# CHAPTER 1

---

## What's this?

---

Welcome to the **documentation repetition** module **doctrep**! This module targets developers that develop complex and nested Python APIs and helps them to create a well-documented piece of software.

The motivation is simple, it comes from the don't repeat yourself principle and tries to reuse already existing documentation code.

Suppose you have a well-documented function

```
In [1]: def do_something(a, b):
....:
....:     """
....:     Add two numbers
....:
....:     Parameters
....:     -----
....:     a: int
....:         The first number
....:     b: int
....:         The second number
....:
....:     Returns
....:     -----
....:     int
....:         `a` + `b`"""
....:     return a + b
....:
```

and you have another function that builds upon this function

```
In [2]: def do_more(a, b):
....:
....:     """
....:     Add two numbers and multiply it by 2
....:
....:     Parameters
....:     -----
....:     a: int
```

(continues on next page)

(continued from previous page)

```
....:     The first number
....:     b: int
....:         The second number
....:
....:     Returns
....:     -----
....:     int
....:         (`a` + `b`) * 2"""
....:     return do_something(a, b) * 2
....:
```

Here for `do_more` we use the function `do_something` and actually we do not even care about `a` anymore. So we could even say

```
In [3]: def do_more(*args, **kwargs):
....:     """...long docstring...
....:     return do_something(*args, **kwargs) * 2
....:
```

because we only care about the result from `do_something`. However, if we want to change something in the parameters documentation of `do_something`, we would have to change it in `do_more`. This can become a severe error source in large and complex APIs!

So instead of copy-and-pasting the entire documentation of `do_something`, we want to automatically repeat the given docstrings and that's what this module is intended for. Hence, The code above could be rewritten via

```
In [4]: import docrep

In [5]: docstrings = docrep.DocstringProcessor()

In [6]: @docstrings.get_sections('do_something')
....: @docstrings.dedent
....: def do_something(a, b):
....:     """
....:     Add two numbers
....:
....:     Parameters
....:     -----
....:     a: int
....:         The first number
....:     b: int
....:         The second number
....:
....:     Returns
....:     -----
....:     int
....:         `a` + `b`"""
....:     return a + b
....:

In [7]: @docstrings.dedent
....: def do_more(*args, **kwargs):
....:     """
....:     Add two numbers and multiply it by 2
....:
....:     Parameters
....:     -----
```

(continues on next page)

(continued from previous page)

```

....:     %(do_something.parameters)s
....:
....:     Returns
....:     -----
....:     int
....:         (`a` + `b`) * 2"""
....:     return do_something(*args, **kwargs) * 2
....:

In [8]: help(do_more)
Help on function do_more in module __main__:

do_more(*args, **kwargs)
    Add two numbers and multiply it by 2

    Parameters
    -----
    a: int
        The first number
    b: int
        The second number

    Returns
    -----
    int
        (`a` + `b`) * 2

```

You can do the same for any other section in the objects documentation and you can even remove or keep only specific parameters or return types (see `keep_params()` and `delete_params()`). The module intensively uses pythons `re` module so it is very efficient. The only restriction is, that your Python code has to be documented following the numpy conventions (i.e. it should follow the conventions from the sphinx napoleon extension).

If your docstring does not start with an empty line as in the example above, you have to use the `DocstringProcessor.with_indent()` method. See for example

```

In [9]: @docstrings.get_sectionsf('do_something')
....: def second_example_source(a, b):
....:     """Summary is on the first line
....:
....:     Parameters
....:     -----
....:     a: int
....:         The first number
....:     b: int
....:         The second number
....:
....:     Returns
....:     -----
....:     int
....:         `a` + `b`"""
....:     return a + b
....:

In [10]: @docstrings.with_indent(4) # we indent the replacements with 4 spaces
....: def second_example_target(*args, **kwargs):
....:     """Target docstring with summary on the first line
....:
....:
```

(continues on next page)

(continued from previous page)

```
....:     Parameters
....:     -----
....:     %(do_something.parameters)s
....:
....:     Returns
....:     -----
....:     int
....:     (`a` + `b`) * 2"""
....:     return second_example_source(*args, **kargs) * 2
....:
```

**In [11]:** help(second\_example\_target)  
Help on function second\_example\_target in module \_\_main\_\_:

```
second_example_target(*args, **kwargs)
    Target docstring with summary on the first line

Parameters
-----
a: int
    The first number
b: int
    The second number

Returns
-----
int
    (`a` + `b`) * 2
```

# CHAPTER 2

---

## Installation

---

Installation simply goes via pip:

```
$ pip install docrep
```

or via conda:

```
$ conda install -c conda-forge docrep
```

or from the source on [github](#) via:

```
$ python setup.py install
```

---

**Note:** When using docrep in python 2.7, there is to mention that the `__doc__` attribute of classes is not writable, so something like

```
In [12]: @docstrings
....: class SomeClass(object):
....:     """An awesome class
....:
....:     Parameters
....:     -----
....:     %(repeated.parameters)s
....:
....:     """
....:
```

---

would raise an error. There are several workarounds (see [the issue on github](#)) but the default for python 2.7 is, to simply not modify class docstrings. You can, however, change this behaviour using the `DocstringProcessor.python2_classes` attribute.

---

# CHAPTER 3

---

## API Reference

---

### Classes

---

<i>DocstringProcessor</i> (*args, **kwargs)	Class that is intended to process docstrings
---	--

---

### Functions

---

<i>safe_modulo</i> (s, meta[, checked, ...])	Safe version of the modulo operation (%) of strings
--	---

---

**class** docrep.**DocstringProcessor**(\*args, \*\*kwargs)  
Bases: *object*

Class that is intended to process docstrings

It is, but only to minor extends, inspired by the `matplotlib.docstring.Substitution` class.

---

### Examples

Create docstring processor via:

```
>>> from docrep import DocstringProcessor  
>>> d = DocstringProcessor(doc_key='My doc string')
```

And then use it as a decorator to process the docstring:

```
>>> @d  
... def doc_test():  
...     '''That's %(doc_key)s'''  
...     pass  
  
>>> print(doc_test.__doc__)  
That's My doc string
```

Use the `get_sections()` method to extract Parameter sections (or others) form the docstring for later

usage (and make sure, that the docstring is dedented):

```
>>> @d.get_sectionsf('docstring_example',
...                     sections=['Parameters', 'Examples'])
...     @d.dedent
...     def doc_test(a=1, b=2):
...         """
...             That's %(doc_key)s
...
...         Parameters
...         -----
...         a: int, optional
...             A dummy parameter description
...         b: int, optional
...             A second dummy parameter
...
...         Examples
...         -----
...         Some dummy example doc"""
...     print(a)

>>> @d.dedent
...     def second_test(a=1, b=2):
...         """
...             My second function where I want to use the docstring from
...             above
...
...         Parameters
...         -----
...         %(docstring_example.parameters)s
...
...         Examples
...         -----
...         %(docstring_example.examples)s"""
...     pass

>>> print(second_test.__doc__)
My second function where I want to use the docstring from
above

Parameters
-----
a: int, optional
    A dummy parameter description
b: int, optional
    A second dummy parameter

Examples
-----
Some dummy example doc
```

Another example uses non-dedented docstrings:

```
>>> @d.get_sectionsf('not_dedented')
...     def doc_test2(a=1):
...         '''That's the summary
...
...     Parameters
```

(continues on next page)

(continued from previous page)

```

...
-----
...     a: int, optional
...         A dummy parameter description'''
...
    print(a)

```

These sections must then be used with the `with_indent()` method to indent the inserted parameters:

```

>>> @d.with_indent(4)
... def second_test2(a=1):
...     """
...     My second function where I want to use the docstring from
...     above
...
...     Parameters
...     -----
...     %(not_dedented.parameters)s"""
... pass

```

## Methods

<code>dedent(func)</code>	Dedent the docstring of a function and substitute with params
<code>dedents(s[, stacklevel])</code>	Dedent a string and substitute with the params attribute
<code>delete_kwargs(base_key[, args, kwargs])</code>	Deletes the <code>*args</code> or <code>**kwargs</code> part from the parameters section
<code>delete_kwargs_s(s[, args, kwargs])</code>	Deletes the <code>*args</code> or <code>**kwargs</code> part from the parameters section
<code>delete_params(base_key, \*params)</code>	Method to delete a parameter from a parameter documentation.
<code>delete_params_s(s, params)</code>	Delete the given parameters from a string
<code>delete_types(base_key, out_key, \*types)</code>	Method to delete a parameter from a parameter documentation.
<code>delete_types_s(s, types)</code>	Delete the given types from a string
<code>get_extended_summary(s[, base])</code>	Get the extended summary from a docstring
<code>get_extended_summaryf(\*args, \*\*kwargs)</code>	Extract the extended summary from a function docstring
<code>get_full_description(s[, base])</code>	Get the full description from a docstring
<code>get_full_descriptionf(\*args, \*\*kwargs)</code>	Extract the full description from a function docstring
<code>get_sections(s, base[, sections])</code>	Method that extracts the specified sections out of the given string if (and only if) the docstring follows the numpy documentation guidelines <sup>1</sup> .
<code>get_sectionsf(\*args, \*\*kwargs)</code>	Decorator method to extract sections from a function docstring
<code>get_summary(s[, base])</code>	Get the summary of the given docstring
<code>get_summaryf(\*args, \*\*kwargs)</code>	Extract the summary from a function docstring
<code>keep_params(base_key, \*params)</code>	Method to keep only specific parameters from a parameter documentation.
<code>keep_params_s(s, params)</code>	Keep the given parameters from a string
<code>keep_types(base_key, out_key, \*types)</code>	Method to keep only specific parameters from a parameter documentation.

Continued on next page

Table 3 – continued from previous page

<code>keep_types_s(s, types)</code>	Keep the given types from a string
<code>save_docstring(key)</code>	Descriptor method to save a docstring from a function
<code>with_indent([indent])</code>	Substitute in the docstring of a function with indented params
<code>with_indent(s[, indent, stacklevel])</code>	Substitute a string with the indented params

## Attributes

<code>param_like_sections</code>	sections that behave the same as the <i>Parameter</i> section by defining a
<code>params</code>	<code>dict</code> . Dictionary containing the parameters that are used in for
<code>patterns</code>	<code>dict</code> . Dictionary containing the compiled patterns to identify
<code>python2_classes</code>	The action on how to react on classes in python 2
<code>text_sections</code>	sections that include (possibly not list-like) text

**Parameters and \*\*kwargs** (`*args`) – Parameters that shall be used for the substitution. Note that you can only provide either `*args` or `**kwargs`, furthermore most of the methods like `get_sections`<sup>1</sup> require `**kwargs` to be provided.

### `dedent(func)`

Dedent the docstring of a function and substitute with `params`

**Parameters func** (`function`) – function with the documentation to dedent and whose sections shall be inserted from the `params` attribute

### `dedents(s, stacklevel=3)`

Dedent a string and substitute with the `params` attribute

#### Parameters

- **s** (`str`) – string to dedent and insert the sections of the `params` attribute
- **stacklevel** (`int`) – The stacklevel for the warning raised in `safe_module()` when encountering an invalid key in the string

### `delete_kwargs(base_key, args=None, kwargs=None)`

Deletes the `*args` or `**kwargs` part from the parameters section

Either `args` or `kwargs` must not be `None`. The resulting key will be stored in

`base_key + 'no_args'` if `args` is not `None` and `kwargs` is `None`

`base_key + 'no_kwargs'` if `args` is `None` and `kwargs` is not `None`

`base_key + 'no_args_kwargs'` if `args` is not `None` and `kwargs` is not `None`

#### Parameters

- **base\_key** (`str`) – The key in the `params` attribute to use
- **args** (`None` or `str`) – The string for the args to delete
- **kwargs** (`None` or `str`) – The string for the kwargs to delete

<sup>1</sup> [https://github.com/numpy/numpy/blob/master/doc/HOWTO\\_DOCUMENT.rst.txt](https://github.com/numpy/numpy/blob/master/doc/HOWTO_DOCUMENT.rst.txt)

## Notes

The type name of *args* in the base has to be like `` \*<args>`` (i.e. the *args* argument preceeded by a '\*' and enclosed by double ' ` '). Similarly, the type name of *kwargs* in *s* has to be like `` \*\*<kwargs>``

**classmethod delete\_kwargs\_s** (*s*, *args=None*, *kwargs=None*)

Deletes the \*args or \*\*kwargs part from the parameters section

Either *args* or *kwargs* must not be None.

### Parameters

- **s** (*str*) – The string to delete the args and kwargs from
- **args** (*None* or *str*) – The string for the args to delete
- **kwargs** (*None* or *str*) – The string for the kwargs to delete

## Notes

The type name of *args* in *s* has to be like `` \*<args>`` (i.e. the *args* argument preceeded by a '\*' and enclosed by double ' ` '). Similarly, the type name of *kwargs* in *s* has to be like `` \*\*<kwargs>``

**delete\_params** (*base\_key*, *\*params*)

Method to delete a parameter from a parameter documentation.

This method deletes the given *param* from the *base\_key* item in the *params* dictionary and creates a new item with the original documentation without the description of the param. This method works for the 'Parameters' sections.

The new docstring without the selected parts will be accessible as *base\_key* + '.no\_' + '|'.join(*params*), e.g. 'original\_key.no\_param1|param2'.

See the [keep\\_params\(\)](#) method for an example.

### Parameters

- **base\_key** (*str*) – key in the *params* dictionary
- **\*params** – str. Parameter identifier of which the documentations shall be deleted

### See also:

[delete\\_types\(\)](#), [keep\\_params\(\)](#)

**static delete\_params\_s** (*s*, *params*)

Delete the given parameters from a string

Same as [delete\\_params\(\)](#) but does not use the *params* dictionary

### Parameters

- **s** (*str*) – The string of the parameters section
- **params** (*list of str*) – The names of the parameters to delete

**Returns** The modified string *s* without the descriptions of *params*

**Return type** *str*

**delete\_types** (*base\_key*, *out\_key*, *\*types*)

Method to delete a parameter from a parameter documentation.

This method deletes the given *param* from the *base\_key* item in the *params* dictionary and creates a new item with the original documentation without the description of the param. This method works for 'Results' like sections.

See the [keep\\_types\(\)](#) method for an example.

#### Parameters

- **base\_key** (*str*) – key in the *params* dictionary
- **out\_key** (*str*) – Extension for the base key (the final key will be like '%s.%s' % (base\_key, out\_key))
- **\*types** – str. The type identifier of which the documentations shall deleted

#### See also:

[delete\\_params\(\)](#)

**static delete\_types\_s** (*s, types*)

Delete the given types from a string

Same as [delete\\_types\(\)](#) but does not use the *params* dictionary

#### Parameters

- **s** (*str*) – The string of the returns like section
- **types** (*list of str*) – The type identifiers to delete

**Returns** The modified string *s* without the descriptions of *types*

**Return type** *str*

**get\_extended\_summary** (*s, base=None*)

Get the extended summary from a docstring

This here is the extended summary

#### Parameters

- **s** (*str*) – The docstring to use
- **base** (*str or None*) – A key under which the summary shall be stored in the *params* attribute. If not None, the summary will be stored in *base* + '.summary\_ext'. Otherwise, it will not be stored at all

**Returns** The extracted extended summary

**Return type** *str*

**get\_extended\_summaryf** (\*args, \*\*kwargs)

Extract the extended summary from a function docstring

This function can be used as a decorator to extract the extended summary of a function docstring (similar to [get\\_sectionsf\(\)](#)).

**Parameters and \*\*kwargs** (\*args) – See the [get\\_extended\\_summary\(\)](#) method.

Note, that the first argument will be the docstring of the specified function

**Returns** Wrapper that takes a function as input and registers its summary via the [get\\_extended\\_summary\(\)](#) method

**Return type** function

**get\_full\_description**(*s*, *base=None*)

Get the full description from a docstring

This here and the line above is the full description (i.e. the combination of the `get_summary()` and the `get_extended_summary()`) output

**Parameters**

- **s** (`str`) – The docstring to use
- **base** (`str or None`) – A key under which the description shall be stored in the `params` attribute. If not `None`, the summary will be stored in `base + '.full_desc'`. Otherwise, it will not be stored at all

**Returns** The extracted full description**Return type** `str`**get\_full\_descriptionf**(\**args*, \*\**kwargs*)

Extract the full description from a function docstring

This function can be used as a decorator to extract the full descriptions of a function docstring (similar to `get_sectionsf()`).

**Parameters and \*\*kwargs**(\**args*) – See the `get_full_description()` method.

Note, that the first argument will be the docstring of the specified function

**Returns** Wrapper that takes a function as input and registers its summary via the `get_full_description()` method**Return type** function**get\_sections**(*s*, *base*, *sections*=['Parameters', 'Other Parameters'])

Method that extracts the specified sections out of the given string if (and only if) the docstring follows the numpy documentation guidelines<sup>1</sup>. Note that the section either must appear in the `param_like_sections` or the `text_sections` attribute.

**Parameters**

- **s** (`str`) – Docstring to split
- **base** (`str`) – base to use in the `sections` attribute
- **sections** (`list of str`) – sections to look for. Each section must be followed by a newline character ('\n') and a bar of '-' (following the numpy (napoleon) docstring conventions).

**Returns** The replaced string**Return type** `str`**References****See also:**

`delete_params()`,      `keep_params()`,      `delete_types()`,      `keep_types()`,  
`delete_kwargs()`

`save_docstring()` for saving an entire docstring

**get\_sectionsf**(\**args*, \*\**kwargs*)

Decorator method to extract sections from a function docstring

**Parameters and \*\*kwargs** (\*args) – See the [get\\_sections\(\)](#) method. Note, that the first argument will be the docstring of the specified function

**Returns** Wrapper that takes a function as input and registers its sections via the [get\\_sections\(\)](#) method

**Return type** function

**get\_summary** (s, base=None)

Get the summary of the given docstring

This method extracts the summary from the given docstring *s* which is basically the part until two newlines appear

**Parameters**

- **s** (*str*) – The docstring to use
- **base** (*str* or *None*) – A key under which the summary shall be stored in the *params* attribute. If not None, the summary will be stored in *base* + '.summary'. Otherwise, it will not be stored at all

**Returns** The extracted summary

**Return type** str

**get\_summaryf** (\*args, \*\*kwargs)

Extract the summary from a function docstring

**Parameters and \*\*kwargs** (\*args) – See the [get\\_summary\(\)](#) method. Note, that the first argument will be the docstring of the specified function

**Returns** Wrapper that takes a function as input and registers its summary via the [get\\_summary\(\)](#) method

**Return type** function

**keep\_params** (base\_key, \*params)

Method to keep only specific parameters from a parameter documentation.

This method extracts the given *param* from the *base\_key* item in the *params* dictionary and creates a new item with the original documentation with only the description of the param. This method works for 'Parameters' like sections.

The new docstring with the selected parts will be accessible as *base\_key* + '.' + '|'.join(*params*), e.g. 'original\_key.param1|param2'

**Parameters**

- **base\_key** (*str*) – key in the *params* dictionary
- **\*params** – str. Parameter identifier of which the documentations shall be in the new section

**See also:**

[keep\\_types\(\)](#), [delete\\_params\(\)](#)

---

## Examples

To extract just two parameters from a function and reuse their docstrings, you can type:

```

>>> from docrep import DocstringProcessor
>>> d = DocstringProcessor()
>>> @d.get_sectionsf('do_something')
... def do_something(a=1, b=2, c=3):
...     """
...     That's %(doc_key)s
...
...     Parameters
...     -----
...     a: int, optional
...         A dummy parameter description
...     b: int, optional
...         A second dummy parameter that will be excluded
...     c: float, optional
...         A third parameter"""
...     print(a)

>>> d.keep_params('do_something.parameters', 'a', 'c')

>>> @d.dedent
... def do_less(a=1, c=4):
...     """
...     My second function with only `a` and `c`
...
...     Parameters
...     -----
...     %(do_something.parameters.a/c)s"""
...     pass

>>> print(do_less.__doc__)
My second function with only `a` and `c`

Parameters
-----
a: int, optional
    A dummy parameter description
c: float, optional
    A third parameter

```

Equivalently, you can use the `delete_params()` method to remove parameters:

```

>>> d.delete_params('do_something.parameters', 'b')

>>> @d.dedent
... def do_less(a=1, c=4):
...     """
...     My second function with only `a` and `c`
...
...     Parameters
...     -----
...     %(do_something.parameters.no_b)s"""
...     pass

```

---

### **static keep\_params\_s(s, params)**

Keep the given parameters from a string

Same as `keep_params()` but does not use the `params` dictionary

## Parameters

- **s** (*str*) – The string of the parameters like section
- **params** (*list of str*) – The parameter names to keep

**Returns** The modified string *s* with only the descriptions of *params*

**Return type** *str*

**keep\_types** (*base\_key*, *out\_key*, *\*types*)

Method to keep only specific parameters from a parameter documentation.

This method extracts the given *type* from the *base\_key* item in the *params* dictionary and creates a new item with the original documentation with only the description of the type. This method works for the 'Results' sections.

## Parameters

- **base\_key** (*str*) – key in the *params* dictionary
- **out\_key** (*str*) – Extension for the base key (the final key will be like '%s.%s' % (*base\_key*, *out\_key*)
- **\*types** – str. The type identifier of which the documentations shall be in the new section

**See also:**

*delete\_types()*, *keep\_params()*

---

## Examples

To extract just two return arguments from a function and reuse their docstrings, you can type:

```
>>> from docrep import DocstringProcessor
>>> d = DocstringProcessor()
>>> @d.get_sectionsf('do_something', sections=['Returns'])
... def do_something():
...     '''
...     That's %(doc_key)s
...
...     Returns
...     -----
...     float
...         A random number
...     int
...         A random integer'''
...     return 1.0, 4

>>> d.keep_types('do_something.returns', 'int_only', 'int')

>>> @d.dedent
... def do_less():
...     '''
...     My second function that only returns an integer
...
...     Returns
...     -----
...     %(do_something.returns.int_only)s'''
...     return do_something() [1]

>>> print(do_less.__doc__)
```

(continues on next page)

(continued from previous page)

```
My second function that only returns an integer

Returns
-----
int
A random integer
```

Equivalently, you can use the `delete_types()` method to remove parameters:

```
>>> d.delete_types('do_something.returns', 'no_float', 'float')

>>> @d.dedent
... def do_less():
...     """
...     My second function with only `a` and `c`
...
...     Returns
...
...     %(do_something.returns.no_float)s"""
...     return do_something() [1]
```

### **static keep\_types\_s(s, types)**

Keep the given types from a string

Same as `keep_types()` but does not use the `params` dictionary

#### **Parameters**

- **s (str)** – The string of the returns like section
- **types (list of str)** – The type identifiers to keep

**Returns** The modified string *s* with only the descriptions of *types*

#### **Return type** str

**param\_like\_sections** = ['Parameters', 'Other Parameters', 'Returns', 'Raises']  
sections that behave the same as the *Parameter* section by defining a list

**params** = {}

`dict`. Dictionary containing the parameters that are used in for substitution.

**patterns** = {}

`dict`. Dictionary containing the compiled patterns to identify the Parameters, Other Parameters, Warnings and Notes sections in a docstring

**python2\_classes** = 'ignore'

The action on how to react on classes in python 2

When calling:

```
>>> @docstrings
... class NewClass(object):
...     """%(replacement)s"""
```

This normally raises an `AttributeError`, because the `__doc__` attribute of a class in python 2 is not writable.  
This attribute may be one of 'ignore', 'raise' or 'warn'

**save\_docstring(key)**

Descriptor method to save a docstring from a function

Like the `get_sectionsf()` method this method serves as a descriptor for functions but saves the entire docstring

```
text_sections = ['Warnings', 'Notes', 'Examples', 'See Also', 'References']  
sections that include (possibly not list-like) text
```

```
with_indent(indent=0)
```

Substitute in the docstring of a function with indented `params`

**Parameters** `indent (int)` – The number of spaces that the substitution should be indented

**Returns** Wrapper that takes a function as input and substitutes it's `__doc__` with the indented versions of `params`

**Return type** function

**See also:**

```
with_indent(), dedent()
```

```
with_indent(s, indent=0, stacklevel=3)
```

Substitute a string with the indented `params`

**Parameters**

- `s (str)` – The string in which to substitute
- `indent (int)` – The number of spaces that the substitution should be indented
- `stacklevel (int)` – The stacklevel for the warning raised in `safe_module()` when encountering an invalid key in the string

**Returns** The substituted string

**Return type** str

**See also:**

```
with_indent(), dedents()
```

```
docrep.safe_modulo(s, meta, checked=False, print_warning=True, stacklevel=2)
```

Safe version of the modulo operation (%) of strings

**Parameters**

- `s (str)` – string to apply the modulo operation with
- `meta (dict or tuple)` – meta informations to insert (usually via `s % meta`)
- `checked ({'KEY': 'VALUE'}, optional)` – Security parameter for the recursive structure of this function. It can be set to 'VALUE' if an error shall be raised when facing a TypeError or ValueError or to 'KEY' if an error shall be raised when facing a KeyError. This parameter is mainly for internal processes.
- `print_warning (bool)` – If True and a key is not existent in `s`, a warning is raised
- `stacklevel (int)` – The stacklevel for the `warnings.warn()` function

---

## Examples

The effects are demonstrated by this example:

```
>>> from docrep import safe_modulo  
>>> s = "That's %(one)s string %(with)s missing 'with' and %s key"  
>>> s % {'one': 1} # raises KeyError because of missing 'with'
```

(continues on next page)

(continued from previous page)

```
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
KeyError: 'with'
>>> s % {'one': 1, 'with': 2}          # raises TypeError because of '%s'
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: not enough arguments for format string
>>> safe_modulo(s, {'one': 1})
"That's 1 string %(with)s missing 'with' and %s key"
```

# CHAPTER 4

---

## Changelog

---

### 4.1 v0.2.4

This new minor release has an improved documentation considering the `keep_params` and `keep_types` section and triggers new builds for python 3.7.

### 4.2 v0.2.3

This minor release contains some backward incompatible changes on how to handle the decorators for classes in python 2.7. Thanks [@lesteve](#) and [@guillaumeeb](#) for your input on this.

#### 4.2.1 Changed

- When using the decorators for classes in python 2.7, e.g. via:

```
>>> @docstrings
... class Something(object):
...     "%(replacement)s"
```

it does not have an effect anymore. This is because class docstrings cannot be modified in python 2.7 (see issue [#5](#)). The original behaviour was to raise an error. You can restore the old behaviour by setting `DocstringProcessor.python2_classes = 'raise'`.

- Some docs have been updated (see PR [#7](#))

#### 4.2.2 Added

- the `DocstringProcessor.python2_classes` to change the handling of classes in python 2.7

## 4.3 v0.2.2

### 4.3.1 Added

- We introduce the `DocstringProcessor.get_extended_summary()` and `DocstringProcessor.get_extended_summaryf()` methods to extract the extended summary (see the numpy documentation guidelines).
- We introduce the `DocstringProcessor.get_full_description()` and `DocstringProcessor.get_full_descriptionf()` methods to extract the full description (i.e. the summary plus extended summary) from a function docstring

## 4.4 v0.2.1

### 4.4.1 Changed

- Minor bug fix in the `get_sections` method

## 4.5 v0.2.0

### 4.5.1 Added

- Changelog
- the `get_sectionsf` and `get_sections` methods now also support non-dedented docstrings that start with the summary, such as:

```
>>> d = DocstringProcessor()
>>> @d.get_sectionsf('source')
... def source_func(a=1):
...     '''That's the summary
...
...     Parameters
-----
...     a: int, optional
...         A dummy parameter description'''
... pass
```

- the new `with_indent` and `with_indentf` methods can be used to replace the argument in a non-dedented docstring, such as:

```
>>> @d.with_indent(4)
... def target_func(a=1):
...     """Another function using arguments of source_func
...
...     Parameters
-----
...     %(source.parameters)s"""
... pass

>>> print(target_func.__doc__)
```

(continues on next page)

(continued from previous page)

```
Another function using arguments of source_func
```

```
Parameters
```

```
-----
```

```
a: int, optional
```

```
    A dummy parameter description
```

## 4.5.2 Changed

- the `get_sectionsf` and `get_sections` method now always uses the dedented version of the docstring. Thereby it first removes the summary.
