Nagios and Shinken monitoring systems.

It uses in-memory structures for status data

It uses a back-end database for historical reporting

It uses an SQL based query language

It has a host of powerful nuts and bolts features (authentication, caching, connection persistence, multiple object methods (JSON, Python)).

What can I do with it? All programs and scripts use (or should use) this method to :

- Obtain the current state of hosts and services
- Obtain the current configuration related to hosts and services
- Send administrative commands (downtimes, comments, forcing checks)
- Filter information to display
- Obtain basic reports and event statistics

Shinken being a modern re-implementation of Nagios has additional features that are available in addition to the standard Livestatus API.

Shinken Livestatus API unique features can :

- Obtain Business Impact information
- Obtain intelligent dependency status hosts or services (combines dependency and parent information)
- Obtain Business Process states (same syntax as standard host and service queries)

How does it work Livestatus uses a powerful SQL-like query language. The standard methods and parameters are defined at :

'MK Livestatus reference methods and query language definition'_

Full list of Shinken Livestatus API methods:

'Shinken mapping.py methods'_

What software uses Livestatus to interact with Shinken

Well known Web frontends

- MK Multisite
- Thruk
- NagVis

- Splunk for Nagios

Mobile Web frontends

- get list

Scripts

- Downtime management scripts
- Debug scripts

Installing Livestatus Have you installed the required packages to use the Livestatus module? You can look at the requirement section of the *10 minute installation guide* for the *requirement lists*.

How to enable Livestatus Very simple, jump to the *Shinken Broker configuration* section to enable it. .. _Shinken mapping.py methods: https://github.com/shinken-monitoring/mod-livestatus/blob/master/module/mapping.py .. _MK Livestatus reference methods and query language definition: http://mathias-kettner.de/checkmk_livestatus.html

NSCA module The NSCA daemon module is used to receive send_nsca packets and submit them to the Shinken command pipe. The NSCA module can be loaded by the Receiver or Arbiter process. It will listen on port TCP/5667 for send_nsca packets.

Tip: Passive checks can be submitted *natively to the Shinken command pipe* or from remote hosts to modules, such as NSCA, AMQP or collectd, loaded in the Shinken Arbiter or Receiver process. AMQP is implemented for integration with the Canopsis Hypervisor, but could be re-used for generic messaging.

Note: The Shinken NSCA module implementation is currently limited to the "xor" obfuscation/encryption.

In your shinken-specific.cfg file, just add (or uncomment):

```
::
```

#You can send check result to Shinken using NSCA #using send_nsca command define module{

module_name NSCA module_type nsca_server host * port 5667 encryption_method 0 password helloworld

}

define receiver{

```
receiver_name    receiver-1
address          localhost
port             7773
modules          NSCA

timeout          3             ; 'ping' timeout
data_timeout     120           ; 'data send' timeout
max_check_attempts       3     ;  if at least max_check_attempts ping failed, the node is DEAD

#advanced
realm    All
}
```

This daemon is totally optional.

It's main goal is to get all passive "things" (checks but why not other commands) in distant realms. It will act as a "passive receive buffer" and will then dispatch the data or commands directly to the appropriate Scheduler or Arbiter process.

Data can be received from any Realm, thus the Realm option is nonsensical.

For now there is no init.d script to launch it. .. note:: Verify that the init script has been added.

It is launched like all other daemons:

```
bin/shinken-receiver -c etc/receiverd.ini
```

Tip: Alternatively, for small installations with you can configure a modules inside your Arbiter instead of the Receiver. It will listen the TCP/5667 port for send_nsca packets.

To configure the NSCA module in your Arbiter instead of Receiver. Add the NSCA module to your Arbiter object configuration.

```
::
```

define arbiter{ arbiter_name Arbiter-Master

 # host_name node1 ;result of the hostname command under Unix address localhost ;IP or DNS adress port 7770 spare 0 modules NSCA

}

Retention troubleshooting The retention file contains the state of your host and services, so that they are kept when shinken is restarted.

Sometimes you'll want to inspect (and possibly fix) the retention file, in case you need to work-around a bug or simply better understand what is stored there.

When you use the PickleRetention module in the scheduler (cf. ''define scheduler" in ''shinken-specific.cfg''), you can simply manipulate the retention file using Python.

For this you can use the following code.

- It assumes Shinken is installed in ''/opt/shinken" with the retention file in ''/tmp/retention.dat'':
- Run and play with it interactively using ''ipython -i inspect_retention.py''.

```
#!/usr/bin/python
import pickle
import sys
sys.path.append('/opt/shinken')
import shinken

r = pickle.load(file('/tmp/retention.dat'))
h = r['hosts']

# Example:
# [(k,v) for (k,v) in h['your_host'].items() if k.find('downtime') >= 0]
#
# del h['your_host']
#
# for k,v in r['services'].items():
#     if 'your_host' in k:
#         del r['services'][k]
```

To save your changes:

- Stop Shinken: ‘’service shinken stop’‘
- Save the pickle: ‘’pickle.dump(r, open(‘/tmp/retention.dat’, ‘w’))’‘
- Start Shinken: ‘’service shinken start’‘

NRPE Module

What is it The NRPE module allows Shinken Pollers to bypass the launch of the check_nrpe process. It reads the check command and opens the connection by itself. It scales the use of NRPE for active supervision of servers hosting NRPE agents.

The command definitions should be identical to the check_nrpe calls.

How to define it The definition is very easy (and you probably just have to uncomment it):

```
define module{
     module_name       NrpeBooster
     module_type       nrpe_poller
}
```

Then you add it to your poller object:

```
define poller {
    [...]
    modules   NrpeBooster
}
```

Then just tag all your check_nrpe commands with this module:

```
define command {
   command_name   check_nrpe
   command_line   $USER1$/check_nrpe -H $HOSTADRESS$ -c $ARG1$ -a $ARG2$
   module_type    nrpe_poller
}
```

That’s it. From now on all checks that use this command will use Shinken’s NRPE module and will be launched by it.

Extending Shinken

Introduction There are a lot of “Modules” and “Addons” that are available for Shinken. Shinken can be extended by using different types of methods.

- Web interfaces from various open-source vendors can be used (Based on Livestatus API)
- Shinken itself can be extended using modules that are embedded into the various daemon processes

** (Arbiter, Poller, Receiver, Broker, Scheduler, Reactionner) * External software can provide functional enhancements for reporting, management or usability aspects

Shinken itself provides methods to extend the base functionality:

- *Broker modules* provide external access to runtime data from Shinken
- Poller modules such as *NRPE* and the *SNMP*
- Receiver modules like *NSCA* provide acquisition methods for Shinken

- Arbiter modules permit manipulating the configuration
- The webUI that permits embedding web interface elements

Independent software that works in concert with Shinken is available for:

- Monitoring remote hosts through agent software (*NIX, Windows, etc.)
- Submitting passive checks from remote hosts
- Managing the config files through a web interface
- Mobile phone UIs
- Desktop UIs and Hypervisors
- Desktop notification addons
- ...and much more

You can find many addons that are compatible with Shinken by visiting. The only caveat is that the addons should not use the status.dat file and preferably the modern API interfaces like Livestatus:

- Nagios.org
- SourceForge.net
- NagiosExchange.org
- Shinken community exchange for monitoring packs

Broker modules The broker module receives messages from the Schedulers related to host, service check results. In addition to that it receives a copy of the compiled configuration at startup. What is special about the broker, is that without modules, the broker does nothing. It makes the configuration and result data available to modules. Modules are the ones in charge of doing something with the data. This could be exporting this "raw" data into flat files, databases or exposing it as an API.

The modules are presented according to their use cases.

- Core modules
- Livestatus Module for frontends
- Exporting data to metric databases
- SQL based Modules for frontends
- Exporting data to logging management systems
- Legacy modules for migration purposes
- Modules no longer supported

Core modules

simple_log: get all logs into one file You can get a log for all your daemons in a single file. With the exception of Debug level logs which are not sent through the network as a safe guard. Shinken state messages are ONLY logged at the debug level in the local log files. These are the ALL CAPS states that some 3rd party interfaces use to mine data from the historical logs. Actual state messages are sent as objects between the various daemons.

It takes the parameters:

- module_name: name of the module called by the brokers

- module_type: simple_log
- path: path of the log file

Here is an example:

```
define module{
```

```
     module_name      Simple-log
     module_type      simple_log
     path             /usr/local/shinken/var/nagios.log
     archive_path     /usr/local/shinken/var/archives/
}
```

Syslog - Send all logs to a local syslog server Send all logs to a local syslog server. Support for remote syslog can be implemented if requested. Just lookup the syslog module, easy to modify. Use for example with Splunk, graylog2, Logstash, Elastic search, Kibana, or other log management and analysis system.

```
define module{
```

```
  module_name Syslog
  module_type syslog
}
```

Lightweight forwarder to Splunk Shinken state data from the local syslog can also be sent to a Splunk server for indexing, reports, SLA and analysis. Via syslog or better yet, the Splunk lightweight forwarder which supports, TCP, buffering and security parameters.

Livestatus API Module - Thruk, Nagvis and Multisite Web frontends There are three well known frontends and various small tools that can interface with the Livestatus API. This API is currently the most efficient method of sharing live data with external interfaces. It provides a rich query language similar to SQL, authentication, command execution, caching,connections persistence, multiple object methods (JSON, Python). All Livestatus data is kept in memory, there is no disk IO involved. It exposes configuration objects, the current state of the hosts and services as well as historical Shinken state log messages.

- MK Multisite
- Thruk
- NagVis

Have you installed the required packages to use the Livestatus module? You can look at the requirement section of the 10 minute installation guide for the requirement lists.

Livestatus Module

It takes the following parameters:

- module_name: name of the module called by the brokers
- module_type: livestatus
- host: IP interface to listen to. The default is '127.0.0.1'. '*' means 'listen on all interfaces'.
- port: TCP port to listen to.
- socket: Unix socket to listen to.

- allowed_hosts: a comma-separated list of IP-addresses which are allowed to contact the TCP port. Please keep in mind that these must be ip-addresses, NOT host names. (DNS lookups for every incoming livestatus request could hang up and therefore block the module)
- modules: a comma-separated list of modules (see below)
- pnp_path: relevant if you use the multisite gui. pnp_path points to the perfdata directory where the pnp4nagios data reside (it's the directory which contains a subdirectory for each host). Multisite needs it to display a small perfdata icon if a rrd file exists.
- To deactivate an input, the port- and socket-attributes can also take the value "none".

The Livestatus module itself can have sub-modules. In fact, it **must** have at least one submodule responsible for storing log events to a database, SQLite or MongoDB.

Livestatus module - Logstore Sqlite Stores log-broks to an sqlite database.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_sqlite
- use_aggressive_sql: Prefer the use of sql queries to pre-filter data prior to python filtering. This is required for very large installations, as the Python structures are not indexed when filtering. Optional argument set to 0 by default. To enable set the value to 1. Some erroneous output may occur, but informal testing has shown these corner cases do not occur.
- read_only: don't send any update to the database. Should be used when you run several livestatus modules : 1 instance is R/W, other are read only.
- database_file: the path to the sqlite database file which is used to store the log broks/messages. The default is 'var/livestatus.db'
- archive_path: the path to a subdirectory where database file archives will be created. Every day the data from the last day will be moved to an archive datafile. The default is 'var/archives'.
- max_logs_age: the maximum age of the log messages (before they are deleted from the database). The default is 1 year. The argument to this parameter takes the form <number>[<period of time>], where <period of time> can be d for days, w for weeks, m for months and y for years. This parameter is currently ignored. In future releases it will be used to automatically delete ancient database files.

Here is an example:

```
define module{
```

```
     module_name      Livestatus
     module_type      livestatus
     host             *       ; * = listen on all configured ip addresses
     port             50000   ; port to listen
     socket           /usr/local/shinken/var/rw/live
     modules          logsqlite
}
define module{
```

```
     module_name      logsqlite
     module_type      logstore_sqlite
     use_aggressive_sql     0 ; optional, by default set to 0. Only for large installations.
     database_file    /usr/local/shinken/var/livelogs.db
     max_logs_age     3m ; three months. Other time intervals are d=days, w=weeks, y=years
}
```

Livestatus module - Logstore MongoDB Stores historical log broks(inter daemon Shinken messages) to a MongoDB database. MongoDB is a distributed and very performant database that permits resilience and high availability. The current implementation has a few known broken pieces (some search functions are broken) and there are bugs in the implementation, so it is considered experimental until power users and developers have ironed out the bugs. It is the database of the future for Shinken.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_mongodb
- mongodb_uri: The address of the master. (Default: i_cant_write_the_uri_here_it_messes_the_wiki_up)
- replica_set: If you are running a MongoDB cluster (called a "replica set" in MongoDB), you need to specify it's name here. With this option set, you can also write the mongodb_uri as a comma-separated list of host:port items. (But one is enough, it will be used as a "seed")
- database: <undocumented>
- collection: <undocumented>
- max_logs_age: <undocumented>

The configuration looks quite similar to the sqlite one. **In a single-node installation and with decent amount of log traffic, the sqlite backend should be considered best practice, as it needs no extra software and is stable and fast (when run in-memory).**

Livestatus module - Logstore Null In case you don't need any logging (for instance, if you dedicate a livestatus module instance to nagvis), you can use this module.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_null

Network Based Modules - Graphite graphing Graphite is a graphing and data analysis tool. It is composed of a web frontend (graphite-web), fixed size databases (whisper) and data redistribution/munging daemon. (carbon) The first step is *having Graphite installed somewhere*, if you do not have Graphite installed, please do this and come back later.

Pre-requisite : Shinken 1.2.2+ is recommended for the best experience with Graphite.

graphite_perfdata: exports check result performance data to Graphite Export all performance data included in check results to Whisper databases managed by Graphite. Data is buffered, then exported once every broker time tick. (Once per second). Should a communication loss occur, it will buffer data for 5 minutes before dropping data. The tick_limit max is configurable, the only limitation is the amount of memory the buffered data can eat.

The graphite broker module (v1.2) sends data to graphite in the following format :

HOSTNAME.SERVICENAME.METRICNAME

It can be optionally enhanced to send it the following format :

_GRAPHITE_PRE.HOSTNAME.SOURCE.SERVICENAME.METRICNAME._GRAPHITE_POST

Each of the three variables are optional :

- The _GRAPHITE_PRE variable can be set per host/service to provide a more flexible naming convention. (ex. Prod.site1.Hostname.servicename)

- The _GRAPHITE_POST variable can be set per host/service to specify the more information concerning the variable being stored that graphite can use to determine the retention rule to use for the variable.
- The SOURCE variable can be set in shinken-specific.cfg for the WebUI module and the Graphite broker.

Metric names are converted from Shinken's format to a more restrictive Graphite naming. Unsupported characters are converted to "_" underscore. So do not be surprised to see that some names differ in the WebUI or directly in Graphite. Permitted characters in Graphite are "**A-Za-z_**.", the hyphen character is permitted from Shinken, though only future versions of Graphite will support it.

Performance data transfer method can be set to pickle, which is a binary format that can send data more efficiently than raw ascii.

It takes the following parameters:

- module_name: name of the module called by the brokers
- module_type: graphite_perfdata
- host: ip address of the graphite server running a carbon instance
- port: port where carbon listens for metrics (default: 2003 for raw socket, 2004 for pickle encoded data)
- use_pickle: Use a more efficient transport for sending check results to graphite instead of raw data on the socket (v1.2)
- tick_limit: Number of ticks to buffer performance data during a communication outage with Graphite. On tick limit exceeded, flush to /dev/null and start buffering again. (v1.2)
- graphite_data_source: Set the source name for all data coming from shinken sent to Graphite. This helps diferentiate between data from other sources for the same hostnames. (ex. Diamond, statsd, ganglia, shinken) (v1.2)

Here is an example:

```
define module {
```

```
module_name Graphite-Perfdata
host xx.xx.xx.xx
module_type graphite_perfdata
port 2004 ; default port 2003 for raw data on the socket, 2004 for pickled data
use_pickle 1 ; default value is 0, 1 for pickled data
tick_limit 300 ; Default value 300
graphite_data_source shinken ; default is that the variable is unset
}
```

SQL Based Modules - PNP4Nagios Graphing PNP4Nagios is a graphing tool that has a web interface for RRDTool based databases. Shinken can export performance data to an npcd database which will feed the RRD files (fixed sized round robin databases). You can *learn how to install PNP4Nagios* if you haven't done it already.

npcdmod: export perfdatas to a PNP interface Export all perfdata for PNP.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: npcdmod
- path: path to the npcd config file

Here is an example:

```
define module{
 module_name  NPCD
 module_type  npcdmod
 config_file  /usr/local/pnp4nagios/etc/npcd.cfg
}
```

SQL Based Modules - Frontend Centreon2 Centreon2 use a NDO database, so you will need the ndodb_mysql module for it.

ndodb_mysql: Export to a NDO Mysql database Export status into a NDO/Mysql database. It needs the python module MySQLdb (apt-get install python-mysqldb or easy_install MySQL-python).

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: ndodb_mysql
- database: database name (ex ndo)
- user: database user
- password: database user passworddt
- host: database host
- character_set: utf8 is a good one

Here is an example:

```
define module{
```

```
     module_name      ToNdodb_Mysql
     module_type      ndodb_mysql
     database         ndo       ; database name
     user             root      ; user of the database
     password         root      ; must be changed
     host             localhost ; host to connect to
     character_set    utf8      ;optionnal, UTF8 is the default
}
```

File based Legacy modules - perfdata export

service_perfdata: export service perfdatas to a flat file

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: service_perfdata
- path: path to the service perfdata file you want

Here is an example:

```
define module{
```

```
    module_name      Service-Perfdata
    module_type      service_perfdata
    path             /usr/local/shinken/src/var/service-perfdata
}
```

host_perfdata: export host perfdatas to a flat file

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: host_perfdata
- path: path to the host perfdata file you want

Here is an example:

```
define module{
```

```
    module_name      Host-Perfdata
    module_type      host_perfdata
    path             /usr/local/shinken/src/var/host-perfdata
}
```

Legacy File based Modules - Old CGI or VShell The Old CGI and VShell use the flat file export. If you can, avoid it! It has awful performance, all modern UIs no longer use this.

status_dat: export status into a flat file Export all status into a flat file in the old Nagios format. It's for small/medium environment because it's very slow to parse. It can be used by the Nagios CGI. It also export the objects.cache file for this interface.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: status_dat
- status_file: path of the status.dat file /usr/local/shinken/var/status.dat
- object_cache_file: path of the objects.cache file
- status_update_interval: interval in seconds to generate the status.dat file

Here is an example:

```
define module{
```

```
    module_name              Status-Dat
    module_type              status_dat
    status_file              /usr/local/shinken/var/status.data
    object_cache_file        /usr/local/shinken/var/objects.cache
    status_update_interval   15 ; update status.dat every 15s
}
```

Deprecated or unsupported modules

SQL Based MerlinDB This interface is no longer supported and is going to be completely removed from Shinken.

SQL based ndodb_oracle - Icinga web frontend using NDO Oracle This interface is no longer supported and is going to be completely removed from Shinken.

CouchDB: Export to a Couchdb database This interface is no longer supported and is going to be completely removed from Shinken.

TSCA (Thrift Service Check Acceptor) TSCA is a receiver/arbiter module to receive hosts and services check results. It provides the same functions as NSCA with additional features. High performance binary transmission, multi line output and auto generated clients for a variety of languages.

What is thrift ? Let's cut and paste the wikipedia definition from'en.wikipedia.org/wiki/Apache_Thrift'_ :

"Thrift is an interface definition language that is used to define and create services for numerous languages.[1] It is used as a remote procedure call (RPC) framework [..]. It combines a software stack with a code generation engine to build services that work efficiently to a varying degree and seamlessly between ActionScript, C#, C++ (on POSIX-compliant systems), Cappuccino, Cocoa, Erlang, Haskell, Java, OCaml, Perl, PHP, Python, Ruby, and Smalltalk."

Installation In any case, you have to install thrift with support for python (on the server side) and languages you want to use for clients.

Get it from thrift.apache.org or in your favorite distribution repository.

Server side Go to the tsca module directory and generate the python stub for the server side installation

```
cd shinken/modules/tsca
$ thrift --gen py tsca.thrift
```

Declare the module is shinken-specific.org

```
define module{
      module_name     TSCA
      module_type     tsca_server
      host            0.0.0.0
      port            9090
}
```

Samples clients There are three(3) client samples written in python, ruby and java in contrib/clients/TSCA of the Shinken distribution. You can use and extend them to send data directly in your code directly to Shinken's TSCA receiver/arbiter module.

The samples clients read a CSV file from stdin and send them the the TSCA running on localhost:9090. The CSV has the following format :

```
hostname,service description,output,rc
```

Any use of TCP in an application should take care not to block the program and to have very short timeouts. For applications that need non blocking functions, prefer a UDP based transport or a local buffer file with a separate application(send_nsca, thrift, etc) to forward your data to Shinken.

Ruby Generate the stub

```
$ thrift --gen rb ../../../shinken/modules/tsca/tsca.thrift
```

Run the client

```
$ cat file_state | ruby RubyClient.rb
```

Python Generate the stub

```
$ thrift --gen py ../../../shinken/modules/tsca/tsca.thrift
```

Run the client

```
$ cat file_state | python PythonClient.py
```

java Generate the stub

```
$ thrift --gen java ../../../shinken/modules/tsca/tsca.thrift
```

Compile the client

```
$ ant
```

Run the client

```
$ cat file_state | java JavaClientThrift
```

VMWare Arbiter module

How it works The arbiter has a module that allows the host->VM automatic host dependency creation. In fact, the module is far more generic than just this. It's a generic "host link dependencies" module.

It reads a mapping file (simple json format) with son->father links. It call an external script at a regular interval : the one I wrote is a VMWare mapping one. It used the check_esx3.pl (that all ESX admin should have) plugin and generate the mapping file. When this file is changed, the module reloads it, creates new links and deletes old ones. So when you VMotion a virtual machine, in the next pass, there will be creation of a new link and deletion of the old one in the scheduler that manages it :)

How to define it The definition is very easy :

```
define module{
     module_name       VMWare_auto_linking
     module_type       hot_dependencies
     mapping_file      /tmp/vmware_mapping_file.json
     mapping_command   /usr/local/shinken/libexec/link_vmware_host_vm.py -x '/usr/local/shinken/libex
     mapping_command_interval 60   ; optionnal
     mapping_command_timeout   300 ; optionnal
}
```

Then you add it in you arbiter object :

```
define arbiter {
    [...]
    modules   VMWare_auto_linking
}
```

So here, it will call the script /usr/local/shinken/libexec/link_vmware_host_vm.py with a listing of the vCenter vcenter.mydomain.com and generate the mapping file /tmp/vmware_mapping_file.json.

You can call : /usr/local/shinken/libexec/link_vmware_host_vm.py –help

for the full help on this script.

It looks at the file modification time each second. This command can also be launch by an external cron of course.

Note: So if you want to write a script that does this for XEN servers, all you need is to generate a json file with all the mapping. I didn't wrote the doc about this, but you can look in the test file for it, the format is very very easy :)

Here is an example of the JSON mapping file syntax:

%%:ref:*["host", "physical_host"], ["host", "virtual_machine"* <["host", "physical_host"], ["host", "virtual_machine">, "host", "physical_host"], ["host", "other_virtual_machine" <"host", "physical_host"], ["host", "other_virtual_machine">]%%

So just a list of couple 'host' string (from now only host are managed) and the host name.

Beware about it : you need the real host_name, including case.

Web Service Module The Ws_arbiter module is a Receiver or Arbiter module to receive passive check results from remote hosts via HTTP(s). This module is considered a work in progress but can be used for testing and improvement.

Configuring the Web Service Module If data is POSTed to this page, it will validate the data to determine if it is a service or host check result and submit the data to the Shinken external command queue.

The web service listens by default to TCP port 7760. The web service supports anonymous or authenticated access. Web service parameters are set in the Shinken-specific.cfg file, in the Ws_arbiter module. To enable the web service, simply add the module to your Arbiter or Receiver daemon configuration in Shinken-specific.cfg

Using the Web Service Module The web service listens for POSTs to: /push_check_result

Use curl or embed the HTTP calls in your software to submit check results.

curl -u user:password -d "time_stamp=$(date +%s)&host_name=host-checked&service_description=service-checked&return_code=0&output=Everything OK" http://shinken-srv:7760/push_check_result

Example with more readability:

```
curl
```

-u user:password -d "time_stamp=$(date +%s)

```
&host_name=host-checked
&service_description=service-checked
&return_code=0
&output=Everything OK
http://shinken-srv:7760/push_check_result
```

SNMP module This part must be splitted and sent in all module repositories

Shinken integrated SNMP Module

SnmpBooster Download Install and Configure

- *What is the SnmpBooster module*
- Install and configure the SNMP acquisition module. [You are here]
- *Reference - SnmpBooster troubleshooting*
- *Reference - SnmpBooster design specification*
- *Reference - SnmpBooster configuration dictionnary*

Downloads

The SnmpBooster module and genDevConfig are currently in public beta prior to integration within Shinken. You can consult t

- github.com/xkilian/genDevConfig
- github.com/titilambert/shinken/tree/snmp_booster/shinken/modules (snmp_booster branch) * Simply right-click and download snmp_poller.py then copy it to shinken/modules/

Requirements The SnmpBooster module requires:

- Python 2.6+
- Shinken 1.2+
- PySNMP 4.2.1+ (Python module and its dependencies)
- ConfigObj (Python module)
- python-memcached
- memcachedb or memcached package for your operating system (ex. For Ubuntu: apt-get install memcachedb) *Note*

The genDevConfig profile generator depends on:

- Perl 5.004+
- 4 perl modules available from CPAN and network repositories. genDevConfig/INSTALL has the installation details.

STRONGLY RECOMMENDED: Use the same version of Python and Pyro on all hosts running Shinken processes.

Installation SnmpBooster:

- Install the dependencies
- Copy the file snmp_poller.py from the git repository to your shinken/modules directory.
- Configuration steps are listed in the present web page.

genDevConfig:

- Download and extract the archive to your server.
- See genDevConfig/INSTALL on how to install and configure it.

Configuration

How to define the SnmpBooster module in the Shinken daemons You need to modify shinken-specific.cfg, which is located in $shinken/etc/shinken-specific.cfg

Arbiter daemon configuration Simply declare the module:

```
modules SnmpBooster</code>
```

Scheduler daemon configuration

Simply declare the module:

<code>modules SnmpBooster

Poller daemon configuration Simply declare the module:

```
modules SnmpBooster</code>
```

SnmpBooster Module declaration

Included in Shinken v1.2.1 shinken-specific.cfg.

<code>define module {

```
module_name          SnmpBooster
module_type          snmp_poller
datasource           /usr/local/shinken/etc/packs/network/SnmpBooster/   ; SET THE DIRECTORY FOR YOUR
memcached_host       x.x.x.x  ; SET THE IP ADDRESS OF YOUR memcached SERVER
memcached_port       11211  ; default port for a memcached process
```

}

If you do not know the IP adress on which your memcache is listening, check under /etc/memcached.conf. Or do a:

```
netstat -a | grep memcached</code>
If you are running a test on the local machine you can leave memcached on 127.0.0.1 (localhost), but
```

How to define a Host and Service

Step 1

Create a template for your SNMP enabled devices.

Sample template:

<code>cd shinken/etc/packs/network/ mkdir SnmpBooster

vi shinken/etc/packs/network/SnmpBooster/templates.cfg

```
define command {
```

```
command_name    check_snmp_booster
command_line    check_snmp_booster -H $HOSTNAME$ -C $SNMPCOMMUNITYREAD$ -V 2c -t $ARG1$ -i $_SERVICE
module_type     snmp_poller
```

}

```
define service {
```

```
name                    default-snmp-template
check_command           check_snmp_booster!$_SERVICEDSTEMPLATE$!$_SERVICEINST$!$_SERVICETRIGGERGROUP
_inst                   None
_triggergroup           None
max_check_attempts      3
check_interval          1
retry_interval          1
register                0
```

}

```
define host{
```

```
name                    SnmpBooster-host
alias                   SnmpBooster-host template
check_command           check_host_alive
max_check_attempts      3
check_interval          1
retry_interval          1
use                     generic-host
register                0
```

}

Step 2 Define some hosts and services. You would typically use genDevConfig or another configuration generator to create these for you.

Mandatory service arguments related to SNMP polling:

```
_dstemplate                Cisco-Generic-Router  ; Name of a DSTEMPLATE defined in the SnmpBooster co
```

```
snmpcommunityread    which is set in your resource.cfg file
```

Optional service arguments related to SNMP polling with default values:

```
_inst                   None   ; Could be numeric: 0, None or an instance mapping function like: map
```

```
_triggergroup           None   ; Name of the triggergroup defined in the SnmpBooster config.ini file
```

Sample Shinken host and service configuration:

```
# Generated by genDevConfig 3.0.0
# Args: --showunused -c publicstring 192.168.2.63
# Date: Thu Aug 30 17:47:59 2012

```
 host_name            192.168.2.63
 service_description  chassis
 display_name         C2960 class chassis
 _dstemplate          Cisco-Generic-Router
 _inst                0
 use                  default-snmp-template
 register             1
}

define service {
```

```
 host_name            192.168.2.63
 service_description  chassis.device-traffic
 display_name         Switch fabric statistics - Packets per Second
 _dstemplate          Device-Traffic
 use                  default-snmp-template
 register             1
}

define service {
```

```
host_name            192.168.2.63
service_description  if.FastEthernet0_1
display_name         FastEthernet0_1 Description: Link to Router-1 100.0 MBits/s ethernetCsmacd
_dstemplate          standard-interface
_inst                map(interface-name,FastEthernet0_1)
use                  default-snmp-template
register             1
```

}

Here is an example configuration of the config.ini file

```
[DATASOURCE]
```

```
  OidmyOidDefinition = .1.3.6.1.45.0

Shinken integrated SNMP Module

Overview

What is it The SnmpBooster module allows Shinken Pollers to directly manage SNMP data acquisition. This is an all Python cross-platform SNMP module. It is tightly integrated with the Shinken Poller, Scheduler and Arbiter daemons to provide the best possible user experience.

- Jump back to *SnmpBooster documentation index*

Design specification summary

- STATUS - DESIGN SPEC PERFORMANCE
- [Done] Functions as an integrated Shinken Poller module
- [Done] Necessary integration code commited to Shinken official release (Integrated starting at v1.2)
- [Done] Ability to collect thousands of SNMP metrics per second
- [Done] Be compatible with distributed data acquisition
- [Done] Collect data for a host/check_interval tuple via SNMP in a single pass
- [Done] Use all builtin Shinken scheduler logic for retries, forced checks, timeouts, dependencies, parents
- [Done] Store collected data for the duration of the check_interval in a memcached/membase
- [Done] On a restart, after the first collection, be able to pick up where the last check left and calculate derived values
- [Done] Forced check are not allowed within 30 seconds of last SNMP query to the same host/check_interval, all other requests get data from the cache.
- [Done] Only a single request to the host/check_interval via SNMP is allowed at a time, all other requests get data from the cache.
- STATUS - DESIGN SPEC USABILITY
- [Done] Usage documentation
- [xxxx] SkonfUI and Discovery usage documentation
- [xxxx] Provide sample configuration packs in Shinken
- [Done] Provide sample config.ini with examples of all types of data * SNMP OIDS, DATASOURCES, DSTEMPLATES, TRIGGERS and TRIGGERGROUPS

- [Done] Directly compatible for use with genDevConfig Shinken SNMP configuration generator
- [Done] Provide meaningful feedback for users on errors
- [Done] Capture all tracebacks and convert them to actual error or warning messages
- STATUS - DESIGN SPEC FEATURES
- [Done] Return state and performance metrics
- [Done] Performance metrics can be returned in a Weathermap compatible format
- [Done] Configuration file format is ConfigObj INI
- [Done] Load all valid INI configuration files from a directory and merge them
- [Done] Load a single INI configuration file
- [xxxx] Load a list of INI configuration files
- [Done] Configuration file describes all generic acquisition parameters (OID, DATASOURCE, DSTEMPLATE, MAP, TRIGGER, TRIGGERGROUP)
- [Done] Supports Triggers which are calculation rules to determine states
- [Done] Triggers support an RPN (Reverse Polish Notation) calculation engine which includes mathematical and logical operators
- [Done] Each TRIGGER is associated with a severity level, WARNING or CRITICAL
- [Done] Multiple TRIGGERS can be associated with a TRIGGERGROUP
- [Done] Use builtin Python Operators
- [Done] Support DERIVE, TEXT, GAUGE and COUNTER data types
- [xxxx] Support TIMETICKS data type
- [Done] Support applying RPN based calculations to received metric for scaling or conversion purposes
- [Done] Use a Python SNMP library which supports asynchronous acquisition PySNMP
- [Done] Datasources can use rule based runtime instance mapping
- [Done] Set Snmp version as a check runtime option
- [Done] Set Snmp DSTEMPLATE as a check runtime option
- [Done] Set Snmp TRIGGERGROUP as a check runtime option
- [Done] Set Snmp COMMUNITY as a check runtime option
- [Done] Use Snmp version 2c GetBulk
- [xxxx] Support Snmp version 2c GetNext if GetBulk is not supported
- [xxxx] Support Snmp version 1 GetNext
- [xxxx] Set Snmp Timeout as a check runtime option, instead of a hardcoded value at 5 seconds
- STATUS - DESIGN SPEC MAINTAINABILITY
- [xxxx] Functions documented in the source code
- [Done] Critical functions documented in the source code
- [Done] Locking sections identified in the code
- [xxxx] Unit tests with at least 80% coverage

- [xxxx] Unit tests integrated with Shinken test suite
- [Done] Code hosted on github
- [xxxx] configuration validity and integrity checking of all INI files
- [xxxx] Pep8 compliant
- [xxxx] Pylint pass

genDevConfig Plugins - Compatibility status with SnmpBooster

- STATUS - genDevConfig maintained Plugins
- [Done] Avaya ES switches
- [Done] Avaya ERS routing switches
- [Done] Cisco 29x0 switches
- [Done] MIB-II Interfaces
- [Done] Cisco PIX/ASA
- [Done] JUNOS devices
- [Done] Cisco IOS routers
- [Done] NetSNMP unix hosts ** Validation required**
- [Done] Packeteer devices ** Validation required**
- [Done] Sensatronics devices ** Validation required**
- [Done] Foundry devices ** Validation required**
- [Done] Packeteer devices ** Validation required**
- [Done] Cisco CSS ** Validation required**
- [InProgress] New Cisco Access points
- STATUS - Other maintained Plugins

Tip: [xxxx] Denotes a specification that is planned but not implemented

[InProgress] Denotes a specification that is under development

[Done] Denotes a specification that is implemented

SnmpBooster reference dictionary

- Jump back to *SnmpBooster documentation index*

SnmpBooster.ini dictionary

There are five dictionaries:

- [DATASOURCE]
- [DSTEMPLATE]
- [MAP]
- [TRIGGER]

- [TRIGGERGROUP]

DATASOURCE DICTIONARY OidVariableName refers to an actual OID that can be queries using SNMP against the device on the network.

[VariableName] refers to a Datasource and all the information required to gather and prepare the data using SNMP ds_type refers to how the data should be prepared ds_calc refers to any scaling manipulations to make the data more understandable. This is an RPN expression, where the first variable is omitted, as it is always the $OidVariable ds_oid refers to the actual $OidVariable name. An instance identifier can be appended to the name to signify that an instance is provided by the Shinken service definition. This information is passed when the check is called. ...

DSTEMPLATE DICTIONNARY [DsTemplateName] refers to the name of the DSTEMPLATE that will be referred to in the Shinken service definitions. ds refers to the list of DATASOURCES to be collected. If an instance is expected for the list of DATASOURCES, it MUST be the same instance for all Oids. If a different instance is required, use a second DSTEMPLATE.

TRIGGER DICTIONNARY

TRIGGERGROUP DICTIONNARY

MAP DICTIONNARY

SnmpBooster.ini example configuration This example definition will be used to explain each section.

[DATASOURCE]

```
OidmyOidDefinition = .1.3.6.1.45.0
[myOidDefinition] ; Use the same name as the myOidDeiniftion, but omit the leading "Oid"
    ds_type = DERIVE
    ds_calc = 8,*  ; RPN expression : Oid, 8, *  Which means Oid * 8 = Total
    ds_oid = $OidmyOidDefinition
```

[DSTEMPLATE]

```
[myCiscoRouter]
    ds = myOidDefinition
```

[TRIGGER]

```
[trigger1]
    warning = RPN expression
    critical = RPN expression
[trigger2]
    warning = RPN expression
    critical = RPN expression
```

[TRIGGERGROUP]

```
[CiscoRouterTriggers]
    triggers = trigger1, trigger2
```

SnmpBooster.ini configuring SNMP Datasources

The first location is generic data related to SNMP parameters.

- DATASOURCE information * SNMP OID * Type of data and how can it be interpreted (GAUGE, COUNTER, COUNTER64, DERIVE, DERIVE64, TEXT, TIMETICK) * Data format preparation (Scaling the data for example bits to bytes) * Is there an instance to append to the
- Instance MAP function * Mapping the instance dynamically using a function * Data or rules related to the mapping function

SnmpBooster.ini configuring SNMP DSTEMPLATES

- DSTEMPLATEs to associate DATASOURCE to actual device classes * List of DATASOURCES associated with a, for example, Cisco 1900 router. Which in turn can be applied to a Shinken service

SnmpBooster.ini setting triggers/thresholds

- TRIGGER and TRIGGERGROUPS to apply thresholding rules * Define triggers and associate them with a TRIGGERGROUP name that can be applied to a Shinken Service

Shinken integrated SNMP Module

Overview

- Jump back to *SnmpBooster documentation index*

Tip: The module is now in public beta as of 2012-10-26! Have Fun!

Nothing new to add, more to come in 2013. 2013-01-19.

What is it The SnmpBooster module allows Shinken Pollers to directly manage SNMP data acquisition. This is an all Python cross-platform SNMP module. It is tightly integrated with the Shinken Poller, Scheduler and Arbiter daemons to provide the best possible user experience.

Why use it The SnmpBooster module is designed to be very efficient and scalable. It has a very flexible configuration method to make it easy to use with Shinken Monitoring Packs and Shinken discovery runners like genDevConfig.

This acquisition module was professionally designed and developed.

It is meant to be used by the very capable discovery engine genDevConfig (**v3.0.5 and newer**) originally developed for the Cricket SNMP monitoring tool and converted for use with Shinken.

It is one of the very few serious SNMP v2c implementation making use of SnmpGetBulk type requests.

How does it work

Shinken Integration

1. The SnmpBooster Arbiter module reads the Shinken SnmpBooster configuration file(s). It reads the check commands and based on the values in the check commands that use the snmp_poller module it will creates a shared configuration cache using memcached/memcachedb. The memcache key is always the combination of the hostname. This permits to tie together Shinken Hosts and Services with the SNMP specific configuration. (MongoDB and Redis are planned to be supported in the future) The Scheduler daemon schedules Host and Service checks as it normally does.

3. The SnmpBooster module will check that a memcache host key exists for the check to be launched. Then the SnmpBooster poller module will query all services related to a host for a given acquisition frequency in one pass. (all checks done every 2 minutes will be executed in bulk, same for those every 5 minutes)

5. Check results are cached for the acquisition check_interval. The next time a check request for data from the same host is received from the Scheduler, the data will be fetched from memcache. Resulting is extremely low check latency.

2. 6. The SNMP checks still benefit from retries, timeouts, forced checks, dependencies and the powerful Scheduler daemon logic.

6. The Scheduler daemon can still force an immediate re-check by flushing the cache. This is required for the dependency model.

Performance SnmpBooster uses SNMP v2c getbulk for high efficiency, unless forced to use SNMP v2c get-next or SNMPv1 get-next. GetBulk uses a single request PDU to ask for multiple OIDs or even entire tables, instead of sending one request PDU per OID.

For example: *A typical 24 port network switch with two uplinks might use 375 OIDS (8 OIDs per interface, plus general OIDs for chassis health, memory, cpu, fans, etc.). **SnmpBooster will only require around 4 request PDUs*

*instead of 375 request PDUs**. Each PDU is a request packet which takes time to create, send get processed and return. More timeouts to manage, more connections, more impact on the remote device and more latency means much fewer checks per second.*

The SnmpBooster module supports automatic instance mapping for OIDs. (Ex. Based on the interface name it will figure out that the SNMP index(or instance) is 136. This is automatically handled by genDevConfig and SnmpBooster, no user input required. :-)

The generic SNMP configuration information is stored in the Shinken SnmpBooster INI files. There is a Defaults_unified.ini and a series of other Defaults files, one per discovery plugin for genDevConfig.

Important: genDevConfig plugins have all been converted to use the new dynamic instance mapping methods. You are now free to use most if not all Defaults*.ini files included with genDevConfig. 2012-10-28

Limitations You should have memcached instances running on each poller responsible for snmp polling. You should have your pollers with SnmpBooster in the same datacenter, as they need to be on the same machine with good connectivity to the active memcached instance. SnmpBooster is not compatible with distributed pollers in multiple datacenters, sorry, the current design of SnmpBooster uses a single centralized memcached instance for storing the timeseries data. For distributed datacenters to be supported, each poller+scheduler+memcached must be realm restrained, which is not the case today.

Design specification *SnmpBooster design specification* and current development status.

Data model The information required to define the data is split in two locations.

The first location is the host and service Shinken configuration (You need to generate or write this)

- Device specific information
  - IP addresses, host_names, device types, instance keys
  - A DSTEMPLATE must be referred to in the Service definition
  - A static SNMP instance could be referred to in the Service definition
  - An SNMP instance MAP function could be referred to in the Service definition
  - A TRIGGERGROUP could be refered to in the Service definition

The second location is SNMP Defaults.* templates. (Here you can create new devices or add new data sources)

- DATASOURCE information
  - SNMP OID
  - Type of data and how can it be interpreted (GAUGE, COUNTER, COUNTER64, DERIVE, DERIVE64, TEXT, TIMETICK)
  - Data format preparation (Scaling the data for example bits to bytes)
  - Is there an instance to append to the
- Instance MAP function * Mapping the instance dynamically using a function * Data or rules related to the mapping function
- DSTEMPLATEs to associate DATASOURCE to actual device classes * List of DATASOURCES associated with a, for example, Cisco 1900 router. Which in turn can be applied to a Shinken service
- TRIGGER and TRIGGERGROUPS to apply thresholding rules * Define triggers and associate them with a TRIGGERGROUP name that can be applied to a Shinken Service

A final location containes rules to build your Shinken configuration.

- genDevConfig plugins create Shinken configurations

Installation and configuration *SnmpBooster installation*

Reference Dictionnary *SnmpBooster reference dictionary*

Troubleshooting *SnmpBooster troubleshooting*

Graph templates These are .graph files defined in your Shinken configuration directory. Refer to the Shinken graphite templates(Not yet created) or PNP4Nagios how-to documentation. The graph templates are independent from SnmpBooster and provide templates for any collected data from Shinken.

SnmpBooster Troubleshooting

- Jump back to *SnmpBooster documentation index*

Check your config

- Have you defined the poller module name?
- Have you defined the correct path to the directory containing your Defaults*.ini files?
- Have you addded the Snmpbooster module to your arbiter, poller, scheduler?
- Have you added copied the genDevConfig templates.cfg in shinken/packs/network/SnmpBooster/
- Have you installed PySNMP, memcached and other dependencies?

Software version consistency Shinken and SnmpBooster now require **the same Python and Pyro version on all hosts running a Shinken daemon**.

If you cannot use the packaged version of Python and its modules (Pyro, memcached, etc.). Use virtualenv to declare a python version to use and install all required modules in that virtualenv.

Software version requirements Have you verified that the *requirements* are met. Python, PySNMP, Shinken, Pyro, memcached, etc.

Validate your check command arguments Use the check_plugin command and comment out the module to learn what were the exact arguments sent by the poller. This will permit you to validate all the arguments, like snmp community string, inheritance, template application, etc.

Validate connectivity

Take a packet trace using a tool like Wireshark to validate that the remote host is responding.

- Has the host responded
- **Is SnmpBooster repeating the request more often than the polling interval.**
  - If you are seeing repeated requests your device may have a compatibility issues.

- Save an snmpwalk of the device, get a packet trace using Wireshark, set the poller to debug and save the poller.log file (shinken/var/poller.log). Send all three to the SnmpBooster developers.
- Note: It is normal to see one or more bulkGet requests if you are getting large amounts of data. Ex. a 24 port switch will take 2-3 request packets.

Performance Make sure you have a low latency connection to your memcache from the Poller. Your memcache server can be replicated to all your poller hosts that should also run memcache instances. Check that memcached is running: netstat -a | grep memcached

Faulty Template A bad snmp_template file was distributed in the genDevConfig sample-config directory, there were two glaring errors.

This was fixed on 2012-10-16. Make sure you update your template, or use the data from the wiki.

Note that the template should be called: SnmpBooster-template.cfg to make it easier to troubleshoot in the logs. So when you search for SnmpBooster in your logs it will show up as well.

Log files All warnings and errors generated by the SnmpBooster module start with "[SnmpBooster] error text" and are logged using the standard Shinken logger.

The Arbiter daemon can output initial configuration, loading of host keys and intervals in memcached type error messages. The Scheduler daemon can output scheduling and alert related messages. The Poller daemon can output messages related to instance mapping, acquisition timeouts, invalid community strings, cache failures and more. These are available in the Web interface, as they are placed in the check results for the service.

You can simply do a "grep SnmpBooster *" in your shinken/var directory to see the latest messages related to the SnmpBooster module. You can also sort messages by timestamp to make it easy to find where and when errors occurred.

cd shinken/var grep SnmpBooster *

memcache persistence If you restart your memcache server or memcache crashes, your poller will no longer be able to validate that a host exists in memcache prior to writing.

You should use memcachedb to achieve persistence in case of memcache failures.

Common errors returned by SnmpBooster in the log file Errors should be fairly explicit and mean what they say, though there can be exceptions. Lets try to clear some of them.

__Arbiter log **errors__**

Missing ds_oid : This means that a variable in your OID definitions is missing, or your DATASOURCE is not named correctly or your ds_oid variable is missing. There is a typo in your ds_oid variable (ex. ds-oid, or ds_oid = $OidNameIncorrectFFFRA.%(instance)s).

Datasource not defined : Your DSTEMPLATE uses a DATASOURCE that doesn't exist check the [DataSourceName] you are referring to. Does it contain the expected OID variable, $OidName.

Missing ds_type : The DATASOURCE always needs to have a ds_type definition, GAUGE, COUNTER, DERIVE, TEXT, TIMETICK, DERIVE64, COUNTER64.

__Poller log **errors__**

Problems with calculations, repeated polling, hosts not responding, etc.

__Memcached **errors__**

memcachedb and memcached do not use the same default port. Configure the correct memcachedb port to match what is declared in your SnmpBooster module under shinken-specific.cfg.

On Ubuntu 12.04 the default installation is on port 21201 instead of 11211. This causes the error "[SnmpBooster] Memcache server (127.0.0.1:11211) is not reachable" when Shinken starts.

To change it, you must edit the file /etc/memcachedb.conf

Memcached Notes On Ubuntu 12.04 the default instalation is on port 21201 instead of 11211. This causes the error "[SnmpBooster] Memcache server (127.0.0.1:11211) is not reachable" when shinken starts.

To change it, you must edit the file /etc/memcachedb.conf

WebUI module This part must be splitted and sent in all module repositories

WebUI integration with Shinken The WebUI is an external broker module. So it's an external process launched by the broker that "eats" broks (broker messages) from the brokers. So it can get *all* broks if you place this broker in your top level realm.

The WebUI does not use a database to get data. Instead, it use a "regenerator" object that will eat each broks, and will "recreate" all Hosts/Services/Contacts objects as if the code was in the scheduler daemon. So basically, WebUI and pages always reflect the CURRENT state of hosts/services objects.

The WebUI http layer is managed by bottle.py. It's a small but powerful framework.

How does the WebUI function globally ?

There a 2 Threads running:

- the main thread is the bottle.py (http) listener. It will use the best backend it finds. We recommend using python-paste. If it does not find one, it will use the default swsgi. Paste is multi-thread, swsgi is mon-thread, so please use paste if you want to avoid locking problems.
- the 2nd thread is the regenerator one. It only gets broks and gives them to the regenerator object.

There is a lock system between the threads. You can have N Http requests in progress without problem, but during this time the renererator one will wait. During execution of the regenerator, no requests are processed. This is not considered a problem, as the regenerator is very quick, and there is only a 1s lock for a 7k service conf loading, so it's not a huge problem.

What is a WebUI User? A WebUI user is a contact. A true contact object. You must match a contact name for your user.

To create a new page? All pages are in the shinken/webui/plugins directory. Each "part" has it's own directory. A part (like the eltdetail, element detail) can have more than one "page" (like /host or /service for eltdetail).

From here we will supose you want to create a "/contact" page.

You can copy the dummy example in the plugins directory into a contact directory.

You need to change the contact/dummy.py file into a contact/contact.py file, because the webui will search for a dir/dir.py file to "load".

Templates Templates are HTML with some Python code in it in the plugins/*/views direcotry for specific templates, and the "global layout" (menu and all common part) in the webui/views directory.

Your template must call the template layout (layout.tpl in the webui/views directory) wit ha "rebase" call.

If you put the rebase call at the beginning of your template, all there is below will be place "inside" the layout that will call the common javascripts and css, make the menu adn then call your html/python code.

The rebase call can take arguments. You MUST give it:

- user: the user you give it in the return dict of your .py code

Then all is optional:

- title: title of the page
- top_right_banner_state: int, global state with clouds to put in your top right page. Look at the problem.tpl code for an example.
- js and css list: list of YOUR specific javascript or css to call AFTER the common ones.
- refresh: boolean, set the refresh to 60s or do not refresh at all

- menu_part: will put the little "^" under this part of the menu.

Example of a call, taken from the problems view:

```
rebase layout title='All problems', top_right_banner_state=top_right_banner_state, js=['problems/js/a
roblems/js/autocompleter.Request.js', 'problems/js/autocompleterObserver.js'], css=['problems/css/acc
ms/css/autocompleter.css', 'problems/css/perfometer.css'], refresh=True, menu_part='/'+page, user=use
```

Call Python objects in your templates Your templates are mainly HTML code. But of course you can call python code in it. The dict you returns in the plugin.py call will be available in this page.

For example, the my_host variable will be available in the page with the host object you find (or None if your give it a bad name of course). Then you can "call" python with for example here to show the host_name: `<span>My host name is *my_host.host_name* </span>` is a way in the templates to "call a variable or function" that will return a string, here the host_name.

If the function or property you call must return HTML code that SHOULD be output as it, without "protection", you must put a ! before your call.

Let use an example where the output value of an host is in fact an html output. If you use the code `my_host.output`, bottle.py will "protect" the html generated by escaping the string, and change <> characters with escaped value. You can change this by calling `my_host.output`. Of course, it's a security problem if the output is with a javascript code...

You can also "loop" or put "if" in your template. You just need to put your code with a % before. Like

```
%for i in xrange(1, 10):
  My valus is  {{i}}
%end
```

You must put the %end here, the indentation will NOT be enougth, sorry.

For an if it's also easy:

```
%if host.active_checks_enabled:
  The host got active checks enabled
%else:
  The host DO NOT have active check enabled
%end
```

Which javascript lib are you using? It's mootools 1.3 with all options :)

What to do?

- Finish the /mobile part
- List of current alerts
- Host info
- Host status
- Host interfaces
- Hostgroup status
- dashboard hierachique with states, and BP
- Nagvis
- add bp in nagvis auto-map

- event sources
- correlation
- pre-filtering/enrichment
- user profile
- host/srv conf

WebUI search syntax work in progress

not that we couldn't tell. ;) eh eh

beware the working men and flying tools!

WebUI SSL Certification Lets start: the goal to to have the server.pem and client.pem file in etc/certs.

Go to the etc/certs directory.

```
openssl req -new -nodes -out server.req -keyout server.key -config ./shinken_openssl_cnf
openssl ca -out server.pem -config ./shinken_openssl_cnf -infiles server.req
cp server.pem server.pem.bkp
cp server.key server.pem
cat server.pem.bkp >> server.pem
cp server.pem client.pem
```

You can try to get the validity with for the arbiter with:

```
openssl s_client -connect localhost:7770</code>
```

Amazon AWS/EC2 import

Description You can import data from Amazon AWS/EC2 **'AWS'**_ into Shinken to create hosts.

Amazon provide VM hosting with EC2. With this arbiter module, you will be able to load your EC2 hosts into Shinken.

Prerequisites

You will need the **'libcloud'**_ package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

```
define module {
 module_name      AWS
 module_type      aws_import

 # Configure your REAL key and secret for AWS
 api_key              PAAAB2CILT80I0ZA0999
 secret           GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH
 default_template generic-host        ; if the host is not tagged, use this one
 }
```

- Put in key and secret your private Landscape access. * default_template will be used if your host is not "tagged" in Landscape

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master

     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           AWS
     }
```

Restart your Arbiter and it's done :)

Generated hosts The configuration generated will look as below :

```
define host {
    host_name            i-3fc56e5a
    address              8.8.4.4
    use                  t1.micro,MyTag,EC2,generic-host
    _EC2_AVAILABILITY    us-east-1a
    _EC2_CLIENTTOKEN
    _EC2_DNS_NAME
    _EC2_GROUPS          quicklaunch-1
    _EC2_IMAGEID         ami-1b814f72
    _EC2_INSTANCEID      i-3fc56e5a
    _EC2_INSTANCETYPE    t1.micro
    _EC2_KERNELID        aki-825ea7eb
    _EC2_KEYNAME         testaws
    _EC2_LAUNCHDATETIME  2012-09-26T12:19:38.000Z
    _EC2_LAUNCHINDEX     0
    _EC2_PRIVATE_DNS
    _EC2_PRIVATE_IP
    _EC2_PRODUCTCODE
    _EC2_PUBLIC_IP       8.8.4.4
    _EC2_RAMDISKID       None
    _EC2_STATUS          stopped
    _EC2_TAGS            demo:myvalue,use:MyTag
 }
```

Here with a stopped t1.micro instance with no name. You can put your how "use" parameter by adding a EC2 tag "use" on your VM. It will be output on the host configuration so you can setup the monitoring as you want. .. _libcloud: http://libcloud.apache.org/index.html .. _AWS: https://console.aws.amazon.com

Amazon AWS/EC2 import

Description You can import data from Amazon AWS/EC3 **'AWS'**_ into Shinken to create hosts.

Amazon provide VM hosting with EC3. With this arbiter module, you will be able to load your EC2 hosts into Shinken.

Prerequisites

You will need the **'libcloud'**_ package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

```
define module {
 module_name      AWS
 module_type      aws_import

 # Configure your REAL key and secret for AWS
 api_key              PAAAB2CILT80I0ZA0999
 secret           GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH
 default_template generic-host        ; if the host is not tagged, use this one
 }
```

- Put in key and secret your private Landscape access. * default_template will be used if your host is not "tagged" in Landscape

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master

     address          localhost                  ;IP or DNS adress
     port             7770
     spare            0
     modules           AWS
     }
```

Restart your Arbiter and it's done :)

Generated hosts The configuration generated will look as below :

```
define host {
    host_name            i-3fc56e5a
    address              8.8.4.4
    use                  t1.micro,MyTag,EC2,generic-host
    _EC2_AVAILABILITY    us-east-1a
    _EC2_CLIENTTOKEN
    _EC2_DNS_NAME
    _EC2_GROUPS          quicklaunch-1
    _EC2_IMAGEID         ami-1b814f72
    _EC2_INSTANCEID      i-3fc56e5a
    _EC2_INSTANCETYPE    t1.micro
    _EC2_KERNELID        aki-825ea7eb
    _EC2_KEYNAME         testaws
    _EC2_LAUNCHDATETIME  2012-09-26T12:19:38.000Z
    _EC2_LAUNCHINDEX     0
    _EC2_PRIVATE_DNS
    _EC2_PRIVATE_IP
    _EC2_PRODUCTCODE
    _EC2_PUBLIC_IP       8.8.4.4
    _EC2_RAMDISKID       None
    _EC2_STATUS          stopped
    _EC2_TAGS            demo:myvalue,use:MyTag
 }
```

Here with a stopped t1.micro instance with no name. You can put your how "use" parameter by adding a EC2 tag "use" on your VM. It will be output on the host configuration so you can setup the monitoring as you want. .. _libcloud: http://libcloud.apache.org/index.html .. _AWS: https://console.aws.amazon.com

The distributed retention modules The high availability allow the Arbiter to send a configuration to a spare scheduler, but a spare scheduler does not have any saved states for hosts and services. It will have to recheck them all. It's better to use a distributed retention module so spares will have all the information they need to start with an accurate picture of the current states and scheduling :)

Non distributed retention modules If you are just running tests on a single server, use the pickle or memcache retention modules You can also use MongoDB if you already have it installed for use with the WebUI.

MongoDB MongoDB is a scalable, high-performance, open source NoSQL database written in C++.

Step 1: Install MongoDB:

We will use mongodb package from 10gen repository, so we start by adding it in apt sources list:

```
echo 'deb http://downloads-distro.mongodb.org/repo/debian-sysvinit dist 10gen' > /etc/apt/sources.lis
apt-get update
```

And we install it:

```
apt-get install mongodb-10gen
```

And we install pymongo, the python interface to MongoDB, with easy_install to avoid packages versions problems (like here **'forums.monitoring-fr.org/index.php?topic=5205.0'_**):

```
apt-get remove python-pymongo
easy_install pymongo
```

And finally we start MongoDB :

```
/etc/init.d/mongodb start
```

Step 2: define a mongodb_retention module in your shinken-specific.cfg file:

```
define module {
  module_name MongodbRetention
  module_type mongodb_retention
  uri mongodb://localhost/?safe=true
  database shinken
}
```

Step 3: Declare a retention module for your scheduler(s) :)

Example:

```
#The scheduler is a "Host manager". It get hosts and theirs
#services. It scheduler checks for them.
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
     port     7768                  ; tcp port of the daemon

     #optionnal: modules for things as retention
     modules    MongodbRetention
     }
```

Step 4: Restart the Arbiter, and your Scheduler will now save its state between restarts. :)

Memcached Memcached is a distributed memory resident key/value server. It's very easy to install:

```
sudo apt-get install memcached
sudo /etc/init.d/memcached start
```

The shinken module also needs the python-memcache package to talk to this server.

```
sudo apt-get install python-memcache
```

To use it,

Step 1: define a memcache_retention module in your shinken-specific.cfg file:

```
define module{
     module_name      MemcacheRetention
     module_type      memcache_retention
     server           127.0.0.1
     port             11211
}
```

Step 2: Declare a retention module for your scheduler(s) :)

Example:

```
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
     port     7768                  ; tcp port of the daemon

     #optional: modules for things as retention
     modules    MemcacheRetention
     }
```

Step 3: Restart the Arbiter, and your Scheduler will now save its state between restarts. :)

Redis Redis is a distributed key/value server (on disk and in-memory). It's very easy to install:

```
sudo apt-get install redis-server
sudo /etc/init.d/redis-server start
```

The shinken module also need the python-redis package to talk to this server.

```
sudo apt-get install python-redis
```

Step 1: define a redis_retention module in your shinken-specific.cfg file:

```
define module{
     module_name      RedisRetention
     module_type      redis_retention
     server           127.0.0.1
}
```

Step 2: Declare a retention module for your scheduler(s) :)

Example:

```
#The scheduler is a "Host manager". It get hosts and theirs
#services. It scheduler checks for them.
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
```

```
    port     7768                  ; tcp port of the daemon

    #optionnal: modules for things as retention
    modules    RedisRetention
    }
```

Step 3: Restart the Arbiter, and your Scheduler will now save its state between restarts. :) .. _forums.monitoring-fr.org/index.php?topic=5205.0: http://forums.monitoring-fr.org/index.php?topic=5205.0

How to enable and use Livestatus module

Define the Livestatus module Start by reviewing the ''/etc/shinken/shinken-specific.cfg" file for this module:

```
define module{
```

```
module_name      Livestatus
module_type      livestatus
host             *       ; * = listen on all configured IP addresses
port             50000   ; port to listen on
database_file    /var/lib/shinken/livestatus.db
```

}

With these parameters:

- module_name: name of the module called by the brokers
- module_type: livestatus
- host: IP interface to listen to. The default is *, which means "listen on all interfaces".
- port: TCP port to listen to.
- socket: Unix socket to listen to.
- database_file: the path to the sqlite database file which is used to store the log broks/messages. The default is "var/livelogs.db"
- max_logs_age: the maximum age of the log messages (before they are deleted from the database). The default is 1 year. The argument to this parameter takes the form <number>[<period of time>], where <period of time> can be d for days, w for weeks, m for months and y for years.
- allowed_hosts: a comma-separated list of IP-addresses which are allowed to contact the TCP port. Please keep in mind that these **must be IP-addresses, NOT host names**. Because DNS lookups for every incoming livestatus request could hang up and therefore block the module.

Enable the Livestatus module Still in ''/etc/shinken/shinken-specific.cfg'', find the object Broker and add "Livestatus" to its "modules":

```
define broker{
```

```
    broker_name      broker-1
[...]
```

```
    modules          Simple-log,Livestatus
}
```

Disable human readable logs In ‘’/etc/shinken/nagios.cfg’‘, verify that the option **human_timestamp_log** is set to **0**.

In version 0.6.5, you can not have at the same time a simple-log file with human readable timestamp and a Livestatus database.

Exporting data for reporting Shinken can export necessary data for reporting in 3rd party systems.

raw_socket module The raw socket module exports reporting data using a syslog format to a raw TCP socket. Theses logs can be captured, parsed and indexed by any log management system like Splunk or Logstash.

Why export reporting data Custom UIs like Thruk, Multisite, WebUI, Adagios, Nagios IX, etc. All have poor or inflexible reporting. Simply because these are not reporting engines.

This also permits to have a generic reporting method that can accept data from any Nagios, Shinken, Icinga or even Riemann.

Reporting module using Splunk Splunk was selected as the reporting platform for creating, managing and presenting reports. Though the raw_socket module does not have any Splunk specific particularities. It is notable that Splunk reports can be embedded in any 3rd party UI using its REST API.

Raw_socket log format The logs are plain-text and compliant with RFC3164. They use an intelligent date format, a configurable seperator ” “(space by default), and key=value pairs in the message data portion of the log. Should a key or value contain a space they must be double quoted. This is syslog using structured data without going to full out JSON that may not be compatible with all log management systems.

The message fields that are supplied in each status update in addition to the standard syslog header are:

- Hostname
- Servicename
- Business impact
- Host/Service status
- Host/Service previous status
- Acknowedgement status
- Maintenance status

Any time the maintenance, host, service or acknowledgement status changes, a log is sent by the Shinken raw_socket module.

Having all relevant data in each log makes it very easy to compute reports for given time periods.

The hostgroup or service group memberships, custom variables or any other configuration related data should be queried from the monitoring system using its API (Livestatus in the case of Shinken and Nagios).

Raw_socket module availability The module is available in both Shinken 1.4 and Shinken 2.0. The module will be integrated in master branches once unit tests and end-to-end testing is completed. 3rd quarter 2013.

Monitoring Linux System with Glances and checkglances.py **‘Glances‘_** is a fantastic multiplatform system monitoring tool writen by Nicolargo. Glances can run on (Linux, Windows, MacOS ...). There is a growing ecosystem around Glances and of course a Nagios/Shinken plugin : checkglances.py.

How does it work Glances can run in server mode. It provide a XML-RPC server (over http) and allow to retrieve system information throuh a restful API. The only thing to do is to install and start Glances as server on the monitored host, then install checkglances.py on the shinken server and finaly install the glances pack.

Install glances See the glances documentation to install glances on Linux.

<code bash> easy_install glances </code>

There is a debian startup script in the glances repository. And another one for centos here.

Install checkglances.py Just follow the documentation for the checkglances.py prerequisites and put it in your nagios plugins folder.

Install the glances pack Open a terminal as the shinken user and just type the following command

<code bash> shinken install glances </code>

Then just edit the configuration for a linux monitored host and tag it as **glances**

```
define host{
 name mylinuxhost
 use glances
 ...
```

Finaly restart the shinken arbiter

```
service shinken-arbiter restart
```

What will be monitored ? For the moment just the basic system (ram, cpu, load, memory, filesystem and network).

If you want to modify the default thresholds for just a host you can do it by overiding the thresholds macro in your host definition. If you want to do it for several hosts, declare a new template and just add the desired thresholds macro to be overide.

Here is a list of the macros

```
::
```

> _LOAD_WARN 2 _LOAD_CRIT 3 _CPU_WARN 80 _CPU_CRIT 90 _MEMORY_WARN 90 _MEMORY_CRIT 95 _FS /, /home _FS_WARN 90 _FS_CRIT 95 _IFACES eth0, eth1 _NET_WARN 7500000 _NET_CRIT 10000000

Note the _FS and _IFACES macros. They leverage the ability to duplicate service for a given list of things to be monitored. Here you see that / and /home partitions will be monitored. If you want to modify this then just add your own in a new template that will inherit the glances template.

Shinken GLPI integration Shinken supports importing hosts from GLPI

For people not familiar with GLPI, it is an Open-Source CMDB. Applicable to servers, routers, printers or anything you want for that matter. It is also a help-desk tool. GLPI also integrates with tools like FusionInventory for IT inventory management.

You can still have flat files AND GLPI if you want. Hosts imported from GLPI will be treated as standard hosts from flat file (inheritance, groups, etc). In fact, in this first version the module only sends the host_name to Shinken, but there should be more information extracted like network connexions for parents relations in the future. :)

Requirements

- python module MySQLdb
- Compatible version of GLPI Shinken module and GLPI version - ...
- etc..

Enabling GLPI Shinken module In your shinken-specific.cfg file, just add (or uncomment):

```
#You know GLPI? You can load all configuration from this app(
#with the webservices plugins for GLPI, in xmlrpc mode
#and with plugin monitoring for GLPI)
# =============== Work with Plugin Monitoring of GLPI ===============
#All configuration read from this will be added to the others of the
#standard flat file
define module{
     module_name      GLPI
     module_type      glpi
     uri              http://localhost/glpi/plugins/webservices/xmlrpc.php
     login_name       glpi
     login_password   glpi
}
```

And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master
#    host_name       node1       ;result of the hostname command under Unix
     address          localhost                  ;IP or DNS adress
     port             7770
     spare            0
     modules           GLPI
     }
```

It's done :)

Ip Tag module

Why tag a host based on it's IP address? We learned on the *DMZ monitoring* that you can "tag" a host with a poller_tag so it will be checked only by DMZ pollers. It can be tedious process to manually tag all these hosts. Shinken provides an automated method to do this.

This is handled by the arbiter ip_tag module.

Ip_tag module The ip_tag module is an arbiter module that looks up the host address during the configuration parsing and compares it to an predefined IP range (IPV4 or IPV6). If the range matches, it can apply or add a property, such as poller_tag. Other types of tags could be related to locations, functions, administrative groups, etc.

Method: replace or append.

replace will put the value if the property is unset. This is the default method. .. warning:: Fix me: replace, implies overriding an existing value. And will cause user issues down the line. Rename it to set. Replace should be a different method altogether, so overall there should be 3 methods(set, append, replace).

append will add with a , if a value already exist

Here is an example that will set the poller_tag property with the value DMZ of all hosts that:

- have a their hostadress ip (or name resolved) in the range 192.168.0.1/24.
- do not already have a poller_tag property set

```
define module{
```

```
     module_name     IpTag
     module_type     ip_tag
     ip_range        192.168.0.1/24
     property        poller_tag
     value           DMZ
}
```

To use the module add it in the arbiter object:

```
::
```

define arbiter { [...] modules NSCA,IpTag

}

Add value instead of setting it In the previous example we set the property poller_tag to a value. But what if we want to "add" a value, like a template name? We can change the "method" property of the module to "append" so we can add the "value" to the host property instead of replace it.

Here is an example where we want to add the "dmz" template on the hosts, while also keeping any defined templates:

```
define module{
```

```
     module_name   IpTag
     module_type   ip_tag
     ip_range      192.168.0.1/24
     property      use
     value         dmz

     # Optional method
     method append
}
```

For a host defined as:

```
define host{
```

```
     host_name   example_host1
     address     192.168.0.2
     use         linux
}
```

It will be "changed" internaly in:

```
define host{
```

```
     host_name   example_host1
     address     192.168.0.2
     use         linux,dmz
}
```

Name resolution Of course you don't need to set IP address in the address of your host. You can set a hostname, and it will be resolved, and then compared to the range. :)

Ubuntu Landscape import

Description You can import data from Ubuntu Landscape into Shinken to create hosts.

Ubuntu Landscape, is a web app to manage all your linux servers (update and co), which is provided by Canonical, Ubuntu's parent company.

This is an Arbiter import module. The Arbiter manages the configuration.

Prerequisites

You will need the landscape-api package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

define module { module_name Landscape module_type landscape_import

Configure your REAL key and secret from Landscape key PAAAB2CILT80I0ZA0999 secret GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH default_template generic-host ; if the host is not tagged, use this one

If you are using a specific certificate for landscape_api #ca /path/to.ca.cert

If you need a proxy to access https://landscape.canonical.com/api/ #https_proxy http://user:secret@myproxy.com:3128

}

- Put in key and secret your private Landscape access.
- default_template will be used if your host is not "tagged" in Landscape
- If you are using a specific certificate for connexion, give the full path in ca
- You will certainly need an https proxy to access the Landscape API. If so, configure it there.

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master
#    host_name       node1       ;result of the hostname command under Unix
     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           Landscape
     }
```

Restart your Arbiter and it's done :)

Tip: Your "tags" will be applied as templates for your hosts.

Shinken Livestatus API

Overview

- Jump back to Getting Started
- Jump back to *Livestatus module configuration*

What is it Livestatus API is the modern method of interacting with Shinken and Nagios based systems alike.

Originally developed for Nagios, MK Livetstatus, was re-implemented in Python for use with Shinken by professional developers. The access methods and query languages are the same.

Why use it It is fast.

It is network based using TCP.

It is standard for all Nagios and Shinken monitoring systems.

It uses in-memory structures for status data

It uses a back-end database for historical reporting

It uses an SQL based query language

It has a host of powerful nuts and bolts features (authentication, caching, connection persistence, multiple object methods (JSON, Python)).

What can I do with it? All programs and scripts use (or should use) this method to :

- Obtain the current state of hosts and services
- Obtain the current configuration related to hosts and services
- Send administrative commands (downtimes, comments, forcing checks)
- Filter information to display
- Obtain basic reports and event statistics

Shinken being a modern re-implementation of Nagios has additional features that are available in addition to the standard Livestatus API.

Shinken Livestatus API unique features can :

- Obtain Business Impact information
- Obtain intelligent dependency status hosts or services (combines dependency and parent information)
- Obtain Business Process states (same syntax as standard host and service queries)

How does it work Livestatus uses a powerful SQL-like query language. The standard methods and parameters are defined at :

'MK Livestatus reference methods and query language definition'_

Full list of Shinken Livestatus API methods:

'Shinken mapping.py methods'_

What software uses Livestatus to interact with Shinken

Well known Web frontends

- MK Multisite
- Thruk
- NagVis

- Splunk for Nagios

Mobile Web frontends

- get list

Scripts

- Downtime management scripts
- Debug scripts

Installing Livestatus Have you installed the required packages to use the Livestatus module? You can look at the requirement section of the *10 minute installation guide* for the *requirement lists*.

How to enable Livestatus Very simple, jump to the *Shinken Broker configuration* section to enable it. .. _Shinken mapping.py methods: https://github.com/shinken-monitoring/mod-livestatus/blob/master/module/mapping.py .. _MK Livestatus reference methods and query language definition: http://mathias-kettner.de/checkmk_livestatus.html

NSCA module The NSCA daemon module is used to receive send_nsca packets and submit them to the Shinken command pipe. The NSCA module can be loaded by the Receiver or Arbiter process. It will listen on port TCP/5667 for send_nsca packets.

Tip: Passive checks can be submitted *natively to the Shinken command pipe* or from remote hosts to modules, such as NSCA, AMQP or collectd, loaded in the Shinken Arbiter or Receiver process. AMQP is implemented for integration with the Canopsis Hypervisor, but could be re-used for generic messaging.

Note: The Shinken NSCA module implementation is currently limited to the "xor" obfuscation/encryption.

In your shinken-specific.cfg file, just add (or uncomment):

```
::
```

#You can send check result to Shinken using NSCA #using send_nsca command define module{

module_name NSCA module_type nsca_server host * port 5667 encryption_method 0 password helloworld

}

define receiver{

```
receiver_name    receiver-1
address          localhost
port             7773
modules          NSCA

timeout          3             ; 'ping' timeout
data_timeout     120           ; 'data send' timeout
max_check_attempts       3     ;  if at least max_check_attempts ping failed, the node is DEAD

#advanced
realm    All
}
```

This daemon is totally optional.

It's main goal is to get all passive "things" (checks but why not other commands) in distant realms. It will act as a "passive receive buffer" and will then dispatch the data or commands directly to the appropriate Scheduler or Arbiter process.

Data can be received from any Realm, thus the Realm option is nonsensical.

For now there is no init.d script to launch it. .. note:: Verify that the init script has been added.

It is launched like all other daemons:

```
bin/shinken-receiver -c etc/receiverd.ini
```

Tip: Alternatively, for small installations with you can configure a modules inside your Arbiter instead of the Receiver. It will listen the TCP/5667 port for send_nsca packets.

To configure the NSCA module in your Arbiter instead of Receiver. Add the NSCA module to your Arbiter object configuration.

```
::
```

define arbiter{ arbiter_name Arbiter-Master

 # host_name node1 ;result of the hostname command under Unix address localhost ;IP or DNS adress port 7770 spare 0 modules NSCA

}

Retention troubleshooting The retention file contains the state of your host and services, so that they are kept when shinken is restarted.

Sometimes you'll want to inspect (and possibly fix) the retention file, in case you need to work-around a bug or simply better understand what is stored there.

When you use the PickleRetention module in the scheduler (cf. ''define scheduler" in ''shinken-specific.cfg''), you can simply manipulate the retention file using Python.

For this you can use the following code.

- It assumes Shinken is installed in ''/opt/shinken" with the retention file in ''/tmp/retention.dat'':
- Run and play with it interactively using ''ipython -i inspect_retention.py''.

```
#!/usr/bin/python
import pickle
import sys
sys.path.append('/opt/shinken')
import shinken

r = pickle.load(file('/tmp/retention.dat'))
h = r['hosts']

# Example:
# [(k,v) for (k,v) in h['your_host'].items() if k.find('downtime') >= 0]
#
# del h['your_host']
#
# for k,v in r['services'].items():
#     if 'your_host' in k:
#         del r['services'][k]
```

To save your changes:

- Stop Shinken: ‘’service shinken stop’‘
- Save the pickle: ‘’pickle.dump(r, open(‘/tmp/retention.dat’, ‘w’))’‘
- Start Shinken: ‘’service shinken start’‘

NRPE Module

What is it The NRPE module allows Shinken Pollers to bypass the launch of the check_nrpe process. It reads the check command and opens the connection by itself. It scales the use of NRPE for active supervision of servers hosting NRPE agents.

The command definitions should be identical to the check_nrpe calls.

How to define it The definition is very easy (and you probably just have to uncomment it):

```
define module{
     module_name       NrpeBooster
     module_type       nrpe_poller
}
```

Then you add it to your poller object:

```
define poller {
    [...]
    modules   NrpeBooster
}
```

Then just tag all your check_nrpe commands with this module:

```
define command {
   command_name   check_nrpe
   command_line   $USER1$/check_nrpe -H $HOSTADRESS$ -c $ARG1$ -a $ARG2$
   module_type    nrpe_poller
}
```

That’s it. From now on all checks that use this command will use Shinken’s NRPE module and will be launched by it.

Extending Shinken

Introduction There are a lot of “Modules” and “Addons” that are available for Shinken. Shinken can be extended by using different types of methods.

- Web interfaces from various open-source vendors can be used (Based on Livestatus API)
- Shinken itself can be extended using modules that are embedded into the various daemon processes

** (Arbiter, Poller, Receiver, Broker, Scheduler, Reactionner) * External software can provide functional enhancements for reporting, management or usability aspects

Shinken itself provides methods to extend the base functionality:

- *Broker modules* provide external access to runtime data from Shinken
- Poller modules such as *NRPE* and the *SNMP*
- Receiver modules like *NSCA* provide acquisition methods for Shinken

- Arbiter modules permit manipulating the configuration
- The webUI that permits embedding web interface elements

Independent software that works in concert with Shinken is available for:

- Monitoring remote hosts through agent software (*NIX, Windows, etc.)
- Submitting passive checks from remote hosts
- Managing the config files through a web interface
- Mobile phone UIs
- Desktop UIs and Hypervisors
- Desktop notification addons
- ...and much more

You can find many addons that are compatible with Shinken by visiting. The only caveat is that the addons should not use the status.dat file and preferably the modern API interfaces like Livestatus:

- Nagios.org
- SourceForge.net
- NagiosExchange.org
- Shinken community exchange for monitoring packs

Broker modules The broker module receives messages from the Schedulers related to host, service check results. In addition to that it receives a copy of the compiled configuration at startup. What is special about the broker, is that without modules, the broker does nothing. It makes the configuration and result data available to modules. Modules are the ones in charge of doing something with the data. This could be exporting this "raw" data into flat files, databases or exposing it as an API.

The modules are presented according to their use cases.

- Core modules
- Livestatus Module for frontends
- Exporting data to metric databases
- SQL based Modules for frontends
- Exporting data to logging management systems
- Legacy modules for migration purposes
- Modules no longer supported

Core modules

simple_log: get all logs into one file You can get a log for all your daemons in a single file. With the exception of Debug level logs which are not sent through the network as a safe guard. Shinken state messages are ONLY logged at the debug level in the local log files. These are the ALL CAPS states that some 3rd party interfaces use to mine data from the historical logs. Actual state messages are sent as objects between the various daemons.

It takes the parameters:

- module_name: name of the module called by the brokers

- module_type: simple_log
- path: path of the log file

Here is an example:

```
define module{
```

```
     module_name      Simple-log
     module_type      simple_log
     path             /usr/local/shinken/var/nagios.log
     archive_path     /usr/local/shinken/var/archives/
}
```

Syslog - Send all logs to a local syslog server Send all logs to a local syslog server. Support for remote syslog can be implemented if requested. Just lookup the syslog module, easy to modify. Use for example with Splunk, graylog2, Logstash, Elastic search, Kibana, or other log management and analysis system.

```
define module{
```

```
  module_name Syslog
  module_type syslog
}
```

Lightweight forwarder to Splunk Shinken state data from the local syslog can also be sent to a Splunk server for indexing, reports, SLA and analysis. Via syslog or better yet, the Splunk lightweight forwarder which supports, TCP, buffering and security parameters.

Livestatus API Module - Thruk, Nagvis and Multisite Web frontends There are three well known frontends and various small tools that can interface with the Livestatus API. This API is currently the most efficient method of sharing live data with external interfaces. It provides a rich query language similar to SQL, authentication, command execution, caching,connections persistence, multiple object methods (JSON, Python). All Livestatus data is kept in memory, there is no disk IO involved. It exposes configuration objects, the current state of the hosts and services as well as historical Shinken state log messages.

- MK Multisite
- Thruk
- NagVis

Have you installed the required packages to use the Livestatus module? You can look at the requirement section of the 10 minute installation guide for the requirement lists.

Livestatus Module

It takes the following parameters:

- module_name: name of the module called by the brokers
- module_type: livestatus
- host: IP interface to listen to. The default is '127.0.0.1'. '*' means 'listen on all interfaces'.
- port: TCP port to listen to.
- socket: Unix socket to listen to.

- allowed_hosts: a comma-separated list of IP-addresses which are allowed to contact the TCP port. Please keep in mind that these must be ip-addresses, NOT host names. (DNS lookups for every incoming livestatus request could hang up and therefore block the module)
- modules: a comma-separated list of modules (see below)
- pnp_path: relevant if you use the multisite gui. pnp_path points to the perfdata directory where the pnp4nagios data reside (it's the directory which contains a subdirectory for each host). Multisite needs it to display a small perfdata icon if a rrd file exists.
- To deactivate an input, the port- and socket-attributes can also take the value "none".

The Livestatus module itself can have sub-modules. In fact, it **must** have at least one submodule responsible for storing log events to a database, SQLite or MongoDB.

Livestatus module - Logstore Sqlite Stores log-broks to an sqlite database.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_sqlite
- use_aggressive_sql: Prefer the use of sql queries to pre-filter data prior to python filtering. This is required for very large installations, as the Python structures are not indexed when filtering. Optional argument set to 0 by default. To enable set the value to 1. Some erroneous output may occur, but informal testing has shown these corner cases do not occur.
- read_only: don't send any update to the database. Should be used when you run several livestatus modules : 1 instance is R/W, other are read only.
- database_file: the path to the sqlite database file which is used to store the log broks/messages. The default is 'var/livestatus.db'
- archive_path: the path to a subdirectory where database file archives will be created. Every day the data from the last day will be moved to an archive datafile. The default is 'var/archives'.
- max_logs_age: the maximum age of the log messages (before they are deleted from the database). The default is 1 year. The argument to this parameter takes the form <number>[<period of time>], where <period of time> can be d for days, w for weeks, m for months and y for years. This parameter is currently ignored. In future releases it will be used to automatically delete ancient database files.

Here is an example:

```
define module{
```

```
     module_name      Livestatus
     module_type      livestatus
     host             *       ; * = listen on all configured ip addresses
     port             50000   ; port to listen
     socket           /usr/local/shinken/var/rw/live
     modules          logsqlite
}
define module{
```

```
     module_name      logsqlite
     module_type      logstore_sqlite
     use_aggressive_sql     0 ; optional, by default set to 0. Only for large installations.
     database_file    /usr/local/shinken/var/livelogs.db
     max_logs_age     3m ; three months. Other time intervals are d=days, w=weeks, y=years
}
```

Livestatus module - Logstore MongoDB Stores historical log broks(inter daemon Shinken messages) to a MongoDB database. MongoDB is a distributed and very performant database that permits resilience and high availability. The current implementation has a few known broken pieces (some search functions are broken) and there are bugs in the implementation, so it is considered experimental until power users and developers have ironed out the bugs. It is the database of the future for Shinken.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_mongodb
- mongodb_uri: The address of the master. (Default: i_cant_write_the_uri_here_it_messes_the_wiki_up)
- replica_set: If you are running a MongoDB cluster (called a "replica set" in MongoDB), you need to specify it's name here. With this option set, you can also write the mongodb_uri as a comma-separated list of host:port items. (But one is enough, it will be used as a "seed")
- database: <undocumented>
- collection: <undocumented>
- max_logs_age: <undocumented>

The configuration looks quite similar to the sqlite one. **In a single-node installation and with decent amount of log traffic, the sqlite backend should be considered best practice, as it needs no extra software and is stable and fast (when run in-memory).**

Livestatus module - Logstore Null In case you don't need any logging (for instance, if you dedicate a livestatus module instance to nagvis), you can use this module.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_null

Network Based Modules - Graphite graphing Graphite is a graphing and data analysis tool. It is composed of a web frontend (graphite-web), fixed size databases (whisper) and data redistribution/munging daemon. (carbon) The first step is *having Graphite installed somewhere*, if you do not have Graphite installed, please do this and come back later.

Pre-requisite : Shinken 1.2.2+ is recommended for the best experience with Graphite.

graphite_perfdata: exports check result performance data to Graphite Export all performance data included in check results to Whisper databases managed by Graphite. Data is buffered, then exported once every broker time tick. (Once per second). Should a communication loss occur, it will buffer data for 5 minutes before dropping data. The tick_limit max is configurable, the only limitation is the amount of memory the buffered data can eat.

The graphite broker module (v1.2) sends data to graphite in the following format :

HOSTNAME.SERVICENAME.METRICNAME

It can be optionally enhanced to send it the following format :

_GRAPHITE_PRE.HOSTNAME.SOURCE.SERVICENAME.METRICNAME._GRAPHITE_POST

Each of the three variables are optional :

- The _GRAPHITE_PRE variable can be set per host/service to provide a more flexible naming convention. (ex. Prod.site1.Hostname.servicename)

- The _GRAPHITE_POST variable can be set per host/service to specify the more information concerning the variable being stored that graphite can use to determine the retention rule to use for the variable.
- The SOURCE variable can be set in shinken-specific.cfg for the WebUI module and the Graphite broker.

Metric names are converted from Shinken's format to a more restrictive Graphite naming. Unsupported characters are converted to "_" underscore. So do not be surprised to see that some names differ in the WebUI or directly in Graphite. Permitted characters in Graphite are "**A-Za-z_**.", the hyphen character is permitted from Shinken, though only future versions of Graphite will support it.

Performance data transfer method can be set to pickle, which is a binary format that can send data more efficiently than raw ascii.

It takes the following parameters:

- module_name: name of the module called by the brokers
- module_type: graphite_perfdata
- host: ip address of the graphite server running a carbon instance
- port: port where carbon listens for metrics (default: 2003 for raw socket, 2004 for pickle encoded data)
- use_pickle: Use a more efficient transport for sending check results to graphite instead of raw data on the socket (v1.2)
- tick_limit: Number of ticks to buffer performance data during a communication outage with Graphite. On tick limit exceeded, flush to /dev/null and start buffering again. (v1.2)
- graphite_data_source: Set the source name for all data coming from shinken sent to Graphite. This helps diferentiate between data from other sources for the same hostnames. (ex. Diamond, statsd, ganglia, shinken) (v1.2)

Here is an example:

```
define module {
```

```
module_name Graphite-Perfdata
host xx.xx.xx.xx
module_type graphite_perfdata
port 2004 ; default port 2003 for raw data on the socket, 2004 for pickled data
use_pickle 1 ; default value is 0, 1 for pickled data
tick_limit 300 ; Default value 300
graphite_data_source shinken ; default is that the variable is unset
}
```

SQL Based Modules - PNP4Nagios Graphing PNP4Nagios is a graphing tool that has a web interface for RRDTool based databases. Shinken can export performance data to an npcd database which will feed the RRD files (fixed sized round robin databases). You can *learn how to install PNP4Nagios* if you haven't done it already.

npcdmod: export perfdatas to a PNP interface Export all perfdata for PNP.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: npcdmod
- path: path to the npcd config file

Here is an example:

```
define module{
 module_name  NPCD
 module_type  npcdmod
 config_file  /usr/local/pnp4nagios/etc/npcd.cfg
}
```

SQL Based Modules - Frontend Centreon2 Centreon2 use a NDO database, so you will need the ndodb_mysql module for it.

ndodb_mysql: Export to a NDO Mysql database Export status into a NDO/Mysql database. It needs the python module MySQLdb (apt-get install python-mysqldb or easy_install MySQL-python).

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: ndodb_mysql
- database: database name (ex ndo)
- user: database user
- password: database user passworddt
- host: database host
- character_set: utf8 is a good one

Here is an example:

```
define module{
```

```
     module_name      ToNdodb_Mysql
     module_type      ndodb_mysql
     database         ndo       ; database name
     user             root      ; user of the database
     password         root      ; must be changed
     host             localhost ; host to connect to
     character_set    utf8      ;optionnal, UTF8 is the default
}
```

File based Legacy modules - perfdata export

service_perfdata: export service perfdatas to a flat file

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: service_perfdata
- path: path to the service perfdata file you want

Here is an example:

```
define module{
```

```
    module_name      Service-Perfdata
    module_type      service_perfdata
    path             /usr/local/shinken/src/var/service-perfdata
}
```

host_perfdata: export host perfdatas to a flat file

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: host_perfdata
- path: path to the host perfdata file you want

Here is an example:

```
define module{
```

```
    module_name      Host-Perfdata
    module_type      host_perfdata
    path             /usr/local/shinken/src/var/host-perfdata
}
```

Legacy File based Modules - Old CGI or VShell The Old CGI and VShell use the flat file export. If you can, avoid it! It has awful performance, all modern UIs no longer use this.

status_dat: export status into a flat file Export all status into a flat file in the old Nagios format. It's for small/medium environment because it's very slow to parse. It can be used by the Nagios CGI. It also export the objects.cache file for this interface.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: status_dat
- status_file: path of the status.dat file /usr/local/shinken/var/status.dat
- object_cache_file: path of the objects.cache file
- status_update_interval: interval in seconds to generate the status.dat file

Here is an example:

```
define module{
```

```
    module_name              Status-Dat
    module_type              status_dat
    status_file              /usr/local/shinken/var/status.data
    object_cache_file        /usr/local/shinken/var/objects.cache
    status_update_interval   15 ; update status.dat every 15s
}
```

Deprecated or unsupported modules

SQL Based MerlinDB This interface is no longer supported and is going to be completely removed from Shinken.

SQL based ndodb_oracle - Icinga web frontend using NDO Oracle This interface is no longer supported and is going to be completely removed from Shinken.

CouchDB: Export to a Couchdb database This interface is no longer supported and is going to be completely removed from Shinken.

TSCA (Thrift Service Check Acceptor) TSCA is a receiver/arbiter module to receive hosts and services check results. It provides the same functions as NSCA with additional features. High performance binary transmission, multi line output and auto generated clients for a variety of languages.

What is thrift ? Let's cut and paste the wikipedia definition from'en.wikipedia.org/wiki/Apache_Thrift'_ :

"Thrift is an interface definition language that is used to define and create services for numerous languages.[1] It is used as a remote procedure call (RPC) framework [..]. It combines a software stack with a code generation engine to build services that work efficiently to a varying degree and seamlessly between ActionScript, C#, C++ (on POSIX-compliant systems), Cappuccino, Cocoa, Erlang, Haskell, Java, OCaml, Perl, PHP, Python, Ruby, and Smalltalk."

Installation In any case, you have to install thrift with support for python (on the server side) and languages you want to use for clients.

Get it from thrift.apache.org or in your favorite distribution repository.

Server side Go to the tsca module directory and generate the python stub for the server side installation

```
cd shinken/modules/tsca
$ thrift --gen py tsca.thrift
```

Declare the module is shinken-specific.org

```
define module{
      module_name     TSCA
      module_type     tsca_server
      host            0.0.0.0
      port            9090
}
```

Samples clients There are three(3) client samples written in python, ruby and java in contrib/clients/TSCA of the Shinken distribution. You can use and extend them to send data directly in your code directly to Shinken's TSCA receiver/arbiter module.

The samples clients read a CSV file from stdin and send them the the TSCA running on localhost:9090. The CSV has the following format :

```
hostname,service description,output,rc
```

Any use of TCP in an application should take care not to block the program and to have very short timeouts. For applications that need non blocking functions, prefer a UDP based transport or a local buffer file with a separate application(send_nsca, thrift, etc) to forward your data to Shinken.

Ruby Generate the stub

```
$ thrift --gen rb ../../../shinken/modules/tsca/tsca.thrift
```

Run the client

```
$ cat file_state | ruby RubyClient.rb
```

Python Generate the stub

```
$ thrift --gen py ../../../shinken/modules/tsca/tsca.thrift
```

Run the client

```
$ cat file_state | python PythonClient.py
```

java Generate the stub

```
$ thrift --gen java ../../../shinken/modules/tsca/tsca.thrift
```

Compile the client

```
$ ant
```

Run the client

```
$ cat file_state | java JavaClientThrift
```

VMWare Arbiter module

How it works The arbiter has a module that allows the host->VM automatic host dependency creation. In fact, the module is far more generic than just this. It's a generic "host link dependencies" module.

It reads a mapping file (simple json format) with son->father links. It call an external script at a regular interval : the one I wrote is a VMWare mapping one. It used the check_esx3.pl (that all ESX admin should have) plugin and generate the mapping file. When this file is changed, the module reloads it, creates new links and deletes old ones. So when you VMotion a virtual machine, in the next pass, there will be creation of a new link and deletion of the old one in the scheduler that manages it :)

How to define it The definition is very easy :

```
define module{
     module_name       VMWare_auto_linking
     module_type       hot_dependencies
     mapping_file      /tmp/vmware_mapping_file.json
     mapping_command   /usr/local/shinken/libexec/link_vmware_host_vm.py -x '/usr/local/shinken/libex
     mapping_command_interval 60   ; optionnal
     mapping_command_timeout   300 ; optionnal
}
```

Then you add it in you arbiter object :

```
define arbiter {
    [...]
    modules   VMWare_auto_linking
}
```

So here, it will call the script /usr/local/shinken/libexec/link_vmware_host_vm.py with a listing of the vCenter vcenter.mydomain.com and generate the mapping file /tmp/vmware_mapping_file.json.

You can call : /usr/local/shinken/libexec/link_vmware_host_vm.py –help

for the full help on this script.

It looks at the file modification time each second. This command can also be launch by an external cron of course.

Note: So if you want to write a script that does this for XEN servers, all you need is to generate a json file with all the mapping. I didn't wrote the doc about this, but you can look in the test file for it, the format is very very easy :)

Here is an example of the JSON mapping file syntax:

%%:ref:*["host", "physical_host"], ["host", "virtual_machine"* <["host", "physical_host"], ["host", "virtual_machine">, "host", "physical_host"], ["host", "other_virtual_machine" <"host", "physical_host"], ["host", "other_virtual_machine">]%%

So just a list of couple 'host' string (from now only host are managed) and the host name.

Beware about it : you need the real host_name, including case.

Web Service Module The Ws_arbiter module is a Receiver or Arbiter module to receive passive check results from remote hosts via HTTP(s). This module is considered a work in progress but can be used for testing and improvement.

Configuring the Web Service Module If data is POSTed to this page, it will validate the data to determine if it is a service or host check result and submit the data to the Shinken external command queue.

The web service listens by default to TCP port 7760. The web service supports anonymous or authenticated access. Web service parameters are set in the Shinken-specific.cfg file, in the Ws_arbiter module. To enable the web service, simply add the module to your Arbiter or Receiver daemon configuration in Shinken-specific.cfg

Using the Web Service Module The web service listens for POSTs to: /push_check_result

Use curl or embed the HTTP calls in your software to submit check results.

curl -u user:password -d "time_stamp=$(date +%s)&host_name=host-checked&service_description=service-checked&return_code=0&output=Everything OK" http://shinken-srv:7760/push_check_result

Example with more readability:

```
curl
```

-u user:password -d "time_stamp=$(date +%s)

```
&host_name=host-checked
&service_description=service-checked
&return_code=0
&output=Everything OK
http://shinken-srv:7760/push_check_result
```

SNMP module This part must be splitted and sent in all module repositories

Shinken integrated SNMP Module

SnmpBooster Download Install and Configure

- *What is the SnmpBooster module*
- Install and configure the SNMP acquisition module. [You are here]
- *Reference - SnmpBooster troubleshooting*
- *Reference - SnmpBooster design specification*
- *Reference - SnmpBooster configuration dictionnary*

Downloads

The SnmpBooster module and genDevConfig are currently in public beta prior to integration within Shinken. You can consult t

- github.com/xkilian/genDevConfig
- github.com/titilambert/shinken/tree/snmp_booster/shinken/modules (snmp_booster branch) * Simply right-click and download snmp_poller.py then copy it to shinken/modules/

Requirements The SnmpBooster module requires:

- Python 2.6+
- Shinken 1.2+
- PySNMP 4.2.1+ (Python module and its dependencies)
- ConfigObj (Python module)
- python-memcached
- memcachedb or memcached package for your operating system (ex. For Ubuntu: apt-get install memcachedb) *Note*

The genDevConfig profile generator depends on:

- Perl 5.004+
- 4 perl modules available from CPAN and network repositories. genDevConfig/INSTALL has the installation details.

STRONGLY RECOMMENDED: Use the same version of Python and Pyro on all hosts running Shinken processes.

Installation SnmpBooster:

- Install the dependencies
- Copy the file snmp_poller.py from the git repository to your shinken/modules directory.
- Configuration steps are listed in the present web page.

genDevConfig:

- Download and extract the archive to your server.
- See genDevConfig/INSTALL on how to install and configure it.

Configuration

How to define the SnmpBooster module in the Shinken daemons You need to modify shinken-specific.cfg, which is located in $shinken/etc/shinken-specific.cfg

Arbiter daemon configuration Simply declare the module:

```
modules SnmpBooster</code>
```

Scheduler daemon configuration

Simply declare the module:

<code>modules SnmpBooster

Poller daemon configuration Simply declare the module:

```
modules SnmpBooster</code>
```

SnmpBooster Module declaration

Included in Shinken v1.2.1 shinken-specific.cfg.

<code>define module {

```
module_name          SnmpBooster
module_type          snmp_poller
datasource           /usr/local/shinken/etc/packs/network/SnmpBooster/   ; SET THE DIRECTORY FOR YOUR
memcached_host       x.x.x.x  ; SET THE IP ADDRESS OF YOUR memcached SERVER
memcached_port       11211  ; default port for a memcached process
```

}

If you do not know the IP adress on which your memcache is listening, check under /etc/memcached.conf. Or do a:

```
netstat -a | grep memcached</code>
If you are running a test on the local machine you can leave memcached on 127.0.0.1 (localhost), but
```

How to define a Host and Service

Step 1

Create a template for your SNMP enabled devices.

Sample template:

<code>cd shinken/etc/packs/network/ mkdir SnmpBooster

vi shinken/etc/packs/network/SnmpBooster/templates.cfg

```
define command {
```

```
command_name    check_snmp_booster
command_line    check_snmp_booster -H $HOSTNAME$ -C $SNMPCOMMUNITYREAD$ -V 2c -t $ARG1$ -i $_SERVICE
module_type     snmp_poller
```

}

```
define service {
```

```
name                    default-snmp-template
check_command           check_snmp_booster!$_SERVICEDSTEMPLATE$!$_SERVICEINST$!$_SERVICETRIGGERGROUP
_inst                   None
_triggergroup           None
max_check_attempts      3
check_interval          1
retry_interval          1
register                0
```

}

```
define host{
```

```
name                    SnmpBooster-host
alias                   SnmpBooster-host template
check_command           check_host_alive
max_check_attempts      3
check_interval          1
retry_interval          1
use                     generic-host
register                0
```

}

Step 2 Define some hosts and services. You would typically use genDevConfig or another configuration generator to create these for you.

Mandatory service arguments related to SNMP polling:

```
_dstemplate                Cisco-Generic-Router  ; Name of a DSTEMPLATE defined in the SnmpBooster co
```

```
snmpcommunityread    which is set in your resource.cfg file
```

Optional service arguments related to SNMP polling with default values:

```
_inst                   None   ; Could be numeric: 0, None or an instance mapping function like: map
```

```
_triggergroup           None   ; Name of the triggergroup defined in the SnmpBooster config.ini file
```

Sample Shinken host and service configuration:

```
# Generated by genDevConfig 3.0.0
# Args: --showunused -c publicstring 192.168.2.63
# Date: Thu Aug 30 17:47:59 2012

#######################################################################

Shinken integrated SNMP Module

Overview

What is it The SnmpBooster module allows Shinken Pollers to directly manage SNMP data acquisition. This is an all Python cross-platform SNMP module. It is tightly integrated with the Shinken Poller, Scheduler and Arbiter daemons to provide the best possible user experience.

- Jump back to *SnmpBooster documentation index*

Design specification summary

- STATUS - DESIGN SPEC PERFORMANCE
- [Done] Functions as an integrated Shinken Poller module
- [Done] Necessary integration code commited to Shinken official release (Integrated starting at v1.2)
- [Done] Ability to collect thousands of SNMP metrics per second
- [Done] Be compatible with distributed data acquisition
- [Done] Collect data for a host/check_interval tuple via SNMP in a single pass
- [Done] Use all builtin Shinken scheduler logic for retries, forced checks, timeouts, dependencies, parents
- [Done] Store collected data for the duration of the check_interval in a memcached/membase
- [Done] On a restart, after the first collection, be able to pick up where the last check left and calculate derived values
- [Done] Forced check are not allowed within 30 seconds of last SNMP query to the same host/check_interval, all other requests get data from the cache.
- [Done] Only a single request to the host/check_interval via SNMP is allowed at a time, all other requests get data from the cache.
- STATUS - DESIGN SPEC USABILITY
- [Done] Usage documentation
- [xxxx] SkonfUI and Discovery usage documentation
- [xxxx] Provide sample configuration packs in Shinken
- [Done] Provide sample config.ini with examples of all types of data * SNMP OIDS, DATASOURCES, DSTEMPLATES, TRIGGERS and TRIGGERGROUPS

- [Done] Directly compatible for use with genDevConfig Shinken SNMP configuration generator
- [Done] Provide meaningful feedback for users on errors
- [Done] Capture all tracebacks and convert them to actual error or warning messages
- STATUS - DESIGN SPEC FEATURES
- [Done] Return state and performance metrics
- [Done] Performance metrics can be returned in a Weathermap compatible format
- [Done] Configuration file format is ConfigObj INI
- [Done] Load all valid INI configuration files from a directory and merge them
- [Done] Load a single INI configuration file
- [xxxx] Load a list of INI configuration files
- [Done] Configuration file describes all generic acquisition parameters (OID, DATASOURCE, DSTEMPLATE, MAP, TRIGGER, TRIGGERGROUP)
- [Done] Supports Triggers which are calculation rules to determine states
- [Done] Triggers support an RPN (Reverse Polish Notation) calculation engine which includes mathematical and logical operators
- [Done] Each TRIGGER is associated with a severity level, WARNING or CRITICAL
- [Done] Multiple TRIGGERS can be associated with a TRIGGERGROUP
- [Done] Use builtin Python Operators
- [Done] Support DERIVE, TEXT, GAUGE and COUNTER data types
- [xxxx] Support TIMETICKS data type
- [Done] Support applying RPN based calculations to received metric for scaling or conversion purposes
- [Done] Use a Python SNMP library which supports asynchronous acquisition PySNMP
- [Done] Datasources can use rule based runtime instance mapping
- [Done] Set Snmp version as a check runtime option
- [Done] Set Snmp DSTEMPLATE as a check runtime option
- [Done] Set Snmp TRIGGERGROUP as a check runtime option
- [Done] Set Snmp COMMUNITY as a check runtime option
- [Done] Use Snmp version 2c GetBulk
- [xxxx] Support Snmp version 2c GetNext if GetBulk is not supported
- [xxxx] Support Snmp version 1 GetNext
- [xxxx] Set Snmp Timeout as a check runtime option, instead of a hardcoded value at 5 seconds
- STATUS - DESIGN SPEC MAINTAINABILITY
- [xxxx] Functions documented in the source code
- [Done] Critical functions documented in the source code
- [Done] Locking sections identified in the code
- [xxxx] Unit tests with at least 80% coverage

- [xxxx] Unit tests integrated with Shinken test suite
- [Done] Code hosted on github
- [xxxx] configuration validity and integrity checking of all INI files
- [xxxx] Pep8 compliant
- [xxxx] Pylint pass

genDevConfig Plugins - Compatibility status with SnmpBooster

- STATUS - genDevConfig maintained Plugins
- [Done] Avaya ES switches
- [Done] Avaya ERS routing switches
- [Done] Cisco 29x0 switches
- [Done] MIB-II Interfaces
- [Done] Cisco PIX/ASA
- [Done] JUNOS devices
- [Done] Cisco IOS routers
- [Done] NetSNMP unix hosts ** Validation required**
- [Done] Packeteer devices ** Validation required**
- [Done] Sensatronics devices ** Validation required**
- [Done] Foundry devices ** Validation required**
- [Done] Packeteer devices ** Validation required**
- [Done] Cisco CSS ** Validation required**
- [InProgress] New Cisco Access points
- STATUS - Other maintained Plugins

Tip: [xxxx] Denotes a specification that is planned but not implemented

[InProgress] Denotes a specification that is under development

[Done] Denotes a specification that is implemented

SnmpBooster reference dictionary

- Jump back to *SnmpBooster documentation index*

SnmpBooster.ini dictionary

There are five dictionaries:

- [DATASOURCE]
- [DSTEMPLATE]
- [MAP]
- [TRIGGER]

- [TRIGGERGROUP]

DATASOURCE DICTIONARY OidVariableName refers to an actual OID that can be queries using SNMP against the device on the network.

[VariableName] refers to a Datasource and all the information required to gather and prepare the data using SNMP ds_type refers to how the data should be prepared ds_calc refers to any scaling manipulations to make the data more understandable. This is an RPN expression, where the first variable is omitted, as it is always the $OidVariable ds_oid refers to the actual $OidVariable name. An instance identifier can be appended to the name to signify that an instance is provided by the Shinken service definition. This information is passed when the check is called. ...

DSTEMPLATE DICTIONNARY [DsTemplateName] refers to the name of the DSTEMPLATE that will be referred to in the Shinken service definitions. ds refers to the list of DATASOURCES to be collected. If an instance is expected for the list of DATASOURCES, it MUST be the same instance for all Oids. If a different instance is required, use a second DSTEMPLATE.

TRIGGER DICTIONNARY

TRIGGERGROUP DICTIONNARY

MAP DICTIONNARY

SnmpBooster.ini example configuration This example definition will be used to explain each section.

[DATASOURCE]

```
OidmyOidDefinition = .1.3.6.1.45.0
[myOidDefinition] ; Use the same name as the myOidDeiniftion, but omit the leading "Oid"
    ds_type = DERIVE
    ds_calc = 8,*  ; RPN expression : Oid, 8, *  Which means Oid * 8 = Total
    ds_oid = $OidmyOidDefinition
```

[DSTEMPLATE]

```
[myCiscoRouter]
    ds = myOidDefinition
```

[TRIGGER]

```
[trigger1]
    warning = RPN expression
    critical = RPN expression
[trigger2]
    warning = RPN expression
    critical = RPN expression
```

[TRIGGERGROUP]

```
[CiscoRouterTriggers]
    triggers = trigger1, trigger2
```

SnmpBooster.ini configuring SNMP Datasources

The first location is generic data related to SNMP parameters.

- DATASOURCE information * SNMP OID * Type of data and how can it be interpreted (GAUGE, COUNTER, COUNTER64, DERIVE, DERIVE64, TEXT, TIMETICK) * Data format preparation (Scaling the data for example bits to bytes) * Is there an instance to append to the
- Instance MAP function * Mapping the instance dynamically using a function * Data or rules related to the mapping function

SnmpBooster.ini configuring SNMP DSTEMPLATES

- DSTEMPLATEs to associate DATASOURCE to actual device classes * List of DATASOURCES associated with a, for example, Cisco 1900 router. Which in turn can be applied to a Shinken service

SnmpBooster.ini setting triggers/thresholds

- TRIGGER and TRIGGERGROUPS to apply thresholding rules * Define triggers and associate them with a TRIGGERGROUP name that can be applied to a Shinken Service

Shinken integrated SNMP Module

Overview

- Jump back to *SnmpBooster documentation index*

Tip: The module is now in public beta as of 2012-10-26! Have Fun!

Nothing new to add, more to come in 2013. 2013-01-19.

What is it The SnmpBooster module allows Shinken Pollers to directly manage SNMP data acquisition. This is an all Python cross-platform SNMP module. It is tightly integrated with the Shinken Poller, Scheduler and Arbiter daemons to provide the best possible user experience.

Why use it The SnmpBooster module is designed to be very efficient and scalable. It has a very flexible configuration method to make it easy to use with Shinken Monitoring Packs and Shinken discovery runners like genDevConfig.

This acquisition module was professionally designed and developed.

It is meant to be used by the very capable discovery engine genDevConfig (**v3.0.5 and newer**) originally developed for the Cricket SNMP monitoring tool and converted for use with Shinken.

It is one of the very few serious SNMP v2c implementation making use of SnmpGetBulk type requests.

How does it work

Shinken Integration

1. The SnmpBooster Arbiter module reads the Shinken SnmpBooster configuration file(s). It reads the check commands and based on the values in the check commands that use the snmp_poller module it will creates a shared configuration cache using memcached/memcachedb. The memcache key is always the combination of the hostname. This permits to tie together Shinken Hosts and Services with the SNMP specific configuration. (MongoDB and Redis are planned to be supported in the future) The Scheduler daemon schedules Host and Service checks as it normally does.

3. The SnmpBooster module will check that a memcache host key exists for the check to be launched. Then the SnmpBooster poller module will query all services related to a host for a given acquisition frequency in one pass. (all checks done every 2 minutes will be executed in bulk, same for those every 5 minutes)

5. Check results are cached for the acquisition check_interval. The next time a check request for data from the same host is received from the Scheduler, the data will be fetched from memcache. Resulting is extremely low check latency.

2. 6. The SNMP checks still benefit from retries, timeouts, forced checks, dependencies and the powerful Scheduler daemon logic.

6. The Scheduler daemon can still force an immediate re-check by flushing the cache. This is required for the dependency model.

Performance SnmpBooster uses SNMP v2c getbulk for high efficiency, unless forced to use SNMP v2c get-next or SNMPv1 get-next. GetBulk uses a single request PDU to ask for multiple OIDs or even entire tables, instead of sending one request PDU per OID.

For example: *A typical 24 port network switch with two uplinks might use 375 OIDS (8 OIDs per interface, plus general OIDs for chassis health, memory, cpu, fans, etc.). **SnmpBooster will only require around 4 request PDUs*

*instead of 375 request PDUs**. Each PDU is a request packet which takes time to create, send get processed and return. More timeouts to manage, more connections, more impact on the remote device and more latency means much fewer checks per second.*

The SnmpBooster module supports automatic instance mapping for OIDs. (Ex. Based on the interface name it will figure out that the SNMP index(or instance) is 136. This is automatically handled by genDevConfig and SnmpBooster, no user input required. :-)

The generic SNMP configuration information is stored in the Shinken SnmpBooster INI files. There is a Defaults_unified.ini and a series of other Defaults files, one per discovery plugin for genDevConfig.

Important: genDevConfig plugins have all been converted to use the new dynamic instance mapping methods. You are now free to use most if not all Defaults*.ini files included with genDevConfig. 2012-10-28

Limitations You should have memcached instances running on each poller responsible for snmp polling. You should have your pollers with SnmpBooster in the same datacenter, as they need to be on the same machine with good connectivity to the active memcached instance. SnmpBooster is not compatible with distributed pollers in multiple datacenters, sorry, the current design of SnmpBooster uses a single centralized memcached instance for storing the timeseries data. For distributed datacenters to be supported, each poller+scheduler+memcached must be realm restrained, which is not the case today.

Design specification *SnmpBooster design specification* and current development status.

Data model The information required to define the data is split in two locations.

The first location is the host and service Shinken configuration (You need to generate or write this)

- Device specific information
  - IP addresses, host_names, device types, instance keys
  - A DSTEMPLATE must be referred to in the Service definition
  - A static SNMP instance could be referred to in the Service definition
  - An SNMP instance MAP function could be referred to in the Service definition
  - A TRIGGERGROUP could be refered to in the Service definition

The second location is SNMP Defaults.* templates. (Here you can create new devices or add new data sources)

- DATASOURCE information
  - SNMP OID
  - Type of data and how can it be interpreted (GAUGE, COUNTER, COUNTER64, DERIVE, DERIVE64, TEXT, TIMETICK)
  - Data format preparation (Scaling the data for example bits to bytes)
  - Is there an instance to append to the
- Instance MAP function * Mapping the instance dynamically using a function * Data or rules related to the mapping function
- DSTEMPLATEs to associate DATASOURCE to actual device classes * List of DATASOURCES associated with a, for example, Cisco 1900 router. Which in turn can be applied to a Shinken service
- TRIGGER and TRIGGERGROUPS to apply thresholding rules * Define triggers and associate them with a TRIGGERGROUP name that can be applied to a Shinken Service

A final location containes rules to build your Shinken configuration.

- genDevConfig plugins create Shinken configurations

Installation and configuration *SnmpBooster installation*

Reference Dictionnary *SnmpBooster reference dictionary*

Troubleshooting *SnmpBooster troubleshooting*

Graph templates These are .graph files defined in your Shinken configuration directory. Refer to the Shinken graphite templates(Not yet created) or PNP4Nagios how-to documentation. The graph templates are independent from SnmpBooster and provide templates for any collected data from Shinken.

SnmpBooster Troubleshooting

- Jump back to *SnmpBooster documentation index*

Check your config

- Have you defined the poller module name?
- Have you defined the correct path to the directory containing your Defaults*.ini files?
- Have you addded the Snmpbooster module to your arbiter, poller, scheduler?
- Have you added copied the genDevConfig templates.cfg in shinken/packs/network/SnmpBooster/
- Have you installed PySNMP, memcached and other dependencies?

Software version consistency Shinken and SnmpBooster now require **the same Python and Pyro version on all hosts running a Shinken daemon**.

If you cannot use the packaged version of Python and its modules (Pyro, memcached, etc.). Use virtualenv to declare a python version to use and install all required modules in that virtualenv.

Software version requirements Have you verified that the *requirements* are met. Python, PySNMP, Shinken, Pyro, memcached, etc.

Validate your check command arguments Use the check_plugin command and comment out the module to learn what were the exact arguments sent by the poller. This will permit you to validate all the arguments, like snmp community string, inheritance, template application, etc.

Validate connectivity

Take a packet trace using a tool like Wireshark to validate that the remote host is responding.

- Has the host responded
- **Is SnmpBooster repeating the request more often than the polling interval.**
  - If you are seeing repeated requests your device may have a compatibility issues.

- Save an snmpwalk of the device, get a packet trace using Wireshark, set the poller to debug and save the poller.log file (shinken/var/poller.log). Send all three to the SnmpBooster developers.
- Note: It is normal to see one or more bulkGet requests if you are getting large amounts of data. Ex. a 24 port switch will take 2-3 request packets.

Performance Make sure you have a low latency connection to your memcache from the Poller. Your memcache server can be replicated to all your poller hosts that should also run memcache instances. Check that memcached is running: netstat -a | grep memcached

Faulty Template A bad snmp_template file was distributed in the genDevConfig sample-config directory, there were two glaring errors.

This was fixed on 2012-10-16. Make sure you update your template, or use the data from the wiki.

Note that the template should be called: SnmpBooster-template.cfg to make it easier to troubleshoot in the logs. So when you search for SnmpBooster in your logs it will show up as well.

Log files All warnings and errors generated by the SnmpBooster module start with "[SnmpBooster] error text" and are logged using the standard Shinken logger.

The Arbiter daemon can output initial configuration, loading of host keys and intervals in memcached type error messages. The Scheduler daemon can output scheduling and alert related messages. The Poller daemon can output messages related to instance mapping, acquisition timeouts, invalid community strings, cache failures and more. These are available in the Web interface, as they are placed in the check results for the service.

You can simply do a "grep SnmpBooster *" in your shinken/var directory to see the latest messages related to the SnmpBooster module. You can also sort messages by timestamp to make it easy to find where and when errors occurred.

cd shinken/var grep SnmpBooster *

memcache persistence If you restart your memcache server or memcache crashes, your poller will no longer be able to validate that a host exists in memcache prior to writing.

You should use memcachedb to achieve persistence in case of memcache failures.

Common errors returned by SnmpBooster in the log file Errors should be fairly explicit and mean what they say, though there can be exceptions. Lets try to clear some of them.

__Arbiter log **errors__**

Missing ds_oid : This means that a variable in your OID definitions is missing, or your DATASOURCE is not named correctly or your ds_oid variable is missing. There is a typo in your ds_oid variable (ex. ds-oid, or ds_oid = $OidNameIncorrectFFFRA.%(instance)s).

Datasource not defined : Your DSTEMPLATE uses a DATASOURCE that doesn't exist check the [DataSourceName] you are referring to. Does it contain the expected OID variable, $OidName.

Missing ds_type : The DATASOURCE always needs to have a ds_type definition, GAUGE, COUNTER, DERIVE, TEXT, TIMETICK, DERIVE64, COUNTER64.

__Poller log **errors__**

Problems with calculations, repeated polling, hosts not responding, etc.

__Memcached **errors__**

memcachedb and memcached do not use the same default port. Configure the correct memcachedb port to match what is declared in your SnmpBooster module under shinken-specific.cfg.

On Ubuntu 12.04 the default installation is on port 21201 instead of 11211. This causes the error "[SnmpBooster] Memcache server (127.0.0.1:11211) is not reachable" when Shinken starts.

To change it, you must edit the file /etc/memcachedb.conf

Memcached Notes On Ubuntu 12.04 the default instalation is on port 21201 instead of 11211. This causes the error "[SnmpBooster] Memcache server (127.0.0.1:11211) is not reachable" when shinken starts.

To change it, you must edit the file /etc/memcachedb.conf

WebUI module This part must be splitted and sent in all module repositories

WebUI integration with Shinken The WebUI is an external broker module. So it's an external process launched by the broker that "eats" broks (broker messages) from the brokers. So it can get *all* broks if you place this broker in your top level realm.

The WebUI does not use a database to get data. Instead, it use a "regenerator" object that will eat each broks, and will "recreate" all Hosts/Services/Contacts objects as if the code was in the scheduler daemon. So basically, WebUI and pages always reflect the CURRENT state of hosts/services objects.

The WebUI http layer is managed by bottle.py. It's a small but powerful framework.

How does the WebUI function globally ?

There a 2 Threads running:

- the main thread is the bottle.py (http) listener. It will use the best backend it finds. We recommend using python-paste. If it does not find one, it will use the default swsgi. Paste is multi-thread, swsgi is mon-thread, so please use paste if you want to avoid locking problems.
- the 2nd thread is the regenerator one. It only gets broks and gives them to the regenerator object.

There is a lock system between the threads. You can have N Http requests in progress without problem, but during this time the renererator one will wait. During execution of the regenerator, no requests are processed. This is not considered a problem, as the regenerator is very quick, and there is only a 1s lock for a 7k service conf loading, so it's not a huge problem.

What is a WebUI User? A WebUI user is a contact. A true contact object. You must match a contact name for your user.

To create a new page? All pages are in the shinken/webui/plugins directory. Each "part" has it's own directory. A part (like the eltdetail, element detail) can have more than one "page" (like /host or /service for eltdetail).

From here we will supose you want to create a "/contact" page.

You can copy the dummy example in the plugins directory into a contact directory.

You need to change the contact/dummy.py file into a contact/contact.py file, because the webui will search for a dir/dir.py file to "load".

Templates Templates are HTML with some Python code in it in the plugins/*/views direcotry for specific templates, and the "global layout" (menu and all common part) in the webui/views directory.

Your template must call the template layout (layout.tpl in the webui/views directory) wit ha "rebase" call.

If you put the rebase call at the beginning of your template, all there is below will be place "inside" the layout that will call the common javascripts and css, make the menu adn then call your html/python code.

The rebase call can take arguments. You MUST give it:

- user: the user you give it in the return dict of your .py code

Then all is optional:

- title: title of the page
- top_right_banner_state: int, global state with clouds to put in your top right page. Look at the problem.tpl code for an example.
- js and css list: list of YOUR specific javascript or css to call AFTER the common ones.
- refresh: boolean, set the refresh to 60s or do not refresh at all

- menu_part: will put the little "^" under this part of the menu.

Example of a call, taken from the problems view:

```
rebase layout title='All problems', top_right_banner_state=top_right_banner_state, js=['problems/js/a
roblems/js/autocompleter.Request.js', 'problems/js/autocompleterObserver.js'], css=['problems/css/acc
ms/css/autocompleter.css', 'problems/css/perfometer.css'], refresh=True, menu_part='/'+page, user=use
```

Call Python objects in your templates Your templates are mainly HTML code. But of course you can call python code in it. The dict you returns in the plugin.py call will be available in this page.

For example, the my_host variable will be available in the page with the host object you find (or None if your give it a bad name of course). Then you can "call" python with for example here to show the host_name: `<span>My host name is *my_host.host_name* </span>` is a way in the templates to "call a variable or function" that will return a string, here the host_name.

If the function or property you call must return HTML code that SHOULD be output as it, without "protection", you must put a ! before your call.

Let use an example where the output value of an host is in fact an html output. If you use the code `my_host.output`, bottle.py will "protect" the html generated by escaping the string, and change <> characters with escaped value. You can change this by calling `my_host.output`. Of course, it's a security problem if the output is with a javascript code...

You can also "loop" or put "if" in your template. You just need to put your code with a % before. Like

```
%for i in xrange(1, 10):
  My valus is  {{i}}
%end
```

You must put the %end here, the indentation will NOT be enougth, sorry.

For an if it's also easy:

```
%if host.active_checks_enabled:
  The host got active checks enabled
%else:
  The host DO NOT have active check enabled
%end
```

Which javascript lib are you using? It's mootools 1.3 with all options :)

What to do?

- Finish the /mobile part
- List of current alerts
- Host info
- Host status
- Host interfaces
- Hostgroup status
- dashboard hierachique with states, and BP
- Nagvis
- add bp in nagvis auto-map

- event sources
- correlation
- pre-filtering/enrichment
- user profile
- host/srv conf

WebUI search syntax work in progress

not that we couldn't tell. ;) eh eh

beware the working men and flying tools!

WebUI SSL Certification Lets start: the goal to to have the server.pem and client.pem file in etc/certs.

Go to the etc/certs directory.

```
openssl req -new -nodes -out server.req -keyout server.key -config ./shinken_openssl_cnf
openssl ca -out server.pem -config ./shinken_openssl_cnf -infiles server.req
cp server.pem server.pem.bkp
cp server.key server.pem
cat server.pem.bkp >> server.pem
cp server.pem client.pem
```

You can try to get the validity with for the arbiter with:

```
openssl s_client -connect localhost:7770</code>
```

Amazon AWS/EC2 import

Description You can import data from Amazon AWS/EC2 **'AWS'**_ into Shinken to create hosts.

Amazon provide VM hosting with EC2. With this arbiter module, you will be able to load your EC2 hosts into Shinken.

Prerequisites

You will need the **'libcloud'**_ package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

```
define module {
 module_name      AWS
 module_type      aws_import

 # Configure your REAL key and secret for AWS
 api_key              PAAAB2CILT80I0ZA0999
 secret           GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH
 default_template generic-host        ; if the host is not tagged, use this one
 }
```

- Put in key and secret your private Landscape access. * default_template will be used if your host is not "tagged" in Landscape

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master

     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           AWS
     }
```

Restart your Arbiter and it's done :)

Generated hosts The configuration generated will look as below :

```
define host {
    host_name            i-3fc56e5a
    address              8.8.4.4
    use                  t1.micro,MyTag,EC2,generic-host
    _EC2_AVAILABILITY    us-east-1a
    _EC2_CLIENTTOKEN
    _EC2_DNS_NAME
    _EC2_GROUPS          quicklaunch-1
    _EC2_IMAGEID         ami-1b814f72
    _EC2_INSTANCEID      i-3fc56e5a
    _EC2_INSTANCETYPE    t1.micro
    _EC2_KERNELID        aki-825ea7eb
    _EC2_KEYNAME         testaws
    _EC2_LAUNCHDATETIME  2012-09-26T12:19:38.000Z
    _EC2_LAUNCHINDEX     0
    _EC2_PRIVATE_DNS
    _EC2_PRIVATE_IP
    _EC2_PRODUCTCODE
    _EC2_PUBLIC_IP       8.8.4.4
    _EC2_RAMDISKID       None
    _EC2_STATUS          stopped
    _EC2_TAGS            demo:myvalue,use:MyTag
 }
```

Here with a stopped t1.micro instance with no name. You can put your how "use" parameter by adding a EC2 tag "use" on your VM. It will be output on the host configuration so you can setup the monitoring as you want. .. _libcloud: http://libcloud.apache.org/index.html .. _AWS: https://console.aws.amazon.com

Amazon AWS/EC2 import

Description You can import data from Amazon AWS/EC3 **'AWS'**_ into Shinken to create hosts.

Amazon provide VM hosting with EC3. With this arbiter module, you will be able to load your EC2 hosts into Shinken.

Prerequisites

You will need the **'libcloud'**_ package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

```
define module {
 module_name      AWS
 module_type      aws_import

 # Configure your REAL key and secret for AWS
 api_key              PAAAB2CILT80I0ZA0999
 secret           GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH
 default_template generic-host        ; if the host is not tagged, use this one
 }
```

- Put in key and secret your private Landscape access. * default_template will be used if your host is not "tagged" in Landscape

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master

     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           AWS
     }
```

Restart your Arbiter and it's done :)

Generated hosts The configuration generated will look as below :

```
define host {
    host_name            i-3fc56e5a
    address              8.8.4.4
    use                  t1.micro,MyTag,EC2,generic-host
    _EC2_AVAILABILITY    us-east-1a
    _EC2_CLIENTTOKEN
    _EC2_DNS_NAME
    _EC2_GROUPS          quicklaunch-1
    _EC2_IMAGEID         ami-1b814f72
    _EC2_INSTANCEID      i-3fc56e5a
    _EC2_INSTANCETYPE    t1.micro
    _EC2_KERNELID        aki-825ea7eb
    _EC2_KEYNAME         testaws
    _EC2_LAUNCHDATETIME  2012-09-26T12:19:38.000Z
    _EC2_LAUNCHINDEX     0
    _EC2_PRIVATE_DNS
    _EC2_PRIVATE_IP
    _EC2_PRODUCTCODE
    _EC2_PUBLIC_IP       8.8.4.4
    _EC2_RAMDISKID       None
    _EC2_STATUS          stopped
    _EC2_TAGS            demo:myvalue,use:MyTag
 }
```

Here with a stopped t1.micro instance with no name. You can put your how "use" parameter by adding a EC2 tag "use" on your VM. It will be output on the host configuration so you can setup the monitoring as you want. .. _libcloud: http://libcloud.apache.org/index.html .. _AWS: https://console.aws.amazon.com

The distributed retention modules

The high availability allow the Arbiter to send a configuration to a spare scheduler, but a spare scheduler does not have any saved states for hosts and services. It will have to recheck them all. It's better to use a distributed retention module so spares will have all the information they need to start with an accurate picture of the current states and scheduling :)

Non distributed retention modules If you are just running tests on a single server, use the pickle or memcache retention modules You can also use MongoDB if you already have it installed for use with the WebUI.

MongoDB MongoDB is a scalable, high-performance, open source NoSQL database written in C++.

Step 1: Install MongoDB:

We will use mongodb package from 10gen repository, so we start by adding it in apt sources list:

```
echo 'deb http://downloads-distro.mongodb.org/repo/debian-sysvinit dist 10gen' > /etc/apt/sources.lis
apt-get update
```

And we install it:

```
apt-get install mongodb-10gen
```

And we install pymongo, the python interface to MongoDB, with easy_install to avoid packages versions problems (like here **'forums.monitoring-fr.org/index.php?topic=5205.0'_**):

```
apt-get remove python-pymongo
easy_install pymongo
```

And finally we start MongoDB :

```
/etc/init.d/mongodb start
```

Step 2: define a mongodb_retention module in your shinken-specific.cfg file:

```
define module {
  module_name MongodbRetention
  module_type mongodb_retention
  uri mongodb://localhost/?safe=true
  database shinken
}
```

Step 3: Declare a retention module for your scheduler(s) :)

Example:

```
#The scheduler is a "Host manager". It get hosts and theirs
#services. It scheduler checks for them.
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
     port     7768                  ; tcp port of the daemon

     #optionnal: modules for things as retention
     modules    MongodbRetention
     }
```

Step 4: Restart the Arbiter, and your Scheduler will now save its state between restarts. :)

Memcached Memcached is a distributed memory resident key/value server. It's very easy to install:

```
sudo apt-get install memcached
sudo /etc/init.d/memcached start
```

The shinken module also needs the python-memcache package to talk to this server.

```
sudo apt-get install python-memcache
```

To use it,

Step 1: define a memcache_retention module in your shinken-specific.cfg file:

```
define module{
     module_name      MemcacheRetention
     module_type      memcache_retention
     server           127.0.0.1
     port             11211
}
```

Step 2: Declare a retention module for your scheduler(s) :)

Example:

```
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
     port     7768                  ; tcp port of the daemon

     #optional: modules for things as retention
     modules    MemcacheRetention
     }
```

Step 3: Restart the Arbiter, and your Scheduler will now save its state between restarts. :)

Redis Redis is a distributed key/value server (on disk and in-memory). It's very easy to install:

```
sudo apt-get install redis-server
sudo /etc/init.d/redis-server start
```

The shinken module also need the python-redis package to talk to this server.

```
sudo apt-get install python-redis
```

Step 1: define a redis_retention module in your shinken-specific.cfg file:

```
define module{
     module_name      RedisRetention
     module_type      redis_retention
     server           127.0.0.1
}
```

Step 2: Declare a retention module for your scheduler(s) :)

Example:

```
#The scheduler is a "Host manager". It get hosts and theirs
#services. It scheduler checks for them.
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
```

```
    port     7768                  ; tcp port of the daemon

    #optionnal: modules for things as retention
    modules    RedisRetention
    }
```

Step 3: Restart the Arbiter, and your Scheduler will now save its state between restarts. :) .. _forums.monitoring-fr.org/index.php?topic=5205.0: http://forums.monitoring-fr.org/index.php?topic=5205.0

How to enable and use Livestatus module

Define the Livestatus module Start by reviewing the ''/etc/shinken/shinken-specific.cfg" file for this module:

```
define module{
```

```
module_name      Livestatus
module_type      livestatus
host             *       ; * = listen on all configured IP addresses
port             50000   ; port to listen on
database_file    /var/lib/shinken/livestatus.db
```

}

With these parameters:

- module_name: name of the module called by the brokers
- module_type: livestatus
- host: IP interface to listen to. The default is *, which means "listen on all interfaces".
- port: TCP port to listen to.
- socket: Unix socket to listen to.
- database_file: the path to the sqlite database file which is used to store the log broks/messages. The default is "var/livelogs.db"
- max_logs_age: the maximum age of the log messages (before they are deleted from the database). The default is 1 year. The argument to this parameter takes the form <number>[<period of time>], where <period of time> can be d for days, w for weeks, m for months and y for years.
- allowed_hosts: a comma-separated list of IP-addresses which are allowed to contact the TCP port. Please keep in mind that these **must be IP-addresses, NOT host names**. Because DNS lookups for every incoming livestatus request could hang up and therefore block the module.

Enable the Livestatus module Still in ''/etc/shinken/shinken-specific.cfg'', find the object Broker and add "Livestatus" to its "modules":

```
define broker{
```

```
    broker_name      broker-1
[...]
```

```
    modules          Simple-log,Livestatus
}
```

Disable human readable logs In ''/etc/shinken/nagios.cfg'', verify that the option **human_timestamp_log** is set to **0**.

In version 0.6.5, you can not have at the same time a simple-log file with human readable timestamp and a Livestatus database.

Exporting data for reporting

Shinken can export necessary data for reporting in 3rd party systems.

raw_socket module The raw socket module exports reporting data using a syslog format to a raw TCP socket. Theses logs can be captured, parsed and indexed by any log management system like Splunk or Logstash.

Why export reporting data Custom UIs like Thruk, Multisite, WebUI, Adagios, Nagios IX, etc. All have poor or inflexible reporting. Simply because these are not reporting engines.

This also permits to have a generic reporting method that can accept data from any Nagios, Shinken, Icinga or even Riemann.

Reporting module using Splunk Splunk was selected as the reporting platform for creating, managing and presenting reports. Though the raw_socket module does not have any Splunk specific particularities. It is notable that Splunk reports can be embedded in any 3rd party UI using its REST API.

Raw_socket log format The logs are plain-text and compliant with RFC3164. They use an intelligent date format, a configurable seperator " "(space by default), and key=value pairs in the message data portion of the log. Should a key or value contain a space they must be double quoted. This is syslog using structured data without going to full out JSON that may not be compatible with all log management systems.

The message fields that are supplied in each status update in addition to the standard syslog header are:

- Hostname
- Servicename
- Business impact
- Host/Service status
- Host/Service previous status
- Acknowedgement status
- Maintenance status

Any time the maintenance, host, service or acknowledgement status changes, a log is sent by the Shinken raw_socket module.

Having all relevant data in each log makes it very easy to compute reports for given time periods.

The hostgroup or service group memberships, custom variables or any other configuration related data should be queried from the monitoring system using its API (Livestatus in the case of Shinken and Nagios).

Raw_socket module availability The module is available in both Shinken 1.4 and Shinken 2.0. The module will be integrated in master branches once unit tests and end-to-end testing is completed. 3rd quarter 2013.

Monitoring Linux System with Glances and checkglances.py

'Glances'_ is a fantastic multiplatform system monitoring tool writen by Nicolargo. Glances can run on (Linux, Windows, MacOS ...). There is a growing ecosystem around Glances and of course a Nagios/Shinken plugin : check-glances.py.

How does it work Glances can run in server mode. It provide a XML-RPC server (over http) and allow to retrieve system information throuh a restful API. The only thing to do is to install and start Glances as server on the monitored host, then install checkglances.py on the shinken server and finaly install the glances pack.

Install glances See the glances documentation to install glances on Linux.

<code bash> easy_install glances </code>

There is a debian startup script in the glances repository. And another one for centos here.

Install checkglances.py Just follow the documentation for the checkglances.py prerequisites and put it in your nagios plugins folder.

Install the glances pack Open a terminal as the shinken user and just type the following command

<code bash> shinken install glances </code>

Then just edit the configuration for a linux monitored host and tag it as **glances**

```
define host{
 name mylinuxhost
 use glances
 ...
```

Finaly restart the shinken arbiter

```
service shinken-arbiter restart
```

What will be monitored ? For the moment just the basic system (ram, cpu, load, memory, filesystem and network).

If you want to modify the default thresholds for just a host you can do it by overiding the thresholds macro in your host definition. If you want to do it for several hosts, declare a new template and just add the desired thresholds macro to be overide.

Here is a list of the macros

```
::
```

> _LOAD_WARN 2 _LOAD_CRIT 3 _CPU_WARN 80 _CPU_CRIT 90 _MEMORY_WARN 90 _MEMORY_CRIT 95 _FS /, /home _FS_WARN 90 _FS_CRIT 95 _IFACES eth0, eth1 _NET_WARN 7500000 _NET_CRIT 10000000

Note the _FS and _IFACES macros. They leverage the ability to duplicate service for a given list of things to be monitored. Here you see that / and /home partitions will be monitored. If you want to modify this then just add your own in a new template that will inherit the glances template.

Shinken GLPI integration

Shinken supports importing hosts from GLPI

For people not familiar with GLPI, it is an Open-Source CMDB. Applicable to servers, routers, printers or anything you want for that matter. It is also a help-desk tool. GLPI also integrates with tools like FusionInventory for IT inventory management.

You can still have flat files AND GLPI if you want. Hosts imported from GLPI will be treated as standard hosts from flat file (inheritance, groups, etc). In fact, in this first version the module only sends the host_name to Shinken, but there should be more information extracted like network connexions for parents relations in the future. :)

Requirements

- python module MySQLdb
- Compatible version of GLPI Shinken module and GLPI version - ...
- etc..

Enabling GLPI Shinken module In your shinken-specific.cfg file, just add (or uncomment):

```
#You know GLPI? You can load all configuration from this app(
#with the webservices plugins for GLPI, in xmlrpc mode
#and with plugin monitoring for GLPI)
# =============== Work with Plugin Monitoring of GLPI ===============
#All configuration read from this will be added to the others of the
#standard flat file
define module{
     module_name      GLPI
     module_type      glpi
     uri              http://localhost/glpi/plugins/webservices/xmlrpc.php
     login_name       glpi
     login_password   glpi
}
```

And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master
#    host_name       node1       ;result of the hostname command under Unix
     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           GLPI
     }
```

It's done :)

Ip Tag module

Why tag a host based on it's IP address? We learned on the *DMZ monitoring* that you can "tag" a host with a poller_tag so it will be checked only by DMZ pollers. It can be tedious process to manually tag all these hosts. Shinken provides an automated method to do this.

This is handled by the arbiter ip_tag module.

Ip_tag module The ip_tag module is an arbiter module that looks up the host address during the configuration parsing and compares it to an predefined IP range (IPV4 or IPV6). If the range matches, it can apply or add a property, such as poller_tag. Other types of tags could be related to locations, functions, administrative groups, etc.

Method: replace or append.

replace will put the value if the property is unset. This is the default method. .. warning:: Fix me: replace, implies overriding an existing value. And will cause user issues down the line. Rename it to set. Replace should be a different method altogether, so overall there should be 3 methods(set, append, replace).

append will add with a , if a value already exist

Here is an example that will set the poller_tag property with the value DMZ of all hosts that:

- have a their hostadress ip (or name resolved) in the range 192.168.0.1/24.
- do not already have a poller_tag property set

```
define module{
```

```
     module_name     IpTag
     module_type     ip_tag
     ip_range        192.168.0.1/24
     property        poller_tag
     value           DMZ
}
```

To use the module add it in the arbiter object:

```
::
```

define arbiter { [...] modules NSCA,IpTag

}

Add value instead of setting it In the previous example we set the property poller_tag to a value. But what if we want to "add" a value, like a template name? We can change the "method" property of the module to "append" so we can add the "value" to the host property instead of replace it.

Here is an example where we want to add the "dmz" template on the hosts, while also keeping any defined templates:

```
define module{
```

```
     module_name   IpTag
     module_type   ip_tag
     ip_range      192.168.0.1/24
     property      use
     value         dmz

     # Optional method
     method append
}
```

For a host defined as:

```
define host{
```

```
     host_name   example_host1
     address     192.168.0.2
     use         linux
}
```

It will be "changed" internaly in:

```
define host{
```

```
     host_name   example_host1
     address     192.168.0.2
     use         linux,dmz
}
```

Name resolution Of course you don't need to set IP address in the address of your host. You can set a hostname, and it will be resolved, and then compared to the range. :)

Ubuntu Landscape import

Description You can import data from Ubuntu Landscape into Shinken to create hosts.

Ubuntu Landscape, is a web app to manage all your linux servers (update and co), which is provided by Canonical, Ubuntu's parent company.

This is an Arbiter import module. The Arbiter manages the configuration.

Prerequisites

You will need the landscape-api package installed on your Arbiter server.

Configuring the Landscape import module In your shinken-specific.cfg file, just add (or uncomment):

define module { module_name Landscape module_type landscape_import

Configure your REAL key and secret from Landscape key PAAAB2CILT80I0ZA0999 secret GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH default_template generic-host ; if the host is not tagged, use this one

If you are using a specific certificate for landscape_api #ca /path/to.ca.cert

If you need a proxy to access https://landscape.canonical.com/api/ #https_proxy http://user:secret@myproxy.com:3128

}

- Put in key and secret your private Landscape access.
- default_template will be used if your host is not "tagged" in Landscape
- If you are using a specific certificate for connexion, give the full path in ca
- You will certainly need an https proxy to access the Landscape API. If so, configure it there.

Configuring the Arbiter module And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master
#    host_name       node1       ;result of the hostname command under Unix
     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           Landscape
     }
```

Restart your Arbiter and it's done :)

Tip: Your "tags" will be applied as templates for your hosts.

Shinken Livestatus API

Overview

- Jump back to Getting Started
- Jump back to *Livestatus module configuration*

What is it Livestatus API is the modern method of interacting with Shinken and Nagios based systems alike.

Originally developed for Nagios, MK Livetstatus, was re-implemented in Python for use with Shinken by professional developers. The access methods and query languages are the same.

Why use it It is fast.

It is network based using TCP.

It is standard for all Nagios and Shinken monitoring systems.

It uses in-memory structures for status data

It uses a back-end database for historical reporting

It uses an SQL based query language

It has a host of powerful nuts and bolts features (authentication, caching, connection persistence, multiple object methods (JSON, Python)).

What can I do with it? All programs and scripts use (or should use) this method to :

- Obtain the current state of hosts and services
- Obtain the current configuration related to hosts and services
- Send administrative commands (downtimes, comments, forcing checks)
- Filter information to display
- Obtain basic reports and event statistics

Shinken being a modern re-implementation of Nagios has additional features that are available in addition to the standard Livestatus API.

Shinken Livestatus API unique features can :

- Obtain Business Impact information
- Obtain intelligent dependency status hosts or services (combines dependency and parent information)
- Obtain Business Process states (same syntax as standard host and service queries)

How does it work Livestatus uses a powerful SQL-like query language. The standard methods and parameters are defined at :

'MK Livestatus reference methods and query language definition'_

Full list of Shinken Livestatus API methods:

'Shinken mapping.py methods'_

What software uses Livestatus to interact with Shinken

Well known Web frontends

- MK Multisite
- Thruk
- NagVis
- Splunk for Nagios

Mobile Web frontends

- get list

Scripts

- Downtime management scripts
- Debug scripts

Installing Livestatus Have you installed the required packages to use the Livestatus module? You can look at the requirement section of the *10 minute installation guide* for the *requirement lists*.

How to enable Livestatus Very simple, jump to the *Shinken Broker configuration* section to enable it. .. _Shinken mapping.py methods: https://github.com/shinken-monitoring/mod-livestatus/blob/master/module/mapping.py .. _MK Livestatus reference methods and query language definition: http://mathias-kettner.de/checkmk_livestatus.html

NSCA module

The NSCA daemon module is used to receive send_nsca packets and submit them to the Shinken command pipe. The NSCA module can be loaded by the Receiver or Arbiter process. It will listen on port TCP/5667 for send_nsca packets.

Tip: Passive checks can be submitted *natively to the Shinken command pipe* or from remote hosts to modules, such as NSCA, AMQP or collectd, loaded in the Shinken Arbiter or Receiver process. AMQP is implemented for integration with the Canopsis Hypervisor, but could be re-used for generic messaging.

Note: The Shinken NSCA module implementation is currently limited to the "xor" obfuscation/encryption.

In your shinken-specific.cfg file, just add (or uncomment):

```
: :
```

#You can send check result to Shinken using NSCA #using send_nsca command define module{

module_name NSCA module_type nsca_server host * port 5667 encryption_method 0 password helloworld

}

define receiver{

```
receiver_name    receiver-1
address          localhost
port             7773
modules          NSCA

timeout          3             ; 'ping' timeout
data_timeout     120           ; 'data send' timeout
max_check_attempts       3     ;  if at least max_check_attempts ping failed, the node is DEAD

#advanced
realm    All
}
```

This daemon is totally optional.

It's main goal is to get all passive "things" (checks but why not other commands) in distant realms. It will act as a "passive receive buffer" and will then dispatch the data or commands directly to the appropriate Scheduler or Arbiter process.

Data can be received from any Realm, thus the Realm option is nonsensical.

For now there is no init.d script to launch it. .. note:: Verify that the init script has been added.

It is launched like all other daemons:

```
bin/shinken-receiver -c etc/receiverd.ini
```

Tip: Alternatively, for small installations with you can configure a modules inside your Arbiter instead of the Receiver. It will listen the TCP/5667 port for send_nsca packets.

To configure the NSCA module in your Arbiter instead of Receiver. Add the NSCA module to your Arbiter object configuration.

```
::
```

define arbiter{ arbiter_name Arbiter-Master

 # host_name node1 ;result of the hostname command under Unix address localhost ;IP or DNS adress port 7770 spare 0 modules NSCA

}

Retention troubleshooting

The retention file contains the state of your host and services, so that they are kept when shinken is restarted.

Sometimes you'll want to inspect (and possibly fix) the retention file, in case you need to work-around a bug or simply better understand what is stored there.

When you use the PickleRetention module in the scheduler (cf. ''define scheduler" in ''shinken-specific.cfg''), you can simply manipulate the retention file using Python.

For this you can use the following code.

- It assumes Shinken is installed in ''/opt/shinken" with the retention file in ''/tmp/retention.dat'':
- Run and play with it interactively using ''ipython -i inspect_retention.py''.

```
#!/usr/bin/python
import pickle
import sys
sys.path.append('/opt/shinken')
import shinken

r = pickle.load(file('/tmp/retention.dat'))
h = r['hosts']

# Example:
# [(k,v) for (k,v) in h['your_host'].items() if k.find('downtime') >= 0]
#
# del h['your_host']
#
# for k,v in r['services'].items():
#     if 'your_host' in k:
#         del r['services'][k]
```

To save your changes:

- Stop Shinken: ‘’service shinken stop’‘
- Save the pickle: ‘’pickle.dump(r, open(‘/tmp/retention.dat’, ‘w’))’‘
- Start Shinken: ‘’service shinken start’‘

NRPE Module

What is it The NRPE module allows Shinken Pollers to bypass the launch of the check_nrpe process. It reads the check command and opens the connection by itself. It scales the use of NRPE for active supervision of servers hosting NRPE agents.

The command definitions should be identical to the check_nrpe calls.

How to define it The definition is very easy (and you probably just have to uncomment it):

```
define module{
     module_name       NrpeBooster
     module_type       nrpe_poller
}
```

Then you add it to your poller object:

```
define poller {
    [...]
    modules   NrpeBooster
}
```

Then just tag all your check_nrpe commands with this module:

```
define command {
   command_name   check_nrpe
   command_line   $USER1$/check_nrpe -H $HOSTADRESS$ -c $ARG1$ -a $ARG2$
   module_type    nrpe_poller
}
```

That’s it. From now on all checks that use this command will use Shinken’s NRPE module and will be launched by it.

Extending Shinken

Introduction There are a lot of "Modules" and "Addons" that are available for Shinken. Shinken can be extended by using different types of methods.

- Web interfaces from various open-source vendors can be used (Based on Livestatus API)
- Shinken itself can be extended using modules that are embedded into the various daemon processes

** (Arbiter, Poller, Receiver, Broker, Scheduler, Reactionner) * External software can provide functional enhancements for reporting, management or usability aspects

Shinken itself provides methods to extend the base functionality:

- *Broker modules* provide external access to runtime data from Shinken
- Poller modules such as *NRPE* and the *SNMP*
- Receiver modules like *NSCA* provide acquisition methods for Shinken
- Arbiter modules permit manipulating the configuration
- The webUI that permits embedding web interface elements

Independent software that works in concert with Shinken is available for:

- Monitoring remote hosts through agent software (*NIX, Windows, etc.)
- Submitting passive checks from remote hosts
- Managing the config files through a web interface
- Mobile phone UIs
- Desktop UIs and Hypervisors
- Desktop notification addons
- ...and much more

You can find many addons that are compatible with Shinken by visiting. The only caveat is that the addons should not use the status.dat file and preferably the modern API interfaces like Livestatus:

- Nagios.org
- SourceForge.net
- NagiosExchange.org
- Shinken community exchange for monitoring packs

Broker modules

The broker module receives messages from the Schedulers related to host, service check results. In addition to that it receives a copy of the compiled configuration at startup. What is special about the broker, is that without modules, the broker does nothing. It makes the configuration and result data available to modules. Modules are the ones in charge of doing something with the data. This could be exporting this "raw" data into flat files, databases or exposing it as an API.

The modules are presented according to their use cases.

- Core modules
- Livestatus Module for frontends
- Exporting data to metric databases

- SQL based Modules for frontends
- Exporting data to logging management systems
- Legacy modules for migration purposes
- Modules no longer supported

Core modules

simple_log: get all logs into one file You can get a log for all your daemons in a single file. With the exception of Debug level logs which are not sent through the network as a safe guard. Shinken state messages are ONLY logged at the debug level in the local log files. These are the ALL CAPS states that some 3rd party interfaces use to mine data from the historical logs. Actual state messages are sent as objects between the various daemons.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: simple_log
- path: path of the log file

Here is an example:

```
define module{
```

```
     module_name      Simple-log
     module_type      simple_log
     path             /usr/local/shinken/var/nagios.log
     archive_path     /usr/local/shinken/var/archives/
}
```

Syslog - Send all logs to a local syslog server Send all logs to a local syslog server. Support for remote syslog can be implemented if requested. Just lookup the syslog module, easy to modify. Use for example with Splunk, graylog2, Logstash, Elastic search, Kibana, or other log management and analysis system.

```
define module{
```

```
  module_name Syslog
  module_type syslog
}
```

Lightweight forwarder to Splunk Shinken state data from the local syslog can also be sent to a Splunk server for indexing, reports, SLA and analysis. Via syslog or better yet, the Splunk lightweight forwarder which supports, TCP, buffering and security parameters.

Livestatus API Module - Thruk, Nagvis and Multisite Web frontends There are three well known frontends and various small tools that can interface with the Livestatus API. This API is currently the most efficient method of sharing live data with external interfaces. It provides a rich query language similar to SQL, authentication, command execution, caching,connections persistence, multiple object methods (JSON, Python). All Livestatus data is kept in memory, there is no disk IO involved. It exposes configuration objects, the current state of the hosts and services as well as historical Shinken state log messages.

- MK Multisite
- Thruk

- NagVis

Have you installed the required packages to use the Livestatus module? You can look at the requirement section of the 10 minute installation guide for the requirement lists.

Livestatus Module

It takes the following parameters:

- module_name: name of the module called by the brokers
- module_type: livestatus
- host: IP interface to listen to. The default is '127.0.0.1'. '*' means 'listen on all interfaces'.
- port: TCP port to listen to.
- socket: Unix socket to listen to.
- allowed_hosts: a comma-separated list of IP-addresses which are allowed to contact the TCP port. Please keep in mind that these must be ip-addresses, NOT host names. (DNS lookups for every incoming livestatus request could hang up and therefore block the module)
- modules: a comma-separated list of modules (see below)
- pnp_path: relevant if you use the multisite gui. pnp_path points to the perfdata directory where the pnp4nagios data reside (it's the directory which contains a subdirectory for each host). Multisite needs it to display a small perfdata icon if a rrd file exists.
- To deactivate an input, the port- and socket-attributes can also take the value "none".

The Livestatus module itself can have sub-modules. In fact, it **must** have at least one submodule responsible for storing log events to a database, SQLite or MongoDB.

Livestatus module - Logstore Sqlite Stores log-broks to an sqlite database.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_sqlite
- use_aggressive_sql: Prefer the use of sql queries to pre-filter data prior to python filtering. This is required for very large installations, as the Python structures are not indexed when filtering. Optional argument set to 0 by default. To enable set the value to 1. Some erroneous output may occur, but informal testing has shown these corner cases do not occur.
- read_only: don't send any update to the database. Should be used when you run several livestatus modules : 1 instance is R/W, other are read only.
- database_file: the path to the sqlite database file which is used to store the log broks/messages. The default is 'var/livestatus.db'
- archive_path: the path to a subdirectory where database file archives will be created. Every day the data from the last day will be moved to an archive datafile. The default is 'var/archives'.
- max_logs_age: the maximum age of the log messages (before they are deleted from the database). The default is 1 year. The argument to this parameter takes the form <number>[<period of time>], where <period of time> can be d for days, w for weeks, m for months and y for years. This parameter is currently ignored. In future releases it will be used to automatically delete ancient database files.

Here is an example:

```
define module{
```

```
     module_name      Livestatus
     module_type      livestatus
     host             *       ; * = listen on all configured ip addresses
     port             50000   ; port to listen
     socket           /usr/local/shinken/var/rw/live
     modules          logsqlite
}
define module{
```

```
     module_name      logsqlite
     module_type      logstore_sqlite
     use_aggressive_sql     0 ; optional, by default set to 0. Only for large installations.
     database_file    /usr/local/shinken/var/livelogs.db
     max_logs_age     3m ; three months. Other time intervals are d=days, w=weeks, y=years
}
```

Livestatus module - Logstore MongoDB Stores historical log broks(inter daemon Shinken messages) to a MongoDB database. MongoDB is a distributed and very performant database that permits resilience and high availability. The current implementation has a few known broken pieces (some search functions are broken) and there are bugs in the implementation, so it is considered experimental until power users and developers have ironed out the bugs. It is the database of the future for Shinken.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_mongodb
- mongodb_uri: The address of the master. (Default: i_cant_write_the_uri_here_it_messes_the_wiki_up)
- replica_set: If you are running a MongoDB cluster (called a "replica set" in MongoDB), you need to specify it's name here. With this option set, you can also write the mongodb_uri as a comma-separated list of host:port items. (But one is enough, it will be used as a "seed")
- database: <undocumented>
- collection: <undocumented>
- max_logs_age: <undocumented>

The configuration looks quite similar to the sqlite one. **In a single-node installation and with decent amount of log traffic, the sqlite backend should be considered best practice, as it needs no extra software and is stable and fast (when run in-memory).**

Livestatus module - Logstore Null In case you don't need any logging (for instance, if you dedicate a livestatus module instance to nagvis), you can use this module.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_null

Network Based Modules - Graphite graphing Graphite is a graphing and data analysis tool. It is composed of a web frontend (graphite-web), fixed size databases (whisper) and data redistribution/munging daemon. (carbon) The first step is *having Graphite installed somewhere*, if you do not have Graphite installed, please do this and come back later.

Pre-requisite : Shinken 1.2.2+ is recommended for the best experience with Graphite.

graphite_perfdata: exports check result performance data to Graphite Export all performance data included in check results to Whisper databases managed by Graphite. Data is buffered, then exported once every broker time tick. (Once per second). Should a communication loss occur, it will buffer data for 5 minutes before dropping data. The tick_limit max is configurable, the only limitation is the amount of memory the buffered data can eat.

The graphite broker module (v1.2) sends data to graphite in the following format :

HOSTNAME.SERVICENAME.METRICNAME

It can be optionally enhanced to send it the following format :

_GRAPHITE_PRE.HOSTNAME.SOURCE.SERVICENAME.METRICNAME._GRAPHITE_POST

Each of the three variables are optional :

- The _GRAPHITE_PRE variable can be set per host/service to provide a more flexible naming convention. (ex. Prod.site1.Hostname.servicename)
- The _GRAPHITE_POST variable can be set per host/service to specify the more information concerning the variable being stored that graphite can use to determine the retention rule to use for the variable.
- The SOURCE variable can be set in shinken-specific.cfg for the WebUI module and the Graphite broker.

Metric names are converted from Shinken's format to a more restrictive Graphite naming. Unsupported characters are converted to "_" underscore. So do not be surprised to see that some names differ in the WebUI or directly in Graphite. Permitted characters in Graphite are "**A-Za-z_**.", the hyphen character is permitted from Shinken, though only future versions of Graphite will support it.

Performance data transfer method can be set to pickle, which is a binary format that can send data more efficiently than raw ascii.

It takes the following parameters:

- module_name: name of the module called by the brokers
- module_type: graphite_perfdata
- host: ip address of the graphite server running a carbon instance
- port: port where carbon listens for metrics (default: 2003 for raw socket, 2004 for pickle encoded data)
- use_pickle: Use a more efficient transport for sending check results to graphite instead of raw data on the socket (v1.2)
- tick_limit: Number of ticks to buffer performance data during a communication outage with Graphite. On tick limit exceeded, flush to /dev/null and start buffering again. (v1.2)
- graphite_data_source: Set the source name for all data coming from shinken sent to Graphite. This helps diferentiate between data from other sources for the same hostnames. (ex. Diamond, statsd, ganglia, shinken) (v1.2)

Here is an example:

```
define module {
```

```
module_name Graphite-Perfdata
host xx.xx.xx.xx
module_type graphite_perfdata
port 2004 ; default port 2003 for raw data on the socket, 2004 for pickled data
use_pickle 1 ; default value is 0, 1 for pickled data
tick_limit 300 ; Default value 300
```

```
graphite_data_source shinken ; default is that the variable is unset
}
```

SQL Based Modules - PNP4Nagios Graphing PNP4Nagios is a graphing tool that has a web interface for RRDTool based databases. Shinken can export performance data to an npcd database which will feed the RRD files (fixed sized round robin databases). You can *learn how to install PNP4Nagios* if you haven't done it already.

npcdmod: export perfdatas to a PNP interface Export all perfdata for PNP.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: npcdmod
- path: path to the npcd config file

Here is an example:

```
define module{
 module_name  NPCD
 module_type  npcdmod
 config_file  /usr/local/pnp4nagios/etc/npcd.cfg
}
```

SQL Based Modules - Frontend Centreon2 Centreon2 use a NDO database, so you will need the ndodb_mysql module for it.

ndodb_mysql: Export to a NDO Mysql database Export status into a NDO/Mysql database. It needs the python module MySQLdb (apt-get install python-mysqldb or easy_install MySQL-python).

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: ndodb_mysql
- database: database name (ex ndo)
- user: database user
- password: database user passworddt
- host: database host
- character_set: utf8 is a good one

Here is an example:

```
define module{
```

```
     module_name      ToNdodb_Mysql
     module_type      ndodb_mysql
     database         ndo       ; database name
     user             root      ; user of the database
     password         root      ; must be changed
     host             localhost ; host to connect to
     character_set    utf8      ;optionnal, UTF8 is the default
}
```

File based Legacy modules - perfdata export

service_perfdata: export service perfdatas to a flat file

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: service_perfdata
- path: path to the service perfdata file you want

Here is an example:

```
define module{
```

```
     module_name      Service-Perfdata
     module_type      service_perfdata
     path             /usr/local/shinken/src/var/service-perfdata
}
```

host_perfdata: export host perfdatas to a flat file

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: host_perfdata
- path: path to the host perfdata file you want

Here is an example:

```
define module{
```

```
     module_name      Host-Perfdata
     module_type      host_perfdata
     path             /usr/local/shinken/src/var/host-perfdata
}
```

Legacy File based Modules - Old CGI or VShell The Old CGI and VShell use the flat file export. If you can, avoid it! It has awful performance, all modern UIs no longer use this.

status_dat: export status into a flat file Export all status into a flat file in the old Nagios format. It's for small/medium environment because it's very slow to parse. It can be used by the Nagios CGI. It also export the objects.cache file for this interface.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: status_dat
- status_file: path of the status.dat file /usr/local/shinken/var/status.dat
- object_cache_file: path of the objects.cache file
- status_update_interval: interval in seconds to generate the status.dat file

Here is an example:

```
define module{
```

```
     module_name              Status-Dat
     module_type              status_dat
     status_file              /usr/local/shinken/var/status.data
     object_cache_file        /usr/local/shinken/var/objects.cache
     status_update_interval   15 ; update status.dat every 15s
}
```

Deprecated or unsupported modules

SQL Based MerlinDB This interface is no longer supported and is going to be completely removed from Shinken.

SQL based ndodb_oracle - Icinga web frontend using NDO Oracle This interface is no longer supported and is going to be completely removed from Shinken.

CouchDB: Export to a Couchdb database This interface is no longer supported and is going to be completely removed from Shinken.

TSCA (Thrift Service Check Acceptor)

TSCA is a receiver/arbiter module to receive hosts and services check results. It provides the same functions as NSCA with additional features. High performance binary transmission, multi line output and auto generated clients for a variety of languages.

What is thrift ? Let's cut and paste the wikipedia definition from'en.wikipedia.org/wiki/Apache_Thrift'_ :

"Thrift is an interface definition language that is used to define and create services for numerous languages.[1] It is used as a remote procedure call (RPC) framework [..]. It combines a software stack with a code generation engine to build services that work efficiently to a varying degree and seamlessly between ActionScript, C#, C++ (on POSIX-compliant systems), Cappuccino, Cocoa, Erlang, Haskell, Java, OCaml, Perl, PHP, Python, Ruby, and Smalltalk."

Installation In any case, you have to install thrift with support for python (on the server side) and languages you want to use for clients.

Get it from thrift.apache.org or in your favorite distribution repository.

Server side Go to the tsca module directory and generate the python stub for the server side installation

```
cd shinken/modules/tsca
$ thrift --gen py tsca.thrift
```

Declare the module is shinken-specific.org

```
define module{
      module_name     TSCA
      module_type     tsca_server
      host            0.0.0.0
      port            9090
}
```

Samples clients There are three(3) client samples written in python, ruby and java in contrib/clients/TSCA of the Shinken distribution. You can use and extend them to send data directly in your code directly to Shinken's TSCA receiver/arbiter module.

The samples clients read a CSV file from stdin and send them the the TSCA running on localhost:9090. The CSV has the following format :

```
hostname,service description,output,rc
```

Any use of TCP in an application should take care not to block the program and to have very short timeouts. For applications that need non blocking functions, prefer a UDP based transport or a local buffer file with a separate application(send_nsca, thrift, etc) to forward your data to Shinken.

Ruby Generate the stub

```
$ thrift --gen rb ../../../shinken/modules/tsca/tsca.thrift
```

Run the client

```
$ cat file_state | ruby RubyClient.rb
```

Python Generate the stub

```
$ thrift --gen py ../../../shinken/modules/tsca/tsca.thrift
```

Run the client

```
$ cat file_state | python PythonClient.py
```

java Generate the stub

```
$ thrift --gen java ../../../shinken/modules/tsca/tsca.thrift
```

Compile the client

```
$ ant
```

Run the client

```
$ cat file_state | java JavaClientThrift
```

VMWare Arbiter module

How it works The arbiter has a module that allows the host->VM automatic host dependency creation. In fact, the module is far more generic than just this. It's a generic "host link dependencies" module.

It reads a mapping file (simple json format) with son->father links. It call an external script at a regular interval : the one I wrote is a VMWare mapping one. It used the check_esx3.pl (that all ESX admin should have) plugin and generate the mapping file. When this file is changed, the module reloads it, creates new links and deletes old ones. So when you VMotion a virtual machine, in the next pass, there will be creation of a new link and deletion of the old one in the scheduler that manages it :)

How to define it The definition is very easy :

```
define module{
     module_name       VMWare_auto_linking
     module_type       hot_dependencies
     mapping_file      /tmp/vmware_mapping_file.json
     mapping_command   /usr/local/shinken/libexec/link_vmware_host_vm.py -x '/usr/local/shinken/libex
     mapping_command_interval 60   ; optionnal
     mapping_command_timeout   300 ; optionnal
}
```

Then you add it in you arbiter object :

```
define arbiter {
    [...]
    modules   VMWare_auto_linking
}
```

So here, it will call the script /usr/local/shinken/libexec/link_vmware_host_vm.py with a listing of the vCenter vcenter.mydomain.com and generate the mapping file /tmp/vmware_mapping_file.json.

You can call : /usr/local/shinken/libexec/link_vmware_host_vm.py –help

for the full help on this script.

It looks at the file modification time each second. This command can also be launch by an external cron of course.

Note: So if you want to write a script that does this for XEN servers, all you need is to generate a json file with all the mapping. I didn't wrote the doc about this, but you can look in the test file for it, the format is very very easy :)

Here is an example of the JSON mapping file syntax:

%%:ref:*["host", "physical_host"], ["host", "virtual_machine"* <["host", "physical_host"], ["host", "virtual_machine">, "host", "physical_host"], ["host", "other_virtual_machine" <"host", "physical_host"], ["host", "other_virtual_machine">]%%

So just a list of couple 'host' string (from now only host are managed) and the host name.

Beware about it : you need the real host_name, including case.

Web Service Module

The Ws_arbiter module is a Receiver or Arbiter module to receive passive check results from remote hosts via HTTP(s). This module is considered a work in progress but can be used for testing and improvement.

Configuring the Web Service Module If data is POSTed to this page, it will validate the data to determine if it is a service or host check result and submit the data to the Shinken external command queue.

The web service listens by default to TCP port 7760. The web service supports anonymous or authenticated access. Web service parameters are set in the Shinken-specific.cfg file, in the Ws_arbiter module. To enable the web service, simply add the module to your Arbiter or Receiver daemon configuration in Shinken-specific.cfg

Using the Web Service Module The web service listens for POSTs to: /push_check_result

Use curl or embed the HTTP calls in your software to submit check results.

curl -u user:password -d "time_stamp=$(date +%s)&host_name=host-checked&service_description=service-checked&return_code=0&output=Everything OK" http://shinken-srv:7760/push_check_result

Example with more readability:

```
curl
```

-u user:password -d "time_stamp=$(date +%s)

```
&host_name=host-checked
&service_description=service-checked
&return_code=0
&output=Everything OK
http://shinken-srv:7760/push_check_result
```

SNMP module

This part must be splitted and sent in all module repositories

Shinken integrated SNMP Module

SnmpBooster Download Install and Configure

- *What is the SnmpBooster module*
- Install and configure the SNMP acquisition module. [You are here]
- *Reference - SnmpBooster troubleshooting*
- *Reference - SnmpBooster design specification*
- *Reference - SnmpBooster configuration dictionnary*

Downloads

The SnmpBooster module and genDevConfig are currently in public beta prior to integration within Shinken. You can consult t

- github.com/xkilian/genDevConfig
- github.com/titilambert/shinken/tree/snmp_booster/shinken/modules (snmp_booster branch) * Simply right-click and download snmp_poller.py then copy it to shinken/modules/

Requirements The SnmpBooster module requires:

- Python 2.6+
- Shinken 1.2+
- PySNMP 4.2.1+ (Python module and its dependencies)
- ConfigObj (Python module)
- python-memcached
- memcachedb or memcached package for your operating system (ex. For Ubuntu: apt-get install memcachedb) *Note*

The genDevConfig profile generator depends on:

- Perl 5.004+
- 4 perl modules available from CPAN and network repositories. genDevConfig/INSTALL has the installation details.

STRONGLY RECOMMENDED: Use the same version of Python and Pyro on all hosts running Shinken processes.

Installation SnmpBooster:

- Install the dependencies
- Copy the file snmp_poller.py from the git repository to your shinken/modules directory.
- Configuration steps are listed in the present web page.

genDevConfig:

- Download and extract the archive to your server.
- See genDevConfig/INSTALL on how to install and configure it.

Configuration

How to define the SnmpBooster module in the Shinken daemons You need to modify shinken-specific.cfg, which is located in $shinken/etc/shinken-specific.cfg

Arbiter daemon configuration Simply declare the module:

```
modules SnmpBooster</code>
```

Scheduler daemon configuration

Simply declare the module:

<code>modules SnmpBooster

Poller daemon configuration Simply declare the module:

```
modules SnmpBooster</code>
```

SnmpBooster Module declaration

Included in Shinken v1.2.1 shinken-specific.cfg.

<code>define module {

```
module_name          SnmpBooster
module_type          snmp_poller
datasource           /usr/local/shinken/etc/packs/network/SnmpBooster/   ; SET THE DIRECTORY FOR YOUR
memcached_host       x.x.x.x  ; SET THE IP ADDRESS OF YOUR memcached SERVER
memcached_port       11211  ; default port for a memcached process
```

}

If you do not know the IP adress on which your memcache is listening, check under /etc/memcached.conf. Or do a:

```
netstat -a | grep memcached</code>
If you are running a test on the local machine you can leave memcached on 127.0.0.1 (localhost), but
```

How to define a Host and Service

Step 1

Create a template for your SNMP enabled devices.

Sample template:

<code>cd shinken/etc/packs/network/ mkdir SnmpBooster

vi shinken/etc/packs/network/SnmpBooster/templates.cfg

```
define command {
```

```
command_name    check_snmp_booster
command_line    check_snmp_booster -H $HOSTNAME$ -C $SNMPCOMMUNITYREAD$ -V 2c -t $ARG1$ -i $_SERVICE
module_type     snmp_poller
```

}

```
define service {
```

```
name                    default-snmp-template
check_command           check_snmp_booster!$_SERVICEDSTEMPLATE$!$_SERVICEINST$!$_SERVICETRIGGERGROUP
_inst                   None
_triggergroup           None
max_check_attempts      3
check_interval          1
retry_interval          1
register                0
```

}

```
define host{
```

```
name                    SnmpBooster-host
alias                   SnmpBooster-host template
check_command           check_host_alive
max_check_attempts      3
check_interval          1
retry_interval          1
use                     generic-host
register                0
```

}

Step 2 Define some hosts and services. You would typically use genDevConfig or another configuration generator to create these for you.

Mandatory service arguments related to SNMP polling:

```
_dstemplate                Cisco-Generic-Router  ; Name of a DSTEMPLATE defined in the SnmpBooster co
```

```
snmpcommunityread    which is set in your resource.cfg file
```

Optional service arguments related to SNMP polling with default values:

```
_inst                   None   ; Could be numeric: 0, None or an instance mapping function like: map
```

```
_triggergroup           None   ; Name of the triggergroup defined in the SnmpBooster config.ini file
```

Sample Shinken host and service configuration:

```
# Generated by genDevConfig 3.0.0
# Args: --showunused -c publicstring 192.168.2.63
# Date: Thu Aug 30 17:47:59 2012

```

Shinken integrated SNMP Module

Overview

What is it The SnmpBooster module allows Shinken Pollers to directly manage SNMP data acquisition. This is an all Python cross-platform SNMP module. It is tightly integrated with the Shinken Poller, Scheduler and Arbiter daemons to provide the best possible user experience.

Design specification summary

- STATUS - DESIGN SPEC PERFORMANCE
- [Done] Functions as an integrated Shinken Poller module
- [Done] Necessary integration code commited to Shinken official release (Integrated starting at v1.2)
- [Done] Ability to collect thousands of SNMP metrics per second
- [Done] Be compatible with distributed data acquisition
- [Done] Collect data for a host/check_interval tuple via SNMP in a single pass
- [Done] Use all builtin Shinken scheduler logic for retries, forced checks, timeouts, dependencies, parents
- [Done] Store collected data for the duration of the check_interval in a memcached/membase
- [Done] On a restart, after the first collection, be able to pick up where the last check left and calculate derived values
- [Done] Forced check are not allowed within 30 seconds of last SNMP query to the same host/check_interval, all other requests get data from the cache.
- [Done] Only a single request to the host/check_interval via SNMP is allowed at a time, all other requests get data from the cache.
- STATUS - DESIGN SPEC USABILITY
- [Done] Usage documentation
- [xxxx] SkonfUI and Discovery usage documentation
- [xxxx] Provide sample configuration packs in Shinken
- [Done] Provide sample config.ini with examples of all types of data * SNMP OIDS, DATASOURCES, DSTEMPLATES, TRIGGERS and TRIGGERGROUPS

- [Done] Directly compatible for use with genDevConfig Shinken SNMP configuration generator
- [Done] Provide meaningful feedback for users on errors
- [Done] Capture all tracebacks and convert them to actual error or warning messages
- STATUS - DESIGN SPEC FEATURES
- [Done] Return state and performance metrics
- [Done] Performance metrics can be returned in a Weathermap compatible format
- [Done] Configuration file format is ConfigObj INI
- [Done] Load all valid INI configuration files from a directory and merge them
- [Done] Load a single INI configuration file
- [xxxx] Load a list of INI configuration files
- [Done] Configuration file describes all generic acquisition parameters (OID, DATASOURCE, DSTEMPLATE, MAP, TRIGGER, TRIGGERGROUP)
- [Done] Supports Triggers which are calculation rules to determine states
- [Done] Triggers support an RPN (Reverse Polish Notation) calculation engine which includes mathematical and logical operators
- [Done] Each TRIGGER is associated with a severity level, WARNING or CRITICAL
- [Done] Multiple TRIGGERS can be associated with a TRIGGERGROUP
- [Done] Use builtin Python Operators
- [Done] Support DERIVE, TEXT, GAUGE and COUNTER data types
- [xxxx] Support TIMETICKS data type
- [Done] Support applying RPN based calculations to received metric for scaling or conversion purposes
- [Done] Use a Python SNMP library which supports asynchronous acquisition PySNMP
- [Done] Datasources can use rule based runtime instance mapping
- [Done] Set Snmp version as a check runtime option
- [Done] Set Snmp DSTEMPLATE as a check runtime option
- [Done] Set Snmp TRIGGERGROUP as a check runtime option
- [Done] Set Snmp COMMUNITY as a check runtime option
- [Done] Use Snmp version 2c GetBulk
- [xxxx] Support Snmp version 2c GetNext if GetBulk is not supported
- [xxxx] Support Snmp version 1 GetNext
- [xxxx] Set Snmp Timeout as a check runtime option, instead of a hardcoded value at 5 seconds
- STATUS - DESIGN SPEC MAINTAINABILITY
- [xxxx] Functions documented in the source code
- [Done] Critical functions documented in the source code
- [Done] Locking sections identified in the code
- [xxxx] Unit tests with at least 80% coverage

- [xxxx] Unit tests integrated with Shinken test suite
- [Done] Code hosted on github
- [xxxx] configuration validity and integrity checking of all INI files
- [xxxx] Pep8 compliant
- [xxxx] Pylint pass

genDevConfig Plugins - Compatibility status with SnmpBooster

- STATUS - genDevConfig maintained Plugins
- [Done] Avaya ES switches
- [Done] Avaya ERS routing switches
- [Done] Cisco 29x0 switches
- [Done] MIB-II Interfaces
- [Done] Cisco PIX/ASA
- [Done] JUNOS devices
- [Done] Cisco IOS routers
- [Done] NetSNMP unix hosts ** Validation required**
- [Done] Packeteer devices ** Validation required**
- [Done] Sensatronics devices ** Validation required**
- [Done] Foundry devices ** Validation required**
- [Done] Packeteer devices ** Validation required**
- [Done] Cisco CSS ** Validation required**
- [InProgress] New Cisco Access points
- STATUS - Other maintained Plugins

Tip: [xxxx] Denotes a specification that is planned but not implemented

[InProgress] Denotes a specification that is under development

[Done] Denotes a specification that is implemented

SnmpBooster reference dictionary

- Jump back to *SnmpBooster documentation index*

SnmpBooster.ini dictionary

There are five dictionaries:

- [DATASOURCE]
- [DSTEMPLATE]
- [MAP]
- [TRIGGER]

- [TRIGGERGROUP]

DATASOURCE DICTIONARY OidVariableName refers to an actual OID that can be queries using SNMP against the device on the network.

[VariableName] refers to a Datasource and all the information required to gather and prepare the data using SNMP ds_type refers to how the data should be prepared ds_calc refers to any scaling manipulations to make the data more understandable. This is an RPN expression, where the first variable is omitted, as it is always the $OidVariable ds_oid refers to the actual $OidVariable name. An instance identifier can be appended to the name to signify that an instance is provided by the Shinken service definition. This information is passed when the check is called. ...

DSTEMPLATE DICTIONNARY [DsTemplateName] refers to the name of the DSTEMPLATE that will be referred to in the Shinken service definitions. ds refers to the list of DATASOURCES to be collected. If an instance is expected for the list of DATASOURCES, it MUST be the same instance for all Oids. If a different instance is required, use a second DSTEMPLATE.

TRIGGER DICTIONNARY

TRIGGERGROUP DICTIONNARY

MAP DICTIONNARY

SnmpBooster.ini example configuration This example definition will be used to explain each section.

[DATASOURCE]

```
OidmyOidDefinition = .1.3.6.1.45.0
[myOidDefinition] ; Use the same name as the myOidDeiniftion, but omit the leading "Oid"
    ds_type = DERIVE
    ds_calc = 8,*  ; RPN expression : Oid, 8, *  Which means Oid * 8 = Total
    ds_oid = $OidmyOidDefinition
```

[DSTEMPLATE]

```
[myCiscoRouter]
    ds = myOidDefinition
```

[TRIGGER]

```
[trigger1]
    warning = RPN expression
    critical = RPN expression
[trigger2]
    warning = RPN expression
    critical = RPN expression
```

[TRIGGERGROUP]

```
[CiscoRouterTriggers]
    triggers = trigger1, trigger2
```

SnmpBooster.ini configuring SNMP Datasources

The first location is generic data related to SNMP parameters.

- DATASOURCE information * SNMP OID * Type of data and how can it be interpreted (GAUGE, COUNTER, COUNTER64, DERIVE, DERIVE64, TEXT, TIMETICK) * Data format preparation (Scaling the data for example bits to bytes) * Is there an instance to append to the
- Instance MAP function * Mapping the instance dynamically using a function * Data or rules related to the mapping function

SnmpBooster.ini configuring SNMP DSTEMPLATES

- DSTEMPLATEs to associate DATASOURCE to actual device classes * List of DATASOURCES associated with a, for example, Cisco 1900 router. Which in turn can be applied to a Shinken service

SnmpBooster.ini setting triggers/thresholds

- TRIGGER and TRIGGERGROUPS to apply thresholding rules * Define triggers and associate them with a TRIGGERGROUP name that can be applied to a Shinken Service

Shinken integrated SNMP Module

Overview

- Jump back to *SnmpBooster documentation index*

Tip: The module is now in public beta as of 2012-10-26! Have Fun!

Nothing new to add, more to come in 2013. 2013-01-19.

What is it The SnmpBooster module allows Shinken Pollers to directly manage SNMP data acquisition. This is an all Python cross-platform SNMP module. It is tightly integrated with the Shinken Poller, Scheduler and Arbiter daemons to provide the best possible user experience.

Why use it The SnmpBooster module is designed to be very efficient and scalable. It has a very flexible configuration method to make it easy to use with Shinken Monitoring Packs and Shinken discovery runners like genDevConfig.

This acquisition module was professionally designed and developed.

It is meant to be used by the very capable discovery engine genDevConfig (**v3.0.5 and newer**) originally developed for the Cricket SNMP monitoring tool and converted for use with Shinken.

It is one of the very few serious SNMP v2c implementation making use of SnmpGetBulk type requests.

How does it work

Shinken Integration

1. The SnmpBooster Arbiter module reads the Shinken SnmpBooster configuration file(s). It reads the check commands and based on the values in the check commands that use the snmp_poller module it will creates a shared configuration cache using memcached/memcachedb. The memcache key is always the combination of the hostname. This permits to tie together Shinken Hosts and Services with the SNMP specific configuration. (MongoDB and Redis are planned to be supported in the future) The Scheduler daemon schedules Host and Service checks as it normally does.

3. The SnmpBooster module will check that a memcache host key exists for the check to be launched. Then the SnmpBooster poller module will query all services related to a host for a given acquisition frequency in one pass. (all checks done every 2 minutes will be executed in bulk, same for those every 5 minutes)

5. Check results are cached for the acquisition check_interval. The next time a check request for data from the same host is received from the Scheduler, the data will be fetched from memcache. Resulting is extremely low check latency.

2. 6. The SNMP checks still benefit from retries, timeouts, forced checks, dependencies and the powerful Scheduler daemon logic.

6. The Scheduler daemon can still force an immediate re-check by flushing the cache. This is required for the dependency model.

Performance SnmpBooster uses SNMP v2c getbulk for high efficiency, unless forced to use SNMP v2c get-next or SNMPv1 get-next. GetBulk uses a single request PDU to ask for multiple OIDs or even entire tables, instead of sending one request PDU per OID.

For example: *A typical 24 port network switch with two uplinks might use 375 OIDS (8 OIDs per interface, plus general OIDs for chassis health, memory, cpu, fans, etc.). **SnmpBooster will only require around 4 request PDUs*

*instead of 375 request PDUs**. Each PDU is a request packet which takes time to create, send get processed and return. More timeouts to manage, more connections, more impact on the remote device and more latency means much fewer checks per second.*

The SnmpBooster module supports automatic instance mapping for OIDs. (Ex. Based on the interface name it will figure out that the SNMP index(or instance) is 136. This is automatically handled by genDevConfig and SnmpBooster, no user input required. :-)

The generic SNMP configuration information is stored in the Shinken SnmpBooster INI files. There is a Defaults_unified.ini and a series of other Defaults files, one per discovery plugin for genDevConfig.

Important: genDevConfig plugins have all been converted to use the new dynamic instance mapping methods. You are now free to use most if not all Defaults*.ini files included with genDevConfig. 2012-10-28

Limitations You should have memcached instances running on each poller responsible for snmp polling. You should have your pollers with SnmpBooster in the same datacenter, as they need to be on the same machine with good connectivity to the active memcached instance. SnmpBooster is not compatible with distributed pollers in multiple datacenters, sorry, the current design of SnmpBooster uses a single centralized memcached instance for storing the timeseries data. For distributed datacenters to be supported, each poller+scheduler+memcached must be realm restrained, which is not the case today.

Design specification *SnmpBooster design specification* and current development status.

Data model The information required to define the data is split in two locations.

The first location is the host and service Shinken configuration (You need to generate or write this)

- Device specific information
  - IP addresses, host_names, device types, instance keys
  - A DSTEMPLATE must be referred to in the Service definition
  - A static SNMP instance could be referred to in the Service definition
  - An SNMP instance MAP function could be referred to in the Service definition
  - A TRIGGERGROUP could be refered to in the Service definition

The second location is SNMP Defaults.* templates. (Here you can create new devices or add new data sources)

- DATASOURCE information
  - SNMP OID
  - Type of data and how can it be interpreted (GAUGE, COUNTER, COUNTER64, DERIVE, DERIVE64, TEXT, TIMETICK)
  - Data format preparation (Scaling the data for example bits to bytes)
  - Is there an instance to append to the
- Instance MAP function * Mapping the instance dynamically using a function * Data or rules related to the mapping function
- DSTEMPLATEs to associate DATASOURCE to actual device classes * List of DATASOURCES associated with a, for example, Cisco 1900 router. Which in turn can be applied to a Shinken service
- TRIGGER and TRIGGERGROUPS to apply thresholding rules * Define triggers and associate them with a TRIGGERGROUP name that can be applied to a Shinken Service

A final location containes rules to build your Shinken configuration.

- genDevConfig plugins create Shinken configurations

Installation and configuration *SnmpBooster installation*

Reference Dictionnary *SnmpBooster reference dictionary*

Troubleshooting *SnmpBooster troubleshooting*

Graph templates These are .graph files defined in your Shinken configuration directory. Refer to the Shinken graphite templates(Not yet created) or PNP4Nagios how-to documentation. The graph templates are independent from SnmpBooster and provide templates for any collected data from Shinken.

SnmpBooster Troubleshooting

- Jump back to *SnmpBooster documentation index*

Check your config

- Have you defined the poller module name?
- Have you defined the correct path to the directory containing your Defaults*.ini files?
- Have you addded the Snmpbooster module to your arbiter, poller, scheduler?
- Have you added copied the genDevConfig templates.cfg in shinken/packs/network/SnmpBooster/
- Have you installed PySNMP, memcached and other dependencies?

Software version consistency Shinken and SnmpBooster now require **the same Python and Pyro version on all hosts running a Shinken daemon**.

If you cannot use the packaged version of Python and its modules (Pyro, memcached, etc.). Use virtualenv to declare a python version to use and install all required modules in that virtualenv.

Software version requirements Have you verified that the *requirements* are met. Python, PySNMP, Shinken, Pyro, memcached, etc.

Validate your check command arguments Use the check_plugin command and comment out the module to learn what were the exact arguments sent by the poller. This will permit you to validate all the arguments, like snmp community string, inheritance, template application, etc.

Validate connectivity

Take a packet trace using a tool like Wireshark to validate that the remote host is responding.

- Has the host responded
- **Is SnmpBooster repeating the request more often than the polling interval.**
  - If you are seeing repeated requests your device may have a compatibility issues.

- Save an snmpwalk of the device, get a packet trace using Wireshark, set the poller to debug and save the poller.log file (shinken/var/poller.log). Send all three to the SnmpBooster developers.
- Note: It is normal to see one or more bulkGet requests if you are getting large amounts of data. Ex. a 24 port switch will take 2-3 request packets.

Performance Make sure you have a low latency connection to your memcache from the Poller. Your memcache server can be replicated to all your poller hosts that should also run memcache instances. Check that memcached is running: netstat -a | grep memcached

Faulty Template A bad snmp_template file was distributed in the genDevConfig sample-config directory, there were two glaring errors.

This was fixed on 2012-10-16. Make sure you update your template, or use the data from the wiki.

Note that the template should be called: SnmpBooster-template.cfg to make it easier to troubleshoot in the logs. So when you search for SnmpBooster in your logs it will show up as well.

Log files All warnings and errors generated by the SnmpBooster module start with "[SnmpBooster] error text" and are logged using the standard Shinken logger.

The Arbiter daemon can output initial configuration, loading of host keys and intervals in memcached type error messages. The Scheduler daemon can output scheduling and alert related messages. The Poller daemon can output messages related to instance mapping, acquisition timeouts, invalid community strings, cache failures and more. These are available in the Web interface, as they are placed in the check results for the service.

You can simply do a "grep SnmpBooster *" in your shinken/var directory to see the latest messages related to the SnmpBooster module. You can also sort messages by timestamp to make it easy to find where and when errors occurred.

cd shinken/var grep SnmpBooster *

memcache persistence If you restart your memcache server or memcache crashes, your poller will no longer be able to validate that a host exists in memcache prior to writing.

You should use memcachedb to achieve persistence in case of memcache failures.

Common errors returned by SnmpBooster in the log file Errors should be fairly explicit and mean what they say, though there can be exceptions. Lets try to clear some of them.

__Arbiter log **errors__**

Missing ds_oid : This means that a variable in your OID definitions is missing, or your DATASOURCE is not named correctly or your ds_oid variable is missing. There is a typo in your ds_oid variable (ex. ds-oid, or ds_oid = $OidNameIncorrectFFFRA.%(instance)s).

Datasource not defined : Your DSTEMPLATE uses a DATASOURCE that doesn't exist check the [DataSourceName] you are referring to. Does it contain the expected OID variable, $OidName.

Missing ds_type : The DATASOURCE always needs to have a ds_type definition, GAUGE, COUNTER, DERIVE, TEXT, TIMETICK, DERIVE64, COUNTER64.

__Poller log **errors__**

Problems with calculations, repeated polling, hosts not responding, etc.

__Memcached **errors__**

memcachedb and memcached do not use the same default port. Configure the correct memcachedb port to match what is declared in your SnmpBooster module under shinken-specific.cfg.

On Ubuntu 12.04 the default installation is on port 21201 instead of 11211. This causes the error "[SnmpBooster] Memcache server (127.0.0.1:11211) is not reachable" when Shinken starts.

To change it, you must edit the file /etc/memcachedb.conf

Memcached Notes On Ubuntu 12.04 the default instalation is on port 21201 instead of 11211. This causes the error "[SnmpBooster] Memcache server (127.0.0.1:11211) is not reachable" when shinken starts.

To change it, you must edit the file /etc/memcachedb.conf

WebUI module

This part must be splitted and sent in all module repositories

WebUI integration with Shinken The WebUI is an external broker module. So it's an external process launched by the broker that "eats" broks (broker messages) from the brokers. So it can get *all* broks if you place this broker in your top level realm.

The WebUI does not use a database to get data. Instead, it use a "regenerator" object that will eat each broks, and will "recreate" all Hosts/Services/Contacts objects as if the code was in the scheduler daemon. So basically, WebUI and pages always reflect the CURRENT state of hosts/services objects.

The WebUI http layer is managed by bottle.py. It's a small but powerful framework.

How does the WebUI function globally ?

There a 2 Threads running:

- the main thread is the bottle.py (http) listener. It will use the best backend it finds. We recommend using python-paste. If it does not find one, it will use the default swsgi. Paste is multi-thread, swsgi is mon-thread, so please use paste if you want to avoid locking problems.
- the 2nd thread is the regenerator one. It only gets broks and gives them to the regenerator object.

There is a lock system between the threads. You can have N Http requests in progress without problem, but during this time the renererator one will wait. During execution of the regenerator, no requests are processed. This is not considered a problem, as the regenerator is very quick, and there is only a 1s lock for a 7k service conf loading, so it's not a huge problem.

What is a WebUI User? A WebUI user is a contact. A true contact object. You must match a contact name for your user.

To create a new page? All pages are in the shinken/webui/plugins directory. Each "part" has it's own directory. A part (like the eltdetail, element detail) can have more than one "page" (like /host or /service for eltdetail).

From here we will supose you want to create a "/contact" page.

You can copy the dummy example in the plugins directory into a contact directory.

You need to change the contact/dummy.py file into a contact/contact.py file, because the webui will search for a dir/dir.py file to "load".

Templates Templates are HTML with some Python code in it in the plugins/*/views direcotry for specific templates, and the "global layout" (menu and all common part) in the webui/views directory.

Your template must call the template layout (layout.tpl in the webui/views directory) wit ha "rebase" call.

If you put the rebase call at the beginning of your template, all there is below will be place "inside" the layout that will call the common javascripts and css, make the menu adn then call your html/python code.

The rebase call can take arguments. You MUST give it:

- user: the user you give it in the return dict of your .py code

Then all is optional:

- title: title of the page
- top_right_banner_state: int, global state with clouds to put in your top right page. Look at the problem.tpl code for an example.
- js and css list: list of YOUR specific javascript or css to call AFTER the common ones.
- refresh: boolean, set the refresh to 60s or do not refresh at all

- menu_part: will put the little "^" under this part of the menu.

Example of a call, taken from the problems view:

```
rebase layout title='All problems', top_right_banner_state=top_right_banner_state, js=['problems/js/a
roblems/js/autocompleter.Request.js', 'problems/js/autocompleterObserver.js'], css=['problems/css/acc
ms/css/autocompleter.css', 'problems/css/perfometer.css'], refresh=True, menu_part='/'+page, user=use
```

Call Python objects in your templates Your templates are mainly HTML code. But of course you can call python code in it. The dict you returns in the plugin.py call will be available in this page.

For example, the my_host variable will be available in the page with the host object you find (or None if your give it a bad name of course). Then you can "call" python with for example here to show the host_name: `<span>My host name is *my_host.host_name* </span>` is a way in the templates to "call a variable or function" that will return a string, here the host_name.

If the function or property you call must return HTML code that SHOULD be output as it, without "protection", you must put a ! before your call.

Let use an example where the output value of an host is in fact an html output. If you use the code `my_host.output`, bottle.py will "protect" the html generated by escaping the string, and change <> characters with escaped value. You can change this by calling `my_host.output`. Of course, it's a security problem if the output is with a javascript code...

You can also "loop" or put "if" in your template. You just need to put your code with a % before. Like

```
%for i in xrange(1, 10):
  My valus is  {{i}}
%end
```

You must put the %end here, the indentation will NOT be enougth, sorry.

For an if it's also easy:

```
%if host.active_checks_enabled:
  The host got active checks enabled
%else:
  The host DO NOT have active check enabled
%end
```

Which javascript lib are you using? It's mootools 1.3 with all options :)

What to do?

- Finish the /mobile part
- List of current alerts
- Host info
- Host status
- Host interfaces
- Hostgroup status
- dashboard hierachique with states, and BP
- Nagvis
- add bp in nagvis auto-map

- event sources
- correlation
- pre-filtering/enrichment
- user profile
- host/srv conf

WebUI search syntax work in progress

not that we couldn't tell. ;) eh eh

beware the working men and flying tools!

WebUI SSL Certification Lets start: the goal to to have the server.pem and client.pem file in etc/certs.

Go to the etc/certs directory.

```
openssl req -new -nodes -out server.req -keyout server.key -config ./shinken_openssl_cnf
openssl ca -out server.pem -config ./shinken_openssl_cnf -infiles server.req
cp server.pem server.pem.bkp
cp server.key server.pem
cat server.pem.bkp >> server.pem
cp server.pem client.pem
```

You can try to get the validity with for the arbiter with:

```
openssl s_client -connect localhost:7770</code>
```

Amazon AWS/EC2 import

Description

You can import data from Amazon AWS/EC2 **'AWS'**_ into Shinken to create hosts.

Amazon provide VM hosting with EC2. With this arbiter module, you will be able to load your EC2 hosts into Shinken.

Prerequisites

You will need the **'libcloud'**_ package installed on your Arbiter server.

Configuring the Landscape import module

In your shinken-specific.cfg file, just add (or uncomment):

```
define module {
 module_name      AWS
 module_type      aws_import

 # Configure your REAL key and secret for AWS
 api_key              PAAAB2CILT80I0ZA0999
 secret           GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH
```

```
 default_template generic-host        ; if the host is not tagged, use this one
 }
```

- Put in key and secret your private Landscape access. * default_template will be used if your host is not "tagged" in Landscape

Configuring the Arbiter module

And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master

     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           AWS
     }
```

Restart your Arbiter and it's done :)

Generated hosts

The configuration generated will look as below :

```
define host {
    host_name            i-3fc56e5a
    address              8.8.4.4
    use                  t1.micro,MyTag,EC2,generic-host
    _EC2_AVAILABILITY    us-east-1a
    _EC2_CLIENTTOKEN
    _EC2_DNS_NAME
    _EC2_GROUPS          quicklaunch-1
    _EC2_IMAGEID         ami-1b814f72
    _EC2_INSTANCEID      i-3fc56e5a
    _EC2_INSTANCETYPE    t1.micro
    _EC2_KERNELID        aki-825ea7eb
    _EC2_KEYNAME         testaws
    _EC2_LAUNCHDATETIME  2012-09-26T12:19:38.000Z
    _EC2_LAUNCHINDEX     0
    _EC2_PRIVATE_DNS
    _EC2_PRIVATE_IP
    _EC2_PRODUCTCODE
    _EC2_PUBLIC_IP       8.8.4.4
    _EC2_RAMDISKID       None
    _EC2_STATUS          stopped
    _EC2_TAGS            demo:myvalue,use:MyTag
 }
```

Here with a stopped t1.micro instance with no name. You can put your how "use" parameter by adding a EC2 tag "use" on your VM. It will be output on the host configuration so you can setup the monitoring as you want. .. _libcloud: http://libcloud.apache.org/index.html .. _AWS: https://console.aws.amazon.com

Amazon AWS/EC2 import

Description

You can import data from Amazon AWS/EC3 **'AWS'**_ into Shinken to create hosts.

Amazon provide VM hosting with EC3. With this arbiter module, you will be able to load your EC2 hosts into Shinken.

Prerequisites

You will need the **'libcloud'**_ package installed on your Arbiter server.

Configuring the Landscape import module

In your shinken-specific.cfg file, just add (or uncomment):

```
define module {
 module_name      AWS
 module_type      aws_import

 # Configure your REAL key and secret for AWS
 api_key              PAAAB2CILT80I0ZA0999
 secret           GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH
 default_template generic-host        ; if the host is not tagged, use this one
 }
```

- Put in key and secret your private Landscape access. * default_template will be used if your host is not "tagged" in Landscape

Configuring the Arbiter module

And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master

     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           AWS
     }
```

Restart your Arbiter and it's done :)

Generated hosts

The configuration generated will look as below :

```
define host {
    host_name            i-3fc56e5a
    address              8.8.4.4
    use                  t1.micro,MyTag,EC2,generic-host
```

```
    _EC2_AVAILABILITY    us-east-1a
    _EC2_CLIENTTOKEN
    _EC2_DNS_NAME
    _EC2_GROUPS          quicklaunch-1
    _EC2_IMAGEID         ami-1b814f72
    _EC2_INSTANCEID      i-3fc56e5a
    _EC2_INSTANCETYPE    t1.micro
    _EC2_KERNELID        aki-825ea7eb
    _EC2_KEYNAME         testaws
    _EC2_LAUNCHDATETIME  2012-09-26T12:19:38.000Z
    _EC2_LAUNCHINDEX     0
    _EC2_PRIVATE_DNS
    _EC2_PRIVATE_IP
    _EC2_PRODUCTCODE
    _EC2_PUBLIC_IP       8.8.4.4
    _EC2_RAMDISKID       None
    _EC2_STATUS          stopped
    _EC2_TAGS            demo:myvalue,use:MyTag
 }
```

Here with a stopped t1.micro instance with no name. You can put your how "use" parameter by adding a EC2 tag "use" on your VM. It will be output on the host configuration so you can setup the monitoring as you want. .. _libcloud: http://libcloud.apache.org/index.html .. _AWS: https://console.aws.amazon.com

The distributed retention modules

The high availability allow the Arbiter to send a configuration to a spare scheduler, but a spare scheduler does not have any saved states for hosts and services. It will have to recheck them all. It's better to use a distributed retention module so spares will have all the information they need to start with an accurate picture of the current states and scheduling :)

Non distributed retention modules

If you are just running tests on a single server, use the pickle or memcache retention modules You can also use MongoDB if you already have it installed for use with the WebUI.

MongoDB

MongoDB is a scalable, high-performance, open source NoSQL database written in C++.

Step 1: Install MongoDB:

We will use mongodb package from 10gen repository, so we start by adding it in apt sources list:

```
echo 'deb http://downloads-distro.mongodb.org/repo/debian-sysvinit dist 10gen' > /etc/apt/sources.lis
apt-get update
```

And we install it:

```
apt-get install mongodb-10gen
```

And we install pymongo, the python interface to MongoDB, with easy_install to avoid packages versions problems (like here **'forums.monitoring-fr.org/index.php?topic=5205.0'_**):

```
apt-get remove python-pymongo
easy_install pymongo
```

And finally we start MongoDB :

```
/etc/init.d/mongodb start
```

Step 2: define a mongodb_retention module in your shinken-specific.cfg file:

```
define module {
  module_name MongodbRetention
  module_type mongodb_retention
  uri mongodb://localhost/?safe=true
  database shinken
}
```

Step 3: Declare a retention module for your scheduler(s) :)

Example:

```
#The scheduler is a "Host manager". It get hosts and theirs
#services. It scheduler checks for them.
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
     port     7768                  ; tcp port of the daemon

     #optionnal: modules for things as retention
     modules    MongodbRetention
     }
```

Step 4: Restart the Arbiter, and your Scheduler will now save its state between restarts. :)

Memcached

Memcached is a distributed memory resident key/value server. It's very easy to install:

```
sudo apt-get install memcached
sudo /etc/init.d/memcached start
```

The shinken module also needs the python-memcache package to talk to this server.

```
sudo apt-get install python-memcache
```

To use it,

Step 1: define a memcache_retention module in your shinken-specific.cfg file:

```
define module{
     module_name      MemcacheRetention
     module_type      memcache_retention
     server           127.0.0.1
     port             11211
}
```

Step 2: Declare a retention module for your scheduler(s) :)

Example:

```
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
     port     7768                  ; tcp port of the daemon
```

```
     #optional: modules for things as retention
     modules    MemcacheRetention
     }
```

Step 3: Restart the Arbiter, and your Scheduler will now save its state between restarts. :)

Redis

Redis is a distributed key/value server (on disk and in-memory). It's very easy to install:

```
sudo apt-get install redis-server
sudo /etc/init.d/redis-server start
```

The shinken module also need the python-redis package to talk to this server.

```
sudo apt-get install python-redis
```

Step 1: define a redis_retention module in your shinken-specific.cfg file:

```
define module{
     module_name      RedisRetention
     module_type      redis_retention
     server           127.0.0.1
}
```

Step 2: Declare a retention module for your scheduler(s) :)

Example:

```
#The scheduler is a "Host manager". It get hosts and theirs
#services. It scheduler checks for them.
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
     port     7768                  ; tcp port of the daemon

     #optionnal: modules for things as retention
     modules    RedisRetention
     }
```

Step 3: Restart the Arbiter, and your Scheduler will now save its state between restarts. :) .. _forums.monitoring-fr.org/index.php?topic=5205.0: http://forums.monitoring-fr.org/index.php?topic=5205.0

How to enable and use Livestatus module

Define the Livestatus module

Start by reviewing the ''/etc/shinken/shinken-specific.cfg" file for this module:

```
define module{
```

```
module_name      Livestatus
module_type      livestatus
host             *       ; * = listen on all configured IP addresses
port             50000   ; port to listen on
database_file    /var/lib/shinken/livestatus.db
```

}

With these parameters:

- module_name: name of the module called by the brokers
- module_type: livestatus
- host: IP interface to listen to. The default is *, which means "listen on all interfaces".
- port: TCP port to listen to.
- socket: Unix socket to listen to.
- database_file: the path to the sqlite database file which is used to store the log broks/messages. The default is "var/livelogs.db"
- max_logs_age: the maximum age of the log messages (before they are deleted from the database). The default is 1 year. The argument to this parameter takes the form <number>[<period of time>], where <period of time> can be d for days, w for weeks, m for months and y for years.
- allowed_hosts: a comma-separated list of IP-addresses which are allowed to contact the TCP port. Please keep in mind that these **must be IP-addresses, NOT host names**. Because DNS lookups for every incoming livestatus request could hang up and therefore block the module.

Enable the Livestatus module

Still in ''/etc/shinken/shinken-specific.cfg'', find the object Broker and add "Livestatus" to its "modules":

```
define broker{
```

```
     broker_name      broker-1
[...]
```

```
     modules          Simple-log,Livestatus
}
```

Disable human readable logs

In ''/etc/shinken/nagios.cfg'', verify that the option **human_timestamp_log** is set to **0**.

In version 0.6.5, you can not have at the same time a simple-log file with human readable timestamp and a Livestatus database.

Exporting data for reporting

Shinken can export necessary data for reporting in 3rd party systems.

raw_socket module

The raw socket module exports reporting data using a syslog format to a raw TCP socket. Theses logs can be captured, parsed and indexed by any log management system like Splunk or Logstash.

Why export reporting data

Custom UIs like Thruk, Multisite, WebUI, Adagios, Nagios IX, etc. All have poor or inflexible reporting. Simply because these are not reporting engines.

This also permits to have a generic reporting method that can accept data from any Nagios, Shinken, Icinga or even Riemann.

Reporting module using Splunk

Splunk was selected as the reporting platform for creating, managing and presenting reports. Though the raw_socket module does not have any Splunk specific particularities. It is notable that Splunk reports can be embedded in any 3rd party UI using its REST API.

Raw_socket log format

The logs are plain-text and compliant with RFC3164. They use an intelligent date format, a configurable seperator " "(space by default), and key=value pairs in the message data portion of the log. Should a key or value contain a space they must be double quoted. This is syslog using structured data without going to full out JSON that may not be compatible with all log management systems.

The message fields that are supplied in each status update in addition to the standard syslog header are:

- Hostname
- Servicename
- Business impact
- Host/Service status
- Host/Service previous status
- Acknowedgement status
- Maintenance status

Any time the maintenance, host, service or acknowledgement status changes, a log is sent by the Shinken raw_socket module.

Having all relevant data in each log makes it very easy to compute reports for given time periods.

The hostgroup or service group memberships, custom variables or any other configuration related data should be queried from the monitoring system using its API (Livestatus in the case of Shinken and Nagios).

Raw_socket module availability

The module is available in both Shinken 1.4 and Shinken 2.0. The module will be integrated in master branches once unit tests and end-to-end testing is completed. 3rd quarter 2013.

Monitoring Linux System with Glances and checkglances.py

'Glances'_ is a fantastic multiplatform system monitoring tool writen by Nicolargo. Glances can run on (Linux, Windows, MacOS ...). There is a growing ecosystem around Glances and of course a Nagios/Shinken plugin : check-glances.py.

How does it work

Glances can run in server mode. It provide a XML-RPC server (over http) and allow to retrieve system information throuh a restful API. The only thing to do is to install and start Glances as server on the monitored host, then install checkglances.py on the shinken server and finaly install the glances pack.

Install glances

See the glances documentation to install glances on Linux.

<code bash> easy_install glances </code>

There is a debian startup script in the glances repository. And another one for centos here.

Install checkglances.py

Just follow the documentation for the checkglances.py prerequisites and put it in your nagios plugins folder.

Install the glances pack

Open a terminal as the shinken user and just type the following command

<code bash> shinken install glances </code>

Then just edit the configuration for a linux monitored host and tag it as **glances**

```
define host{
 name mylinuxhost
 use glances
 ...
```

Finaly restart the shinken arbiter

```
service shinken-arbiter restart
```

What will be monitored ?

For the moment just the basic system (ram, cpu, load, memory, filesystem and network).

If you want to modify the default thresholds for just a host you can do it by overiding the thresholds macro in your host definition. If you want to do it for several hosts, declare a new template and just add the desired thresholds macro to be overide.

Here is a list of the macros

```
::
```

> _LOAD_WARN 2 _LOAD_CRIT 3 _CPU_WARN 80 _CPU_CRIT 90 _MEMORY_WARN 90 _MEMORY_CRIT 95 _FS /, /home _FS_WARN 90 _FS_CRIT 95 _IFACES eth0, eth1 _NET_WARN 7500000 _NET_CRIT 10000000

Note the _FS and _IFACES macros. They leverage the ability to duplicate service for a given list of things to be monitored. Here you see that / and /home partitions will be monitored. If you want to modify this then just add your own in a new template that will inherit the glances template.

Shinken GLPI integration

Shinken supports importing hosts from GLPI

For people not familiar with GLPI, it is an Open-Source CMDB. Applicable to servers, routers, printers or anything you want for that matter. It is also a help-desk tool. GLPI also integrates with tools like FusionInventory for IT inventory management.

You can still have flat files AND GLPI if you want. Hosts imported from GLPI will be treated as standard hosts from flat file (inheritance, groups, etc). In fact, in this first version the module only sends the host_name to Shinken, but there should be more information extracted like network connexions for parents relations in the future. :)

Requirements

- python module MySQLdb
- Compatible version of GLPI Shinken module and GLPI version - ...
- etc..

Enabling GLPI Shinken module

In your shinken-specific.cfg file, just add (or uncomment):

```
#You know GLPI? You can load all configuration from this app(
#with the webservices plugins for GLPI, in xmlrpc mode
#and with plugin monitoring for GLPI)
# =============== Work with Plugin Monitoring of GLPI ===============
#All configuration read from this will be added to the others of the
#standard flat file
define module{
     module_name      GLPI
     module_type      glpi
     uri              http://localhost/glpi/plugins/webservices/xmlrpc.php
     login_name       glpi
     login_password   glpi
}
```

And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master
#    host_name       node1       ;result of the hostname command under Unix
     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           GLPI
     }
```

It's done :)

Ip Tag module

Why tag a host based on it's IP address?

We learned on the *DMZ monitoring* that you can "tag" a host with a poller_tag so it will be checked only by DMZ pollers. It can be tedious process to manually tag all these hosts. Shinken provides an automated method to do this.

This is handled by the arbiter ip_tag module.

Ip_tag module

The ip_tag module is an arbiter module that looks up the host address during the configuration parsing and compares it to an predefined IP range (IPV4 or IPV6). If the range matches, it can apply or add a property, such as poller_tag. Other types of tags could be related to locations, functions, administrative groups, etc.

Method: replace or append.

replace will put the value if the property is unset. This is the default method. .. warning:: Fix me: replace, implies overriding an existing value. And will cause user issues down the line. Rename it to set. Replace should be a different method altogether, so overall there should be 3 methods(set, append, replace).

append will add with a , if a value already exist

Here is an example that will set the poller_tag property with the value DMZ of all hosts that:

- have a their hostadress ip (or name resolved) in the range 192.168.0.1/24.
- do not already have a poller_tag property set

```
define module{
```

```
     module_name     IpTag
     module_type     ip_tag
     ip_range        192.168.0.1/24
     property        poller_tag
     value           DMZ
}
```

To use the module add it in the arbiter object:

```
::
```

define arbiter { [...] modules NSCA,IpTag

}

Add value instead of setting it

In the previous example we set the property poller_tag to a value. But what if we want to "add" a value, like a template name? We can change the "method" property of the module to "append" so we can add the "value" to the host property instead of replace it.

Here is an example where we want to add the "dmz" template on the hosts, while also keeping any defined templates:

```
define module{
```

```
    module_name   IpTag
    module_type   ip_tag
    ip_range      192.168.0.1/24
    property      use
    value         dmz

    # Optional method
    method append
}
```

For a host defined as:

```
define host{
```

```
    host_name   example_host1
    address     192.168.0.2
    use         linux
}
```

It will be "changed" internaly in:

```
define host{
```

```
    host_name   example_host1
    address     192.168.0.2
    use         linux,dmz
}
```

Name resolution Of course you don't need to set IP address in the address of your host. You can set a hostname, and it will be resolved, and then compared to the range. :)

Ubuntu Landscape import

Description

You can import data from Ubuntu Landscape into Shinken to create hosts.

Ubuntu Landscape, is a web app to manage all your linux servers (update and co), which is provided by Canonical, Ubuntu's parent company.

This is an Arbiter import module. The Arbiter manages the configuration.

Prerequisites

You will need the landscape-api package installed on your Arbiter server.

Configuring the Landscape import module

In your shinken-specific.cfg file, just add (or uncomment):

define module { module_name Landscape module_type landscape_import

Configure your REAL key and secret from Landscape key PAAAB2CILT80I0ZA0999 secret GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH default_template generic-host ; if the host is not tagged, use this one

If you are using a specific certificate for landscape_api #ca /path/to.ca.cert

If you need a proxy to access https://landscape.canonical.com/api/ #https_proxy http://user:secret@myproxy.com:3128

}

- Put in key and secret your private Landscape access.
- default_template will be used if your host is not "tagged" in Landscape
- If you are using a specific certificate for connexion, give the full path in ca
- You will certainly need an https proxy to access the Landscape API. If so, configure it there.

Configuring the Arbiter module

And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master
#    host_name       node1       ;result of the hostname command under Unix
     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           Landscape
     }
```

Restart your Arbiter and it's done :)

Tip: Your "tags" will be applied as templates for your hosts.

Shinken Livestatus API

Overview

- Jump back to Getting Started
- Jump back to *Livestatus module configuration*

What is it Livestatus API is the modern method of interacting with Shinken and Nagios based systems alike.

Originally developed for Nagios, MK Livetstatus, was re-implemented in Python for use with Shinken by professional developers. The access methods and query languages are the same.

Why use it It is fast.

It is network based using TCP.

It is standard for all Nagios and Shinken monitoring systems.

It uses in-memory structures for status data

It uses a back-end database for historical reporting

It uses an SQL based query language

It has a host of powerful nuts and bolts features (authentication, caching, connection persistence, multiple object methods (JSON, Python)).

What can I do with it? All programs and scripts use (or should use) this method to :

- Obtain the current state of hosts and services
- Obtain the current configuration related to hosts and services
- Send administrative commands (downtimes, comments, forcing checks)
- Filter information to display
- Obtain basic reports and event statistics

Shinken being a modern re-implementation of Nagios has additional features that are available in addition to the standard Livestatus API.

Shinken Livestatus API unique features can :

- Obtain Business Impact information
- Obtain intelligent dependency status hosts or services (combines dependency and parent information)
- Obtain Business Process states (same syntax as standard host and service queries)

How does it work

Livestatus uses a powerful SQL-like query language. The standard methods and parameters are defined at :

'MK Livestatus reference methods and query language definition'_

Full list of Shinken Livestatus API methods:

'Shinken mapping.py methods'_

What software uses Livestatus to interact with Shinken

Well known Web frontends

- MK Multisite
- Thruk
- NagVis
- Splunk for Nagios

Mobile Web frontends

- get list

Scripts

- Downtime management scripts
- Debug scripts

Installing Livestatus Have you installed the required packages to use the Livestatus module? You can look at the requirement section of the *10 minute installation guide* for the *requirement lists*.

How to enable Livestatus Very simple, jump to the *Shinken Broker configuration* section to enable it. .. _Shinken mapping.py methods: https://github.com/shinken-monitoring/mod-livestatus/blob/master/module/mapping.py .. _MK Livestatus reference methods and query language definition: http://mathias-kettner.de/checkmk_livestatus.html

NSCA module

The NSCA daemon module is used to receive send_nsca packets and submit them to the Shinken command pipe. The NSCA module can be loaded by the Receiver or Arbiter process. It will listen on port TCP/5667 for send_nsca packets.

Tip: Passive checks can be submitted *natively to the Shinken command pipe* or from remote hosts to modules, such as NSCA, AMQP or collectd, loaded in the Shinken Arbiter or Receiver process. AMQP is implemented for integration with the Canopsis Hypervisor, but could be re-used for generic messaging.

Note: The Shinken NSCA module implementation is currently limited to the "xor" obfuscation/encryption.

In your shinken-specific.cfg file, just add (or uncomment):

```
::
```

#You can send check result to Shinken using NSCA #using send_nsca command define module{

module_name NSCA module_type nsca_server host * port 5667 encryption_method 0 password helloworld

}

define receiver{

```
receiver_name    receiver-1
address          localhost
port             7773
modules          NSCA

timeout          3             ; 'ping' timeout
data_timeout     120           ; 'data send' timeout
max_check_attempts       3     ;  if at least max_check_attempts ping failed, the node is DEAD

#advanced
realm    All
}
```

This daemon is totally optional.

It's main goal is to get all passive "things" (checks but why not other commands) in distant realms. It will act as a "passive receive buffer" and will then dispatch the data or commands directly to the appropriate Scheduler or Arbiter process.

Data can be received from any Realm, thus the Realm option is nonsensical.

For now there is no init.d script to launch it. .. note:: Verify that the init script has been added.

It is launched like all other daemons:

```
bin/shinken-receiver -c etc/receiverd.ini
```

Tip: Alternatively, for small installations with you can configure a modules inside your Arbiter instead of the Receiver. It will listen the TCP/5667 port for send_nsca packets.

To configure the NSCA module in your Arbiter instead of Receiver. Add the NSCA module to your Arbiter object configuration.

```
::
```

define arbiter{ arbiter_name Arbiter-Master

 # host_name node1 ;result of the hostname command under Unix address localhost ;IP or DNS adress port 7770 spare 0 modules NSCA

}

Retention troubleshooting

The retention file contains the state of your host and services, so that they are kept when shinken is restarted.

Sometimes you'll want to inspect (and possibly fix) the retention file, in case you need to work-around a bug or simply better understand what is stored there.

When you use the PickleRetention module in the scheduler (cf. ''define scheduler" in ''shinken-specific.cfg''), you can simply manipulate the retention file using Python.

For this you can use the following code.

- It assumes Shinken is installed in ''/opt/shinken" with the retention file in ''/tmp/retention.dat'':
- Run and play with it interactively using ''ipython -i inspect_retention.py''.

```
#!/usr/bin/python
import pickle
import sys
sys.path.append('/opt/shinken')
import shinken

r = pickle.load(file('/tmp/retention.dat'))
h = r['hosts']

# Example:
# [(k,v) for (k,v) in h['your_host'].items() if k.find('downtime') >= 0]
#
# del h['your_host']
#
# for k,v in r['services'].items():
#     if 'your_host' in k:
#         del r['services'][k]
```

To save your changes:

- Stop Shinken: ''service shinken stop''
- Save the pickle: ''pickle.dump(r, open('/tmp/retention.dat', 'w'))''
- Start Shinken: ''service shinken start''

NRPE Module

What is it

The NRPE module allows Shinken Pollers to bypass the launch of the check_nrpe process. It reads the check command and opens the connection by itself. It scales the use of NRPE for active supervision of servers hosting NRPE agents.

The command definitions should be identical to the check_nrpe calls.

How to define it

The definition is very easy (and you probably just have to uncomment it):

```
define module{
     module_name       NrpeBooster
     module_type       nrpe_poller
}
```

Then you add it to your poller object:

```
define poller {
    [...]
    modules   NrpeBooster
}
```

Then just tag all your check_nrpe commands with this module:

```
define command {
   command_name   check_nrpe
   command_line   $USER1$/check_nrpe -H $HOSTADRESS$ -c $ARG1$ -a $ARG2$
   module_type    nrpe_poller
}
```

That's it. From now on all checks that use this command will use Shinken's NRPE module and will be launched by it.

Extending Shinken

Introduction

There are a lot of "Modules" and "Addons" that are available for Shinken. Shinken can be extended by using different types of methods.

- Web interfaces from various open-source vendors can be used (Based on Livestatus API)
- Shinken itself can be extended using modules that are embedded into the various daemon processes

** (Arbiter, Poller, Receiver, Broker, Scheduler, Reactionner) * External software can provide functional enhancements for reporting, management or usability aspects

Shinken itself provides methods to extend the base functionality:

- *Broker modules* provide external access to runtime data from Shinken
- Poller modules such as *NRPE* and the *SNMP*
- Receiver modules like *NSCA* provide acquisition methods for Shinken
- Arbiter modules permit manipulating the configuration
- The webUI that permits embedding web interface elements

Independent software that works in concert with Shinken is available for:

- Monitoring remote hosts through agent software (*NIX, Windows, etc.)
- Submitting passive checks from remote hosts

- Managing the config files through a web interface
- Mobile phone UIs
- Desktop UIs and Hypervisors
- Desktop notification addons
- ...and much more

You can find many addons that are compatible with Shinken by visiting. The only caveat is that the addons should not use the status.dat file and preferably the modern API interfaces like Livestatus:

- Nagios.org
- SourceForge.net
- NagiosExchange.org
- Shinken community exchange for monitoring packs

Broker modules

The broker module receives messages from the Schedulers related to host, service check results. In addition to that it receives a copy of the compiled configuration at startup. What is special about the broker, is that without modules, the broker does nothing. It makes the configuration and result data available to modules. Modules are the ones in charge of doing something with the data. This could be exporting this "raw" data into flat files, databases or exposing it as an API.

The modules are presented according to their use cases.

- Core modules
- Livestatus Module for frontends
- Exporting data to metric databases
- SQL based Modules for frontends
- Exporting data to logging management systems
- Legacy modules for migration purposes
- Modules no longer supported

Core modules

simple_log: get all logs into one file You can get a log for all your daemons in a single file. With the exception of Debug level logs which are not sent through the network as a safe guard. Shinken state messages are ONLY logged at the debug level in the local log files. These are the ALL CAPS states that some 3rd party interfaces use to mine data from the historical logs. Actual state messages are sent as objects between the various daemons.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: simple_log
- path: path of the log file

Here is an example:

```
define module{
```

```
     module_name      Simple-log
     module_type      simple_log
     path             /usr/local/shinken/var/nagios.log
     archive_path     /usr/local/shinken/var/archives/
}
```

Syslog - Send all logs to a local syslog server Send all logs to a local syslog server. Support for remote syslog can be implemented if requested. Just lookup the syslog module, easy to modify. Use for example with Splunk, graylog2, Logstash, Elastic search, Kibana, or other log management and analysis system.

```
define module{
```

```
  module_name Syslog
  module_type syslog
}
```

Lightweight forwarder to Splunk Shinken state data from the local syslog can also be sent to a Splunk server for indexing, reports, SLA and analysis. Via syslog or better yet, the Splunk lightweight forwarder which supports, TCP, buffering and security parameters.

Livestatus API Module - Thruk, Nagvis and Multisite Web frontends

There are three well known frontends and various small tools that can interface with the Livestatus API. This API is currently the most efficient method of sharing live data with external interfaces. It provides a rich query language similar to SQL, authentication, command execution, caching,connections persistence, multiple object methods (JSON, Python). All Livestatus data is kept in memory, there is no disk IO involved. It exposes configuration objects, the current state of the hosts and services as well as historical Shinken state log messages.

- MK Multisite
- Thruk
- NagVis

Have you installed the required packages to use the Livestatus module? You can look at the requirement section of the 10 minute installation guide for the requirement lists.

Livestatus Module

It takes the following parameters:

- module_name: name of the module called by the brokers
- module_type: livestatus
- host: IP interface to listen to. The default is '127.0.0.1'. '*' means 'listen on all interfaces'.
- port: TCP port to listen to.
- socket: Unix socket to listen to.
- allowed_hosts: a comma-separated list of IP-addresses which are allowed to contact the TCP port. Please keep in mind that these must be ip-addresses, NOT host names. (DNS lookups for every incoming livestatus request could hang up and therefore block the module)

- modules: a comma-separated list of modules (see below)
- pnp_path: relevant if you use the multisite gui. pnp_path points to the perfdata directory where the pnp4nagios data reside (it's the directory which contains a subdirectory for each host). Multisite needs it to display a small perfdata icon if a rrd file exists.
- To deactivate an input, the port- and socket-attributes can also take the value "none".

The Livestatus module itself can have sub-modules. In fact, it **must** have at least one submodule responsible for storing log events to a database, SQLite or MongoDB.

Livestatus module - Logstore Sqlite Stores log-broks to an sqlite database.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_sqlite
- use_aggressive_sql: Prefer the use of sql queries to pre-filter data prior to python filtering. This is required for very large installations, as the Python structures are not indexed when filtering. Optional argument set to 0 by default. To enable set the value to 1. Some erroneous output may occur, but informal testing has shown these corner cases do not occur.
- read_only: don't send any update to the database. Should be used when you run several livestatus modules : 1 instance is R/W, other are read only.
- database_file: the path to the sqlite database file which is used to store the log broks/messages. The default is 'var/livestatus.db'
- archive_path: the path to a subdirectory where database file archives will be created. Every day the data from the last day will be moved to an archive datafile. The default is 'var/archives'.
- max_logs_age: the maximum age of the log messages (before they are deleted from the database). The default is 1 year. The argument to this parameter takes the form <number>[<period of time>], where <period of time> can be d for days, w for weeks, m for months and y for years. This parameter is currently ignored. In future releases it will be used to automatically delete ancient database files.

Here is an example:

```
define module{
```

```
     module_name      Livestatus
     module_type      livestatus
     host             *       ; * = listen on all configured ip addresses
     port             50000   ; port to listen
     socket           /usr/local/shinken/var/rw/live
     modules          logsqlite
}
define module{
```

```
     module_name      logsqlite
     module_type      logstore_sqlite
     use_aggressive_sql     0 ; optional, by default set to 0. Only for large installations.
     database_file    /usr/local/shinken/var/livelogs.db
     max_logs_age     3m ; three months. Other time intervals are d=days, w=weeks, y=years
}
```

Livestatus module - Logstore MongoDB Stores historical log broks(inter daemon Shinken messages) to a MongoDB database. MongoDB is a distributed and very performant database that permits resilience and high availability.

The current implementation has a few known broken pieces (some search functions are broken) and there are bugs in the implementation, so it is considered experimental until power users and developers have ironed out the bugs. It is the database of the future for Shinken.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_mongodb
- mongodb_uri: The address of the master. (Default: i_cant_write_the_uri_here_it_messes_the_wiki_up)
- replica_set: If you are running a MongoDB cluster (called a "replica set" in MongoDB), you need to specify it's name here. With this option set, you can also write the mongodb_uri as a comma-separated list of host:port items. (But one is enough, it will be used as a "seed")
- database: <undocumented>
- collection: <undocumented>
- max_logs_age: <undocumented>

The configuration looks quite similar to the sqlite one. **In a single-node installation and with decent amount of log traffic, the sqlite backend should be considered best practice, as it needs no extra software and is stable and fast (when run in-memory).**

Livestatus module - Logstore Null In case you don't need any logging (for instance, if you dedicate a livestatus module instance to nagvis), you can use this module.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_null

Network Based Modules - Graphite graphing

Graphite is a graphing and data analysis tool. It is composed of a web frontend (graphite-web), fixed size databases (whisper) and data redistribution/munging daemon. (carbon) The first step is *having Graphite installed somewhere*, if you do not have Graphite installed, please do this and come back later.

Pre-requisite : Shinken 1.2.2+ is recommended for the best experience with Graphite.

graphite_perfdata: exports check result performance data to Graphite Export all performance data included in check results to Whisper databases managed by Graphite. Data is buffered, then exported once every broker time tick. (Once per second). Should a communication loss occur, it will buffer data for 5 minutes before dropping data. The tick_limit max is configurable, the only limitation is the amount of memory the buffered data can eat.

The graphite broker module (v1.2) sends data to graphite in the following format :

HOSTNAME.SERVICENAME.METRICNAME

It can be optionally enhanced to send it the following format :

_GRAPHITE_PRE.HOSTNAME.SOURCE.SERVICENAME.METRICNAME._GRAPHITE_POST

Each of the three variables are optional :

- The _GRAPHITE_PRE variable can be set per host/service to provide a more flexible naming convention. (ex. Prod.site1.Hostname.servicename)

- The _GRAPHITE_POST variable can be set per host/service to specify the more information concerning the variable being stored that graphite can use to determine the retention rule to use for the variable.
- The SOURCE variable can be set in shinken-specific.cfg for the WebUI module and the Graphite broker.

Metric names are converted from Shinken's format to a more restrictive Graphite naming. Unsupported characters are converted to "_" underscore. So do not be surprised to see that some names differ in the WebUI or directly in Graphite. Permitted characters in Graphite are "**A-Za-z_**.", the hyphen character is permitted from Shinken, though only future versions of Graphite will support it.

Performance data transfer method can be set to pickle, which is a binary format that can send data more efficiently than raw ascii.

It takes the following parameters:

- module_name: name of the module called by the brokers
- module_type: graphite_perfdata
- host: ip address of the graphite server running a carbon instance
- port: port where carbon listens for metrics (default: 2003 for raw socket, 2004 for pickle encoded data)
- use_pickle: Use a more efficient transport for sending check results to graphite instead of raw data on the socket (v1.2)
- tick_limit: Number of ticks to buffer performance data during a communication outage with Graphite. On tick limit exceeded, flush to /dev/null and start buffering again. (v1.2)
- graphite_data_source: Set the source name for all data coming from shinken sent to Graphite. This helps diferentiate between data from other sources for the same hostnames. (ex. Diamond, statsd, ganglia, shinken) (v1.2)

Here is an example:

```
define module {
```

```
module_name Graphite-Perfdata
host xx.xx.xx.xx
module_type graphite_perfdata
port 2004 ; default port 2003 for raw data on the socket, 2004 for pickled data
use_pickle 1 ; default value is 0, 1 for pickled data
tick_limit 300 ; Default value 300
graphite_data_source shinken ; default is that the variable is unset
}
```

SQL Based Modules - PNP4Nagios Graphing

PNP4Nagios is a graphing tool that has a web interface for RRDTool based databases. Shinken can export performance data to an npcd database which will feed the RRD files (fixed sized round robin databases). You can *learn how to install PNP4Nagios* if you haven't done it already.

npcdmod: export perfdatas to a PNP interface Export all perfdata for PNP.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: npcdmod
- path: path to the npcd config file

Here is an example:

```
define module{
 module_name  NPCD
 module_type  npcdmod
 config_file  /usr/local/pnp4nagios/etc/npcd.cfg
}
```

SQL Based Modules - Frontend Centreon2

Centreon2 use a NDO database, so you will need the ndodb_mysql module for it.

ndodb_mysql: Export to a NDO Mysql database Export status into a NDO/Mysql database. It needs the python module MySQLdb (apt-get install python-mysqldb or easy_install MySQL-python).

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: ndodb_mysql
- database: database name (ex ndo)
- user: database user
- password: database user passworddt
- host: database host
- character_set: utf8 is a good one

Here is an example:

```
define module{
```

```
     module_name      ToNdodb_Mysql
     module_type      ndodb_mysql
     database         ndo       ; database name
     user             root      ; user of the database
     password         root      ; must be changed
     host             localhost ; host to connect to
     character_set    utf8      ;optionnal, UTF8 is the default
}
```

File based Legacy modules - perfdata export

service_perfdata: export service perfdatas to a flat file

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: service_perfdata
- path: path to the service perfdata file you want

Here is an example:

```
define module{
```

```
    module_name      Service-Perfdata
    module_type      service_perfdata
    path             /usr/local/shinken/src/var/service-perfdata
}
```

host_perfdata: export host perfdatas to a flat file

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: host_perfdata
- path: path to the host perfdata file you want

Here is an example:

```
define module{
```

```
    module_name      Host-Perfdata
    module_type      host_perfdata
    path             /usr/local/shinken/src/var/host-perfdata
}
```

Legacy File based Modules - Old CGI or VShell

The Old CGI and VShell use the flat file export. If you can, avoid it! It has awful performance, all modern UIs no longer use this.

status_dat: export status into a flat file Export all status into a flat file in the old Nagios format. It's for small/medium environment because it's very slow to parse. It can be used by the Nagios CGI. It also export the objects.cache file for this interface.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: status_dat
- status_file: path of the status.dat file /usr/local/shinken/var/status.dat
- object_cache_file: path of the objects.cache file
- status_update_interval: interval in seconds to generate the status.dat file

Here is an example:

```
define module{
```

```
    module_name              Status-Dat
    module_type              status_dat
    status_file              /usr/local/shinken/var/status.data
    object_cache_file        /usr/local/shinken/var/objects.cache
    status_update_interval   15 ; update status.dat every 15s
}
```

Deprecated or unsupported modules

SQL Based MerlinDB This interface is no longer supported and is going to be completely removed from Shinken.

SQL based ndodb_oracle - Icinga web frontend using NDO Oracle This interface is no longer supported and is going to be completely removed from Shinken.

CouchDB: Export to a Couchdb database This interface is no longer supported and is going to be completely removed from Shinken.

TSCA (Thrift Service Check Acceptor)

TSCA is a receiver/arbiter module to receive hosts and services check results. It provides the same functions as NSCA with additional features. High performance binary transmission, multi line output and auto generated clients for a variety of languages.

What is thrift ?

Let's cut and paste the wikipedia definition from'en.wikipedia.org/wiki/Apache_Thrift'_ :

"Thrift is an interface definition language that is used to define and create services for numerous languages.[1] It is used as a remote procedure call (RPC) framework [..]. It combines a software stack with a code generation engine to build services that work efficiently to a varying degree and seamlessly between ActionScript, C#, C++ (on POSIX-compliant systems), Cappuccino, Cocoa, Erlang, Haskell, Java, OCaml, Perl, PHP, Python, Ruby, and Smalltalk."

Installation

In any case, you have to install thrift with support for python (on the server side) and languages you want to use for clients.

Get it from thrift.apache.org or in your favorite distribution repository.

Server side Go to the tsca module directory and generate the python stub for the server side installation

```
cd shinken/modules/tsca
$ thrift --gen py tsca.thrift
```

Declare the module is shinken-specific.org

```
define module{
      module_name     TSCA
      module_type     tsca_server
      host            0.0.0.0
      port            9090
}
```

Samples clients There are three(3) client samples written in python, ruby and java in contrib/clients/TSCA of the Shinken distribution. You can use and extend them to send data directly in your code directly to Shinken's TSCA receiver/arbiter module.

The samples clients read a CSV file from stdin and send them the the TSCA running on localhost:9090. The CSV has the following format :

```
hostname,service description,output,rc
```

Any use of TCP in an application should take care not to block the program and to have very short timeouts. For applications that need non blocking functions, prefer a UDP based transport or a local buffer file with a separate application(send_nsca, thrift, etc) to forward your data to Shinken.

Ruby Generate the stub

```
$ thrift --gen rb ../../../shinken/modules/tsca/tsca.thrift
```

Run the client

```
$ cat file_state | ruby RubyClient.rb
```

Python Generate the stub

```
$ thrift --gen py ../../../shinken/modules/tsca/tsca.thrift
```

Run the client

```
$ cat file_state | python PythonClient.py
```

java Generate the stub

```
$ thrift --gen java ../../../shinken/modules/tsca/tsca.thrift
```

Compile the client

```
$ ant
```

Run the client

```
$ cat file_state | java JavaClientThrift
```

VMWare Arbiter module

How it works

The arbiter has a module that allows the host->VM automatic host dependency creation. In fact, the module is far more generic than just this. It's a generic "host link dependencies" module.

It reads a mapping file (simple json format) with son->father links. It call an external script at a regular interval : the one I wrote is a VMWare mapping one. It used the check_esx3.pl (that all ESX admin should have) plugin and generate the mapping file. When this file is changed, the module reloads it, creates new links and deletes old ones. So when you VMotion a virtual machine, in the next pass, there will be creation of a new link and deletion of the old one in the scheduler that manages it :)

How to define it

The definition is very easy :

```
define module{
     module_name       VMWare_auto_linking
     module_type       hot_dependencies
     mapping_file      /tmp/vmware_mapping_file.json
     mapping_command   /usr/local/shinken/libexec/link_vmware_host_vm.py -x '/usr/local/shinken/libex
     mapping_command_interval 60   ; optionnal
     mapping_command_timeout   300 ; optionnal
}
```

Then you add it in you arbiter object :

```
define arbiter {
    [...]
    modules   VMWare_auto_linking
}
```

So here, it will call the script /usr/local/shinken/libexec/link_vmware_host_vm.py with a listing of the vCenter vcenter.mydomain.com and generate the mapping file /tmp/vmware_mapping_file.json.

You can call : /usr/local/shinken/libexec/link_vmware_host_vm.py –help

for the full help on this script.

It looks at the file modification time each second. This command can also be launch by an external cron of course.

Note: So if you want to write a script that does this for XEN servers, all you need is to generate a json file with all the mapping. I didn't wrote the doc about this, but you can look in the test file for it, the format is very very easy :)

Here is an example of the JSON mapping file syntax:

%%:ref:*["host", "physical_host"], ["host", "virtual_machine"* <["host", "physical_host"], ["host", "virtual_machine">, "host", "physical_host"], ["host", "other_virtual_machine" <"host", "physical_host"], ["host", "other_virtual_machine">]*%%*

So just a list of couple 'host' string (from now only host are managed) and the host name.

Beware about it : you need the real host_name, including case.

Web Service Module

The Ws_arbiter module is a Receiver or Arbiter module to receive passive check results from remote hosts via HTTP(s). This module is considered a work in progress but can be used for testing and improvement.

Configuring the Web Service Module

If data is POSTed to this page, it will validate the data to determine if it is a service or host check result and submit the data to the Shinken external command queue.

The web service listens by default to TCP port 7760. The web service supports anonymous or authenticated access. Web service parameters are set in the Shinken-specific.cfg file, in the Ws_arbiter module. To enable the web service, simply add the module to your Arbiter or Receiver daemon configuration in Shinken-specific.cfg

Using the Web Service Module

The web service listens for POSTs to: /push_check_result

Use curl or embed the HTTP calls in your software to submit check results.

curl -u user:password -d "time_stamp=$(date +%s)&host_name=host-checked&service_description=service-checked&return_code=0&output=Everything OK" http://shinken-srv:7760/push_check_result

Example with more readability:

```
curl
```

-u user:password -d "time_stamp=$(date +%s)

```
&host_name=host-checked
&service_description=service-checked
&return_code=0
&output=Everything OK
http://shinken-srv:7760/push_check_result
```

SNMP module

This part must be splitted and sent in all module repositories

Shinken integrated SNMP Module

The SnmpBooster module and genDevConfig are currently in public beta prior to integration within Shinken. You can consult t

- github.com/xkilian/genDevConfig
- github.com/titilambert/shinken/tree/snmp_booster/shinken/modules (snmp_booster branch) * Simply right-click and download snmp_poller.py then copy it to shinken/modules/

Requirements The SnmpBooster module requires:

- Python 2.6+
- Shinken 1.2+
- PySNMP 4.2.1+ (Python module and its dependencies)
- ConfigObj (Python module)
- python-memcached
- memcachedb or memcached package for your operating system (ex. For Ubuntu: apt-get install memcachedb) *Note*

The genDevConfig profile generator depends on:

- Perl 5.004+
- 4 perl modules available from CPAN and network repositories. genDevConfig/INSTALL has the installation details.

STRONGLY RECOMMENDED: Use the same version of Python and Pyro on all hosts running Shinken processes.

Installation SnmpBooster:

- Install the dependencies
- Copy the file snmp_poller.py from the git repository to your shinken/modules directory.
- Configuration steps are listed in the present web page.

genDevConfig:

- Download and extract the archive to your server.
- See genDevConfig/INSTALL on how to install and configure it.

Configuration

How to define the SnmpBooster module in the Shinken daemons You need to modify shinken-specific.cfg, which is located in $shinken/etc/shinken-specific.cfg

Arbiter daemon configuration Simply declare the module:

```
modules SnmpBooster</code>
```

Scheduler daemon configuration

Simply declare the module:

<code>modules SnmpBooster

Poller daemon configuration Simply declare the module:

```
modules SnmpBooster</code>
```

SnmpBooster Module declaration

Included in Shinken v1.2.1 shinken-specific.cfg.

<code>define module {

```
module_name          SnmpBooster
module_type          snmp_poller
datasource           /usr/local/shinken/etc/packs/network/SnmpBooster/   ; SET THE DIRECTORY FOR YOUR
memcached_host       x.x.x.x  ; SET THE IP ADDRESS OF YOUR memcached SERVER
memcached_port       11211  ; default port for a memcached process
```

}

If you do not know the IP adress on which your memcache is listening, check under /etc/memcached.conf. Or do a:

```
netstat -a | grep memcached</code>
If you are running a test on the local machine you can leave memcached on 127.0.0.1 (localhost), but
```

How to define a Host and Service

Step 1

Create a template for your SNMP enabled devices.

Sample template:

<code>cd shinken/etc/packs/network/ mkdir SnmpBooster

vi shinken/etc/packs/network/SnmpBooster/templates.cfg

```
define command {
```

```
command_name    check_snmp_booster
command_line    check_snmp_booster -H $HOSTNAME$ -C $SNMPCOMMUNITYREAD$ -V 2c -t $ARG1$ -i $_SERVICE
module_type     snmp_poller
```

}

```
define service {
```

```
name                    default-snmp-template
check_command           check_snmp_booster!$_SERVICEDSTEMPLATE$!$_SERVICEINST$!$_SERVICETRIGGERGROUP
_inst                   None
_triggergroup           None
max_check_attempts      3
check_interval          1
retry_interval          1
register                0
```

}

```
define host{
```

```
name                    SnmpBooster-host
alias                   SnmpBooster-host template
check_command           check_host_alive
max_check_attempts      3
check_interval          1
retry_interval          1
use                     generic-host
register                0
```

}

Step 2 Define some hosts and services. You would typically use genDevConfig or another configuration generator to create these for you.

Mandatory service arguments related to SNMP polling:

```
_dstemplate                Cisco-Generic-Router  ; Name of a DSTEMPLATE defined in the SnmpBooster co
```

```
snmpcommunityread    which is set in your resource.cfg file
```

Optional service arguments related to SNMP polling with default values:

```
_inst                   None   ; Could be numeric: 0, None or an instance mapping function like: map
```

```
_triggergroup           None   ; Name of the triggergroup defined in the SnmpBooster config.ini file
```

Sample Shinken host and service configuration:

```
# Generated by genDevConfig 3.0.0
# Args: --showunused -c publicstring 192.168.2.63
# Date: Thu Aug 30 17:47:59 2012

 notes
 parents
 use                  default-snmp-host-template
 register             1
}

define service {
```

```
 host_name            192.168.2.63
 service_description  chassis
 display_name         C2960 class chassis
 _dstemplate          Cisco-Generic-Router
 _inst                0
 use                  default-snmp-template
 register             1
}

define service {
```

```
 host_name            192.168.2.63
 service_description  chassis.device-traffic
 display_name         Switch fabric statistics - Packets per Second
 _dstemplate          Device-Traffic
 use                  default-snmp-template
 register             1
}

define service {
```

```
host_name            192.168.2.63
service_description  if.FastEthernet0_1
display_name         FastEthernet0_1 Description: Link to Router-1 100.0 MBits/s ethernetCsmacd
_dstemplate          standard-interface
_inst                map(interface-name,FastEthernet0_1)
use                  default-snmp-template
register             1
```

}

Here is an example configuration of the config.ini file

```
[DATASOURCE]
```

```
  OidmyOidDefinition = .1.3.6.1.45.0
  [myOidDefinition] ; Use the same name as the myOidDeiniftion, but omit the leading "Oid"
      ds_type = DERIVE
      ds_calc = 8,*  ; RPN expression : Oid, 8, *  Which means Oid * 8 = ds_calc
      ds_oid = $OidmyOidDefinition
[DSTEMPLATE]
```

```
  [myCiscoRouter]
      ds = myOidDefinition
[TRIGGER]
```

```
  [trigger1]
      warning = RPN expression
      critical = RPN expression
  [trigger2]
      warning = RPN expression
      critical = RPN expression
[TRIGGERGROUP]
```

```
[CiscoRouterTriggers]
    triggers = trigger1, trigger2
```

Shinken integrated SNMP Module

Overview

What is it The SnmpBooster module allows Shinken Pollers to directly manage SNMP data acquisition. This is an all Python cross-platform SNMP module. It is tightly integrated with the Shinken Poller, Scheduler and Arbiter daemons to provide the best possible user experience.

Design specification summary

- STATUS - DESIGN SPEC PERFORMANCE
- [Done] Functions as an integrated Shinken Poller module
- [Done] Necessary integration code commited to Shinken official release (Integrated starting at v1.2)
- [Done] Ability to collect thousands of SNMP metrics per second
- [Done] Be compatible with distributed data acquisition
- [Done] Collect data for a host/check_interval tuple via SNMP in a single pass
- [Done] Use all builtin Shinken scheduler logic for retries, forced checks, timeouts, dependencies, parents
- [Done] Store collected data for the duration of the check_interval in a memcached/membase
- [Done] On a restart, after the first collection, be able to pick up where the last check left and calculate derived values
- [Done] Forced check are not allowed within 30 seconds of last SNMP query to the same host/check_interval, all other requests get data from the cache.
- [Done] Only a single request to the host/check_interval via SNMP is allowed at a time, all other requests get data from the cache.
- STATUS - DESIGN SPEC USABILITY
- [Done] Usage documentation
- [xxxx] SkonfUI and Discovery usage documentation
- [xxxx] Provide sample configuration packs in Shinken
- [Done] Provide sample config.ini with examples of all types of data * SNMP OIDS, DATASOURCES, DSTEMPLATES, TRIGGERS and TRIGGERGROUPS
- [Done] Directly compatible for use with genDevConfig Shinken SNMP configuration generator

- [Done] Provide meaningful feedback for users on errors
- [Done] Capture all tracebacks and convert them to actual error or warning messages
- STATUS - DESIGN SPEC FEATURES
- [Done] Return state and performance metrics
- [Done] Performance metrics can be returned in a Weathermap compatible format
- [Done] Configuration file format is ConfigObj INI
- [Done] Load all valid INI configuration files from a directory and merge them
- [Done] Load a single INI configuration file
- [xxxx] Load a list of INI configuration files
- [Done] Configuration file describes all generic acquisition parameters (OID, DATASOURCE, DSTEMPLATE, MAP, TRIGGER, TRIGGERGROUP)
- [Done] Supports Triggers which are calculation rules to determine states
- [Done] Triggers support an RPN (Reverse Polish Notation) calculation engine which includes mathematical and logical operators
- [Done] Each TRIGGER is associated with a severity level, WARNING or CRITICAL
- [Done] Multiple TRIGGERS can be associated with a TRIGGERGROUP
- [Done] Use builtin Python Operators
- [Done] Support DERIVE, TEXT, GAUGE and COUNTER data types
- [xxxx] Support TIMETICKS data type
- [Done] Support applying RPN based calculations to received metric for scaling or conversion purposes
- [Done] Use a Python SNMP library which supports asynchronous acquisition PySNMP
- [Done] Datasources can use rule based runtime instance mapping
- [Done] Set Snmp version as a check runtime option
- [Done] Set Snmp DSTEMPLATE as a check runtime option
- [Done] Set Snmp TRIGGERGROUP as a check runtime option
- [Done] Set Snmp COMMUNITY as a check runtime option
- [Done] Use Snmp version 2c GetBulk
- [xxxx] Support Snmp version 2c GetNext if GetBulk is not supported
- [xxxx] Support Snmp version 1 GetNext
- [xxxx] Set Snmp Timeout as a check runtime option, instead of a hardcoded value at 5 seconds
- STATUS - DESIGN SPEC MAINTAINABILITY
- [xxxx] Functions documented in the source code
- [Done] Critical functions documented in the source code
- [Done] Locking sections identified in the code
- [xxxx] Unit tests with at least 80% coverage
- [xxxx] Unit tests integrated with Shinken test suite

- [Done] Code hosted on github
- [xxxx] configuration validity and integrity checking of all INI files
- [xxxx] Pep8 compliant
- [xxxx] Pylint pass

genDevConfig Plugins - Compatibility status with SnmpBooster

- STATUS - genDevConfig maintained Plugins
- [Done] Avaya ES switches
- [Done] Avaya ERS routing switches
- [Done] Cisco 29x0 switches
- [Done] MIB-II Interfaces
- [Done] Cisco PIX/ASA
- [Done] JUNOS devices
- [Done] Cisco IOS routers
- [Done] NetSNMP unix hosts ** Validation required**
- [Done] Packeteer devices ** Validation required**
- [Done] Sensatronics devices ** Validation required**
- [Done] Foundry devices ** Validation required**
- [Done] Packeteer devices ** Validation required**
- [Done] Cisco CSS ** Validation required**
- [InProgress] New Cisco Access points
- STATUS - Other maintained Plugins

Tip: [xxxx] Denotes a specification that is planned but not implemented

[InProgress] Denotes a specification that is under development

[Done] Denotes a specification that is implemented

SnmpBooster reference dictionary

- Jump back to *SnmpBooster documentation index*

SnmpBooster.ini dictionary

There are five dictionaries:

- [DATASOURCE]
- [DSTEMPLATE]
- [MAP]
- [TRIGGER]
- [TRIGGERGROUP]

DATASOURCE DICTIONARY OidVariableName refers to an actual OID that can be queries using SNMP against the device on the network.

[VariableName] refers to a Datasource and all the information required to gather and prepare the data using SNMP ds_type refers to how the data should be prepared ds_calc refers to any scaling manipulations to make the data more understandable. This is an RPN expression, where the first variable is omitted, as it is always the $OidVariable ds_oid refers to the actual $OidVariable name. An instance identifier can be appended to the name to signify that an instance is provided by the Shinken service definition. This information is passed when the check is called. ...

DSTEMPLATE DICTIONNARY [DsTemplateName] refers to the name of the DSTEMPLATE that will be referred to in the Shinken service definitions. ds refers to the list of DATASOURCES to be collected. If an instance is expected for the list of DATASOURCES, it MUST be the same instance for all Oids. If a different instance is required, use a second DSTEMPLATE.

TRIGGER DICTIONNARY

TRIGGERGROUP DICTIONNARY

MAP DICTIONNARY

SnmpBooster.ini example configuration This example definition will be used to explain each section.

[DATASOURCE]

```
OidmyOidDefinition = .1.3.6.1.45.0
[myOidDefinition] ; Use the same name as the myOidDeiniftion, but omit the leading "Oid"
    ds_type = DERIVE
    ds_calc = 8,*  ; RPN expression : Oid, 8, *  Which means Oid * 8 = Total
    ds_oid = $OidmyOidDefinition
```

[DSTEMPLATE]

```
[myCiscoRouter]
    ds = myOidDefinition
```

[TRIGGER]

```
[trigger1]
    warning = RPN expression
    critical = RPN expression
[trigger2]
    warning = RPN expression
    critical = RPN expression
```

[TRIGGERGROUP]

```
[CiscoRouterTriggers]
    triggers = trigger1, trigger2
```

SnmpBooster.ini configuring SNMP Datasources

The first location is generic data related to SNMP parameters.

- DATASOURCE information * SNMP OID * Type of data and how can it be interpreted (GAUGE, COUNTER, COUNTER64, DERIVE, DERIVE64, TEXT, TIMETICK) * Data format preparation (Scaling the data for example bits to bytes) * Is there an instance to append to the
- Instance MAP function * Mapping the instance dynamically using a function * Data or rules related to the mapping function

SnmpBooster.ini configuring SNMP DSTEMPLATES

- DSTEMPLATEs to associate DATASOURCE to actual device classes * List of DATASOURCES associated with a, for example, Cisco 1900 router. Which in turn can be applied to a Shinken service

SnmpBooster.ini setting triggers/thresholds

- TRIGGER and TRIGGERGROUPS to apply thresholding rules * Define triggers and associate them with a TRIGGERGROUP name that can be applied to a Shinken Service

Shinken integrated SNMP Module

Overview

- Jump back to *SnmpBooster documentation index*

Tip: The module is now in public beta as of 2012-10-26! Have Fun!

Nothing new to add, more to come in 2013. 2013-01-19.

What is it The SnmpBooster module allows Shinken Pollers to directly manage SNMP data acquisition. This is an all Python cross-platform SNMP module. It is tightly integrated with the Shinken Poller, Scheduler and Arbiter daemons to provide the best possible user experience.

Why use it The SnmpBooster module is designed to be very efficient and scalable. It has a very flexible configuration method to make it easy to use with Shinken Monitoring Packs and Shinken discovery runners like genDevConfig.

This acquisition module was professionally designed and developed.

It is meant to be used by the very capable discovery engine genDevConfig (**v3.0.5 and newer**) originally developed for the Cricket SNMP monitoring tool and converted for use with Shinken.

It is one of the very few serious SNMP v2c implementation making use of SnmpGetBulk type requests.

How does it work

Shinken Integration

1. The SnmpBooster Arbiter module reads the Shinken SnmpBooster configuration file(s). It reads the check commands and based on the values in the check commands that use the snmp_poller module it will creates a shared configuration cache using memcached/memcachedb. The memcache key is always the combination of the hostname. This permits to tie together Shinken Hosts and Services with the SNMP specific configuration. (MongoDB and Redis are planned to be supported in the future) The Scheduler daemon schedules Host and Service checks as it normally does.

3. The SnmpBooster module will check that a memcache host key exists for the check to be launched. Then the SnmpBooster poller module will query all services related to a host for a given acquisition frequency in one pass. (all checks done every 2 minutes will be executed in bulk, same for those every 5 minutes)

5. Check results are cached for the acquisition check_interval. The next time a check request for data from the same host is received from the Scheduler, the data will be fetched from memcache. Resulting is extremely low check latency.

2. 6. The SNMP checks still benefit from retries, timeouts, forced checks, dependencies and the powerful Scheduler daemon logic.

6. The Scheduler daemon can still force an immediate re-check by flushing the cache. This is required for the dependency model.

Performance SnmpBooster uses SNMP v2c getbulk for high efficiency, unless forced to use SNMP v2c get-next or SNMPv1 get-next. GetBulk uses a single request PDU to ask for multiple OIDs or even entire tables, instead of sending one request PDU per OID.

For example: *A typical 24 port network switch with two uplinks might use 375 OIDS (8 OIDs per interface, plus general OIDs for chassis health, memory, cpu, fans, etc.). **SnmpBooster will only require around 4 request PDUs*

*instead of 375 request PDUs**. Each PDU is a request packet which takes time to create, send get processed and return. More timeouts to manage, more connections, more impact on the remote device and more latency means much fewer checks per second.*

The SnmpBooster module supports automatic instance mapping for OIDs. (Ex. Based on the interface name it will figure out that the SNMP index(or instance) is 136. This is automatically handled by genDevConfig and SnmpBooster, no user input required. :-)

The generic SNMP configuration information is stored in the Shinken SnmpBooster INI files. There is a Defaults_unified.ini and a series of other Defaults files, one per discovery plugin for genDevConfig.

Important: genDevConfig plugins have all been converted to use the new dynamic instance mapping methods. You are now free to use most if not all Defaults*.ini files included with genDevConfig. 2012-10-28

Limitations You should have memcached instances running on each poller responsible for snmp polling. You should have your pollers with SnmpBooster in the same datacenter, as they need to be on the same machine with good connectivity to the active memcached instance. SnmpBooster is not compatible with distributed pollers in multiple datacenters, sorry, the current design of SnmpBooster uses a single centralized memcached instance for storing the timeseries data. For distributed datacenters to be supported, each poller+scheduler+memcached must be realm restrained, which is not the case today.

Design specification *SnmpBooster design specification* and current development status.

Data model The information required to define the data is split in two locations.

The first location is the host and service Shinken configuration (You need to generate or write this)

- Device specific information
  - IP addresses, host_names, device types, instance keys
  - A DSTEMPLATE must be referred to in the Service definition
  - A static SNMP instance could be referred to in the Service definition
  - An SNMP instance MAP function could be referred to in the Service definition
  - A TRIGGERGROUP could be refered to in the Service definition

The second location is SNMP Defaults.* templates. (Here you can create new devices or add new data sources)

- DATASOURCE information
  - SNMP OID
  - Type of data and how can it be interpreted (GAUGE, COUNTER, COUNTER64, DERIVE, DERIVE64, TEXT, TIMETICK)
  - Data format preparation (Scaling the data for example bits to bytes)
  - Is there an instance to append to the
- Instance MAP function * Mapping the instance dynamically using a function * Data or rules related to the mapping function
- DSTEMPLATEs to associate DATASOURCE to actual device classes * List of DATASOURCES associated with a, for example, Cisco 1900 router. Which in turn can be applied to a Shinken service
- TRIGGER and TRIGGERGROUPS to apply thresholding rules * Define triggers and associate them with a TRIGGERGROUP name that can be applied to a Shinken Service

A final location containes rules to build your Shinken configuration.

- genDevConfig plugins create Shinken configurations

Installation and configuration *SnmpBooster installation*

Reference Dictionnary *SnmpBooster reference dictionary*

Troubleshooting *SnmpBooster troubleshooting*

Graph templates These are .graph files defined in your Shinken configuration directory. Refer to the Shinken graphite templates(Not yet created) or PNP4Nagios how-to documentation. The graph templates are independent from SnmpBooster and provide templates for any collected data from Shinken.

SnmpBooster Troubleshooting

- Jump back to *SnmpBooster documentation index*

Check your config

- Have you defined the poller module name?
- Have you defined the correct path to the directory containing your Defaults*.ini files?
- Have you addded the Snmpbooster module to your arbiter, poller, scheduler?
- Have you added copied the genDevConfig templates.cfg in shinken/packs/network/SnmpBooster/
- Have you installed PySNMP, memcached and other dependencies?

Software version consistency Shinken and SnmpBooster now require **the same Python and Pyro version on all hosts running a Shinken daemon**.

If you cannot use the packaged version of Python and its modules (Pyro, memcached, etc.). Use virtualenv to declare a python version to use and install all required modules in that virtualenv.

Software version requirements Have you verified that the *requirements* are met. Python, PySNMP, Shinken, Pyro, memcached, etc.

Validate your check command arguments Use the check_plugin command and comment out the module to learn what were the exact arguments sent by the poller. This will permit you to validate all the arguments, like snmp community string, inheritance, template application, etc.

Validate connectivity

Take a packet trace using a tool like Wireshark to validate that the remote host is responding.

- Has the host responded
- **Is SnmpBooster repeating the request more often than the polling interval.**
  - If you are seeing repeated requests your device may have a compatibility issues.

- Save an snmpwalk of the device, get a packet trace using Wireshark, set the poller to debug and save the poller.log file (shinken/var/poller.log). Send all three to the SnmpBooster developers.
- Note: It is normal to see one or more bulkGet requests if you are getting large amounts of data. Ex. a 24 port switch will take 2-3 request packets.

Performance Make sure you have a low latency connection to your memcache from the Poller. Your memcache server can be replicated to all your poller hosts that should also run memcache instances. Check that memcached is running: netstat -a | grep memcached

Faulty Template A bad snmp_template file was distributed in the genDevConfig sample-config directory, there were two glaring errors.

This was fixed on 2012-10-16. Make sure you update your template, or use the data from the wiki.

Note that the template should be called: SnmpBooster-template.cfg to make it easier to troubleshoot in the logs. So when you search for SnmpBooster in your logs it will show up as well.

Log files All warnings and errors generated by the SnmpBooster module start with "[SnmpBooster] error text" and are logged using the standard Shinken logger.

The Arbiter daemon can output initial configuration, loading of host keys and intervals in memcached type error messages. The Scheduler daemon can output scheduling and alert related messages. The Poller daemon can output messages related to instance mapping, acquisition timeouts, invalid community strings, cache failures and more. These are available in the Web interface, as they are placed in the check results for the service.

You can simply do a "grep SnmpBooster *" in your shinken/var directory to see the latest messages related to the SnmpBooster module. You can also sort messages by timestamp to make it easy to find where and when errors occurred.

cd shinken/var grep SnmpBooster *

memcache persistence If you restart your memcache server or memcache crashes, your poller will no longer be able to validate that a host exists in memcache prior to writing.

You should use memcachedb to achieve persistence in case of memcache failures.

Common errors returned by SnmpBooster in the log file Errors should be fairly explicit and mean what they say, though there can be exceptions. Lets try to clear some of them.

__Arbiter log **errors__**

Missing ds_oid : This means that a variable in your OID definitions is missing, or your DATASOURCE is not named correctly or your ds_oid variable is missing. There is a typo in your ds_oid variable (ex. ds-oid, or ds_oid = $OidNameIncorrectFFFRA.%(instance)s).

Datasource not defined : Your DSTEMPLATE uses a DATASOURCE that doesn't exist check the [DataSourceName] you are referring to. Does it contain the expected OID variable, $OidName.

Missing ds_type : The DATASOURCE always needs to have a ds_type definition, GAUGE, COUNTER, DERIVE, TEXT, TIMETICK, DERIVE64, COUNTER64.

__Poller log **errors__**

Problems with calculations, repeated polling, hosts not responding, etc.

__Memcached **errors__**

memcachedb and memcached do not use the same default port. Configure the correct memcachedb port to match what is declared in your SnmpBooster module under shinken-specific.cfg.

On Ubuntu 12.04 the default installation is on port 21201 instead of 11211. This causes the error "[SnmpBooster] Memcache server (127.0.0.1:11211) is not reachable" when Shinken starts.

To change it, you must edit the file /etc/memcachedb.conf

Memcached Notes

On Ubuntu 12.04 the default instalation is on port 21201 instead of 11211. This causes the error "[SnmpBooster] Memcache server (127.0.0.1:11211) is not reachable" when shinken starts.

To change it, you must edit the file /etc/memcachedb.conf

WebUI module

This part must be splitted and sent in all module repositories

WebUI integration with Shinken

The WebUI is an external broker module. So it's an external process launched by the broker that "eats" broks (broker messages) from the brokers. So it can get *all* broks if you place this broker in your top level realm.

The WebUI does not use a database to get data. Instead, it use a "regenerator" object that will eat each broks, and will "recreate" all Hosts/Services/Contacts objects as if the code was in the scheduler daemon. So basically, WebUI and pages always reflect the CURRENT state of hosts/services objects.

The WebUI http layer is managed by bottle.py. It's a small but powerful framework.

How does the WebUI function globally ?

There a 2 Threads running:

- the main thread is the bottle.py (http) listener. It will use the best backend it finds. We recommend using python-paste. If it does not find one, it will use the default swsgi. Paste is multi-thread, swsgi is mon-thread, so please use paste if you want to avoid locking problems.
- the 2nd thread is the regenerator one. It only gets broks and gives them to the regenerator object.

There is a lock system between the threads. You can have N Http requests in progress without problem, but during this time the renererator one will wait. During execution of the regenerator, no requests are processed. This is not considered a problem, as the regenerator is very quick, and there is only a 1s lock for a 7k service conf loading, so it's not a huge problem.

What is a WebUI User? A WebUI user is a contact. A true contact object. You must match a contact name for your user.

To create a new page? All pages are in the shinken/webui/plugins directory. Each "part" has it's own directory. A part (like the eltdetail, element detail) can have more than one "page" (like /host or /service for eltdetail).

From here we will supose you want to create a "/contact" page.

You can copy the dummy example in the plugins directory into a contact directory.

You need to change the contact/dummy.py file into a contact/contact.py file, because the webui will search for a dir/dir.py file to "load".

Templates Templates are HTML with some Python code in it in the plugins/*/views direcotry for specific templates, and the "global layout" (menu and all common part) in the webui/views directory.

Your template must call the template layout (layout.tpl in the webui/views directory) wit ha "rebase" call.

If you put the rebase call at the beginning of your template, all there is below will be place "inside" the layout that will call the common javascripts and css, make the menu adn then call your html/python code.

The rebase call can take arguments. You MUST give it:

- user: the user you give it in the return dict of your .py code

Then all is optional:

- title: title of the page
- top_right_banner_state: int, global state with clouds to put in your top right page. Look at the problem.tpl code for an example.
- js and css list: list of YOUR specific javascript or css to call AFTER the common ones.

- refresh: boolean, set the refresh to 60s or do not refresh at all
- menu_part: will put the little "^" under this part of the menu.

Example of a call, taken from the problems view:

```
rebase layout title='All problems', top_right_banner_state=top_right_banner_state, js=['problems/js/a
roblems/js/autocompleter.Request.js', 'problems/js/autocompleterObserver.js'], css=['problems/css/acc
ms/css/autocompleter.css', 'problems/css/perfometer.css'], refresh=True, menu_part='/'+page, user=use
```

Call Python objects in your templates Your templates are mainly HTML code. But of course you can call python code in it. The dict you returns in the plugin.py call will be available in this page.

For example, the my_host variable will be available in the page with the host object you find (or None if your give it a bad name of course). Then you can "call" python with for example here to show the host_name: `<span>My host name is *my_host.host_name* </span>` is a way in the templates to "call a variable or function" that will return a string, here the host_name.

If the function or property you call must return HTML code that SHOULD be output as it, without "protection", you must put a ! before your call.

Let use an example where the output value of an host is in fact an html output. If you use the code `my_host.output`, bottle.py will "protect" the html generated by escaping the string, and change <> characters with escaped value. You can change this by calling `my_host.output`. Of course, it's a security problem if the output is with a javascript code...

You can also "loop" or put "if" in your template. You just need to put your code with a % before. Like

```
%for i in xrange(1, 10):
  My valus is  {{i}}
%end
```

You must put the %end here, the indentation will NOT be enougth, sorry.

For an if it's also easy:

```
%if host.active_checks_enabled:
  The host got active checks enabled
%else:
  The host DO NOT have active check enabled
%end
```

Which javascript lib are you using? It's mootools 1.3 with all options :)

What to do?

- Finish the /mobile part
- List of current alerts
- Host info
- Host status
- Host interfaces
- Hostgroup status
- dashboard hierachique with states, and BP
- Nagvis

- add bp in nagvis auto-map
- event sources
- correlation
- pre-filtering/enrichment
- user profile
- host/srv conf

WebUI search syntax

work in progress

not that we couldn't tell. ;) eh eh

beware the working men and flying tools!

WebUI SSL Certification

Lets start: the goal to to have the server.pem and client.pem file in etc/certs.

Go to the etc/certs directory.

```
openssl req -new -nodes -out server.req -keyout server.key -config ./shinken_openssl_cnf
openssl ca -out server.pem -config ./shinken_openssl_cnf -infiles server.req
cp server.pem server.pem.bkp
cp server.key server.pem
cat server.pem.bkp >> server.pem
cp server.pem client.pem
```

You can try to get the validity with for the arbiter with:

```
openssl s_client -connect localhost:7770</code>
```

16.1.2 Amazon AWS/EC2 import

Description

You can import data from Amazon AWS/EC2 **'AWS'**_ into Shinken to create hosts.

Amazon provide VM hosting with EC2. With this arbiter module, you will be able to load your EC2 hosts into Shinken.

Prerequisites

You will need the **'libcloud'**_ package installed on your Arbiter server.

Configuring the Landscape import module

In your shinken-specific.cfg file, just add (or uncomment):

```
define module {
 module_name      AWS
 module_type      aws_import

 # Configure your REAL key and secret for AWS
 api_key              PAAAB2CILT80I0ZA0999
 secret           GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH
 default_template generic-host        ; if the host is not tagged, use this one
 }
```

- Put in key and secret your private Landscape access. * default_template will be used if your host is not "tagged" in Landscape

Configuring the Arbiter module

And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master

     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           AWS
     }
```

Restart your Arbiter and it's done :)

Generated hosts

The configuration generated will look as below :

```
define host {
    host_name            i-3fc56e5a
    address              8.8.4.4
    use                  t1.micro,MyTag,EC2,generic-host
    _EC2_AVAILABILITY    us-east-1a
    _EC2_CLIENTTOKEN
    _EC2_DNS_NAME
    _EC2_GROUPS          quicklaunch-1
    _EC2_IMAGEID         ami-1b814f72
    _EC2_INSTANCEID      i-3fc56e5a
    _EC2_INSTANCETYPE    t1.micro
    _EC2_KERNELID        aki-825ea7eb
    _EC2_KEYNAME         testaws
    _EC2_LAUNCHDATETIME  2012-09-26T12:19:38.000Z
    _EC2_LAUNCHINDEX     0
    _EC2_PRIVATE_DNS
    _EC2_PRIVATE_IP
    _EC2_PRODUCTCODE
    _EC2_PUBLIC_IP       8.8.4.4
    _EC2_RAMDISKID       None
    _EC2_STATUS          stopped
    _EC2_TAGS            demo:myvalue,use:MyTag
 }
```

Here with a stopped t1.micro instance with no name. You can put your how "use" parameter by adding a EC2 tag "use" on your VM. It will be output on the host configuration so you can setup the monitoring as you want. .. _libcloud: http://libcloud.apache.org/index.html .. _AWS: https://console.aws.amazon.com

16.1.3 Amazon AWS/EC2 import

Description

You can import data from Amazon AWS/EC3 **'AWS'_** into Shinken to create hosts.

Amazon provide VM hosting with EC3. With this arbiter module, you will be able to load your EC2 hosts into Shinken.

Prerequisites

You will need the **'libcloud'_** package installed on your Arbiter server.

Configuring the Landscape import module

In your shinken-specific.cfg file, just add (or uncomment):

```
define module {
 module_name      AWS
 module_type      aws_import

 # Configure your REAL key and secret for AWS
 api_key              PAAAB2CILT80I0ZA0999
 secret           GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH
 default_template generic-host        ; if the host is not tagged, use this one
 }
```

- Put in key and secret your private Landscape access. * default_template will be used if your host is not "tagged" in Landscape

Configuring the Arbiter module

And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master

     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           AWS
     }
```

Restart your Arbiter and it's done :)

Generated hosts

The configuration generated will look as below :

```
define host {
    host_name            i-3fc56e5a
    address              8.8.4.4
    use                  t1.micro,MyTag,EC2,generic-host
    _EC2_AVAILABILITY    us-east-1a
    _EC2_CLIENTTOKEN
    _EC2_DNS_NAME
    _EC2_GROUPS          quicklaunch-1
    _EC2_IMAGEID         ami-1b814f72
    _EC2_INSTANCEID      i-3fc56e5a
    _EC2_INSTANCETYPE    t1.micro
    _EC2_KERNELID        aki-825ea7eb
    _EC2_KEYNAME         testaws
    _EC2_LAUNCHDATETIME  2012-09-26T12:19:38.000Z
    _EC2_LAUNCHINDEX     0
    _EC2_PRIVATE_DNS
    _EC2_PRIVATE_IP
    _EC2_PRODUCTCODE
    _EC2_PUBLIC_IP       8.8.4.4
    _EC2_RAMDISKID       None
    _EC2_STATUS          stopped
    _EC2_TAGS            demo:myvalue,use:MyTag
 }
```

Here with a stopped t1.micro instance with no name. You can put your how "use" parameter by adding a EC2 tag "use" on your VM. It will be output on the host configuration so you can setup the monitoring as you want. .. _libcloud: http://libcloud.apache.org/index.html .. _AWS: https://console.aws.amazon.com

16.1.4 The distributed retention modules

The high availability allow the Arbiter to send a configuration to a spare scheduler, but a spare scheduler does not have any saved states for hosts and services. It will have to recheck them all. It's better to use a distributed retention module so spares will have all the information they need to start with an accurate picture of the current states and scheduling :)

Non distributed retention modules

If you are just running tests on a single server, use the pickle or memcache retention modules You can also use MongoDB if you already have it installed for use with the WebUI.

MongoDB

MongoDB is a scalable, high-performance, open source NoSQL database written in C++.

Step 1: Install MongoDB:

We will use mongodb package from 10gen repository, so we start by adding it in apt sources list:

```
echo 'deb http://downloads-distro.mongodb.org/repo/debian-sysvinit dist 10gen' > /etc/apt/sources.lis
apt-get update
```

And we install it:

```
apt-get install mongodb-10gen
```

And we install pymongo, the python interface to MongoDB, with easy_install to avoid packages versions problems (like here **'forums.monitoring-fr.org/index.php?topic=5205.0'_**):

```
apt-get remove python-pymongo
easy_install pymongo
```

And finally we start MongoDB :

```
/etc/init.d/mongodb start
```

Step 2: define a mongodb_retention module in your shinken-specific.cfg file:

```
define module {
  module_name MongodbRetention
  module_type mongodb_retention
  uri mongodb://localhost/?safe=true
  database shinken
}
```

Step 3: Declare a retention module for your scheduler(s) :)

Example:

```
#The scheduler is a "Host manager". It get hosts and theirs
#services. It scheduler checks for them.
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
     port     7768                  ; tcp port of the daemon

     #optionnal: modules for things as retention
     modules    MongodbRetention
     }
```

Step 4: Restart the Arbiter, and your Scheduler will now save its state between restarts. :)

Memcached

Memcached is a distributed memory resident key/value server. It's very easy to install:

```
sudo apt-get install memcached
sudo /etc/init.d/memcached start
```

The shinken module also needs the python-memcache package to talk to this server.

```
sudo apt-get install python-memcache
```

To use it,

Step 1: define a memcache_retention module in your shinken-specific.cfg file:

```
define module{
     module_name      MemcacheRetention
     module_type      memcache_retention
     server           127.0.0.1
     port             11211
}
```

Step 2: Declare a retention module for your scheduler(s) :)

Example:

```
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
     port     7768                  ; tcp port of the daemon

     #optional: modules for things as retention
     modules    MemcacheRetention
     }
```

Step 3: Restart the Arbiter, and your Scheduler will now save its state between restarts. :)

Redis

Redis is a distributed key/value server (on disk and in-memory). It's very easy to install:

```
sudo apt-get install redis-server
sudo /etc/init.d/redis-server start
```

The shinken module also need the python-redis package to talk to this server.

```
sudo apt-get install python-redis
```

Step 1: define a redis_retention module in your shinken-specific.cfg file:

```
define module{
     module_name      RedisRetention
     module_type      redis_retention
     server           127.0.0.1
}
```

Step 2: Declare a retention module for your scheduler(s) :)

Example:

```
#The scheduler is a "Host manager". It get hosts and theirs
#services. It scheduler checks for them.
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
     port     7768                  ; tcp port of the daemon

     #optionnal: modules for things as retention
     modules    RedisRetention
     }
```

Step 3: Restart the Arbiter, and your Scheduler will now save its state between restarts. :) .. _forums.monitoring-fr.org/index.php?topic=5205.0: http://forums.monitoring-fr.org/index.php?topic=5205.0

16.1.5 How to enable and use Livestatus module

Define the Livestatus module

Start by reviewing the ''/etc/shinken/shinken-specific.cfg" file for this module:

```
define module{
```

```
module_name      Livestatus
module_type      livestatus
host             *       ; * = listen on all configured IP addresses
port             50000   ; port to listen on
database_file    /var/lib/shinken/livestatus.db
```

}

With these parameters:

- module_name: name of the module called by the brokers
- module_type: livestatus
- host: IP interface to listen to. The default is *, which means "listen on all interfaces".
- port: TCP port to listen to.
- socket: Unix socket to listen to.
- database_file: the path to the sqlite database file which is used to store the log broks/messages. The default is "var/livelogs.db"
- max_logs_age: the maximum age of the log messages (before they are deleted from the database). The default is 1 year. The argument to this parameter takes the form <number>[<period of time>], where <period of time> can be d for days, w for weeks, m for months and y for years.
- allowed_hosts: a comma-separated list of IP-addresses which are allowed to contact the TCP port. Please keep in mind that these **must be IP-addresses, NOT host names**. Because DNS lookups for every incoming livestatus request could hang up and therefore block the module.

Enable the Livestatus module

Still in ''/etc/shinken/shinken-specific.cfg'', find the object Broker and add "Livestatus" to its "modules":

```
define broker{
```

```
     broker_name      broker-1
[...]
```

```
     modules          Simple-log,Livestatus
}
```

Disable human readable logs

In ''/etc/shinken/nagios.cfg'', verify that the option **human_timestamp_log** is set to **0**.

In version 0.6.5, you can not have at the same time a simple-log file with human readable timestamp and a Livestatus database.

16.1.6 Exporting data for reporting

Shinken can export necessary data for reporting in 3rd party systems.

raw_socket module

The raw socket module exports reporting data using a syslog format to a raw TCP socket. Theses logs can be captured, parsed and indexed by any log management system like Splunk or Logstash.

Why export reporting data

Custom UIs like Thruk, Multisite, WebUI, Adagios, Nagios IX, etc. All have poor or inflexible reporting. Simply because these are not reporting engines.

This also permits to have a generic reporting method that can accept data from any Nagios, Shinken, Icinga or even Riemann.

Reporting module using Splunk

Splunk was selected as the reporting platform for creating, managing and presenting reports. Though the raw_socket module does not have any Splunk specific particularities. It is notable that Splunk reports can be embedded in any 3rd party UI using its REST API.

Raw_socket log format

The logs are plain-text and compliant with RFC3164. They use an intelligent date format, a configurable seperator " "(space by default), and key=value pairs in the message data portion of the log. Should a key or value contain a space they must be double quoted. This is syslog using structured data without going to full out JSON that may not be compatible with all log management systems.

The message fields that are supplied in each status update in addition to the standard syslog header are:

- Hostname
- Servicename
- Business impact
- Host/Service status
- Host/Service previous status
- Acknowedgement status
- Maintenance status

Any time the maintenance, host, service or acknowledgement status changes, a log is sent by the Shinken raw_socket module.

Having all relevant data in each log makes it very easy to compute reports for given time periods.

The hostgroup or service group memberships, custom variables or any other configuration related data should be queried from the monitoring system using its API (Livestatus in the case of Shinken and Nagios).

Raw_socket module availability

The module is available in both Shinken 1.4 and Shinken 2.0. The module will be integrated in master branches once unit tests and end-to-end testing is completed. 3rd quarter 2013.

16.1.7 Monitoring Linux System with Glances and checkglances.py

'Glances'_ is a fantastic multiplatform system monitoring tool writen by Nicolargo. Glances can run on (Linux, Windows, MacOS ...). There is a growing ecosystem around Glances and of course a Nagios/Shinken plugin : check-glances.py.

How does it work

Glances can run in server mode. It provide a XML-RPC server (over http) and allow to retrieve system information throuh a restful API. The only thing to do is to install and start Glances as server on the monitored host, then install checkglances.py on the shinken server and finaly install the glances pack.

Install glances

See the glances documentation to install glances on Linux.

<code bash> easy_install glances </code>

There is a debian startup script in the glances repository. And another one for centos here.

Install checkglances.py

Just follow the documentation for the checkglances.py prerequisites and put it in your nagios plugins folder.

Install the glances pack

Open a terminal as the shinken user and just type the following command

<code bash> shinken install glances </code>

Then just edit the configuration for a linux monitored host and tag it as **glances**

```
define host{
 name mylinuxhost
 use glances
 ...
```

Finaly restart the shinken arbiter

```
service shinken-arbiter restart
```

What will be monitored ?

For the moment just the basic system (ram, cpu, load, memory, filesystem and network).

If you want to modify the default thresholds for just a host you can do it by overiding the thresholds macro in your host definition. If you want to do it for several hosts, declare a new template and just add the desired thresholds macro to be overide.

Here is a list of the macros

```
::
```

> _LOAD_WARN 2 _LOAD_CRIT 3 _CPU_WARN 80 _CPU_CRIT 90 _MEMORY_WARN 90 _MEMORY_CRIT 95 _FS /, /home _FS_WARN 90 _FS_CRIT 95 _IFACES eth0, eth1 _NET_WARN 7500000 _NET_CRIT 10000000

Note the _FS and _IFACES macros. They leverage the ability to duplicate service for a given list of things to be monitored. Here you see that / and /home partitions will be monitored. If you want to modify this then just add your own in a new template that will inherit the glances template.

16.1.8 Shinken GLPI integration

Shinken supports importing hosts from GLPI

For people not familiar with GLPI, it is an Open-Source CMDB. Applicable to servers, routers, printers or anything you want for that matter. It is also a help-desk tool. GLPI also integrates with tools like FusionInventory for IT inventory management.

You can still have flat files AND GLPI if you want. Hosts imported from GLPI will be treated as standard hosts from flat file (inheritance, groups, etc). In fact, in this first version the module only sends the host_name to Shinken, but there should be more information extracted like network connexions for parents relations in the future. :)

Requirements

- python module MySQLdb
- Compatible version of GLPI Shinken module and GLPI version - ...
- etc..

Enabling GLPI Shinken module

In your shinken-specific.cfg file, just add (or uncomment):

```
#You know GLPI? You can load all configuration from this app(
#with the webservices plugins for GLPI, in xmlrpc mode
#and with plugin monitoring for GLPI)
# =============== Work with Plugin Monitoring of GLPI ===============
#All configuration read from this will be added to the others of the
#standard flat file
define module{
     module_name      GLPI
     module_type      glpi
     uri              http://localhost/glpi/plugins/webservices/xmlrpc.php
     login_name       glpi
     login_password   glpi
}
```

And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master
#    host_name       node1       ;result of the hostname command under Unix
     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           GLPI
     }
```

It's done :)

16.1.9 Ip Tag module

Why tag a host based on it's IP address?

We learned on the *DMZ monitoring* that you can "tag" a host with a poller_tag so it will be checked only by DMZ pollers. It can be tedious process to manually tag all these hosts. Shinken provides an automated method to do this.

This is handled by the arbiter ip_tag module.

Ip_tag module

The ip_tag module is an arbiter module that looks up the host address during the configuration parsing and compares it to an predefined IP range (IPV4 or IPV6). If the range matches, it can apply or add a property, such as poller_tag. Other types of tags could be related to locations, functions, administrative groups, etc.

Method: replace or append.

replace will put the value if the property is unset. This is the default method. .. warning:: Fix me: replace, implies overriding an existing value. And will cause user issues down the line. Rename it to set. Replace should be a different method altogether, so overall there should be 3 methods(set, append, replace).

append will add with a , if a value already exist

Here is an example that will set the poller_tag property with the value DMZ of all hosts that:

- have a their hostadress ip (or name resolved) in the range 192.168.0.1/24.
- do not already have a poller_tag property set

```
define module{
```

```
     module_name     IpTag
     module_type     ip_tag
     ip_range        192.168.0.1/24
     property        poller_tag
     value           DMZ
}
```

To use the module add it in the arbiter object:

```
::
```

define arbiter { [...] modules NSCA,IpTag

}

Add value instead of setting it

In the previous example we set the property poller_tag to a value. But what if we want to "add" a value, like a template name? We can change the "method" property of the module to "append" so we can add the "value" to the host property instead of replace it.

Here is an example where we want to add the "dmz" template on the hosts, while also keeping any defined templates:

```
define module{
```

```
     module_name   IpTag
     module_type   ip_tag
     ip_range      192.168.0.1/24
```

```
    property      use
    value         dmz

    # Optional method
    method append
}
```

For a host defined as:

```
define host{
```

```
    host_name   example_host1
    address     192.168.0.2
    use         linux
}
```

It will be "changed" internaly in:

```
define host{
```

```
    host_name   example_host1
    address     192.168.0.2
    use         linux,dmz
}
```

Name resolution

Of course you don't need to set IP address in the address of your host. You can set a hostname, and it will be resolved, and then compared to the range. :)

16.1.10 Ubuntu Landscape import

Description

You can import data from Ubuntu Landscape into Shinken to create hosts.

Ubuntu Landscape, is a web app to manage all your linux servers (update and co), which is provided by Canonical, Ubuntu's parent company.

This is an Arbiter import module. The Arbiter manages the configuration.

Prerequisites

You will need the landscape-api package installed on your Arbiter server.

Configuring the Landscape import module

In your shinken-specific.cfg file, just add (or uncomment):

define module { module_name Landscape module_type landscape_import

Configure your REAL key and secret from Landscape key PAAAB2CILT80I0ZA0999 secret GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH default_template generic-host ; if the host is not tagged, use this one

If you are using a specific certificate for landscape_api #ca /path/to.ca.cert

If you need a proxy to access https://landscape.canonical.com/api/ #https_proxy http://user:secret@myproxy.com:3128

}

- Put in key and secret your private Landscape access.
- default_template will be used if your host is not "tagged" in Landscape
- If you are using a specific certificate for connexion, give the full path in ca
- You will certainly need an https proxy to access the Landscape API. If so, configure it there.

Configuring the Arbiter module

And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master
#    host_name       node1       ;result of the hostname command under Unix
     address          localhost                  ;IP or DNS adress
     port             7770
     spare            0
     modules           Landscape
     }
```

Restart your Arbiter and it's done :)

Tip: Your "tags" will be applied as templates for your hosts.

16.1.11 Shinken Livestatus API

Overview

- Jump back to Getting Started
- Jump back to *Livestatus module configuration*

What is it

Livestatus API is the modern method of interacting with Shinken and Nagios based systems alike.

Originally developed for Nagios, MK Livetstatus, was re-implemented in Python for use with Shinken by professional developers. The access methods and query languages are the same.

Why use it

It is fast.

It is network based using TCP.

It is standard for all Nagios and Shinken monitoring systems.

It uses in-memory structures for status data

It uses a back-end database for historical reporting

It uses an SQL based query language

It has a host of powerful nuts and bolts features (authentication, caching, connection persistence, multiple object methods (JSON, Python)).

What can I do with it?

All programs and scripts use (or should use) this method to :

- Obtain the current state of hosts and services
- Obtain the current configuration related to hosts and services
- Send administrative commands (downtimes, comments, forcing checks)
- Filter information to display
- Obtain basic reports and event statistics

Shinken being a modern re-implementation of Nagios has additional features that are available in addition to the standard Livestatus API.

Shinken Livestatus API unique features can :

- Obtain Business Impact information
- Obtain intelligent dependency status hosts or services (combines dependency and parent information)
- Obtain Business Process states (same syntax as standard host and service queries)

How does it work

Livestatus uses a powerful SQL-like query language. The standard methods and parameters are defined at :

'MK Livestatus reference methods and query language definition'_

Full list of Shinken Livestatus API methods:

'Shinken mapping.py methods'_

What software uses Livestatus to interact with Shinken

Well known Web frontends

- MK Multisite
- Thruk
- NagVis
- Splunk for Nagios

Mobile Web frontends

- get list

Scripts

- Downtime management scripts

- Debug scripts

Installing Livestatus

Have you installed the required packages to use the Livestatus module? You can look at the requirement section of the *10 minute installation guide* for the *requirement lists*.

How to enable Livestatus

Very simple, jump to the *Shinken Broker configuration* section to enable it. .. _Shinken mapping.py methods: https://github.com/shinken-monitoring/mod-livestatus/blob/master/module/mapping.py .. _MK Livestatus reference methods and query language definition: http://mathias-kettner.de/checkmk_livestatus.html

16.1.12 NSCA module

The NSCA daemon module is used to receive send_nsca packets and submit them to the Shinken command pipe. The NSCA module can be loaded by the Receiver or Arbiter process. It will listen on port TCP/5667 for send_nsca packets.

Tip: Passive checks can be submitted *natively to the Shinken command pipe* or from remote hosts to modules, such as NSCA, AMQP or collectd, loaded in the Shinken Arbiter or Receiver process. AMQP is implemented for integration with the Canopsis Hypervisor, but could be re-used for generic messaging.

Note: The Shinken NSCA module implementation is currently limited to the "xor" obfuscation/encryption.

In your shinken-specific.cfg file, just add (or uncomment):

```
::
```

#You can send check result to Shinken using NSCA #using send_nsca command define module{

module_name NSCA module_type nsca_server host * port 5667 encryption_method 0 password helloworld

}

define receiver{

```
receiver_name    receiver-1
address          localhost
port             7773
modules          NSCA

timeout          3             ; 'ping' timeout
data_timeout     120           ; 'data send' timeout
max_check_attempts       3     ;  if at least max_check_attempts ping failed, the node is DEAD

#advanced
realm    All
}
```

This daemon is totally optional.

It's main goal is to get all passive "things" (checks but why not other commands) in distant realms. It will act as a "passive receive buffer" and will then dispatch the data or commands directly to the appropriate Scheduler or Arbiter process.

Data can be received from any Realm, thus the Realm option is nonsensical.

For now there is no init.d script to launch it. .. note:: Verify that the init script has been added.

It is launched like all other daemons:

```
bin/shinken-receiver -c etc/receiverd.ini
```

Tip: Alternatively, for small installations with you can configure a modules inside your Arbiter instead of the Receiver. It will listen the TCP/5667 port for send_nsca packets.

To configure the NSCA module in your Arbiter instead of Receiver. Add the NSCA module to your Arbiter object configuration.

```
::
```

define arbiter{ arbiter_name Arbiter-Master

 # host_name node1 ;result of the hostname command under Unix address localhost ;IP or DNS adress port 7770 spare 0 modules NSCA

}

16.1.13 Retention troubleshooting

The retention file contains the state of your host and services, so that they are kept when shinken is restarted.

Sometimes you'll want to inspect (and possibly fix) the retention file, in case you need to work-around a bug or simply better understand what is stored there.

When you use the PickleRetention module in the scheduler (cf. ''define scheduler" in ''shinken-specific.cfg''), you can simply manipulate the retention file using Python.

For this you can use the following code.

- It assumes Shinken is installed in ''/opt/shinken" with the retention file in ''/tmp/retention.dat'':
- Run and play with it interactively using ''ipython -i inspect_retention.py''.

```
#!/usr/bin/python
import pickle
import sys
sys.path.append('/opt/shinken')
import shinken

r = pickle.load(file('/tmp/retention.dat'))
h = r['hosts']

# Example:
# [(k,v) for (k,v) in h['your_host'].items() if k.find('downtime') >= 0]
#
# del h['your_host']
#
# for k,v in r['services'].items():
#     if 'your_host' in k:
#         del r['services'][k]
```

To save your changes:

- Stop Shinken: ‘’service shinken stop’‘
- Save the pickle: ‘’pickle.dump(r, open(‘/tmp/retention.dat’, ‘w’))’‘
- Start Shinken: ‘’service shinken start’‘

16.1.14 NRPE Module

What is it

The NRPE module allows Shinken Pollers to bypass the launch of the check_nrpe process. It reads the check command and opens the connection by itself. It scales the use of NRPE for active supervision of servers hosting NRPE agents.

The command definitions should be identical to the check_nrpe calls.

How to define it

The definition is very easy (and you probably just have to uncomment it):

```
define module{
     module_name       NrpeBooster
     module_type       nrpe_poller
}
```

Then you add it to your poller object:

```
define poller {
    [...]
    modules   NrpeBooster
}
```

Then just tag all your check_nrpe commands with this module:

```
define command {
   command_name   check_nrpe
   command_line   $USER1$/check_nrpe -H $HOSTADRESS$ -c $ARG1$ -a $ARG2$
   module_type    nrpe_poller
}
```

That’s it. From now on all checks that use this command will use Shinken’s NRPE module and will be launched by it.

16.1.15 Extending Shinken

Introduction

There are a lot of “Modules” and “Addons” that are available for Shinken. Shinken can be extended by using different types of methods.

- Web interfaces from various open-source vendors can be used (Based on Livestatus API)
- Shinken itself can be extended using modules that are embedded into the various daemon processes

** (Arbiter, Poller, Receiver, Broker, Scheduler, Reactionner) * External software can provide functional enhancements for reporting, management or usability aspects

Shinken itself provides methods to extend the base functionality:

- *Broker modules* provide external access to runtime data from Shinken
- Poller modules such as *NRPE* and the *SNMP*
- Receiver modules like *NSCA* provide acquisition methods for Shinken
- Arbiter modules permit manipulating the configuration
- The webUI that permits embedding web interface elements

Independent software that works in concert with Shinken is available for:

- Monitoring remote hosts through agent software (*NIX, Windows, etc.)
- Submitting passive checks from remote hosts
- Managing the config files through a web interface
- Mobile phone UIs
- Desktop UIs and Hypervisors
- Desktop notification addons
- ...and much more

You can find many addons that are compatible with Shinken by visiting. The only caveat is that the addons should not use the status.dat file and preferably the modern API interfaces like Livestatus:

- Nagios.org
- SourceForge.net
- NagiosExchange.org
- Shinken community exchange for monitoring packs

16.1.16 Broker modules

The broker module receives messages from the Schedulers related to host, service check results. In addition to that it receives a copy of the compiled configuration at startup. What is special about the broker, is that without modules, the broker does nothing. It makes the configuration and result data available to modules. Modules are the ones in charge of doing something with the data. This could be exporting this "raw" data into flat files, databases or exposing it as an API.

The modules are presented according to their use cases.

- Core modules
- Livestatus Module for frontends
- Exporting data to metric databases
- SQL based Modules for frontends
- Exporting data to logging management systems
- Legacy modules for migration purposes
- Modules no longer supported

Core modules

simple_log: get all logs into one file

You can get a log for all your daemons in a single file. With the exception of Debug level logs which are not sent through the network as a safe guard. Shinken state messages are ONLY logged at the debug level in the local log files. These are the ALL CAPS states that some 3rd party interfaces use to mine data from the historical logs. Actual state messages are sent as objects between the various daemons.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: simple_log
- path: path of the log file

Here is an example:

```
define module{
```

```
     module_name      Simple-log
     module_type      simple_log
     path             /usr/local/shinken/var/nagios.log
     archive_path     /usr/local/shinken/var/archives/
}
```

Syslog - Send all logs to a local syslog server

Send all logs to a local syslog server. Support for remote syslog can be implemented if requested. Just lookup the syslog module, easy to modify. Use for example with Splunk, graylog2, Logstash, Elastic search, Kibana, or other log management and analysis system.

```
define module{
```

```
  module_name Syslog
  module_type syslog
}
```

Lightweight forwarder to Splunk

Shinken state data from the local syslog can also be sent to a Splunk server for indexing, reports, SLA and analysis. Via syslog or better yet, the Splunk lightweight forwarder which supports, TCP, buffering and security parameters.

Livestatus API Module - Thruk, Nagvis and Multisite Web frontends

There are three well known frontends and various small tools that can interface with the Livestatus API. This API is currently the most efficient method of sharing live data with external interfaces. It provides a rich query language similar to SQL, authentication, command execution, caching,connections persistence, multiple object methods (JSON, Python). All Livestatus data is kept in memory, there is no disk IO involved. It exposes configuration objects, the current state of the hosts and services as well as historical Shinken state log messages.

- MK Multisite
- Thruk

- NagVis

Have you installed the required packages to use the Livestatus module? You can look at the requirement section of the 10 minute installation guide for the requirement lists.

Livestatus Module

It takes the following parameters:

- module_name: name of the module called by the brokers
- module_type: livestatus
- host: IP interface to listen to. The default is '127.0.0.1'. '*' means 'listen on all interfaces'.
- port: TCP port to listen to.
- socket: Unix socket to listen to.
- allowed_hosts: a comma-separated list of IP-addresses which are allowed to contact the TCP port. Please keep in mind that these must be ip-addresses, NOT host names. (DNS lookups for every incoming livestatus request could hang up and therefore block the module)
- modules: a comma-separated list of modules (see below)
- pnp_path: relevant if you use the multisite gui. pnp_path points to the perfdata directory where the pnp4nagios data reside (it's the directory which contains a subdirectory for each host). Multisite needs it to display a small perfdata icon if a rrd file exists.
- To deactivate an input, the port- and socket-attributes can also take the value "none".

The Livestatus module itself can have sub-modules. In fact, it **must** have at least one submodule responsible for storing log events to a database, SQLite or MongoDB.

Livestatus module - Logstore Sqlite

Stores log-broks to an sqlite database.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_sqlite
- use_aggressive_sql: Prefer the use of sql queries to pre-filter data prior to python filtering. This is required for very large installations, as the Python structures are not indexed when filtering. Optional argument set to 0 by default. To enable set the value to 1. Some erroneous output may occur, but informal testing has shown these corner cases do not occur.
- read_only: don't send any update to the database. Should be used when you run several livestatus modules : 1 instance is R/W, other are read only.
- database_file: the path to the sqlite database file which is used to store the log broks/messages. The default is 'var/livestatus.db'
- archive_path: the path to a subdirectory where database file archives will be created. Every day the data from the last day will be moved to an archive datafile. The default is 'var/archives'.
- max_logs_age: the maximum age of the log messages (before they are deleted from the database). The default is 1 year. The argument to this parameter takes the form <number>[<period of time>], where <period of time> can be d for days, w for weeks, m for months and y for years. This parameter is currently ignored. In future releases it will be used to automatically delete ancient database files.

Here is an example:

```
define module{
```

```
     module_name      Livestatus
     module_type      livestatus
     host             *       ; * = listen on all configured ip addresses
     port             50000   ; port to listen
     socket           /usr/local/shinken/var/rw/live
     modules          logsqlite
}
define module{
```

```
     module_name      logsqlite
     module_type      logstore_sqlite
     use_aggressive_sql     0 ; optional, by default set to 0. Only for large installations.
     database_file    /usr/local/shinken/var/livelogs.db
     max_logs_age     3m ; three months. Other time intervals are d=days, w=weeks, y=years
}
```

Livestatus module - Logstore MongoDB

Stores historical log broks(inter daemon Shinken messages) to a MongoDB database. MongoDB is a distributed and very performant database that permits resilience and high availability. The current implementation has a few known broken pieces (some search functions are broken) and there are bugs in the implementation, so it is considered experimental until power users and developers have ironed out the bugs. It is the database of the future for Shinken.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_mongodb
- mongodb_uri: The address of the master. (Default: i_cant_write_the_uri_here_it_messes_the_wiki_up)
- replica_set: If you are running a MongoDB cluster (called a "replica set" in MongoDB), you need to specify it's name here. With this option set, you can also write the mongodb_uri as a comma-separated list of host:port items. (But one is enough, it will be used as a "seed")
- database: <undocumented>
- collection: <undocumented>
- max_logs_age: <undocumented>

The configuration looks quite similar to the sqlite one. **In a single-node installation and with decent amount of log traffic, the sqlite backend should be considered best practice, as it needs no extra software and is stable and fast (when run in-memory).**

Livestatus module - Logstore Null

In case you don't need any logging (for instance, if you dedicate a livestatus module instance to nagvis), you can use this module.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_null

Network Based Modules - Graphite graphing

Graphite is a graphing and data analysis tool. It is composed of a web frontend (graphite-web), fixed size databases (whisper) and data redistribution/munging daemon. (carbon) The first step is *having Graphite installed somewhere*, if you do not have Graphite installed, please do this and come back later.

Pre-requisite : Shinken 1.2.2+ is recommended for the best experience with Graphite.

graphite_perfdata: exports check result performance data to Graphite

Export all performance data included in check results to Whisper databases managed by Graphite. Data is buffered, then exported once every broker time tick. (Once per second). Should a communication loss occur, it will buffer data for 5 minutes before dropping data. The tick_limit max is configurable, the only limitation is the amount of memory the buffered data can eat.

The graphite broker module (v1.2) sends data to graphite in the following format :

HOSTNAME.SERVICENAME.METRICNAME

It can be optionally enhanced to send it the following format :

_GRAPHITE_PRE.HOSTNAME.SOURCE.SERVICENAME.METRICNAME._GRAPHITE_POST

Each of the three variables are optional :

- The _GRAPHITE_PRE variable can be set per host/service to provide a more flexible naming convention. (ex. Prod.site1.Hostname.servicename)
- The _GRAPHITE_POST variable can be set per host/service to specify the more information concerning the variable being stored that graphite can use to determine the retention rule to use for the variable.
- The SOURCE variable can be set in shinken-specific.cfg for the WebUI module and the Graphite broker.

Metric names are converted from Shinken's format to a more restrictive Graphite naming. Unsupported characters are converted to "_" underscore. So do not be surprised to see that some names differ in the WebUI or directly in Graphite. Permitted characters in Graphite are "**A-Za-z_**.", the hyphen character is permitted from Shinken, though only future versions of Graphite will support it.

Performance data transfer method can be set to pickle, which is a binary format that can send data more efficiently than raw ascii.

It takes the following parameters:

- module_name: name of the module called by the brokers
- module_type: graphite_perfdata
- host: ip address of the graphite server running a carbon instance
- port: port where carbon listens for metrics (default: 2003 for raw socket, 2004 for pickle encoded data)
- use_pickle: Use a more efficient transport for sending check results to graphite instead of raw data on the socket (v1.2)
- tick_limit: Number of ticks to buffer performance data during a communication outage with Graphite. On tick limit exceeded, flush to /dev/null and start buffering again. (v1.2)
- graphite_data_source: Set the source name for all data coming from shinken sent to Graphite. This helps diferentiate between data from other sources for the same hostnames. (ex. Diamond, statsd, ganglia, shinken) (v1.2)

Here is an example:

```
define module {
```

```
module_name Graphite-Perfdata
host xx.xx.xx.xx
module_type graphite_perfdata
port 2004 ; default port 2003 for raw data on the socket, 2004 for pickled data
use_pickle 1 ; default value is 0, 1 for pickled data
tick_limit 300 ; Default value 300
graphite_data_source shinken ; default is that the variable is unset
}
```

SQL Based Modules - PNP4Nagios Graphing

PNP4Nagios is a graphing tool that has a web interface for RRDTool based databases. Shinken can export performance data to an npcd database which will feed the RRD files (fixed sized round robin databases). You can *learn how to install PNP4Nagios* if you haven't done it already.

npcdmod: export perfdatas to a PNP interface

Export all perfdata for PNP.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: npcdmod
- path: path to the npcd config file

Here is an example:

```
define module{
 module_name  NPCD
 module_type  npcdmod
 config_file  /usr/local/pnp4nagios/etc/npcd.cfg
}
```

SQL Based Modules - Frontend Centreon2

Centreon2 use a NDO database, so you will need the ndodb_mysql module for it.

ndodb_mysql: Export to a NDO Mysql database

Export status into a NDO/Mysql database. It needs the python module MySQLdb (apt-get install python-mysqldb or easy_install MySQL-python).

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: ndodb_mysql
- database: database name (ex ndo)
- user: database user
- password: database user passworddt

- host: database host
- character_set: utf8 is a good one

Here is an example:

```
define module{
```

```
     module_name      ToNdodb_Mysql
     module_type      ndodb_mysql
     database         ndo       ; database name
     user             root      ; user of the database
     password         root      ; must be changed
     host             localhost ; host to connect to
     character_set    utf8      ;optionnal, UTF8 is the default
}
```

File based Legacy modules - perfdata export

service_perfdata: export service perfdatas to a flat file

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: service_perfdata
- path: path to the service perfdata file you want

Here is an example:

```
define module{
```

```
     module_name      Service-Perfdata
     module_type      service_perfdata
     path             /usr/local/shinken/src/var/service-perfdata
}
```

host_perfdata: export host perfdatas to a flat file

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: host_perfdata
- path: path to the host perfdata file you want

Here is an example:

```
define module{
```

```
     module_name      Host-Perfdata
     module_type      host_perfdata
     path             /usr/local/shinken/src/var/host-perfdata
}
```

Legacy File based Modules - Old CGI or VShell

The Old CGI and VShell use the flat file export. If you can, avoid it! It has awful performance, all modern UIs no longer use this.

status_dat: export status into a flat file

Export all status into a flat file in the old Nagios format. It's for small/medium environment because it's very slow to parse. It can be used by the Nagios CGI. It also export the objects.cache file for this interface.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: status_dat
- status_file: path of the status.dat file /usr/local/shinken/var/status.dat
- object_cache_file: path of the objects.cache file
- status_update_interval: interval in seconds to generate the status.dat file

Here is an example:

```
define module{
```

```
     module_name              Status-Dat
     module_type              status_dat
     status_file              /usr/local/shinken/var/status.data
     object_cache_file        /usr/local/shinken/var/objects.cache
     status_update_interval   15 ; update status.dat every 15s
}
```

Deprecated or unsupported modules

SQL Based MerlinDB

This interface is no longer supported and is going to be completely removed from Shinken.

SQL based ndodb_oracle - Icinga web frontend using NDO Oracle

This interface is no longer supported and is going to be completely removed from Shinken.

CouchDB: Export to a Couchdb database

This interface is no longer supported and is going to be completely removed from Shinken.

16.1.17 TSCA (Thrift Service Check Acceptor)

TSCA is a receiver/arbiter module to receive hosts and services check results. It provides the same functions as NSCA with additional features. High performance binary transmission, multi line output and auto generated clients for a variety of languages.

What is thrift ?

Let's cut and paste the wikipedia definition from'en.wikipedia.org/wiki/Apache_Thrift'_ :

"Thrift is an interface definition language that is used to define and create services for numerous languages.[1] It is used as a remote procedure call (RPC) framework [..]. It combines a software stack with a code generation engine to build services that work efficiently to a varying degree and seamlessly between ActionScript, C#, C++ (on POSIX-compliant systems), Cappuccino, Cocoa, Erlang, Haskell, Java, OCaml, Perl, PHP, Python, Ruby, and Smalltalk."

Installation

In any case, you have to install thrift with support for python (on the server side) and languages you want to use for clients.

Get it from thrift.apache.org or in your favorite distribution repository.

Server side

Go to the tsca module directory and generate the python stub for the server side installation

```
cd shinken/modules/tsca
$ thrift --gen py tsca.thrift
```

Declare the module is shinken-specific.org

```
define module{
      module_name     TSCA
      module_type     tsca_server
      host            0.0.0.0
      port            9090
}
```

Samples clients

There are three(3) client samples written in python, ruby and java in contrib/clients/TSCA of the Shinken distribution. You can use and extend them to send data directly in your code directly to Shinken's TSCA receiver/arbiter module.

The samples clients read a CSV file from stdin and send them the the TSCA running on localhost:9090. The CSV has the following format :

```
hostname,service description,output,rc
```

Any use of TCP in an application should take care not to block the program and to have very short timeouts. For applications that need non blocking functions, prefer a UDP based transport or a local buffer file with a separate application(send_nsca, thrift, etc) to forward your data to Shinken.

Ruby Generate the stub

```
$ thrift --gen rb ../../../shinken/modules/tsca/tsca.thrift
```

Run the client

```
$ cat file_state | ruby RubyClient.rb
```

Python Generate the stub

```
$ thrift --gen py ../../../shinken/modules/tsca/tsca.thrift
```

Run the client

```
$ cat file_state | python PythonClient.py
```

java Generate the stub

```
$ thrift --gen java ../../../shinken/modules/tsca/tsca.thrift
```

Compile the client

```
$ ant
```

Run the client

```
$ cat file_state | java JavaClientThrift
```

16.1.18 VMWare Arbiter module

How it works

The arbiter has a module that allows the host->VM automatic host dependency creation. In fact, the module is far more generic than just this. It's a generic "host link dependencies" module.

It reads a mapping file (simple json format) with son->father links. It call an external script at a regular interval : the one I wrote is a VMWare mapping one. It used the check_esx3.pl (that all ESX admin should have) plugin and generate the mapping file. When this file is changed, the module reloads it, creates new links and deletes old ones. So when you VMotion a virtual machine, in the next pass, there will be creation of a new link and deletion of the old one in the scheduler that manages it :)

How to define it

The definition is very easy :

```
define module{
     module_name       VMWare_auto_linking
     module_type       hot_dependencies
     mapping_file      /tmp/vmware_mapping_file.json
     mapping_command   /usr/local/shinken/libexec/link_vmware_host_vm.py -x '/usr/local/shinken/libex
     mapping_command_interval 60   ; optionnal
     mapping_command_timeout   300 ; optionnal
}
```

Then you add it in you arbiter object :

```
define arbiter {
    [...]
    modules   VMWare_auto_linking
}
```

So here, it will call the script /usr/local/shinken/libexec/link_vmware_host_vm.py with a listing of the vCenter vcenter.mydomain.com and generate the mapping file /tmp/vmware_mapping_file.json.

You can call : /usr/local/shinken/libexec/link_vmware_host_vm.py –help

for the full help on this script.

It looks at the file modification time each second. This command can also be launch by an external cron of course.

Note: So if you want to write a script that does this for XEN servers, all you need is to generate a json file with all the mapping. I didn't wrote the doc about this, but you can look in the test file for it, the format is very very easy :)

Here is an example of the JSON mapping file syntax:

%%:ref:*["host", "physical_host"], ["host", "virtual_machine"* <["host", "physical_host"], ["host", "virtual_machine">, "host", "physical_host"], ["host", "other_virtual_machine" <"host", "physical_host"], ["host", "other_virtual_machine">]%%

So just a list of couple 'host' string (from now only host are managed) and the host name.

Beware about it : you need the real host_name, including case.

16.1.19 Web Service Module

The Ws_arbiter module is a Receiver or Arbiter module to receive passive check results from remote hosts via HTTP(s). This module is considered a work in progress but can be used for testing and improvement.

Configuring the Web Service Module

If data is POSTed to this page, it will validate the data to determine if it is a service or host check result and submit the data to the Shinken external command queue.

The web service listens by default to TCP port 7760. The web service supports anonymous or authenticated access. Web service parameters are set in the Shinken-specific.cfg file, in the Ws_arbiter module. To enable the web service, simply add the module to your Arbiter or Receiver daemon configuration in Shinken-specific.cfg

Using the Web Service Module

The web service listens for POSTs to: /push_check_result

Use curl or embed the HTTP calls in your software to submit check results.

curl -u user:password -d "time_stamp=$(date +%s)&host_name=host-checked&service_description=service-checked&return_code=0&output=Everything OK" http://shinken-srv:7760/push_check_result

Example with more readability:

```
curl
```

-u user:password -d "time_stamp=$(date +%s)

```
&host_name=host-checked
&service_description=service-checked
&return_code=0
&output=Everything OK
http://shinken-srv:7760/push_check_result
```

16.1.20 SNMP module

This part must be splitted and sent in all module repositories

Shinken integrated SNMP Module

SnmpBooster Download Install and Configure

- *What is the SnmpBooster module*
- Install and configure the SNMP acquisition module. [You are here]
- *Reference - SnmpBooster troubleshooting*
- *Reference - SnmpBooster design specification*
- *Reference - SnmpBooster configuration dictionnary*

Downloads

The SnmpBooster module and genDevConfig are currently in public beta prior to integration within Shinken. You can consult t

- github.com/xkilian/genDevConfig
- github.com/titilambert/shinken/tree/snmp_booster/shinken/modules (snmp_booster branch) * Simply right-click and download snmp_poller.py then copy it to shinken/modules/

Requirements

The SnmpBooster module requires:

- Python 2.6+
- Shinken 1.2+
- PySNMP 4.2.1+ (Python module and its dependencies)
- ConfigObj (Python module)
- python-memcached
- memcachedb or memcached package for your operating system (ex. For Ubuntu: apt-get install memcachedb) *Note*

The genDevConfig profile generator depends on:

- Perl 5.004+
- 4 perl modules available from CPAN and network repositories. genDevConfig/INSTALL has the installation details.

STRONGLY RECOMMENDED: Use the same version of Python and Pyro on all hosts running Shinken processes.

Installation

SnmpBooster:

- Install the dependencies
- Copy the file snmp_poller.py from the git repository to your shinken/modules directory.
- Configuration steps are listed in the present web page.

genDevConfig:

- Download and extract the archive to your server.
- See genDevConfig/INSTALL on how to install and configure it.

Configuration

How to define the SnmpBooster module in the Shinken daemons You need to modify shinken-specific.cfg, which is located in $shinken/etc/shinken-specific.cfg

Arbiter daemon configuration Simply declare the module:

```
modules SnmpBooster</code>
```

Scheduler daemon configuration

Simply declare the module:

<code>modules SnmpBooster

Poller daemon configuration Simply declare the module:

```
modules SnmpBooster</code>
```

SnmpBooster Module declaration

Included in Shinken v1.2.1 shinken-specific.cfg.

<code>define module {

```
module_name          SnmpBooster
module_type          snmp_poller
datasource           /usr/local/shinken/etc/packs/network/SnmpBooster/   ; SET THE DIRECTORY FOR YOUR
memcached_host       x.x.x.x  ; SET THE IP ADDRESS OF YOUR memcached SERVER
memcached_port       11211  ; default port for a memcached process
```

}

If you do not know the IP adress on which your memcache is listening, check under /etc/memcached.conf. Or do a:

```
netstat -a | grep memcached</code>
If you are running a test on the local machine you can leave memcached on 127.0.0.1 (localhost), but
```

How to define a Host and Service

Step 1

Create a template for your SNMP enabled devices.

Sample template:

<code>cd shinken/etc/packs/network/ mkdir SnmpBooster

vi shinken/etc/packs/network/SnmpBooster/templates.cfg

```
define command {
```

```
command_name    check_snmp_booster
command_line    check_snmp_booster -H $HOSTNAME$ -C $SNMPCOMMUNITYREAD$ -V 2c -t $ARG1$ -i $_SERVICE
module_type     snmp_poller
```

}

```
define service {
```

```
name                    default-snmp-template
check_command           check_snmp_booster!$_SERVICEDSTEMPLATE$!$_SERVICEINST$!$_SERVICETRIGGERGROUP
_inst                   None
_triggergroup           None
max_check_attempts      3
check_interval          1
retry_interval          1
register                0
```

}

```
define host{
```

```
name                    SnmpBooster-host
alias                   SnmpBooster-host template
check_command           check_host_alive
max_check_attempts      3
check_interval          1
retry_interval          1
use                     generic-host
register                0
```

}

Step 2 Define some hosts and services. You would typically use genDevConfig or another configuration generator to create these for you.

Mandatory service arguments related to SNMP polling:

```
_dstemplate                Cisco-Generic-Router  ; Name of a DSTEMPLATE defined in the SnmpBooster co
```

```
snmpcommunityread    which is set in your resource.cfg file
```

Optional service arguments related to SNMP polling with default values:

```
_inst                   None   ; Could be numeric: 0, None or an instance mapping function like: map
```

```
_triggergroup           None   ; Name of the triggergroup defined in the SnmpBooster config.ini file
```

Sample Shinken host and service configuration:

```
# Generated by genDevConfig 3.0.0
# Args: --showunused -c publicstring 192.168.2.63
# Date: Thu Aug 30 17:47:59 2012

#######################################################################
# Description: Cisco IOS Software, C2960 Software (C2960-LANBASEK9-M), Version 12.2(50)SE4, RELEASE S
#     Contact:
# System Name: SITE1-ASW-Lab04
```

```
#    Location:
#######################################################################

define host {
```

```
 host_name            192.168.2.63
 display_name         192.168.2.63
 _sys_location
 address              192.168.2.63
 hostgroups
 notes
 parents
 use                  default-snmp-host-template
 register             1
}

define service {
```

```
 host_name            192.168.2.63
 service_description  chassis
 display_name         C2960 class chassis
 _dstemplate          Cisco-Generic-Router
 _inst                0
 use                  default-snmp-template
 register             1
}

define service {
```

```
 host_name            192.168.2.63
 service_description  chassis.device-traffic
 display_name         Switch fabric statistics - Packets per Second
 _dstemplate          Device-Traffic
 use                  default-snmp-template
 register             1
}

define service {
```

```
host_name            192.168.2.63
service_description  if.FastEthernet0_1
display_name         FastEthernet0_1 Description: Link to Router-1 100.0 MBits/s ethernetCsmacd
_dstemplate          standard-interface
_inst                map(interface-name,FastEthernet0_1)
use                  default-snmp-template
register             1
```

}

Here is an example configuration of the config.ini file

```
[DATASOURCE]
```

```
  OidmyOidDefinition = .1.3.6.1.45.0
  [myOidDefinition] ; Use the same name as the myOidDeiniftion, but omit the leading "Oid"
      ds_type = DERIVE
      ds_calc = 8,*  ; RPN expression : Oid, 8, *  Which means Oid * 8 = ds_calc
      ds_oid = $OidmyOidDefinition
```

```
[DSTEMPLATE]
```

```
  [myCiscoRouter]
      ds = myOidDefinition
[TRIGGER]
```

```
  [trigger1]
      warning = RPN expression
      critical = RPN expression
  [trigger2]
      warning = RPN expression
      critical = RPN expression
[TRIGGERGROUP]
```

```
[CiscoRouterTriggers]
    triggers = trigger1, trigger2
```

Shinken integrated SNMP Module

Overview

What is it The SnmpBooster module allows Shinken Pollers to directly manage SNMP data acquisition. This is an all Python cross-platform SNMP module. It is tightly integrated with the Shinken Poller, Scheduler and Arbiter daemons to provide the best possible user experience.

Design specification summary

- STATUS - DESIGN SPEC PERFORMANCE
- [Done] Functions as an integrated Shinken Poller module
- [Done] Necessary integration code commited to Shinken official release (Integrated starting at v1.2)
- [Done] Ability to collect thousands of SNMP metrics per second
- [Done] Be compatible with distributed data acquisition
- [Done] Collect data for a host/check_interval tuple via SNMP in a single pass
- [Done] Use all builtin Shinken scheduler logic for retries, forced checks, timeouts, dependencies, parents
- [Done] Store collected data for the duration of the check_interval in a memcached/membase
- [Done] On a restart, after the first collection, be able to pick up where the last check left and calculate derived values
- [Done] Forced check are not allowed within 30 seconds of last SNMP query to the same host/check_interval, all other requests get data from the cache.
- [Done] Only a single request to the host/check_interval via SNMP is allowed at a time, all other requests get data from the cache.
- STATUS - DESIGN SPEC USABILITY
- [Done] Usage documentation
- [xxxx] SkonfUI and Discovery usage documentation

- [xxxx] Provide sample configuration packs in Shinken
- [Done] Provide sample config.ini with examples of all types of data * SNMP OIDS, DATASOURCES, DSTEMPLATES, TRIGGERS and TRIGGERGROUPS
- [Done] Directly compatible for use with genDevConfig Shinken SNMP configuration generator
- [Done] Provide meaningful feedback for users on errors
- [Done] Capture all tracebacks and convert them to actual error or warning messages
- STATUS - DESIGN SPEC FEATURES
- [Done] Return state and performance metrics
- [Done] Performance metrics can be returned in a Weathermap compatible format
- [Done] Configuration file format is ConfigObj INI
- [Done] Load all valid INI configuration files from a directory and merge them
- [Done] Load a single INI configuration file
- [xxxx] Load a list of INI configuration files
- [Done] Configuration file describes all generic acquisition parameters (OID, DATASOURCE, DSTEMPLATE, MAP, TRIGGER, TRIGGERGROUP)
- [Done] Supports Triggers which are calculation rules to determine states
- [Done] Triggers support an RPN (Reverse Polish Notation) calculation engine which includes mathematical and logical operators
- [Done] Each TRIGGER is associated with a severity level, WARNING or CRITICAL
- [Done] Multiple TRIGGERS can be associated with a TRIGGERGROUP
- [Done] Use builtin Python Operators
- [Done] Support DERIVE, TEXT, GAUGE and COUNTER data types
- [xxxx] Support TIMETICKS data type
- [Done] Support applying RPN based calculations to received metric for scaling or conversion purposes
- [Done] Use a Python SNMP library which supports asynchronous acquisition PySNMP
- [Done] Datasources can use rule based runtime instance mapping
- [Done] Set Snmp version as a check runtime option
- [Done] Set Snmp DSTEMPLATE as a check runtime option
- [Done] Set Snmp TRIGGERGROUP as a check runtime option
- [Done] Set Snmp COMMUNITY as a check runtime option
- [Done] Use Snmp version 2c GetBulk
- [xxxx] Support Snmp version 2c GetNext if GetBulk is not supported
- [xxxx] Support Snmp version 1 GetNext
- [xxxx] Set Snmp Timeout as a check runtime option, instead of a hardcoded value at 5 seconds
- STATUS - DESIGN SPEC MAINTAINABILITY
- [xxxx] Functions documented in the source code

- [Done] Critical functions documented in the source code
- [Done] Locking sections identified in the code
- [xxxx] Unit tests with at least 80% coverage
- [xxxx] Unit tests integrated with Shinken test suite
- [Done] Code hosted on github
- [xxxx] configuration validity and integrity checking of all INI files
- [xxxx] Pep8 compliant
- [xxxx] Pylint pass

genDevConfig Plugins - Compatibility status with SnmpBooster

- STATUS - genDevConfig maintained Plugins
- [Done] Avaya ES switches
- [Done] Avaya ERS routing switches
- [Done] Cisco 29x0 switches
- [Done] MIB-II Interfaces
- [Done] Cisco PIX/ASA
- [Done] JUNOS devices
- [Done] Cisco IOS routers
- [Done] NetSNMP unix hosts ** Validation required**
- [Done] Packeteer devices ** Validation required**
- [Done] Sensatronics devices ** Validation required**
- [Done] Foundry devices ** Validation required**
- [Done] Packeteer devices ** Validation required**
- [Done] Cisco CSS ** Validation required**
- [InProgress] New Cisco Access points
- STATUS - Other maintained Plugins

Tip: [xxxx] Denotes a specification that is planned but not implemented

[InProgress] Denotes a specification that is under development

[Done] Denotes a specification that is implemented

SnmpBooster reference dictionary

- Jump back to *SnmpBooster documentation index*

SnmpBooster.ini dictionary

There are five dictionaries:

- [DATASOURCE]
- [DSTEMPLATE]
- [MAP]
- [TRIGGER]
- [TRIGGERGROUP]

DATASOURCE DICTIONARY OidVariableName refers to an actual OID that can be queries using SNMP against the device on the network.

[VariableName] refers to a Datasource and all the information required to gather and prepare the data using SNMP ds_type refers to how the data should be prepared ds_calc refers to any scaling manipulations to make the data more understandable. This is an RPN expression, where the first variable is omitted, as it is always the $OidVariable ds_oid refers to the actual $OidVariable name. An instance identifier can be appended to the name to signify that an instance is provided by the Shinken service definition. This information is passed when the check is called. ...

DSTEMPLATE DICTIONNARY [DsTemplateName] refers to the name of the DSTEMPLATE that will be referred to in the Shinken service definitions. ds refers to the list of DATASOURCES to be collected. If an instance is expected for the list of DATASOURCES, it MUST be the same instance for all Oids. If a different instance is required, use a second DSTEMPLATE.

TRIGGER DICTIONNARY

TRIGGERGROUP DICTIONNARY

MAP DICTIONNARY

SnmpBooster.ini example configuration

This example definition will be used to explain each section.

[DATASOURCE]

```
OidmyOidDefinition = .1.3.6.1.45.0
[myOidDefinition] ; Use the same name as the myOidDeiniftion, but omit the leading "Oid"
    ds_type = DERIVE
    ds_calc = 8,*  ; RPN expression : Oid, 8, *  Which means Oid * 8 = Total
    ds_oid = $OidmyOidDefinition
```

[DSTEMPLATE]

```
[myCiscoRouter]
    ds = myOidDefinition
```

[TRIGGER]

```
[trigger1]
    warning = RPN expression
    critical = RPN expression
[trigger2]
    warning = RPN expression
    critical = RPN expression
```

[TRIGGERGROUP]

```
[CiscoRouterTriggers]
    triggers = trigger1, trigger2
```

SnmpBooster.ini configuring SNMP Datasources

The first location is generic data related to SNMP parameters.

- DATASOURCE information * SNMP OID * Type of data and how can it be interpreted (GAUGE, COUNTER, COUNTER64, DERIVE, DERIVE64, TEXT, TIMETICK) * Data format preparation (Scaling the data for example bits to bytes) * Is there an instance to append to the
- Instance MAP function * Mapping the instance dynamically using a function * Data or rules related to the mapping function

SnmpBooster.ini configuring SNMP DSTEMPLATES

- DSTEMPLATEs to associate DATASOURCE to actual device classes * List of DATASOURCES associated with a, for example, Cisco 1900 router. Which in turn can be applied to a Shinken service

SnmpBooster.ini setting triggers/thresholds

- TRIGGER and TRIGGERGROUPS to apply thresholding rules * Define triggers and associate them with a TRIGGERGROUP name that can be applied to a Shinken Service

Shinken integrated SNMP Module

Overview

- Jump back to *SnmpBooster documentation index*

Tip: The module is now in public beta as of 2012-10-26! Have Fun!

Nothing new to add, more to come in 2013. 2013-01-19.

What is it The SnmpBooster module allows Shinken Pollers to directly manage SNMP data acquisition. This is an all Python cross-platform SNMP module. It is tightly integrated with the Shinken Poller, Scheduler and Arbiter daemons to provide the best possible user experience.

Why use it The SnmpBooster module is designed to be very efficient and scalable. It has a very flexible configuration method to make it easy to use with Shinken Monitoring Packs and Shinken discovery runners like genDevConfig.

This acquisition module was professionally designed and developed.

It is meant to be used by the very capable discovery engine genDevConfig (**v3.0.5 and newer**) originally developed for the Cricket SNMP monitoring tool and converted for use with Shinken.

It is one of the very few serious SNMP v2c implementation making use of SnmpGetBulk type requests.

How does it work

Shinken Integration

1. The SnmpBooster Arbiter module reads the Shinken SnmpBooster configuration file(s). It reads the check commands and based on the values in the check commands that use the snmp_poller module it will creates a shared configuration cache using memcached/memcachedb. The memcache key is always the combination of the hostname. This permits to tie together Shinken Hosts and Services with the SNMP specific configuration. (MongoDB and Redis are planned to be supported in the future) The Scheduler daemon schedules Host and Service checks as it normally does.

3. The SnmpBooster module will check that a memcache host key exists for the check to be launched. Then the SnmpBooster poller module will query all services related to a host for a given acquisition frequency in one pass. (all checks done every 2 minutes will be executed in bulk, same for those every 5 minutes)

5. Check results are cached for the acquisition check_interval. The next time a check request for data from the same host is received from the Scheduler, the data will be fetched from memcache. Resulting is extremely low check latency.

2. 6. The SNMP checks still benefit from retries, timeouts, forced checks, dependencies and the powerful Scheduler daemon logic.

6. The Scheduler daemon can still force an immediate re-check by flushing the cache. This is required for the dependency model.

Performance SnmpBooster uses SNMP v2c getbulk for high efficiency, unless forced to use SNMP v2c get-next or SNMPv1 get-next. GetBulk uses a single request PDU to ask for multiple OIDs or even entire tables, instead of sending one request PDU per OID.

For example: *A typical 24 port network switch with two uplinks might use 375 OIDS (8 OIDs per interface, plus general OIDs for chassis health, memory, cpu, fans, etc.). **SnmpBooster will only require around 4 request PDUs instead of 375 request PDUs**.* Each PDU is a request packet which takes time to create, send get processed and return. More timeouts to manage, more connections, more impact on the remote device and more latency means much fewer checks per second.*

The SnmpBooster module supports automatic instance mapping for OIDs. (Ex. Based on the interface name it will figure out that the SNMP index(or instance) is 136. This is automatically handled by genDevConfig and SnmpBooster, no user input required. :-)

The generic SNMP configuration information is stored in the Shinken SnmpBooster INI files. There is a Defaults_unified.ini and a series of other Defaults files, one per discovery plugin for genDevConfig.

Important: genDevConfig plugins have all been converted to use the new dynamic instance mapping methods. You are now free to use most if not all Defaults*.ini files included with genDevConfig. 2012-10-28

Limitations

You should have memcached instances running on each poller responsible for snmp polling. You should have your pollers with SnmpBooster in the same datacenter, as they need to be on the same machine with good connectivity to the active memcached instance. SnmpBooster is not compatible with distributed pollers in multiple datacenters, sorry, the current design of SnmpBooster uses a single centralized memcached instance for storing the timeseries data. For distributed datacenters to be supported, each poller+scheduler+memcached must be realm restrained, which is not the case today.

Design specification

SnmpBooster design specification and current development status.

Data model

The information required to define the data is split in two locations.

The first location is the host and service Shinken configuration (You need to generate or write this)

- Device specific information
  - IP addresses, host_names, device types, instance keys
  - A DSTEMPLATE must be referred to in the Service definition
  - A static SNMP instance could be referred to in the Service definition
  - An SNMP instance MAP function could be referred to in the Service definition

  - A TRIGGERGROUP could be refered to in the Service definition

The second location is SNMP Defaults.* templates. (Here you can create new devices or add new data sources)

- DATASOURCE information
  - SNMP OID
  - Type of data and how can it be interpreted (GAUGE, COUNTER, COUNTER64, DERIVE, DERIVE64, TEXT, TIMETICK)
  - Data format preparation (Scaling the data for example bits to bytes)
  - Is there an instance to append to the
- Instance MAP function * Mapping the instance dynamically using a function * Data or rules related to the mapping function
- DSTEMPLATEs to associate DATASOURCE to actual device classes * List of DATASOURCES associated with a, for example, Cisco 1900 router. Which in turn can be applied to a Shinken service
- TRIGGER and TRIGGERGROUPS to apply thresholding rules * Define triggers and associate them with a TRIGGERGROUP name that can be applied to a Shinken Service

A final location containes rules to build your Shinken configuration.

  - genDevConfig plugins create Shinken configurations

Installation and configuration

SnmpBooster installation

Reference Dictionnary

SnmpBooster reference dictionary

Troubleshooting

SnmpBooster troubleshooting

Graph templates

These are .graph files defined in your Shinken configuration directory. Refer to the Shinken graphite templates(Not yet created) or PNP4Nagios how-to documentation. The graph templates are independent from SnmpBooster and provide templates for any collected data from Shinken.

SnmpBooster Troubleshooting

- Jump back to *SnmpBooster documentation index*

Check your config

- Have you defined the poller module name?
- Have you defined the correct path to the directory containing your Defaults*.ini files?
- Have you addded the Snmpbooster module to your arbiter, poller, scheduler?
- Have you added copied the genDevConfig templates.cfg in shinken/packs/network/SnmpBooster/
- Have you installed PySNMP, memcached and other dependencies?

Software version consistency

Shinken and SnmpBooster now require **the same Python and Pyro version on all hosts running a Shinken daemon**.

If you cannot use the packaged version of Python and its modules (Pyro, memcached, etc.). Use virtualenv to declare a python version to use and install all required modules in that virtualenv.

Software version requirements

Have you verified that the *requirements* are met. Python, PySNMP, Shinken, Pyro, memcached, etc.

Validate your check command arguments

Use the check_plugin command and comment out the module to learn what were the exact arguments sent by the poller. This will permit you to validate all the arguments, like snmp community string, inheritance, template application, etc.

Validate connectivity

Take a packet trace using a tool like Wireshark to validate that the remote host is responding.

- Has the host responded
- **Is SnmpBooster repeating the request more often than the polling interval.**
  - If you are seeing repeated requests your device may have a compatibility issues.
  - Save an snmpwalk of the device, get a packet trace using Wireshark, set the poller to debug and save the poller.log file (shinken/var/poller.log). Send all three to the SnmpBooster developers.
  - Note: It is normal to see one or more bulkGet requests if you are getting large amounts of data. Ex. a 24 port switch will take 2-3 request packets.

Performance

Make sure you have a low latency connection to your memcache from the Poller. Your memcache server can be replicated to all your poller hosts that should also run memcache instances. Check that memcached is running: netstat -a | grep memcached

Faulty Template

A bad snmp_template file was distributed in the genDevConfig sample-config directory, there were two glaring errors.

This was fixed on 2012-10-16. Make sure you update your template, or use the data from the wiki.

Note that the template should be called: SnmpBooster-template.cfg to make it easier to troubleshoot in the logs. So when you search for SnmpBooster in your logs it will show up as well.

Log files

All warnings and errors generated by the SnmpBooster module start with "[SnmpBooster] error text" and are logged using the standard Shinken logger.

The Arbiter daemon can output initial configuration, loading of host keys and intervals in memcached type error messages. The Scheduler daemon can output scheduling and alert related messages. The Poller daemon can output messages related to instance mapping, acquisition timeouts, invalid community strings, cache failures and more. These are available in the Web interface, as they are placed in the check results for the service.

You can simply do a "grep SnmpBooster *" in your shinken/var directory to see the latest messages related to the SnmpBooster module. You can also sort messages by timestamp to make it easy to find where and when errors occurred.

cd shinken/var grep SnmpBooster *

memcache persistence

If you restart your memcache server or memcache crashes, your poller will no longer be able to validate that a host exists in memcache prior to writing.

You should use memcachedb to achieve persistence in case of memcache failures.

Common errors returned by SnmpBooster in the log file

Errors should be fairly explicit and mean what they say, though there can be exceptions. Lets try to clear some of them.

__Arbiter log **errors__**

Missing ds_oid : This means that a variable in your OID definitions is missing, or your DATASOURCE is not named correctly or your ds_oid variable is missing. There is a typo in your ds_oid variable (ex. ds-oid, or ds_oid = $OidNameIncorrectFFFRA.%(instance)s).

Datasource not defined : Your DSTEMPLATE uses a DATASOURCE that doesn't exist check the [DataSourceName] you are referring to. Does it contain the expected OID variable, $OidName.

Missing ds_type : The DATASOURCE always needs to have a ds_type definition, GAUGE, COUNTER, DERIVE, TEXT, TIMETICK, DERIVE64, COUNTER64.

__Poller log **errors__**

Problems with calculations, repeated polling, hosts not responding, etc.

__Memcached **errors__**

memcachedb and memcached do not use the same default port. Configure the correct memcachedb port to match what is declared in your SnmpBooster module under shinken-specific.cfg.

On Ubuntu 12.04 the default installation is on port 21201 instead of 11211. This causes the error "[SnmpBooster] Memcache server (127.0.0.1:11211) is not reachable" when Shinken starts.

To change it, you must edit the file /etc/memcachedb.conf

Memcached Notes

On Ubuntu 12.04 the default instalation is on port 21201 instead of 11211. This causes the error "[SnmpBooster] Memcache server (127.0.0.1:11211) is not reachable" when shinken starts.

To change it, you must edit the file /etc/memcachedb.conf

16.1.21 WebUI module

This part must be splitted and sent in all module repositories

WebUI integration with Shinken

The WebUI is an external broker module. So it's an external process launched by the broker that "eats" broks (broker messages) from the brokers. So it can get *all* broks if you place this broker in your top level realm.

The WebUI does not use a database to get data. Instead, it use a "regenerator" object that will eat each broks, and will "recreate" all Hosts/Services/Contacts objects as if the code was in the scheduler daemon. So basically, WebUI and pages always reflect the CURRENT state of hosts/services objects.

The WebUI http layer is managed by bottle.py. It's a small but powerful framework.

How does the WebUI function globally ?

There a 2 Threads running:

- the main thread is the bottle.py (http) listener. It will use the best backend it finds. We recommend using python-paste. If it does not find one, it will use the default swsgi. Paste is multi-thread, swsgi is mon-thread, so please use paste if you want to avoid locking problems.
- the 2nd thread is the regenerator one. It only gets broks and gives them to the regenerator object.

There is a lock system between the threads. You can have N Http requests in progress without problem, but during this time the renererator one will wait. During execution of the regenerator, no requests are processed. This is not considered a problem, as the regenerator is very quick, and there is only a 1s lock for a 7k service conf loading, so it's not a huge problem.

What is a WebUI User?

A WebUI user is a contact. A true contact object. You must match a contact name for your user.

To create a new page?

All pages are in the shinken/webui/plugins directory. Each "part" has it's own directory. A part (like the eltdetail, element detail) can have more than one "page" (like /host or /service for eltdetail).

From here we will supose you want to create a "/contact" page.

You can copy the dummy example in the plugins directory into a contact directory.

You need to change the contact/dummy.py file into a contact/contact.py file, because the webui will search for a dir/dir.py file to "load".

Templates

Templates are HTML with some Python code in it in the plugins/*/views direcotry for specific templates, and the "global layout" (menu and all common part) in the webui/views directory.

Your template must call the template layout (layout.tpl in the webui/views directory) wit ha "rebase" call.

If you put the rebase call at the beginning of your template, all there is below will be place "inside" the layout that will call the common javascripts and css, make the menu adn then call your html/python code.

The rebase call can take arguments. You MUST give it:

- user: the user you give it in the return dict of your .py code

Then all is optional:

- title: title of the page
- top_right_banner_state: int, global state with clouds to put in your top right page. Look at the problem.tpl code for an example.
- js and css list: list of YOUR specific javascript or css to call AFTER the common ones.
- refresh: boolean, set the refresh to 60s or do not refresh at all
- menu_part: will put the little "^" under this part of the menu.

Example of a call, taken from the problems view:

```
rebase layout title='All problems', top_right_banner_state=top_right_banner_state, js=['problems/js/a
roblems/js/autocompleter.Request.js', 'problems/js/autocompleterObserver.js'], css=['problems/css/acc
ms/css/autocompleter.css', 'problems/css/perfometer.css'], refresh=True, menu_part='/'+page, user=use
```

Call Python objects in your templates

Your templates are mainly HTML code. But of course you can call python code in it. The dict you returns in the plugin.py call will be available in this page.

For example, the my_host variable will be available in the page with the host object you find (or None if your give it a bad name of course). Then you can "call" python with for example here to show the host_name: `<span>My host name is *my_host.host_name* </span>` is a way in the templates to "call a variable or function" that will return a string, here the host_name.

If the function or property you call must return HTML code that SHOULD be output as it, without "protection", you must put a ! before your call.

Let use an example where the output value of an host is in fact an html output. If you use the code `my_host.output`, bottle.py will "protect" the html generated by escaping the string, and change <> characters with escaped value. You can change this by calling `my_host.output`. Of course, it's a security problem if the output is with a javascript code...

You can also "loop" or put "if" in your template. You just need to put your code with a % before. Like

```
%for i in xrange(1, 10):
  My valus is  {{i}}
%end
```

You must put the %end here, the indentation will NOT be enougth, sorry.

For an if it's also easy:

```
%if host.active_checks_enabled:
  The host got active checks enabled
%else:
  The host DO NOT have active check enabled
%end
```

Which javascript lib are you using?

It's mootools 1.3 with all options :)

What to do?

- Finish the /mobile part

- List of current alerts
- Host info
- Host status
- Host interfaces
- Hostgroup status
- dashboard hierachique with states, and BP
- Nagvis
- add bp in nagvis auto-map
- event sources
- correlation
- pre-filtering/enrichment
- user profile
- host/srv conf

WebUI search syntax

work in progress

not that we couldn't tell. ;) eh eh

beware the working men and flying tools!

WebUI SSL Certification

Lets start: the goal to to have the server.pem and client.pem file in etc/certs.

Go to the etc/certs directory.

```
openssl req -new -nodes -out server.req -keyout server.key -config ./shinken_openssl_cnf
openssl ca -out server.pem -config ./shinken_openssl_cnf -infiles server.req
cp server.pem server.pem.bkp
cp server.key server.pem
cat server.pem.bkp >> server.pem
cp server.pem client.pem
```

You can try to get the validity with for the arbiter with:

```
openssl s_client -connect localhost:7770</code>
```

16.2 Amazon AWS/EC2 import

16.2.1 Description

You can import data from Amazon AWS/EC2 **'AWS'**_ into Shinken to create hosts.

Amazon provide VM hosting with EC2. With this arbiter module, you will be able to load your EC2 hosts into Shinken.

16.2.2 Prerequisites

You will need the **'libcloud'**_ package installed on your Arbiter server.

16.2.3 Configuring the Landscape import module

In your shinken-specific.cfg file, just add (or uncomment):

```
define module {
 module_name      AWS
 module_type      aws_import

 # Configure your REAL key and secret for AWS
 api_key              PAAAB2CILT80I0ZA0999
 secret           GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH
 default_template generic-host        ; if the host is not tagged, use this one
 }
```

- Put in key and secret your private Landscape access. * default_template will be used if your host is not "tagged" in Landscape

16.2.4 Configuring the Arbiter module

And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master

     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           AWS
     }
```

Restart your Arbiter and it's done :)

16.2.5 Generated hosts

The configuration generated will look as below :

```
define host {
    host_name            i-3fc56e5a
    address              8.8.4.4
    use                  t1.micro,MyTag,EC2,generic-host
    _EC2_AVAILABILITY    us-east-1a
    _EC2_CLIENTTOKEN
    _EC2_DNS_NAME
    _EC2_GROUPS          quicklaunch-1
    _EC2_IMAGEID         ami-1b814f72
    _EC2_INSTANCEID      i-3fc56e5a
    _EC2_INSTANCETYPE    t1.micro
    _EC2_KERNELID        aki-825ea7eb
    _EC2_KEYNAME         testaws
    _EC2_LAUNCHDATETIME  2012-09-26T12:19:38.000Z
    _EC2_LAUNCHINDEX     0
```

```
    _EC2_PRIVATE_DNS
    _EC2_PRIVATE_IP
    _EC2_PRODUCTCODE
    _EC2_PUBLIC_IP       8.8.4.4
    _EC2_RAMDISKID       None
    _EC2_STATUS          stopped
    _EC2_TAGS            demo:myvalue,use:MyTag
 }
```

Here with a stopped t1.micro instance with no name. You can put your how "use" parameter by adding a EC2 tag "use" on your VM. It will be output on the host configuration so you can setup the monitoring as you want. .. _libcloud: http://libcloud.apache.org/index.html .. _AWS: https://console.aws.amazon.com

16.3 Amazon AWS/EC2 import

16.3.1 Description

You can import data from Amazon AWS/EC3 **'AWS'**_ into Shinken to create hosts.

Amazon provide VM hosting with EC3. With this arbiter module, you will be able to load your EC2 hosts into Shinken.

16.3.2 Prerequisites

You will need the **'libcloud'**_ package installed on your Arbiter server.

16.3.3 Configuring the Landscape import module

In your shinken-specific.cfg file, just add (or uncomment):

```
define module {
 module_name      AWS
 module_type      aws_import

 # Configure your REAL key and secret for AWS
 api_key              PAAAB2CILT80I0ZA0999
 secret           GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH
 default_template generic-host        ; if the host is not tagged, use this one
 }
```

- Put in key and secret your private Landscape access. * default_template will be used if your host is not "tagged" in Landscape

16.3.4 Configuring the Arbiter module

And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master

     address          localhost                   ;IP or DNS adress
     port             7770
```

```
    spare            0
    modules           AWS
    }
```

Restart your Arbiter and it's done :)

16.3.5 Generated hosts

The configuration generated will look as below :

```
define host {
    host_name            i-3fc56e5a
    address              8.8.4.4
    use                  t1.micro,MyTag,EC2,generic-host
    _EC2_AVAILABILITY    us-east-1a
    _EC2_CLIENTTOKEN
    _EC2_DNS_NAME
    _EC2_GROUPS          quicklaunch-1
    _EC2_IMAGEID         ami-1b814f72
    _EC2_INSTANCEID      i-3fc56e5a
    _EC2_INSTANCETYPE    t1.micro
    _EC2_KERNELID        aki-825ea7eb
    _EC2_KEYNAME         testaws
    _EC2_LAUNCHDATETIME  2012-09-26T12:19:38.000Z
    _EC2_LAUNCHINDEX     0
    _EC2_PRIVATE_DNS
    _EC2_PRIVATE_IP
    _EC2_PRODUCTCODE
    _EC2_PUBLIC_IP       8.8.4.4
    _EC2_RAMDISKID       None
    _EC2_STATUS          stopped
    _EC2_TAGS            demo:myvalue,use:MyTag
 }
```

Here with a stopped t1.micro instance with no name. You can put your how "use" parameter by adding a EC2 tag "use" on your VM. It will be output on the host configuration so you can setup the monitoring as you want. .. _libcloud: http://libcloud.apache.org/index.html .. _AWS: https://console.aws.amazon.com

16.4 The distributed retention modules

The high availability allow the Arbiter to send a configuration to a spare scheduler, but a spare scheduler does not have any saved states for hosts and services. It will have to recheck them all. It's better to use a distributed retention module so spares will have all the information they need to start with an accurate picture of the current states and scheduling :)

16.4.1 Non distributed retention modules

If you are just running tests on a single server, use the pickle or memcache retention modules You can also use MongoDB if you already have it installed for use with the WebUI.

16.4.2 MongoDB

MongoDB is a scalable, high-performance, open source NoSQL database written in C++.

Step 1: Install MongoDB:

We will use mongodb package from 10gen repository, so we start by adding it in apt sources list:

```
echo 'deb http://downloads-distro.mongodb.org/repo/debian-sysvinit dist 10gen' > /etc/apt/sources.lis
apt-get update
```

And we install it:

```
apt-get install mongodb-10gen
```

And we install pymongo, the python interface to MongoDB, with easy_install to avoid packages versions problems (like here **'forums.monitoring-fr.org/index.php?topic=5205.0'_**):

```
apt-get remove python-pymongo
easy_install pymongo
```

And finally we start MongoDB :

```
/etc/init.d/mongodb start
```

Step 2: define a mongodb_retention module in your shinken-specific.cfg file:

```
define module {
  module_name MongodbRetention
  module_type mongodb_retention
  uri mongodb://localhost/?safe=true
  database shinken
}
```

Step 3: Declare a retention module for your scheduler(s) :)

Example:

```
#The scheduler is a "Host manager". It get hosts and theirs
#services. It scheduler checks for them.
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
     port     7768                  ; tcp port of the daemon

     #optionnal: modules for things as retention
     modules    MongodbRetention
     }
```

Step 4: Restart the Arbiter, and your Scheduler will now save its state between restarts. :)

16.4.3 Memcached

Memcached is a distributed memory resident key/value server. It's very easy to install:

```
sudo apt-get install memcached
sudo /etc/init.d/memcached start
```

The shinken module also needs the python-memcache package to talk to this server.

```
sudo apt-get install python-memcache
```

To use it,

Step 1: define a memcache_retention module in your shinken-specific.cfg file:

```
define module{
     module_name      MemcacheRetention
     module_type      memcache_retention
     server           127.0.0.1
     port             11211
}
```

Step 2: Declare a retention module for your scheduler(s) :)

Example:

```
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
     port     7768                  ; tcp port of the daemon

     #optional: modules for things as retention
     modules    MemcacheRetention
     }
```

Step 3: Restart the Arbiter, and your Scheduler will now save its state between restarts. :)

16.4.4 Redis

Redis is a distributed key/value server (on disk and in-memory). It's very easy to install:

```
sudo apt-get install redis-server
sudo /etc/init.d/redis-server start
```

The shinken module also need the python-redis package to talk to this server.

```
sudo apt-get install python-redis
```

Step 1: define a redis_retention module in your shinken-specific.cfg file:

```
define module{
     module_name      RedisRetention
     module_type      redis_retention
     server           127.0.0.1
}
```

Step 2: Declare a retention module for your scheduler(s) :)

Example:

```
#The scheduler is a "Host manager". It get hosts and theirs
#services. It scheduler checks for them.
define scheduler{
     scheduler_name   scheduler-1   ; just the name
     address  localhost             ; ip or dns address of the daemon
     port     7768                  ; tcp port of the daemon

     #optionnal: modules for things as retention
     modules    RedisRetention
     }
```

Step 3: Restart the Arbiter, and your Scheduler will now save its state between restarts. :) .. _forums.monitoring-fr.org/index.php?topic=5205.0: http://forums.monitoring-fr.org/index.php?topic=5205.0

16.5 How to enable and use Livestatus module

16.5.1 Define the Livestatus module

Start by reviewing the ‘’/etc/shinken/shinken-specific.cfg” file for this module:

```
define module{
```

```
module_name      Livestatus
module_type      livestatus
host             *       ; * = listen on all configured IP addresses
port             50000   ; port to listen on
database_file    /var/lib/shinken/livestatus.db
```

}

With these parameters:

- module_name: name of the module called by the brokers
- module_type: livestatus
- host: IP interface to listen to. The default is *, which means “listen on all interfaces”.
- port: TCP port to listen to.
- socket: Unix socket to listen to.
- database_file: the path to the sqlite database file which is used to store the log broks/messages. The default is “var/livelogs.db”
- max_logs_age: the maximum age of the log messages (before they are deleted from the database). The default is 1 year. The argument to this parameter takes the form <number>[<period of time>], where <period of time> can be d for days, w for weeks, m for months and y for years.
- allowed_hosts: a comma-separated list of IP-addresses which are allowed to contact the TCP port. Please keep in mind that these **must be IP-addresses, NOT host names**. Because DNS lookups for every incoming livestatus request could hang up and therefore block the module.

16.5.2 Enable the Livestatus module

Still in ‘’/etc/shinken/shinken-specific.cfg’‘, find the object Broker and add “Livestatus” to its “modules”:

```
define broker{
```

```
     broker_name      broker-1
[...]
```

```
     modules          Simple-log,Livestatus
}
```

16.5.3 Disable human readable logs

In ‘’/etc/shinken/nagios.cfg’‘, verify that the option **human_timestamp_log** is set to **0**.

In version 0.6.5, you can not have at the same time a simple-log file with human readable timestamp and a Livestatus database.

16.6 Exporting data for reporting

Shinken can export necessary data for reporting in 3rd party systems.

16.6.1 raw_socket module

The raw socket module exports reporting data using a syslog format to a raw TCP socket. Theses logs can be captured, parsed and indexed by any log management system like Splunk or Logstash.

16.6.2 Why export reporting data

Custom UIs like Thruk, Multisite, WebUI, Adagios, Nagios IX, etc. All have poor or inflexible reporting. Simply because these are not reporting engines.

This also permits to have a generic reporting method that can accept data from any Nagios, Shinken, Icinga or even Riemann.

16.6.3 Reporting module using Splunk

Splunk was selected as the reporting platform for creating, managing and presenting reports. Though the raw_socket module does not have any Splunk specific particularities. It is notable that Splunk reports can be embedded in any 3rd party UI using its REST API.

16.6.4 Raw_socket log format

The logs are plain-text and compliant with RFC3164. They use an intelligent date format, a configurable seperator " "(space by default), and key=value pairs in the message data portion of the log. Should a key or value contain a space they must be double quoted. This is syslog using structured data without going to full out JSON that may not be compatible with all log management systems.

The message fields that are supplied in each status update in addition to the standard syslog header are:

- Hostname
- Servicename
- Business impact
- Host/Service status
- Host/Service previous status
- Acknowedgement status
- Maintenance status

Any time the maintenance, host, service or acknowledgement status changes, a log is sent by the Shinken raw_socket module.

Having all relevant data in each log makes it very easy to compute reports for given time periods.

The hostgroup or service group memberships, custom variables or any other configuration related data should be queried from the monitoring system using its API (Livestatus in the case of Shinken and Nagios).

16.6.5 Raw_socket module availability

The module is available in both Shinken 1.4 and Shinken 2.0. The module will be integrated in master branches once unit tests and end-to-end testing is completed. 3rd quarter 2013.

16.7 Monitoring Linux System with Glances and checkglances.py

'Glances'_ is a fantastic multiplatform system monitoring tool writen by Nicolargo. Glances can run on (Linux, Windows, MacOS ...). There is a growing ecosystem around Glances and of course a Nagios/Shinken plugin : check-glances.py.

16.7.1 How does it work

Glances can run in server mode. It provide a XML-RPC server (over http) and allow to retrieve system information throuh a restful API. The only thing to do is to install and start Glances as server on the monitored host, then install checkglances.py on the shinken server and finaly install the glances pack.

16.7.2 Install glances

See the glances documentation to install glances on Linux.

<code bash> easy_install glances </code>

There is a debian startup script in the glances repository. And another one for centos here.

16.7.3 Install checkglances.py

Just follow the documentation for the checkglances.py prerequisites and put it in your nagios plugins folder.

16.7.4 Install the glances pack

Open a terminal as the shinken user and just type the following command

<code bash> shinken install glances </code>

Then just edit the configuration for a linux monitored host and tag it as **glances**

```
define host{
 name mylinuxhost
 use glances
 ...
```

Finaly restart the shinken arbiter

```
service shinken-arbiter restart
```

16.7.5 What will be monitored ?

For the moment just the basic system (ram, cpu, load, memory, filesystem and network).

If you want to modify the default thresholds for just a host you can do it by overiding the thresholds macro in your host definition. If you want to do it for several hosts, declare a new template and just add the desired thresholds macro to be overide.

Here is a list of the macros

```
::
```

> _LOAD_WARN 2 _LOAD_CRIT 3 _CPU_WARN 80 _CPU_CRIT 90 _MEMORY_WARN 90 _MEMORY_CRIT 95 _FS /, /home _FS_WARN 90 _FS_CRIT 95 _IFACES eth0, eth1 _NET_WARN 7500000 _NET_CRIT 10000000

Note the _FS and _IFACES macros. They leverage the ability to duplicate service for a given list of things to be monitored. Here you see that / and /home partitions will be monitored. If you want to modify this then just add your own in a new template that will inherit the glances template.

16.8 Shinken GLPI integration

Shinken supports importing hosts from GLPI

For people not familiar with GLPI, it is an Open-Source CMDB. Applicable to servers, routers, printers or anything you want for that matter. It is also a help-desk tool. GLPI also integrates with tools like FusionInventory for IT inventory management.

You can still have flat files AND GLPI if you want. Hosts imported from GLPI will be treated as standard hosts from flat file (inheritance, groups, etc). In fact, in this first version the module only sends the host_name to Shinken, but there should be more information extracted like network connexions for parents relations in the future. :)

16.8.1 Requirements

- python module MySQLdb
- Compatible version of GLPI Shinken module and GLPI version - ...
- etc..

16.8.2 Enabling GLPI Shinken module

In your shinken-specific.cfg file, just add (or uncomment):

```
#You know GLPI? You can load all configuration from this app(
#with the webservices plugins for GLPI, in xmlrpc mode
#and with plugin monitoring for GLPI)
# =============== Work with Plugin Monitoring of GLPI ===============
#All configuration read from this will be added to the others of the
#standard flat file
define module{
     module_name      GLPI
     module_type      glpi
     uri              http://localhost/glpi/plugins/webservices/xmlrpc.php
     login_name       glpi
```

```
     login_password   glpi
}
```

And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master
#    host_name       node1       ;result of the hostname command under Unix
     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           GLPI
     }
```

It's done :)

16.9 Ip Tag module

16.9.1 Why tag a host based on it's IP address?

We learned on the *DMZ monitoring* that you can "tag" a host with a poller_tag so it will be checked only by DMZ pollers. It can be tedious process to manually tag all these hosts. Shinken provides an automated method to do this.

This is handled by the arbiter ip_tag module.

16.9.2 Ip_tag module

The ip_tag module is an arbiter module that looks up the host address during the configuration parsing and compares it to an predefined IP range (IPV4 or IPV6). If the range matches, it can apply or add a property, such as poller_tag. Other types of tags could be related to locations, functions, administrative groups, etc.

Method: replace or append.

replace will put the value if the property is unset. This is the default method. .. warning:: Fix me: replace, implies overriding an existing value. And will cause user issues down the line. Rename it to set. Replace should be a different method altogether, so overall there should be 3 methods(set, append, replace).

append will add with a , if a value already exist

Here is an example that will set the poller_tag property with the value DMZ of all hosts that:

- have a their hostadress ip (or name resolved) in the range 192.168.0.1/24.
- do not already have a poller_tag property set

```
define module{
```

```
     module_name     IpTag
     module_type     ip_tag
     ip_range        192.168.0.1/24
     property        poller_tag
     value           DMZ
}
```

To use the module add it in the arbiter object:

```
::
```

define arbiter { [...] modules NSCA,IpTag

}

16.9.3 Add value instead of setting it

In the previous example we set the property poller_tag to a value. But what if we want to "add" a value, like a template name? We can change the "method" property of the module to "append" so we can add the "value" to the host property instead of replace it.

Here is an example where we want to add the "dmz" template on the hosts, while also keeping any defined templates:

```
define module{
```

```
     module_name   IpTag
     module_type   ip_tag
     ip_range      192.168.0.1/24
     property      use
     value         dmz

     # Optional method
     method append
}
```

For a host defined as:

```
define host{
```

```
     host_name   example_host1
     address     192.168.0.2
     use         linux
}
```

It will be "changed" internaly in:

```
define host{
```

```
     host_name   example_host1
     address     192.168.0.2
     use         linux,dmz
}
```

Name resolution

Of course you don't need to set IP address in the address of your host. You can set a hostname, and it will be resolved, and then compared to the range. :)

16.10 Ubuntu Landscape import

16.10.1 Description

You can import data from Ubuntu Landscape into Shinken to create hosts.

Ubuntu Landscape, is a web app to manage all your linux servers (update and co), which is provided by Canonical, Ubuntu's parent company.

This is an Arbiter import module. The Arbiter manages the configuration.

16.10.2 Prerequisites

You will need the landscape-api package installed on your Arbiter server.

16.10.3 Configuring the Landscape import module

In your shinken-specific.cfg file, just add (or uncomment):

define module { module_name Landscape module_type landscape_import

Configure your REAL key and secret from Landscape key PAAAB2CILT80I0ZA0999 secret GGtWAAAzEItz0utWUeCe9BJKIYWX/hdSbA6YCHHH default_template generic-host ; if the host is not tagged, use this one

If you are using a specific certificate for landscape_api #ca /path/to.ca.cert

If you need a proxy to access https://landscape.canonical.com/api/ #https_proxy http://user:secret@myproxy.com:3128

}

- Put in key and secret your private Landscape access.
- default_template will be used if your host is not "tagged" in Landscape
- If you are using a specific certificate for connexion, give the full path in ca
- You will certainly need an https proxy to access the Landscape API. If so, configure it there.

16.10.4 Configuring the Arbiter module

And add it in your Arbiter object as a module.

```
define arbiter{
     arbiter_name     Arbiter-Master
#    host_name       node1       ;result of the hostname command under Unix
     address          localhost                   ;IP or DNS adress
     port             7770
     spare            0
     modules           Landscape
     }
```

Restart your Arbiter and it's done :)

Tip: Your "tags" will be applied as templates for your hosts.

16.11 Shinken Livestatus API

16.11.1 Overview

- Jump back to Getting Started
- Jump back to *Livestatus module configuration*

What is it

Livestatus API is the modern method of interacting with Shinken and Nagios based systems alike.

Originally developed for Nagios, MK Livetstatus, was re-implemented in Python for use with Shinken by professional developers. The access methods and query languages are the same.

Why use it

It is fast.

It is network based using TCP.

It is standard for all Nagios and Shinken monitoring systems.

It uses in-memory structures for status data

It uses a back-end database for historical reporting

It uses an SQL based query language

It has a host of powerful nuts and bolts features (authentication, caching, connection persistence, multiple object methods (JSON, Python)).

What can I do with it?

All programs and scripts use (or should use) this method to :

- Obtain the current state of hosts and services
- Obtain the current configuration related to hosts and services
- Send administrative commands (downtimes, comments, forcing checks)
- Filter information to display
- Obtain basic reports and event statistics

Shinken being a modern re-implementation of Nagios has additional features that are available in addition to the standard Livestatus API.

Shinken Livestatus API unique features can :

- Obtain Business Impact information
- Obtain intelligent dependency status hosts or services (combines dependency and parent information)
- Obtain Business Process states (same syntax as standard host and service queries)

16.11.2 How does it work

Livestatus uses a powerful SQL-like query language. The standard methods and parameters are defined at :

'MK Livestatus reference methods and query language definition'_

Full list of Shinken Livestatus API methods:

'Shinken mapping.py methods'_

16.11.3 What software uses Livestatus to interact with Shinken

Well known Web frontends

- MK Multisite
- Thruk
- NagVis
- Splunk for Nagios

Mobile Web frontends

- get list

Scripts

- Downtime management scripts
- Debug scripts

Installing Livestatus

Have you installed the required packages to use the Livestatus module? You can look at the requirement section of the *10 minute installation guide* for the *requirement lists*.

How to enable Livestatus

Very simple, jump to the *Shinken Broker configuration* section to enable it. .. _Shinken mapping.py methods: https://github.com/shinken-monitoring/mod-livestatus/blob/master/module/mapping.py .. _MK Livestatus reference methods and query language definition: http://mathias-kettner.de/checkmk_livestatus.html

16.12 NSCA module

The NSCA daemon module is used to receive send_nsca packets and submit them to the Shinken command pipe. The NSCA module can be loaded by the Receiver or Arbiter process. It will listen on port TCP/5667 for send_nsca packets.

Tip: Passive checks can be submitted *natively to the Shinken command pipe* or from remote hosts to modules, such as NSCA, AMQP or collectd, loaded in the Shinken Arbiter or Receiver process. AMQP is implemented for integration with the Canopsis Hypervisor, but could be re-used for generic messaging.

Note: The Shinken NSCA module implementation is currently limited to the "xor" obfuscation/encryption.

In your shinken-specific.cfg file, just add (or uncomment):

```
::
```

#You can send check result to Shinken using NSCA #using send_nsca command define module{

module_name NSCA module_type nsca_server host * port 5667 encryption_method 0 password helloworld

}

define receiver{

```
receiver_name    receiver-1
address          localhost
port             7773
modules          NSCA

timeout          3             ; 'ping' timeout
data_timeout     120           ; 'data send' timeout
max_check_attempts       3     ;  if at least max_check_attempts ping failed, the node is DEAD

#advanced
realm    All
}
```

This daemon is totally optional.

It's main goal is to get all passive "things" (checks but why not other commands) in distant realms. It will act as a "passive receive buffer" and will then dispatch the data or commands directly to the appropriate Scheduler or Arbiter process.

Data can be received from any Realm, thus the Realm option is nonsensical.

For now there is no init.d script to launch it. .. note:: Verify that the init script has been added.

It is launched like all other daemons:

```
bin/shinken-receiver -c etc/receiverd.ini
```

Tip: Alternatively, for small installations with you can configure a modules inside your Arbiter instead of the Receiver. It will listen the TCP/5667 port for send_nsca packets.

To configure the NSCA module in your Arbiter instead of Receiver. Add the NSCA module to your Arbiter object configuration.

```
::
```

define arbiter{ arbiter_name Arbiter-Master

 # host_name node1 ;result of the hostname command under Unix address localhost ;IP or DNS adress port 7770 spare 0 modules NSCA

}

16.13 Retention troubleshooting

The retention file contains the state of your host and services, so that they are kept when shinken is restarted.

Sometimes you'll want to inspect (and possibly fix) the retention file, in case you need to work-around a bug or simply better understand what is stored there.

When you use the PickleRetention module in the scheduler (cf. ''define scheduler" in ''shinken-specific.cfg''), you can simply manipulate the retention file using Python.

For this you can use the following code.

- It assumes Shinken is installed in ''/opt/shinken" with the retention file in ''/tmp/retention.dat'':
- Run and play with it interactively using ''ipython -i inspect_retention.py''.

```
#!/usr/bin/python
import pickle
import sys
sys.path.append('/opt/shinken')
import shinken

r = pickle.load(file('/tmp/retention.dat'))
h = r['hosts']

# Example:
# [(k,v) for (k,v) in h['your_host'].items() if k.find('downtime') >= 0]
#
# del h['your_host']
#
# for k,v in r['services'].items():
#     if 'your_host' in k:
#         del r['services'][k]
```

To save your changes:

- Stop Shinken: ''service shinken stop''
- Save the pickle: ''pickle.dump(r, open('/tmp/retention.dat', 'w'))''
- Start Shinken: ''service shinken start''

16.14 NRPE Module

16.14.1 What is it

The NRPE module allows Shinken Pollers to bypass the launch of the check_nrpe process. It reads the check command and opens the connection by itself. It scales the use of NRPE for active supervision of servers hosting NRPE agents.

The command definitions should be identical to the check_nrpe calls.

16.14.2 How to define it

The definition is very easy (and you probably just have to uncomment it):

```
define module{
     module_name       NrpeBooster
     module_type       nrpe_poller
}
```

Then you add it to your poller object:

```
define poller {
    [...]
```

```
    modules   NrpeBooster
}
```

Then just tag all your check_nrpe commands with this module:

```
define command {
   command_name   check_nrpe
   command_line   $USER1$/check_nrpe -H $HOSTADRESS$ -c $ARG1$ -a $ARG2$
   module_type    nrpe_poller
}
```

That's it. From now on all checks that use this command will use Shinken's NRPE module and will be launched by it.

16.15 Extending Shinken

16.15.1 Introduction

There are a lot of "Modules" and "Addons" that are available for Shinken. Shinken can be extended by using different types of methods.

- Web interfaces from various open-source vendors can be used (Based on Livestatus API)
- Shinken itself can be extended using modules that are embedded into the various daemon processes

** (Arbiter, Poller, Receiver, Broker, Scheduler, Reactionner) * External software can provide functional enhancements for reporting, management or usability aspects

Shinken itself provides methods to extend the base functionality:

- *Broker modules* provide external access to runtime data from Shinken
- Poller modules such as *NRPE* and the *SNMP*
- Receiver modules like *NSCA* provide acquisition methods for Shinken
- Arbiter modules permit manipulating the configuration
- The webUI that permits embedding web interface elements

Independent software that works in concert with Shinken is available for:

- Monitoring remote hosts through agent software (*NIX, Windows, etc.)
- Submitting passive checks from remote hosts
- Managing the config files through a web interface
- Mobile phone UIs
- Desktop UIs and Hypervisors
- Desktop notification addons
- ...and much more

You can find many addons that are compatible with Shinken by visiting. The only caveat is that the addons should not use the status.dat file and preferably the modern API interfaces like Livestatus:

- Nagios.org
- SourceForge.net

- NagiosExchange.org
- Shinken community exchange for monitoring packs

16.16 Broker modules

The broker module receives messages from the Schedulers related to host, service check results. In addition to that it receives a copy of the compiled configuration at startup. What is special about the broker, is that without modules, the broker does nothing. It makes the configuration and result data available to modules. Modules are the ones in charge of doing something with the data. This could be exporting this "raw" data into flat files, databases or exposing it as an API.

The modules are presented according to their use cases.

- Core modules
- Livestatus Module for frontends
- Exporting data to metric databases
- SQL based Modules for frontends
- Exporting data to logging management systems
- Legacy modules for migration purposes
- Modules no longer supported

16.16.1 Core modules

simple_log: get all logs into one file

You can get a log for all your daemons in a single file. With the exception of Debug level logs which are not sent through the network as a safe guard. Shinken state messages are ONLY logged at the debug level in the local log files. These are the ALL CAPS states that some 3rd party interfaces use to mine data from the historical logs. Actual state messages are sent as objects between the various daemons.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: simple_log
- path: path of the log file

Here is an example:

```
define module{
```

```
     module_name      Simple-log
     module_type      simple_log
     path             /usr/local/shinken/var/nagios.log
     archive_path     /usr/local/shinken/var/archives/
}
```

Syslog - Send all logs to a local syslog server

Send all logs to a local syslog server. Support for remote syslog can be implemented if requested. Just lookup the syslog module, easy to modify. Use for example with Splunk, graylog2, Logstash, Elastic search, Kibana, or other log management and analysis system.

```
define module{
```

```
  module_name Syslog
  module_type syslog
}
```

Lightweight forwarder to Splunk

Shinken state data from the local syslog can also be sent to a Splunk server for indexing, reports, SLA and analysis. Via syslog or better yet, the Splunk lightweight forwarder which supports, TCP, buffering and security parameters.

16.16.2 Livestatus API Module - Thruk, Nagvis and Multisite Web frontends

There are three well known frontends and various small tools that can interface with the Livestatus API. This API is currently the most efficient method of sharing live data with external interfaces. It provides a rich query language similar to SQL, authentication, command execution, caching,connections persistence, multiple object methods (JSON, Python). All Livestatus data is kept in memory, there is no disk IO involved. It exposes configuration objects, the current state of the hosts and services as well as historical Shinken state log messages.

- MK Multisite
- Thruk
- NagVis

Have you installed the required packages to use the Livestatus module? You can look at the requirement section of the 10 minute installation guide for the requirement lists.

Livestatus Module

It takes the following parameters:

- module_name: name of the module called by the brokers
- module_type: livestatus
- host: IP interface to listen to. The default is '127.0.0.1'. '*' means 'listen on all interfaces'.
- port: TCP port to listen to.
- socket: Unix socket to listen to.
- allowed_hosts: a comma-separated list of IP-addresses which are allowed to contact the TCP port. Please keep in mind that these must be ip-addresses, NOT host names. (DNS lookups for every incoming livestatus request could hang up and therefore block the module)
- modules: a comma-separated list of modules (see below)
- pnp_path: relevant if you use the multisite gui. pnp_path points to the perfdata directory where the pnp4nagios data reside (it's the directory which contains a subdirectory for each host). Multisite needs it to display a small perfdata icon if a rrd file exists.
- To deactivate an input, the port- and socket-attributes can also take the value "none".

The Livestatus module itself can have sub-modules. In fact, it **must** have at least one submodule responsible for storing log events to a database, SQLite or MongoDB.

Livestatus module - Logstore Sqlite

Stores log-broks to an sqlite database.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_sqlite
- use_aggressive_sql: Prefer the use of sql queries to pre-filter data prior to python filtering. This is required for very large installations, as the Python structures are not indexed when filtering. Optional argument set to 0 by default. To enable set the value to 1. Some erroneous output may occur, but informal testing has shown these corner cases do not occur.
- read_only: don't send any update to the database. Should be used when you run several livestatus modules : 1 instance is R/W, other are read only.
- database_file: the path to the sqlite database file which is used to store the log broks/messages. The default is 'var/livestatus.db'
- archive_path: the path to a subdirectory where database file archives will be created. Every day the data from the last day will be moved to an archive datafile. The default is 'var/archives'.
- max_logs_age: the maximum age of the log messages (before they are deleted from the database). The default is 1 year. The argument to this parameter takes the form <number>[<period of time>], where <period of time> can be d for days, w for weeks, m for months and y for years. This parameter is currently ignored. In future releases it will be used to automatically delete ancient database files.

Here is an example:

```
define module{
```

```
     module_name      Livestatus
     module_type      livestatus
     host             *       ; * = listen on all configured ip addresses
     port             50000   ; port to listen
     socket           /usr/local/shinken/var/rw/live
     modules          logsqlite
}
define module{
```

```
     module_name      logsqlite
     module_type      logstore_sqlite
     use_aggressive_sql     0 ; optional, by default set to 0. Only for large installations.
     database_file    /usr/local/shinken/var/livelogs.db
     max_logs_age     3m ; three months. Other time intervals are d=days, w=weeks, y=years
}
```

Livestatus module - Logstore MongoDB

Stores historical log broks(inter daemon Shinken messages) to a MongoDB database. MongoDB is a distributed and very performant database that permits resilience and high availability. The current implementation has a few known broken pieces (some search functions are broken) and there are bugs in the implementation, so it is considered experimental until power users and developers have ironed out the bugs. It is the database of the future for Shinken.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_mongodb
- mongodb_uri: The address of the master. (Default: i_cant_write_the_uri_here_it_messes_the_wiki_up)
- replica_set: If you are running a MongoDB cluster (called a "replica set" in MongoDB), you need to specify it's name here. With this option set, you can also write the mongodb_uri as a comma-separated list of host:port items. (But one is enough, it will be used as a "seed")
- database: <undocumented>
- collection: <undocumented>
- max_logs_age: <undocumented>

The configuration looks quite similar to the sqlite one. **In a single-node installation and with decent amount of log traffic, the sqlite backend should be considered best practice, as it needs no extra software and is stable and fast (when run in-memory).**

Livestatus module - Logstore Null

In case you don't need any logging (for instance, if you dedicate a livestatus module instance to nagvis), you can use this module.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: logstore_null

16.16.3 Network Based Modules - Graphite graphing

Graphite is a graphing and data analysis tool. It is composed of a web frontend (graphite-web), fixed size databases (whisper) and data redistribution/munging daemon. (carbon) The first step is *having Graphite installed somewhere*, if you do not have Graphite installed, please do this and come back later.

Pre-requisite : Shinken 1.2.2+ is recommended for the best experience with Graphite.

graphite_perfdata: exports check result performance data to Graphite

Export all performance data included in check results to Whisper databases managed by Graphite. Data is buffered, then exported once every broker time tick. (Once per second). Should a communication loss occur, it will buffer data for 5 minutes before dropping data. The tick_limit max is configurable, the only limitation is the amount of memory the buffered data can eat.

The graphite broker module (v1.2) sends data to graphite in the following format :

HOSTNAME.SERVICENAME.METRICNAME

It can be optionally enhanced to send it the following format :

_GRAPHITE_PRE.HOSTNAME.SOURCE.SERVICENAME.METRICNAME._GRAPHITE_POST

Each of the three variables are optional :

- The _GRAPHITE_PRE variable can be set per host/service to provide a more flexible naming convention. (ex. Prod.site1.Hostname.servicename)

- The _GRAPHITE_POST variable can be set per host/service to specify the more information concerning the variable being stored that graphite can use to determine the retention rule to use for the variable.
- The SOURCE variable can be set in shinken-specific.cfg for the WebUI module and the Graphite broker.

Metric names are converted from Shinken's format to a more restrictive Graphite naming. Unsupported characters are converted to "_" underscore. So do not be surprised to see that some names differ in the WebUI or directly in Graphite. Permitted characters in Graphite are "**A-Za-z_**.", the hyphen character is permitted from Shinken, though only future versions of Graphite will support it.

Performance data transfer method can be set to pickle, which is a binary format that can send data more efficiently than raw ascii.

It takes the following parameters:

- module_name: name of the module called by the brokers
- module_type: graphite_perfdata
- host: ip address of the graphite server running a carbon instance
- port: port where carbon listens for metrics (default: 2003 for raw socket, 2004 for pickle encoded data)
- use_pickle: Use a more efficient transport for sending check results to graphite instead of raw data on the socket (v1.2)
- tick_limit: Number of ticks to buffer performance data during a communication outage with Graphite. On tick limit exceeded, flush to /dev/null and start buffering again. (v1.2)
- graphite_data_source: Set the source name for all data coming from shinken sent to Graphite. This helps diferentiate between data from other sources for the same hostnames. (ex. Diamond, statsd, ganglia, shinken) (v1.2)

Here is an example:

```
define module {
```

```
module_name Graphite-Perfdata
host xx.xx.xx.xx
module_type graphite_perfdata
port 2004 ; default port 2003 for raw data on the socket, 2004 for pickled data
use_pickle 1 ; default value is 0, 1 for pickled data
tick_limit 300 ; Default value 300
graphite_data_source shinken ; default is that the variable is unset
}
```

16.16.4 SQL Based Modules - PNP4Nagios Graphing

PNP4Nagios is a graphing tool that has a web interface for RRDTool based databases. Shinken can export performance data to an npcd database which will feed the RRD files (fixed sized round robin databases). You can *learn how to install PNP4Nagios* if you haven't done it already.

npcdmod: export perfdatas to a PNP interface

Export all perfdata for PNP.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: npcdmod

- path: path to the npcd config file

Here is an example:

```
define module{
 module_name  NPCD
 module_type  npcdmod
 config_file  /usr/local/pnp4nagios/etc/npcd.cfg
}
```

16.16.5 SQL Based Modules - Frontend Centreon2

Centreon2 use a NDO database, so you will need the ndodb_mysql module for it.

ndodb_mysql: Export to a NDO Mysql database

Export status into a NDO/Mysql database. It needs the python module MySQLdb (apt-get install python-mysqldb or easy_install MySQL-python).

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: ndodb_mysql
- database: database name (ex ndo)
- user: database user
- password: database user passworddt
- host: database host
- character_set: utf8 is a good one

Here is an example:

```
define module{
```

```
     module_name      ToNdodb_Mysql
     module_type      ndodb_mysql
     database         ndo       ; database name
     user             root      ; user of the database
     password         root      ; must be changed
     host             localhost ; host to connect to
     character_set    utf8      ;optionnal, UTF8 is the default
}
```

16.16.6 File based Legacy modules - perfdata export

service_perfdata: export service perfdatas to a flat file

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: service_perfdata
- path: path to the service perfdata file you want

Here is an example:

```
define module{
```

```
     module_name      Service-Perfdata
     module_type      service_perfdata
     path             /usr/local/shinken/src/var/service-perfdata
}
```

host_perfdata: export host perfdatas to a flat file

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: host_perfdata
- path: path to the host perfdata file you want

Here is an example:

```
define module{
```

```
     module_name      Host-Perfdata
     module_type      host_perfdata
     path             /usr/local/shinken/src/var/host-perfdata
}
```

16.16.7 Legacy File based Modules - Old CGI or VShell

The Old CGI and VShell use the flat file export. If you can, avoid it! It has awful performance, all modern UIs no longer use this.

status_dat: export status into a flat file

Export all status into a flat file in the old Nagios format. It's for small/medium environment because it's very slow to parse. It can be used by the Nagios CGI. It also export the objects.cache file for this interface.

It takes the parameters:

- module_name: name of the module called by the brokers
- module_type: status_dat
- status_file: path of the status.dat file /usr/local/shinken/var/status.dat
- object_cache_file: path of the objects.cache file
- status_update_interval: interval in seconds to generate the status.dat file

Here is an example:

```
define module{
```

```
     module_name              Status-Dat
     module_type              status_dat
     status_file              /usr/local/shinken/var/status.data
     object_cache_file        /usr/local/shinken/var/objects.cache
```

```
    status_update_interval   15 ; update status.dat every 15s
}
```

16.16.8 Deprecated or unsupported modules

SQL Based MerlinDB

This interface is no longer supported and is going to be completely removed from Shinken.

SQL based ndodb_oracle - Icinga web frontend using NDO Oracle

This interface is no longer supported and is going to be completely removed from Shinken.

CouchDB: Export to a Couchdb database

This interface is no longer supported and is going to be completely removed from Shinken.

16.17 TSCA (Thrift Service Check Acceptor)

TSCA is a receiver/arbiter module to receive hosts and services check results. It provides the same functions as NSCA with additional features. High performance binary transmission, multi line output and auto generated clients for a variety of languages.

16.17.1 What is thrift ?

Let's cut and paste the wikipedia definition from'en.wikipedia.org/wiki/Apache_Thrift'_ :

"Thrift is an interface definition language that is used to define and create services for numerous languages.[1] It is used as a remote procedure call (RPC) framework [..]. It combines a software stack with a code generation engine to build services that work efficiently to a varying degree and seamlessly between ActionScript, C#, C++ (on POSIX-compliant systems), Cappuccino, Cocoa, Erlang, Haskell, Java, OCaml, Perl, PHP, Python, Ruby, and Smalltalk."

16.17.2 Installation

In any case, you have to install thrift with support for python (on the server side) and languages you want to use for clients.

Get it from thrift.apache.org or in your favorite distribution repository.

Server side

Go to the tsca module directory and generate the python stub for the server side installation

```
cd shinken/modules/tsca
$ thrift --gen py tsca.thrift
```

Declare the module is shinken-specific.org

```
define module{
      module_name     TSCA
      module_type     tsca_server
      host            0.0.0.0
      port            9090
}
```

Samples clients

There are three(3) client samples written in python, ruby and java in contrib/clients/TSCA of the Shinken distribution. You can use and extend them to send data directly in your code directly to Shinken's TSCA receiver/arbiter module.

The samples clients read a CSV file from stdin and send them the the TSCA running on localhost:9090. The CSV has the following format :

```
hostname,service description,output,rc
```

Any use of TCP in an application should take care not to block the program and to have very short timeouts. For applications that need non blocking functions, prefer a UDP based transport or a local buffer file with a separate application(send_nsca, thrift, etc) to forward your data to Shinken.

Ruby

Generate the stub

```
$ thrift --gen rb ../../../shinken/modules/tsca/tsca.thrift
```

Run the client

```
$ cat file_state | ruby RubyClient.rb
```

Python

Generate the stub

```
$ thrift --gen py ../../../shinken/modules/tsca/tsca.thrift
```

Run the client

```
$ cat file_state | python PythonClient.py
```

java

Generate the stub

```
$ thrift --gen java ../../../shinken/modules/tsca/tsca.thrift
```

Compile the client

```
$ ant
```

Run the client

```
$ cat file_state | java JavaClientThrift
```

16.18 VMWare Arbiter module

16.18.1 How it works

The arbiter has a module that allows the host->VM automatic host dependency creation. In fact, the module is far more generic than just this. It's a generic "host link dependencies" module.

It reads a mapping file (simple json format) with son->father links. It call an external script at a regular interval : the one I wrote is a VMWare mapping one. It used the check_esx3.pl (that all ESX admin should have) plugin and generate the mapping file. When this file is changed, the module reloads it, creates new links and deletes old ones. So when you VMotion a virtual machine, in the next pass, there will be creation of a new link and deletion of the old one in the scheduler that manages it :)

16.18.2 How to define it

The definition is very easy :

```
define module{
     module_name       VMWare_auto_linking
     module_type       hot_dependencies
     mapping_file      /tmp/vmware_mapping_file.json
     mapping_command   /usr/local/shinken/libexec/link_vmware_host_vm.py -x '/usr/local/shinken/libex
     mapping_command_interval 60   ; optionnal
     mapping_command_timeout   300 ; optionnal
}
```

Then you add it in you arbiter object :

```
define arbiter {
    [...]
    modules   VMWare_auto_linking
}
```

So here, it will call the script /usr/local/shinken/libexec/link_vmware_host_vm.py with a listing of the vCenter vcenter.mydomain.com and generate the mapping file /tmp/vmware_mapping_file.json.

You can call : /usr/local/shinken/libexec/link_vmware_host_vm.py –help

for the full help on this script.

It looks at the file modification time each second. This command can also be launch by an external cron of course.

Note: So if you want to write a script that does this for XEN servers, all you need is to generate a json file with all the mapping. I didn't wrote the doc about this, but you can look in the test file for it, the format is very very easy :)

Here is an example of the JSON mapping file syntax:

%%:ref:*["host", "physical_host"], ["host", "virtual_machine"* <["host", "physical_host"], ["host", "virtual_machine">, "host", "physical_host"], ["host", "other_virtual_machine" <"host", "physical_host"], ["host", "other_virtual_machine">]%%

So just a list of couple 'host' string (from now only host are managed) and the host name.

Beware about it : you need the real host_name, including case.

16.19 Web Service Module

The Ws_arbiter module is a Receiver or Arbiter module to receive passive check results from remote hosts via HTTP(s). This module is considered a work in progress but can be used for testing and improvement.

16.19.1 Configuring the Web Service Module

If data is POSTed to this page, it will validate the data to determine if it is a service or host check result and submit the data to the Shinken external command queue.

The web service listens by default to TCP port 7760. The web service supports anonymous or authenticated access. Web service parameters are set in the Shinken-specific.cfg file, in the Ws_arbiter module. To enable the web service, simply add the module to your Arbiter or Receiver daemon configuration in Shinken-specific.cfg

16.19.2 Using the Web Service Module

The web service listens for POSTs to: /push_check_result

Use curl or embed the HTTP calls in your software to submit check results.

curl -u user:password -d "time_stamp=$(date +%s)&host_name=host-checked&service_description=service-checked&return_code=0&output=Everything OK" http://shinken-srv:7760/push_check_result

Example with more readability:

```
curl
```

-u user:password -d "time_stamp=$(date +%s)

```
&host_name=host-checked
&service_description=service-checked
&return_code=0
&output=Everything OK
http://shinken-srv:7760/push_check_result
```

16.20 SNMP module

This part must be splitted and sent in all module repositories

16.20.1 Shinken integrated SNMP Module

SnmpBooster Download Install and Configure

- *What is the SnmpBooster module*
- Install and configure the SNMP acquisition module. [You are here]
- *Reference - SnmpBooster troubleshooting*
- *Reference - SnmpBooster design specification*
- *Reference - SnmpBooster configuration dictionnary*

Downloads

The SnmpBooster module and genDevConfig are currently in public beta prior to integration within Shinken. You can consult t

- github.com/xkilian/genDevConfig
- github.com/titilambert/shinken/tree/snmp_booster/shinken/modules (snmp_booster branch) * Simply right-click and download snmp_poller.py then copy it to shinken/modules/

Requirements

The SnmpBooster module requires:

- Python 2.6+
- Shinken 1.2+
- PySNMP 4.2.1+ (Python module and its dependencies)
- ConfigObj (Python module)
- python-memcached
- memcachedb or memcached package for your operating system (ex. For Ubuntu: apt-get install memcachedb) *Note*

The genDevConfig profile generator depends on:

- Perl 5.004+
- 4 perl modules available from CPAN and network repositories. genDevConfig/INSTALL has the installation details.

STRONGLY RECOMMENDED: Use the same version of Python and Pyro on all hosts running Shinken processes.

Installation

SnmpBooster:

- Install the dependencies
- Copy the file snmp_poller.py from the git repository to your shinken/modules directory.
- Configuration steps are listed in the present web page.

genDevConfig:

- Download and extract the archive to your server.
- See genDevConfig/INSTALL on how to install and configure it.

Configuration

How to define the SnmpBooster module in the Shinken daemons

You need to modify shinken-specific.cfg, which is located in $shinken/etc/shinken-specific.cfg

Arbiter daemon configuration Simply declare the module:

```
modules SnmpBooster</code>
```

Scheduler daemon configuration

Simply declare the module:

<code>modules SnmpBooster

Poller daemon configuration Simply declare the module:

```
modules SnmpBooster</code>
```

SnmpBooster Module declaration

Included in Shinken v1.2.1 shinken-specific.cfg.

<code>define module {

```
module_name          SnmpBooster
module_type          snmp_poller
datasource           /usr/local/shinken/etc/packs/network/SnmpBooster/   ; SET THE DIRECTORY FOR YOUR
memcached_host       x.x.x.x  ; SET THE IP ADDRESS OF YOUR memcached SERVER
memcached_port       11211  ; default port for a memcached process
```

}

If you do not know the IP adress on which your memcache is listening, check under /etc/memcached.conf. Or do a:

```
netstat -a | grep memcached</code>
If you are running a test on the local machine you can leave memcached on 127.0.0.1 (localhost), but
```

How to define a Host and Service

Step 1

Create a template for your SNMP enabled devices.

Sample template:

<code>cd shinken/etc/packs/network/ mkdir SnmpBooster

vi shinken/etc/packs/network/SnmpBooster/templates.cfg

```
define command {
```

```
command_name    check_snmp_booster
command_line    check_snmp_booster -H $HOSTNAME$ -C $SNMPCOMMUNITYREAD$ -V 2c -t $ARG1$ -i $_SERVICE
module_type     snmp_poller
```

}

```
define service {
```

```
name                    default-snmp-template
check_command           check_snmp_booster!$_SERVICEDSTEMPLATE$!$_SERVICEINST$!$_SERVICETRIGGERGROUP
_inst                   None
_triggergroup           None
max_check_attempts      3
check_interval          1
retry_interval          1
register                0
```

}

```
define host{
```

```
name                    SnmpBooster-host
alias                   SnmpBooster-host template
check_command           check_host_alive
max_check_attempts      3
check_interval          1
retry_interval          1
use                     generic-host
register                0
```

}

Step 2 Define some hosts and services. You would typically use genDevConfig or another configuration generator to create these for you.

Mandatory service arguments related to SNMP polling:

```
_dstemplate                Cisco-Generic-Router  ; Name of a DSTEMPLATE defined in the SnmpBooster co
```

```
snmpcommunityread    which is set in your resource.cfg file
```

Optional service arguments related to SNMP polling with default values:

```
_inst                   None   ; Could be numeric: 0, None or an instance mapping function like: map
```

```
_triggergroup           None   ; Name of the triggergroup defined in the SnmpBooster config.ini file
```

Sample Shinken host and service configuration:

```
# Generated by genDevConfig 3.0.0
# Args: --showunused -c publicstring 192.168.2.63
# Date: Thu Aug 30 17:47:59 2012

#######################################################################
# Description: Cisco IOS Software, C2960 Software (C2960-LANBASEK9-M), Version 12.2(50)SE4, RELEASE S
#     Contact:
# System Name: SITE1-ASW-Lab04
```

```
#    Location:
#######################################################################

define host {
```

```
 host_name            192.168.2.63
 display_name         192.168.2.63
 _sys_location
 address              192.168.2.63
 hostgroups
 notes
 parents
 use                  default-snmp-host-template
 register             1
}

define service {
```

```
 host_name            192.168.2.63
 service_description  chassis
 display_name         C2960 class chassis
 _dstemplate          Cisco-Generic-Router
 _inst                0
 use                  default-snmp-template
 register             1
}

define service {
```

```
 host_name            192.168.2.63
 service_description  chassis.device-traffic
 display_name         Switch fabric statistics - Packets per Second
 _dstemplate          Device-Traffic
 use                  default-snmp-template
 register             1
}

define service {
```

```
host_name            192.168.2.63
service_description  if.FastEthernet0_1
display_name         FastEthernet0_1 Description: Link to Router-1 100.0 MBits/s ethernetCsmacd
_dstemplate          standard-interface
_inst                map(interface-name,FastEthernet0_1)
use                  default-snmp-template
register             1
```

}

Here is an example configuration of the config.ini file

```
[DATASOURCE]
```

```
  OidmyOidDefinition = .1.3.6.1.45.0
  [myOidDefinition] ; Use the same name as the myOidDeiniftion, but omit the leading "Oid"
      ds_type = DERIVE
      ds_calc = 8,*  ; RPN expression : Oid, 8, *  Which means Oid * 8 = ds_calc
```

```
      ds_oid = $OidmyOidDefinition
[DSTEMPLATE]
```

```
  [myCiscoRouter]
      ds = myOidDefinition
[TRIGGER]
```

```
  [trigger1]
      warning = RPN expression
      critical = RPN expression
  [trigger2]
      warning = RPN expression
      critical = RPN expression
[TRIGGERGROUP]
```

```
[CiscoRouterTriggers]
    triggers = trigger1, trigger2
```

16.20.2 Shinken integrated SNMP Module

Overview

What is it

The SnmpBooster module allows Shinken Pollers to directly manage SNMP data acquisition. This is an all Python cross-platform SNMP module. It is tightly integrated with the Shinken Poller, Scheduler and Arbiter daemons to provide the best possible user experience.

- Jump back to *SnmpBooster documentation index*

Design specification summary

- STATUS - DESIGN SPEC PERFORMANCE
- [Done] Functions as an integrated Shinken Poller module
- [Done] Necessary integration code commited to Shinken official release (Integrated starting at v1.2)
- [Done] Ability to collect thousands of SNMP metrics per second
- [Done] Be compatible with distributed data acquisition
- [Done] Collect data for a host/check_interval tuple via SNMP in a single pass
- [Done] Use all builtin Shinken scheduler logic for retries, forced checks, timeouts, dependencies, parents
- [Done] Store collected data for the duration of the check_interval in a memcached/membase
- [Done] On a restart, after the first collection, be able to pick up where the last check left and calculate derived values
- [Done] Forced check are not allowed within 30 seconds of last SNMP query to the same host/check_interval, all other requests get data from the cache.
- [Done] Only a single request to the host/check_interval via SNMP is allowed at a time, all other requests get data from the cache.

- STATUS - DESIGN SPEC USABILITY
- [Done] Usage documentation
- [xxxx] SkonfUI and Discovery usage documentation
- [xxxx] Provide sample configuration packs in Shinken
- [Done] Provide sample config.ini with examples of all types of data * SNMP OIDS, DATASOURCES, DSTEMPLATES, TRIGGERS and TRIGGERGROUPS
- [Done] Directly compatible for use with genDevConfig Shinken SNMP configuration generator
- [Done] Provide meaningful feedback for users on errors
- [Done] Capture all tracebacks and convert them to actual error or warning messages
- STATUS - DESIGN SPEC FEATURES
- [Done] Return state and performance metrics
- [Done] Performance metrics can be returned in a Weathermap compatible format
- [Done] Configuration file format is ConfigObj INI
- [Done] Load all valid INI configuration files from a directory and merge them
- [Done] Load a single INI configuration file
- [xxxx] Load a list of INI configuration files
- [Done] Configuration file describes all generic acquisition parameters (OID, DATASOURCE, DSTEMPLATE, MAP, TRIGGER, TRIGGERGROUP)
- [Done] Supports Triggers which are calculation rules to determine states
- [Done] Triggers support an RPN (Reverse Polish Notation) calculation engine which includes mathematical and logical operators
- [Done] Each TRIGGER is associated with a severity level, WARNING or CRITICAL
- [Done] Multiple TRIGGERS can be associated with a TRIGGERGROUP
- [Done] Use builtin Python Operators
- [Done] Support DERIVE, TEXT, GAUGE and COUNTER data types
- [xxxx] Support TIMETICKS data type
- [Done] Support applying RPN based calculations to received metric for scaling or conversion purposes
- [Done] Use a Python SNMP library which supports asynchronous acquisition PySNMP
- [Done] Datasources can use rule based runtime instance mapping
- [Done] Set Snmp version as a check runtime option
- [Done] Set Snmp DSTEMPLATE as a check runtime option
- [Done] Set Snmp TRIGGERGROUP as a check runtime option
- [Done] Set Snmp COMMUNITY as a check runtime option
- [Done] Use Snmp version 2c GetBulk
- [xxxx] Support Snmp version 2c GetNext if GetBulk is not supported
- [xxxx] Support Snmp version 1 GetNext

- [xxxx] Set Snmp Timeout as a check runtime option, instead of a hardcoded value at 5 seconds
- STATUS - DESIGN SPEC MAINTAINABILITY
- [xxxx] Functions documented in the source code
- [Done] Critical functions documented in the source code
- [Done] Locking sections identified in the code
- [xxxx] Unit tests with at least 80% coverage
- [xxxx] Unit tests integrated with Shinken test suite
- [Done] Code hosted on github
- [xxxx] configuration validity and integrity checking of all INI files
- [xxxx] Pep8 compliant
- [xxxx] Pylint pass

genDevConfig Plugins - Compatibility status with SnmpBooster

- STATUS - genDevConfig maintained Plugins
- [Done] Avaya ES switches
- [Done] Avaya ERS routing switches
- [Done] Cisco 29x0 switches
- [Done] MIB-II Interfaces
- [Done] Cisco PIX/ASA
- [Done] JUNOS devices
- [Done] Cisco IOS routers
- [Done] NetSNMP unix hosts ** Validation required**
- [Done] Packeteer devices ** Validation required**
- [Done] Sensatronics devices ** Validation required**
- [Done] Foundry devices ** Validation required**

[InProgress] Denotes a specification that is under development

[Done] Denotes a specification that is implemented

16.20.3 SnmpBooster reference dictionary

- Jump back to *SnmpBooster documentation index*

SnmpBooster.ini dictionary

There are five dictionaries:

- [DATASOURCE]
- [DSTEMPLATE]
- [MAP]
- [TRIGGER]
- [TRIGGERGROUP]

DATASOURCE DICTIONARY

OidVariableName refers to an actual OID that can be queries using SNMP against the device on the network.

[VariableName] refers to a Datasource and all the information required to gather and prepare the data using SNMP ds_type refers to how the data should be prepared ds_calc refers to any scaling manipulations to make the data more understandable. This is an RPN expression, where the first variable is omitted, as it is always the $OidVariable ds_oid refers to the actual $OidVariable name. An instance identifier can be appended to the name to signify that an instance is provided by the Shinken service definition. This information is passed when the check is called. ...

DSTEMPLATE DICTIONNARY

[DsTemplateName] refers to the name of the DSTEMPLATE that will be referred to in the Shinken service definitions. ds refers to the list of DATASOURCES to be collected. If an instance is expected for the list of DATASOURCES, it MUST be the same instance for all Oids. If a different instance is required, use a second DSTEMPLATE.

TRIGGER DICTIONNARY

TRIGGERGROUP DICTIONNARY

MAP DICTIONNARY

SnmpBooster.ini example configuration

This example definition will be used to explain each section.

[DATASOURCE]

```
OidmyOidDefinition = .1.3.6.1.45.0
[myOidDefinition] ; Use the same name as the myOidDeiniftion, but omit the leading "Oid"
    ds_type = DERIVE
    ds_calc = 8,*  ; RPN expression : Oid, 8, *  Which means Oid * 8 = Total
    ds_oid = $OidmyOidDefinition
```

[DSTEMPLATE]

```
[myCiscoRouter]
    ds = myOidDefinition
```

[TRIGGER]

```
[trigger1]
    warning = RPN expression
    critical = RPN expression
[trigger2]
    warning = RPN expression
    critical = RPN expression
```

[TRIGGERGROUP]

```
[CiscoRouterTriggers]
    triggers = trigger1, trigger2
```

SnmpBooster.ini configuring SNMP Datasources

The first location is generic data related to SNMP parameters.

- DATASOURCE information * SNMP OID * Type of data and how can it be interpreted (GAUGE, COUNTER, COUNTER64, DERIVE, DERIVE64, TEXT, TIMETICK) * Data format preparation (Scaling the data for example bits to bytes) * Is there an instance to append to the
- Instance MAP function * Mapping the instance dynamically using a function * Data or rules related to the mapping function

SnmpBooster.ini configuring SNMP DSTEMPLATES

- DSTEMPLATEs to associate DATASOURCE to actual device classes * List of DATASOURCES associated with a, for example, Cisco 1900 router. Which in turn can be applied to a Shinken service

SnmpBooster.ini setting triggers/thresholds

- TRIGGER and TRIGGERGROUPS to apply thresholding rules * Define triggers and associate them with a TRIGGERGROUP name that can be applied to a Shinken Service

16.20.4 Shinken integrated SNMP Module

Overview

- Jump back to *SnmpBooster documentation index*

Tip: The module is now in public beta as of 2012-10-26! Have Fun!

Nothing new to add, more to come in 2013. 2013-01-19.

What is it

The SnmpBooster module allows Shinken Pollers to directly manage SNMP data acquisition. This is an all Python cross-platform SNMP module. It is tightly integrated with the Shinken Poller, Scheduler and Arbiter daemons to provide the best possible user experience.

Why use it

The SnmpBooster module is designed to be very efficient and scalable. It has a very flexible configuration method to make it easy to use with Shinken Monitoring Packs and Shinken discovery runners like genDevConfig.

This acquisition module was professionally designed and developed.

It is meant to be used by the very capable discovery engine genDevConfig (**v3.0.5 and newer**) originally developed for the Cricket SNMP monitoring tool and converted for use with Shinken.

It is one of the very few serious SNMP v2c implementation making use of SnmpGetBulk type requests.

How does it work

Shinken Integration

1. The SnmpBooster Arbiter module reads the Shinken SnmpBooster configuration file(s). It reads the check commands and based on the values in the check commands that use the snmp_poller module it will creates a shared configuration cache using memcached/memcachedb. The memcache key is always the combination of the hostname. This permits to tie together Shinken Hosts and Services with the SNMP specific configuration. (MongoDB and Redis are planned to be supported in the future) The Scheduler daemon schedules Host and Service checks as it normally does.

3. The SnmpBooster module will check that a memcache host key exists for the check to be launched. Then the SnmpBooster poller module will query all services related to a host for a given acquisition frequency in one pass. (all checks done every 2 minutes will be executed in bulk, same for those every 5 minutes)

5. Check results are cached for the acquisition check_interval. The next time a check request for data from the same host is received from the Scheduler, the data will be fetched from memcache. Resulting is extremely low check latency.

2. 6. The SNMP checks still benefit from retries, timeouts, forced checks, dependencies and the powerful Scheduler daemon logic.

6. The Scheduler daemon can still force an immediate re-check by flushing the cache. This is required for the dependency model.

Performance

SnmpBooster uses SNMP v2c getbulk for high efficiency, unless forced to use SNMP v2c get-next or SNMPv1 get-next. GetBulk uses a single request PDU to ask for multiple OIDs or even entire tables, instead of sending one request PDU per OID.

For example: *A typical 24 port network switch with two uplinks might use 375 OIDS (8 OIDs per interface, plus general OIDs for chassis health, memory, cpu, fans, etc.). **SnmpBooster will only require around 4 request PDUs instead of 375 request PDUs**.* Each PDU is a request packet which takes time to create, send get processed and return. More timeouts to manage, more connections, more impact on the remote device and more latency means much fewer checks per second.*

The SnmpBooster module supports automatic instance mapping for OIDs. (Ex. Based on the interface name it will figure out that the SNMP index(or instance) is 136. This is automatically handled by genDevConfig and SnmpBooster, no user input required. :-)

The generic SNMP configuration information is stored in the Shinken SnmpBooster INI files. There is a Defaults_unified.ini and a series of other Defaults files, one per discovery plugin for genDevConfig.

Important: genDevConfig plugins have all been converted to use the new dynamic instance mapping methods. You are now free to use most if not all Defaults*.ini files included with genDevConfig. 2012-10-28

Limitations

You should have memcached instances running on each poller responsible for snmp polling. You should have your pollers with SnmpBooster in the same datacenter, as they need to be on the same machine with good connectivity to the active memcached instance. SnmpBooster is not compatible with distributed pollers in multiple datacenters, sorry, the current design of SnmpBooster uses a single centralized memcached instance for storing the timeseries data. For distributed datacenters to be supported, each poller+scheduler+memcached must be realm restrained, which is not the case today.

Design specification

SnmpBooster design specification and current development status.

Data model

The information required to define the data is split in two locations.

The first location is the host and service Shinken configuration (You need to generate or write this)

- Device specific information
  - IP addresses, host_names, device types, instance keys

  - A DSTEMPLATE must be referred to in the Service definition
  - A static SNMP instance could be referred to in the Service definition
  - An SNMP instance MAP function could be referred to in the Service definition
  - A TRIGGERGROUP could be refered to in the Service definition

The second location is SNMP Defaults.* templates. (Here you can create new devices or add new data sources)

- DATASOURCE information
  - SNMP OID
  - Type of data and how can it be interpreted (GAUGE, COUNTER, COUNTER64, DERIVE, DERIVE64, TEXT, TIMETICK)
  - Data format preparation (Scaling the data for example bits to bytes)
  - Is there an instance to append to the
- Instance MAP function * Mapping the instance dynamically using a function * Data or rules related to the mapping function
- DSTEMPLATEs to associate DATASOURCE to actual device classes * List of DATASOURCES associated with a, for example, Cisco 1900 router. Which in turn can be applied to a Shinken service
- TRIGGER and TRIGGERGROUPS to apply thresholding rules * Define triggers and associate them with a TRIGGERGROUP name that can be applied to a Shinken Service

A final location containes rules to build your Shinken configuration.

- genDevConfig plugins create Shinken configurations

Installation and configuration

SnmpBooster installation

Reference Dictionnary

SnmpBooster reference dictionary

Troubleshooting

SnmpBooster troubleshooting

Graph templates

These are .graph files defined in your Shinken configuration directory. Refer to the Shinken graphite templates(Not yet created) or PNP4Nagios how-to documentation. The graph templates are independent from SnmpBooster and provide templates for any collected data from Shinken.

16.20.5 SnmpBooster Troubleshooting

- Jump back to *SnmpBooster documentation index*

Check your config

- Have you defined the poller module name?
- Have you defined the correct path to the directory containing your Defaults*.ini files?
- Have you addded the Snmpbooster module to your arbiter, poller, scheduler?
- Have you added copied the genDevConfig templates.cfg in shinken/packs/network/SnmpBooster/
- Have you installed PySNMP, memcached and other dependencies?

Software version consistency

Shinken and SnmpBooster now require **the same Python and Pyro version on all hosts running a Shinken daemon**.

If you cannot use the packaged version of Python and its modules (Pyro, memcached, etc.). Use virtualenv to declare a python version to use and install all required modules in that virtualenv.

Software version requirements

Have you verified that the *requirements* are met. Python, PySNMP, Shinken, Pyro, memcached, etc.

Validate your check command arguments

Use the check_plugin command and comment out the module to learn what were the exact arguments sent by the poller. This will permit you to validate all the arguments, like snmp community string, inheritance, template application, etc.

Validate connectivity

Take a packet trace using a tool like Wireshark to validate that the remote host is responding.

- Has the host responded
- **Is SnmpBooster repeating the request more often than the polling interval.**
  - If you are seeing repeated requests your device may have a compatibility issues.
  - Save an snmpwalk of the device, get a packet trace using Wireshark, set the poller to debug and save the poller.log file (shinken/var/poller.log). Send all three to the SnmpBooster developers.
  - Note: It is normal to see one or more bulkGet requests if you are getting large amounts of data. Ex. a 24 port switch will take 2-3 request packets.

Performance

Make sure you have a low latency connection to your memcache from the Poller. Your memcache server can be replicated to all your poller hosts that should also run memcache instances. Check that memcached is running: netstat -a | grep memcached

Faulty Template

A bad snmp_template file was distributed in the genDevConfig sample-config directory, there were two glaring errors.

This was fixed on 2012-10-16. Make sure you update your template, or use the data from the wiki.

Note that the template should be called: SnmpBooster-template.cfg to make it easier to troubleshoot in the logs. So when you search for SnmpBooster in your logs it will show up as well.

Log files

All warnings and errors generated by the SnmpBooster module start with "[SnmpBooster] error text" and are logged using the standard Shinken logger.

The Arbiter daemon can output initial configuration, loading of host keys and intervals in memcached type error messages. The Scheduler daemon can output scheduling and alert related messages. The Poller daemon can output messages related to instance mapping, acquisition timeouts, invalid community strings, cache failures and more. These are available in the Web interface, as they are placed in the check results for the service.

You can simply do a "grep SnmpBooster *" in your shinken/var directory to see the latest messages related to the SnmpBooster module. You can also sort messages by timestamp to make it easy to find where and when errors occurred.

cd shinken/var grep SnmpBooster *

memcache persistence

If you restart your memcache server or memcache crashes, your poller will no longer be able to validate that a host exists in memcache prior to writing.

You should use memcachedb to achieve persistence in case of memcache failures.

Common errors returned by SnmpBooster in the log file

Errors should be fairly explicit and mean what they say, though there can be exceptions. Lets try to clear some of them.

__Arbiter log **errors**__

Missing ds_oid : This means that a variable in your OID definitions is missing, or your DATASOURCE is not named correctly or your ds_oid variable is missing. There is a typo in your ds_oid variable (ex. ds-oid, or ds_oid = $OidNameIncorrectFFFRA.%(instance)s).

Datasource not defined : Your DSTEMPLATE uses a DATASOURCE that doesn't exist check the [DataSourceName] you are referring to. Does it contain the expected OID variable, $OidName.

Missing ds_type : The DATASOURCE always needs to have a ds_type definition, GAUGE, COUNTER, DERIVE, TEXT, TIMETICK, DERIVE64, COUNTER64.

__Poller log **errors**__

Problems with calculations, repeated polling, hosts not responding, etc.

__Memcached **errors**__

memcachedb and memcached do not use the same default port. Configure the correct memcachedb port to match what is declared in your SnmpBooster module under shinken-specific.cfg.

On Ubuntu 12.04 the default installation is on port 21201 instead of 11211. This causes the error "[SnmpBooster] Memcache server (127.0.0.1:11211) is not reachable" when Shinken starts.

To change it, you must edit the file /etc/memcachedb.conf

16.20.6 Memcached Notes

On Ubuntu 12.04 the default instalation is on port 21201 instead of 11211. This causes the error "[SnmpBooster] Memcache server (127.0.0.1:11211) is not reachable" when shinken starts.

To change it, you must edit the file /etc/memcachedb.conf

16.21 WebUI module

This part must be splitted and sent in all module repositories

16.21.1 WebUI integration with Shinken

The WebUI is an external broker module. So it's an external process launched by the broker that "eats" broks (broker messages) from the brokers. So it can get *all* broks if you place this broker in your top level realm.

The WebUI does not use a database to get data. Instead, it use a "regenerator" object that will eat each broks, and will "recreate" all Hosts/Services/Contacts objects as if the code was in the scheduler daemon. So basically, WebUI and pages always reflect the CURRENT state of hosts/services objects.

The WebUI http layer is managed by bottle.py. It's a small but powerful framework.

How does the WebUI function globally ?

There a 2 Threads running:

- the main thread is the bottle.py (http) listener. It will use the best backend it finds. We recommend using python-paste. If it does not find one, it will use the default swsgi. Paste is multi-thread, swsgi is mon-thread, so please use paste if you want to avoid locking problems.
- the 2nd thread is the regenerator one. It only gets broks and gives them to the regenerator object.

There is a lock system between the threads. You can have N Http requests in progress without problem, but during this time the renererator one will wait. During execution of the regenerator, no requests are processed. This is not considered a problem, as the regenerator is very quick, and there is only a 1s lock for a 7k service conf loading, so it's not a huge problem.

What is a WebUI User?

A WebUI user is a contact. A true contact object. You must match a contact name for your user.

To create a new page?

All pages are in the shinken/webui/plugins directory. Each "part" has it's own directory. A part (like the eltdetail, element detail) can have more than one "page" (like /host or /service for eltdetail).

From here we will supose you want to create a "/contact" page.

You can copy the dummy example in the plugins directory into a contact directory.

You need to change the contact/dummy.py file into a contact/contact.py file, because the webui will search for a dir/dir.py file to "load".

Templates

Templates are HTML with some Python code in it in the plugins/*/views direcotry for specific templates, and the "global layout" (menu and all common part) in the webui/views directory.

Your template must call the template layout (layout.tpl in the webui/views directory) wit ha "rebase" call.

If you put the rebase call at the beginning of your template, all there is below will be place "inside" the layout that will call the common javascripts and css, make the menu adn then call your html/python code.

The rebase call can take arguments. You MUST give it:

- user: the user you give it in the return dict of your .py code

Then all is optional:

- title: title of the page
- top_right_banner_state: int, global state with clouds to put in your top right page. Look at the problem.tpl code for an example.
- js and css list: list of YOUR specific javascript or css to call AFTER the common ones.
- refresh: boolean, set the refresh to 60s or do not refresh at all
- menu_part: will put the little "^" under this part of the menu.

Example of a call, taken from the problems view:

```
rebase layout title='All problems', top_right_banner_state=top_right_banner_state, js=['problems/js/a
roblems/js/autocompleter.Request.js', 'problems/js/autocompleterObserver.js'], css=['problems/css/acc
ms/css/autocompleter.css', 'problems/css/perfometer.css'], refresh=True, menu_part='/'+page, user=use
```

Call Python objects in your templates

Your templates are mainly HTML code. But of course you can call python code in it. The dict you returns in the plugin.py call will be available in this page.

For example, the my_host variable will be available in the page with the host object you find (or None if your give it a bad name of course). Then you can "call" python with for example here to show the host_name: `<span>My host name is *my_host.host_name* </span>` is a way in the templates to "call a variable or function" that will return a string, here the host_name.

If the function or property you call must return HTML code that SHOULD be output as it, without "protection", you must put a ! before your call.

Let use an example where the output value of an host is in fact an html output. If you use the code `my_host.output`, bottle.py will "protect" the html generated by escaping the string, and change <> characters with escaped value. You can change this by calling `my_host.output`. Of course, it's a security problem if the output is with a javascript code...

You can also "loop" or put "if" in your template. You just need to put your code with a % before. Like

```
%for i in xrange(1, 10):
  My valus is  {{i}}
%end
```

You must put the %end here, the indentation will NOT be enougth, sorry.

For an if it's also easy:

```
%if host.active_checks_enabled:
  The host got active checks enabled
%else:
  The host DO NOT have active check enabled
%end
```

Which javascript lib are you using?

It's mootools 1.3 with all options :)

What to do?

- Finish the /mobile part

- List of current alerts
- Host info
- Host status
- Host interfaces
- Hostgroup status
- dashboard hierachique with states, and BP
- Nagvis
- add bp in nagvis auto-map
- event sources
- correlation
- pre-filtering/enrichment
- user profile
- host/srv conf

16.21.2 WebUI search syntax

work in progress

not that we couldn't tell. ;) eh eh

beware the working men and flying tools!

16.21.3 WebUI SSL Certification

Lets start: the goal to to have the server.pem and client.pem file in etc/certs.

Go to the etc/certs directory.

```
openssl req -new -nodes -out server.req -keyout server.key -config ./shinken_openssl_cnf
openssl ca -out server.pem -config ./shinken_openssl_cnf -infiles server.req
cp server.pem server.pem.bkp
cp server.key server.pem
cat server.pem.bkp >> server.pem
cp server.pem client.pem
```

You can try to get the validity with for the arbiter with:

```
openssl s_client -connect localhost:7770</code>
```

CHAPTER 17

Reference

17.1 shinken

17.1.1 shinken Package

shinken Package

acknowledge Module

class shinken.acknowledge.**Acknowledge**(*ref*, *sticky*, *notify*, *persistent*, *author*, *comment*, *end_time=0*)

Allows you to acknowledge the current problem for the specified service. By acknowledging the current problem, future notifications (for the same servicestate) are disabled.

id = 1

properties = {'comment': None, 'author': None, 'sticky': None, 'end_time': None, 'id': None, 'notify': None}

action Module

class shinken.action.**Action**

Bases: shinken.action.__Action

execute__(*force_shell=False*)

kill__()

shinken.action.**no_block_read**(*output*)

arbiterlink Module

autoslots Module

The AutoSlots Class is a MetaClass: it manages how other classes are created (Classes, not instances of theses classes). Here it's role is to create the __slots__ list of the class with all properties of Class.properties and Class.running_properties so we do not have to add manually all properties to the __slots__ list when we add a new entry

class shinken.autoslots.**AutoSlots**

Bases: type

basemodule Module

This python module contains the class BaseModule that shinken modules will subclass

class shinken.basemodule.**BaseModule**(*mod_conf*)

Bases: object

This is the base class for the shinken modules. Modules can be used by the different shinken daemons/services for different tasks. Example of task that a shinken module can do:

- load additional configuration objects.
- recurrently save hosts/services status/perfdata informations in different format.
- ...

clear_queues(*manager*)

Release the resources associated to the queues of this instance

create_queues(*manager=None*)

The manager is None on android, but a true Manager() elsewhere Create the shared queues that will be used by shinken daemon process and this module process. But clear queues if they were already set before recreating new one.

do_loop_turn()

For external modules only: implement in this method the body of you main loop

do_stop()

Called just before the module will exit Put in this method all you need to cleanly release all open resources used by your module

get_name()

has(*prop*)

The classic has: do we have a prop or not?

init()

Handle this module "post" init ; just before it'll be started. Like just open necessaries file(s), database(s), or whatever the module will need.

main()

module "main" method. Only used by external modules.

manage_brok(*brok*)

Request the module to manage the given brok. There a lot of different possible broks to manage.

manage_signal(*sig, frame*)

set_exit_handler(*sigs=None*)

set_loaded_into(*daemon_name*)

set_proctitle(*name*)

set_signal_handler(*sigs=None*)

start()

stop_process()

Request the module process to stop and release it

want_brok(*b*)

work()

module "main" method. Only used by external modules.

class shinken.basemodule.**ModulePhases**
TODO: Add some comment about this class for the doc

CONFIGURATION = 1

LATE_CONFIGURATION = 2

RETENTION = 8

RUNNING = 4

bin Module

borg Module

class shinken.borg.**Borg**
Bases: object

Here is the new-style Borg (not much more complex then the "old-style")

brok Module

class shinken.brok.**Brok**(*type*, *data*)
A Brok is a piece of information exported by Shinken to the Broker. Broker can do whatever he wants with it.

id = 0

my_type = 'brok'

prepare()

brokerlink Module

check Module

class shinken.check.**Check**(*status*, *command*, *ref*, *t_to_go*, *dep_check=None*, *id=None*, *timeout=10*, *poller_tag='None'*, *reactionner_tag='None'*, *env={}*, *module_type='fork'*, *from_trigger=False*, *dependency_check=False*)
Bases: *shinken.action.Action*

ODO: Add some comment about this class for the doc

check_time

check_type

copy_shell()
return a copy of the check but just what is important for execution So we remove the ref and all

dep_check

depend_on

env

execution_time

exit_status

from_trigger

get_id()

get_return_from(*c*)

internal

is_a

is_dependent()

is_launchable(*t*)

long_output

module_type

my_type = 'check'

output

perf_data

poller_tag

properties = {'check_type': <shinken.property.IntegerProp object at 0x7fa5c5c8a710>, 'exit_status': <shinken.proper

status

t_to_go

type

u_time

worker

commandcall Module

class shinken.commandcall.**CommandCall**(*commands*, *call*, *poller_tag='None'*, *reactionner_tag='None'*)

Bases: *shinken.commandcall.DummyCommandCall*

This class is use when a service, contact or host define a command with args.

args

call

command

get_command_and_args()

We want to get the command and the args with ! splitting. but don't forget to protect against the ! to do not split them

get_name()

id = 0

is_valid()

late_linkify_with_command(*commands*)

late_relink_done

module_type

my_type = 'CommandCall'

poller_tag

properties = {'poller_tag': <shinken.property.StringProp object at 0x7fa5c5ba0b10>, 'reactionner_tag': <shinken.pro

reactionner_tag

timeout

valid

class shinken.commandcall.**DummyCommandCall**

Bases: object

Ok, slots are fun: you cannot set the __autoslots__ on the same class you use, fun isn't it? So we define* a dummy useless class to get such :)

comment Module

class shinken.comment.**Comment**(*ref*, *persistent*, *author*, *comment*, *comment_type*, *entry_type*, *source*, *expires*, *expire_time*)

id = 1

properties = {'comment': None, 'source': None, 'entry_time': None, 'comment_type': None, 'author': None, 'expire_

get_start_and_end_time(*ref=None*)

shinken.daterange.**find_day_by_offset**(*year*, *month*, *offset*)

shinken.daterange.**find_day_by_weekday_offset**(*year*, *month*, *weekday*, *offset*)

db Module

class shinken.db.**DB**(*table_prefix=''*)

Bases: object

DB is a generic class for SQL Database

create_insert_query(*table*, *data*)

Create a INSERT query in table with all data of data (a dict)

create_update_query(*table*, *data*, *where_data*)

Create a update query of table with data, and use where data for the WHERE clause

fetchone()

Just get an entry

stringify(*val*)
Get a unicode from a value

db_mysql Module

class shinken.db_mysql.**DBMysql**(*host*, *user*, *password*, *database*, *character_set*, *table_prefix=''*, *port=3306*)
Bases: shinken.db.DB

DBMysql is a MySQL access database class

connect_database()
Create the database connection TODO: finish (begin :)) error catch and conf parameters... Import to catch exception

execute_query(*query*, *do_debug=False*)
Just run the query TODO: finish catch

db_oracle Module

class shinken.db_oracle.**DBOracle**(*user*, *password*, *database*, *table_prefix=''*)
Bases: shinken.db.DB

Manage connection and query execution against Oracle databases.

connect_database()
Create the database connection TODO: finish (begin :)) error catch and conf parameters...

execute_query(*query*)
Execute a query against an Oracle database.

db_sqlite Module

class shinken.db_sqlite.**DBSqlite**(*db_path*, *table_prefix=''*)
Bases: shinken.db.DB

DBSqlite is a sqlite access database class

connect_database()
Create the database connection

execute_query(*query*)
Just run the query

dependencynode Module

class shinken.dependencynode.**DependencyNode**
Bases: object

get_reverse_state(*state*)

get_state()

is_valid()

list_all_elements()

switch_zeros_of_values()

class shinken.dependencynode.**DependencyNodeFactory**

Bases: object

eval_cor_pattern(*pattern*, *hosts*, *services*)

find_object(*pattern*, *hosts*, *services*)

dispatcher Module

This is the class of the dispatcher. Its role is to dispatch configurations to other elements like schedulers, reactionner, pollers, receivers and brokers. It is responsible for high availability part. If an element dies and the element type has a spare, it sends the config of the dead one to the spare

class shinken.dispatcher.**Dispatcher**(*conf*, *arbiter*)

check_alive()

check_bad_dispatch()

check_dispatch()

dispatch()

get_scheduler_ordered_list(*r*)

downtime Module

class shinken.downtime.**Downtime**(*ref*, *start_time*, *end_time*, *fixed*, *trigger_id*, *duration*, *author*, *comment*)

add_automatic_comment()

cancel()

del_automatic_comment()

enter()

exit()

fill_data_brok_from(*data*, *brok_type*)

get_initial_status_brok()

id = 1

in_scheduled_downtime()

properties = {'comment': <shinken.property.StringProp object at 0x7fa5c44a7550>, 'entry_time': <shinken.property.

trigger_me(*other_downtime*)

easter Module

shinken.easter.**dark**()

graph Module

class shinken.graph.**Graph**

Graph is a class to make graph things like DFS checks or accessibility Why use an atomic bomb when a little hammer is enough?

add_edge(*from_node*, *to_node*)

add_node(*node*)

add_nodes(*nodes*)

dfs_get_all_childs(*root*)

dfs_loop_search(*root*)

get_accessibility_packs()

loop_check()

http_client Module

http_daemon Module

load Module

class shinken.load.**Load**(*m=1*, *initial_value=0*)

This class is for having a easy Load calculation without having to send value at regular interval (but it's more efficient if you do this :)) and without having a list or other stuff. It's just an object, an update and a get You can define m: the average for m minutes. The val is the initial value. It's better if it's 0 but you can choose.

get_load()

update_load(*new_val*, *forced_interval=None*)

log Module

class shinken.log.**Log**

Shinken logger class, wrapping access to Python logging standard library.

CRITICAL = 50

DEBUG = 10

ERROR = 40

INFO = 20

NOTSET = 0

WARNING = 30

critical(*msg*, **args*, ***kwargs*)

debug(*msg*, **args*, ***kwargs*)

error(*msg*, **args*, ***kwargs*)

get_level()

static get_level_id(*lvlName*)
Convert a level name (string) to its integer value and vice-versa. Input a level and it will return a name. Raise KeyError when name or level not found

info(*msg*, **args*, ***kwargs*)

load_obj(*object*, *name_=None*)
We load the object where we will put log broks with the 'add' method

log(*message*, *format=None*, *print_it=True*)
Old log method, kept for NAGIOS compatibility What strings should not use the new format ??

quit()
Close the local log file at program exit

register_local_log(*path*, *level=None*)
The shinken logging wrapper can write to a local file if needed and return the file descriptor so we can avoid to close it.

set_human_format(*on=True*)
Set the output as human format.

If the optional parameter *on* is False, the timestamps format will be reset to the default format.

set_level(*level*)

warning(*msg*, **args*, ***kwargs*)

shinken.log.**cprint**(*s*, *color*)

shinken.log.**is_tty**()

macroresolver Module

class shinken.macroresolver.**MacroResolver**
Bases: *shinken.borg.Borg*

Please Add a Docstring to describe the class here

get_env_macros(*data*)

init(*conf*)

macros = {'TOTALSERVICESCRITICALUNHANDLED': '_get_total_services_critical_unhandled', 'PROCESSSTART

my_type = 'macroresolver'

resolve_command(*com*, *data*)

resolve_simple_macros_in_string(*c_line*, *data*, *args=None*)

memoized Module

class shinken.memoized.**memoized**(*func*)
Bases: object

Decorator that caches a function's return value each time it is called. If called later with the same arguments, the cached value is returned, and not re-evaluated.

message Module

class shinken.message.**Message**(*id*, *type*, *data=None*, *source=None*)

This is a simple message class for communications between actionners and workers

get_data()

get_from()

get_type()

my_type = 'message'

pythonize(*val*)

reactionnerlink Module

receiverlink Module

satellite Module

satellitelink Module

scheduler Module

schedulerlink Module

singleton Module

class shinken.singleton.**Singleton**(*name*, *bases*, *dict*)

Bases: type

The classic Singleton class. So all instance of this class will be the same instance in fact.

sorteddict Module

class shinken.sorteddict.**SortedDict**(**args*, ***kwargs*)

Bases: dict

Dictionary with sorted keys.

The interface is similar to the ordinary dict's one, but: * methods: __repr__(), __str__(), __iter__(), iterkeys(), itervalues(),

iteritems(), keys(), values(), items() and popitem() – return results taking into consideration sorted keys order;

•new methods: largest_key(), largest_item(), smallest_key(), smallest_item() added.

clear() → None. Remove all items from D.

copy() → a shallow copy of D (still as a SortedDict).

classmethod fromkeys(*S*[, *v*]) → New dict with keys from S and values equal to v.

v defaults to None.

items() → a list of (key, value) pairs sorted by keys

(add reverse=True for reverse ordering).

iteritems() → an iterator over (key, value) pairs sorted by keys

(add reverse=True for reverse ordering).

iterkeys(*reverse=False*)

D.__iter__() <==> iter(D) <==> D.iterkeys() -> an iterator over sorted keys (add reverse=True for reverse ordering).

itervalues() → an iterator over values sorted by keys

(add reverse=True for reverse ordering).

keys() → a sorted list of keys

(add reverse=True for reverse ordering).

largest_item() → a (key, value) pair with the largest key;

raise KeyError if D is empty.

largest_key() → the largest key; raise KeyError if D is empty.

pop(*k*[, *d*]) → v, remove specified key and return the corresponding value.
If key is not found, d is returned if given, otherwise KeyError is raised

popitem() → (k, v). Remove and return a (key, value) pair with
the largest key; raise KeyError if D is empty.

setdefault(*k*[, *d*]) → D.get(k,d), also set D[k]=d if k not in D

smallest_item() → a (key, value) pair with the smallest key;
raise KeyError if D is empty.

smallest_key() → the smallest key; raise KeyError if D is empty.

update([*E*], **F) → None. Update D from dict/iterable E and F.
If E present and has a .keys() method, does: for k in E: D[k] = E[k] If E present and lacks .keys() method, does: for (k, v) in E: D[k] = v In either case, this is followed by: for k in F: D[k] = F[k]

values() → a list of values sorted by keys
(add reverse=True for reverse ordering).

shinken.sorteddict.**dictdoc**(*method*)
A decorator making reuse of the ordinary dict's docstrings more concise.

trigger_functions Module

util Module

filter Module Helper functions for some filtering, like for user based

shinken.misc.filter.**only_related_to**(*lst*, *user*)

md5crypt Module md5crypt.py - Provides interoperable MD5-based crypt() function

SYNOPSIS

import md5crypt.py

cryptedpassword = md5crypt.md5crypt(password, salt);

DESCRIPTION

unix_md5_crypt() provides a crypt()-compatible interface to the rather new MD5-based crypt() function found in modern operating systems. It's based on the implementation found on FreeBSD 2.2.[56]-RELEASE and contains the following license in it:

> "THE BEER-WARE LICENSE" (Revision 42): <phk@login.dknet.dk> wrote this file. As long as you retain this notice you can do whatever you want with this stuff. If we meet some day, and you think this stuff is worth it, you can buy me a beer in return. Poul-Henning Kamp

apache_md5_crypt() provides a function compatible with Apache's .htpasswd files. This was contributed by Bryan Hart <bryan@eai.com>.

shinken.misc.md5crypt.**apache_md5_crypt**(*pw*, *salt*)

shinken.misc.md5crypt.**md5crypt**(*pw*, *salt*, *magic=None*)

shinken.misc.md5crypt.**to64**(*v*, *n*)

shinken.misc.md5crypt.**unix_md5_crypt**(*pw*, *salt*, *magic=None*)

perfdata Module

class shinken.misc.perfdata.**Metric**(*s*)

class shinken.misc.perfdata.**PerfDatas**(*s*)

shinken.misc.perfdata.**guess_int_or_float**(*val*)

regenerator Module

sorter Module Helper functions for some sorting

shinken.misc.sorter.**hst_srv_sort**(*s1*, *s2*)

shinken.misc.sorter.**last_state_change_earlier**(*s1*, *s2*)

shinken.misc.sorter.**worse_first**(*s1*, *s2*)

termcolor Module ANSII Color formatting for output in terminal.

shinken.misc.termcolor.**colored**(*text*, *color=None*, *on_color=None*, *attrs=None*)
Colorize text.
Available text colors: red, green, yellow, blue, magenta, cyan, white.
Available text highlights: on_red, on_green, on_yellow, on_blue, on_magenta, on_cyan, on_white.
Available attributes: bold, dark, underline, blink, reverse, concealed.
Example: colored('Hello, World!', 'red', 'on_grey', ['blue', 'blink']) colored('Hello, World!', 'green')

shinken.misc.termcolor.**cprint**(*text*, *color=None*, *on_color=None*, *attrs=None*, ***kwargs*)
Print colorize text.

It accepts arguments of print function.

webui Package

webui Package

bottlecore Module

bottlewebui Module

17.2 shinken Package

17.2.1 shinken Package

17.2.2 acknowledge Module

class shinken.acknowledge.**Acknowledge**(*ref*, *sticky*, *notify*, *persistent*, *author*, *comment*, *end_time=0*)

Allows you to acknowledge the current problem for the specified service. By acknowledging the current problem, future notifications (for the same servicestate) are disabled.

id = 1

properties = {'comment': None, 'author': None, 'sticky': None, 'end_time': None, 'id': None, 'notify': None}

17.2.3 action Module

class shinken.action.**Action**

Bases: shinken.action.__Action

execute__(*force_shell=False*)

kill__()

shinken.action.**no_block_read**(*output*)

17.2.4 arbiterlink Module

17.2.5 autoslots Module

The AutoSlots Class is a MetaClass: it manages how other classes are created (Classes, not instances of theses classes). Here it's role is to create the __slots__ list of the class with all properties of Class.properties and Class.running_properties so we do not have to add manually all properties to the __slots__ list when we add a new entry

class shinken.autoslots.**AutoSlots**

Bases: type

17.2.6 basemodule Module

This python module contains the class BaseModule that shinken modules will subclass

class shinken.basemodule.**BaseModule**(*mod_conf*)

Bases: object

This is the base class for the shinken modules. Modules can be used by the different shinken daemons/services for different tasks. Example of task that a shinken module can do:

- load additional configuration objects.
- recurrently save hosts/services status/perfdata informations in different format.
- ...

clear_queues(*manager*)

Release the resources associated to the queues of this instance

create_queues(*manager=None*)

The manager is None on android, but a true Manager() elsewhere Create the shared queues that will be used by shinken daemon process and this module process. But clear queues if they were already set before recreating new one.

do_loop_turn()

For external modules only: implement in this method the body of you main loop

do_stop()

Called just before the module will exit Put in this method all you need to cleanly release all open resources used by your module

get_name()

has(*prop*)

The classic has: do we have a prop or not?

init()

Handle this module "post" init ; just before it'll be started. Like just open necessaries file(s), database(s), or whatever the module will need.

main()

module "main" method. Only used by external modules.

manage_brok(*brok*)

Request the module to manage the given brok. There a lot of different possible broks to manage.

manage_signal(*sig*, *frame*)

set_exit_handler(*sigs=None*)

set_loaded_into(*daemon_name*)

set_proctitle(*name*)

set_signal_handler(*sigs=None*)

start()

stop_process()

Request the module process to stop and release it

want_brok(*b*)

work()

module "main" method. Only used by external modules.

class shinken.basemodule.**ModulePhases**

17.2.18 db Module

class shinken.db.**DB**(*table_prefix=''*)

Bases: object

DB is a generic class for SQL Database

create_insert_query(*table*, *data*)

Create a INSERT query in table with all data of data (a dict)

create_update_query(*table*, *data*, *where_data*)

Create a update query of table with data, and use where data for the WHERE clause

fetchone()

Just get an entry

stringify(*val*)

Get a unicode from a value

17.2.19 db_mysql Module

class shinken.db_mysql.**DBMysql**(*host*, *user*, *password*, *database*, *character_set*, *table_prefix=''*, *port=3306*)

Bases: *shinken.db.DB*

DBMysql is a MySQL access database class

connect_database()

Create the database connection TODO: finish (begin :)) error catch and conf parameters... Import to catch exception

execute_query(*query*, *do_debug=False*)

Just run the query TODO: finish catch

17.2.20 db_oracle Module

class shinken.db_oracle.**DBOracle**(*user*, *password*, *database*, *table_prefix=''*)

Bases: *shinken.db.DB*

Manage connection and query execution against Oracle databases.

connect_database()

Create the database connection TODO: finish (begin :)) error catch and conf parameters...

execute_query(*query*)

Execute a query against an Oracle database.

17.2.21 db_sqlite Module

class shinken.db_sqlite.**DBSqlite**(*db_path*, *table_prefix=''*)

Bases: *shinken.db.DB*

DBSqlite is a sqlite access database class

connect_database()

Create the database connection

execute_query(*query*)

Just run the query

17.2.22 dependencynode Module

class shinken.dependencynode.**DependencyNode**

Bases: object

get_reverse_state(*state*)

get_state()

is_valid()

list_all_elements()

switch_zeros_of_values()

class shinken.dependencynode.**DependencyNodeFactory**

Bases: object

eval_cor_pattern(*pattern*, *hosts*, *services*)

find_object(*pattern*, *hosts*, *services*)

17.2.23 dispatcher Module

This is the class of the dispatcher. Its role is to dispatch configurations to other elements like schedulers, reactionner, pollers, receivers and brokers. It is responsible for high availability part. If an element dies and the element type has a spare, it sends the config of the dead one to the spare

class shinken.dispatcher.**Dispatcher**(*conf*, *arbiter*)

17.2.28 graph Module

class shinken.graph.**Graph**

Graph is a class to make graph things like DFS checks or accessibility Why use an atomic bomb when a little hammer is enough?

add_edge(*from_node*, *to_node*)

add_node(*node*)

add_nodes(*nodes*)

dfs_get_all_childs(*root*)

dfs_loop_search(*root*)

get_accessibility_packs()

loop_check()

17.2.29 `http_client` Module

17.2.30 `http_daemon` Module

17.2.31 `load` Module

class `shinken.load.`**Load**(*m=1*, *initial_value=0*)

This class is for having a easy Load calculation without having to send value at regular interval (but it's more efficient if you do this :)) and without having a list or other stuff. It's just an object, an update and a get You can define m: the average for m minutes. The val is the initial value. It's better if it's 0 but you can choose.

get_load()

update_load(*new_val*, *forced_interval=None*)

17.2.32 `log` Module

class `shinken.log.`**Log**

Shinken logger class, wrapping access to Python logging standard library.

CRITICAL = 50

DEBUG = 10

ERROR = 40

INFO = 20

NOTSET = 0

WARNING = 30

critical(*msg*, **args*, ***kwargs*)

debug(*msg*, **args*, ***kwargs*)

error(*msg*, **args*, ***kwargs*)

get_level()

static get_level_id(*lvlName*)

Convert a level name (string) to its integer value and vice-versa. Input a level and it will return a name. Raise KeyError when name or level not found

info(*msg*, **args*, ***kwargs*)

load_obj(*object*, *name_=None*)

We load the object where we will put log broks with the 'add' method

log (*message*, *format=None*, *print_it=True*)
Old log method, kept for NAGIOS compatibility What strings should not use the new format ??

quit ()
Close the local log file at program exit

register_local_log (*path*, *level=None*)
The shinken logging wrapper can write to a local file if needed and return the file descriptor so we can avoid to close it.

set_human_format (*on=True*)
Set the output as human format.

If the optional parameter *on* is False, the timestamps format will be reset to the default format.

set_level (*level*)

warning (*msg*, **args*, ***kwargs*)

shinken.log.**cprint** (*s*, *color*)

shinken.log.**is_tty** ()

17.2.33 macroresolver Module

class shinken.macroresolver.**MacroResolver**
Bases: *shinken.borg.Borg*

Please Add a Docstring to describe the class here

get_env_macros (*data*)

init (*conf*)

macros = {'TOTALSERVICESCRITICALUNHANDLED': '_get_total_services_critical_unhandled', 'PROCESSSTART

my_type = 'macroresolver'

resolve_command (*com*, *data*)

resolve_simple_macros_in_string (*c_line*, *data*, *args=None*)

17.2.34 memoized Module

class shinken.memoized.**memoized** (*func*)
Bases: object

Decorator that caches a function's return value each time it is called. If called later with the same arguments, the cached value is returned, and not re-evaluated.

17.2.35 message Module

class shinken.message.**Message** (*id*, *type*, *data=None*, *source=None*)
This is a simple message class for communications between actionners and workers

get_data ()

get_from ()

get_type ()

my_type = 'message'

str()

17.2.36 modulesctx Module

17.2.37 modulesmanager Module

class shinken.modulesmanager.**ModulesManager**(*modules_type*, *modules_path*, *modules*)

Bases: object

This class is use to manage modules and call callback

check_alive_instances()

clear_instances(*insts=None*)

get_external_from_queues()

get_external_instances(*phase=None*)

get_external_to_queues()

get_instances()

get_internal_instances(*phase=None*)

load()

load_and_init()

load_manager(*manager*)

remove_instance(*inst*)

set_max_queue_size(*max_queue_size*)

set_modules(*modules*)

set_to_restart(*inst*)

start_external_instances(*late_start=False*)

stop_all()

try_instance_init(*inst*, *late_start=False*)

try_to_restart_deads()

17.2.38 notification Module

class shinken.notification.**Notification**(*type='PROBLEM'*, *status='scheduled'*, *command='UNSET'*, *command_call=None*, *ref=None*, *contact=None*, *t_to_go=0*, *contact_name=''*, *host_name=''*, *service_description=''*, *reason_type=1*, *state=0*, *ack_author=''*, *ack_data=''*, *escalated=False*, *contacts_notified=0*, *start_time=0*, *end_time=0*, *notification_type=0*, *id=None*, *notif_nb=1*, *timeout=10*, *env={}*, *module_type='fork'*, *reactionner_tag='None'*)

Bases: shinken.action.Action

17.2.39 pollerlink Module

17.2.40 property Module

class shinken.property.**UnusedProp**(*text=None*)

Bases: shinken.property.Property

A unused Property. These are typically used by Nagios but no longer useful/used by Shinken.

This is just to warn the user that the option he uses is no more used in Shinken.

class shinken.property.**BoolProp**(*default=<object object>, class_inherit=None, unmanaged=False, help='', no_slots=False, fill_brok=None, conf_send_preparation=None, brok_transformation=None, retention=False, retention_preparation=None, to_send=False, override=False, managed=True*)

Bases: shinken.property.Property

A Boolean Property.

Boolean values are currently case insensitively defined as 0, false, no, off for False, and 1, true, yes, on for True).

pythonize(*val*)

class shinken.property.**IntegerProp**(*default=<object object>, class_inherit=None, unmanaged=False, help='', no_slots=False, fill_brok=None, conf_send_preparation=None, brok_transformation=None, retention=False, retention_preparation=None, to_send=False, override=False, managed=True*)

Bases: shinken.property.Property

Please Add a Docstring to describe the class here

pythonize(*val*)

class shinken.property.**FloatProp**(*default=<object object>, class_inherit=None, unmanaged=False, help='', no_slots=False, fill_brok=None, conf_send_preparation=None, brok_transformation=None, retention=False, retention_preparation=None, to_send=False, override=False, managed=True*)

Bases: shinken.property.Property

Please Add a Docstring to describe the class here

pythonize(*val*)

class shinken.property.**CharProp**(*default=<object object>, class_inherit=None, unmanaged=False, help='', no_slots=False, fill_brok=None, conf_send_preparation=None, brok_transformation=None, retention=False, retention_preparation=None, to_send=False, override=False, managed=True*)

pythonize(*val*)

17.2.41 reactionnerlink Module

17.2.42 receiverlink Module

17.2.43 satellite Module

17.2.44 satellitelink Module

17.2.45 scheduler Module

17.2.46 schedulerlink Module

17.2.47 singleton Module

class shinken.singleton.**Singleton**(*name, bases, dict*)

Bases: type

The classic Singleton class. So all instance of this class will be the same instance in fact.

17.2.48 sorteddict Module

class shinken.sorteddict.**SortedDict**(**args, **kwargs*)

Bases: dict

Dictionary with sorted keys.

The interface is similar to the ordinary dict's one, but: * methods: __repr__(), __str__(), __iter__(), iterkeys(), itervalues(),
iteritems(), keys(), values(), items() and popitem() – return results taking into consideration sorted keys order;

•new methods: largest_key(), largest_item(), smallest_key(), smallest_item() added.

clear() → None. Remove all items from D.

copy() → a shallow copy of D (still as a SortedDict).

classmethod fromkeys(*S*[, *v*]) → New dict with keys from S and values equal to v.
v defaults to None.

items() → a list of (key, value) pairs sorted by keys
(add reverse=True for reverse ordering).

iteritems() → an iterator over (key, value) pairs sorted by keys
(add reverse=True for reverse ordering).

iterkeys(*reverse=False*)
D.__iter__() <==> iter(D) <==> D.iterkeys() -> an iterator over sorted keys (add reverse=True for reverse ordering).

itervalues() → an iterator over values sorted by keys
(add reverse=True for reverse ordering).

keys() → a sorted list of keys
(add reverse=True for reverse ordering).

largest_item() → a (key, value) pair with the largest key;
raise KeyError if D is empty.

largest_key() → the largest key; raise KeyError if D is empty.

pop(*k*[, *d*]) → v, remove specified key and return the corresponding value.
If key is not found, d is returned if given, otherwise KeyError is raised

popitem() → (k, v). Remove and return a (key, value) pair with
the largest key; raise KeyError if D is empty.

setdefault(*k*[, *d*]) → D.get(k,d), also set D[k]=d if k not in D

smallest_item() → a (key, value) pair with the smallest key;
raise KeyError if D is empty.

smallest_key() → the smallest key; raise KeyError if D is empty.

update([*E*], **F) → None. Update D from dict/iterable E and F.
If E present and has a .keys() method, does: for k in E: D[k] = E[k] If E present and lacks .keys() method, does: for (k, v) in E: D[k] = v In either case, this is followed by: for k in F: D[k] = F[k]

values() → a list of values sorted by keys
(add reverse=True for reverse ordering).

shinken.sorteddict.**dictdoc**(*method*)
A decorator making reuse of the ordinary dict's docstrings more concise.

17.2.49 `trigger_functions` Module

17.2.50 `util` Module

shinken.util.**alive_then_spare_then_deads**(*x*, *y*)

filter Module

Helper functions for some filtering, like for user based

shinken.misc.filter.**only_related_to**(*lst*, *user*)

md5crypt Module

md5crypt.py - Provides interoperable MD5-based crypt() function

SYNOPSIS

import md5crypt.py

cryptedpassword = md5crypt.md5crypt(password, salt);

DESCRIPTION

unix_md5_crypt() provides a crypt()-compatible interface to the rather new MD5-based crypt() function found in modern operating systems. It's based on the implementation found on FreeBSD 2.2.[56]-RELEASE and contains the following license in it:

> "THE BEER-WARE LICENSE" (Revision 42): <phk@login.dknet.dk> wrote this file. As long as you retain this notice you can do whatever you want with this stuff. If we meet some day, and you think this stuff is worth it, you can buy me a beer in return. Poul-Henning Kamp

apache_md5_crypt() provides a function compatible with Apache's .htpasswd files. This was contributed by Bryan Hart <bryan@eai.com>.

`shinken.misc.md5crypt.`**`apache_md5_crypt`**(*pw*, *salt*)

`shinken.misc.md5crypt.`**`md5crypt`**(*pw*, *salt*, *magic=None*)

`shinken.misc.md5crypt.`**`to64`**(*v*, *n*)

`shinken.misc.md5crypt.`**`unix_md5_crypt`**(*pw*, *salt*, *magic=None*)

`perfdata` Module

class `shinken.misc.perfdata.`**`Metric`**(*s*)

class `shinken.misc.perfdata.`**`PerfDatas`**(*s*)

`shinken.misc.perfdata.`**`guess_int_or_float`**(*val*)

`regenerator` Module

`sorter` Module

Helper functions for some sorting

`shinken.misc.sorter.`**`hst_srv_sort`**(*s1*, *s2*)

`shinken.misc.sorter.`**`last_state_change_earlier`**(*s1*, *s2*)

`shinken.misc.sorter.`**`worse_first`**(*s1*, *s2*)

`termcolor` Module

ANSII Color formatting for output in terminal.

`shinken.misc.termcolor.`**`colored`**(*text*, *color=None*, *on_color=None*, *attrs=None*)

Colorize text.
Available text colors: red, green, yellow, blue, magenta, cyan, white.
Available text highlights: on_red, on_green, on_yellow, on_blue, on_magenta, on_cyan, on_white.
Available attributes: bold, dark, underline, blink, reverse, concealed.
Example: colored('Hello, World!', 'red', 'on_grey', ['blue', 'blink']) colored('Hello, World!', 'green')

`shinken.misc.termcolor.`**`cprint`**(*text*, *color=None*, *on_color=None*, *attrs=None*, ***kwargs*)

Print colorize text.

It accepts arguments of print function.

objects Package

`objects` Package

17.6.3 `filter` Module

Helper functions for some filtering, like for user based

`shinken.misc.filter.`**only_related_to**(*lst*, *user*)

17.6.4 `md5crypt` Module

md5crypt.py - Provides interoperable MD5-based crypt() function

SYNOPSIS

import md5crypt.py

cryptedpassword = md5crypt.md5crypt(password, salt);

DESCRIPTION

unix_md5_crypt() provides a crypt()-compatible interface to the rather new MD5-based crypt() function found in modern operating systems. It's based on the implementation found on FreeBSD 2.2.[56]-RELEASE and contains the following license in it:

> "THE BEER-WARE LICENSE" (Revision 42): <phk@login.dknet.dk> wrote this file. As long as you retain this notice you can do whatever you want with this stuff. If we meet some day, and you think this stuff is worth it, you can buy me a beer in return. Poul-Henning Kamp

apache_md5_crypt() provides a function compatible with Apache's .htpasswd files. This was contributed by Bryan Hart <bryan@eai.com>.

`shinken.misc.md5crypt.`**`apache_md5_crypt`**(*pw*, *salt*)

`shinken.misc.md5crypt.`**`md5crypt`**(*pw*, *salt*, *magic=None*)

`shinken.misc.md5crypt.`**`to64`**(*v*, *n*)

`shinken.misc.md5crypt.`**`unix_md5_crypt`**(*pw*, *salt*, *magic=None*)

17.6.5 `perfdata` Module

class `shinken.misc.perfdata.`**`Metric`**(*s*)

class `shinken.misc.perfdata.`**`PerfDatas`**(*s*)

`shinken.misc.perfdata.`**`guess_int_or_float`**(*val*)

17.6.6 `regenerator` Module

17.6.7 `sorter` Module

Helper functions for some sorting

`shinken.misc.sorter.`**`hst_srv_sort`**(*s1*, *s2*)

`shinken.misc.sorter.`**`last_state_change_earlier`**(*s1*, *s2*)

`shinken.misc.sorter.`**`worse_first`**(*s1*, *s2*)

17.6.8 `termcolor` Module

ANSII Color formatting for output in terminal.

`shinken.misc.termcolor.`**`colored`**(*text*, *color=None*, *on_color=None*, *attrs=None*)

Colorize text.

Available text colors: red, green, yellow, blue, magenta, cyan, white.

Available text highlights: on_red, on_green, on_yellow, on_blue, on_magenta, on_cyan, on_white.

Available attributes: bold, dark, underline, blink, reverse, concealed.

Example: colored('Hello, World!', 'red', 'on_grey', ['blue', 'blink']) colored('Hello, World!', 'green')

`shinken.misc.termcolor.`**`cprint`**(*text*, *color=None*, *on_color=None*, *attrs=None*, ***kwargs*)

Print colorize text.

It accepts arguments of print function.
