CHAPTER 1

About

2 Chapter 1. About

CHAPTER 2

Why csvkit?

Because it makes your life easier.

Convert Excel to CSV:

in2csv data.xls > data.csv

Convert JSON to CSV:

in2csv data.json > data.csv

Print column names:

csvcut -n data.csv

Select a subset of columns:

csvcut -c column_a,column_c data.csv > new.csv

Reorder columns:

csvcut -c column_c,column_a data.csv > new.csv

Find rows with matching ells:

csvgrep -c phone_number -r 555-555-\d{4}" data.csv > matching.csv

Convert to JSON:

csvjson data.csv > data.json

Generate summary statistics:

csvstat data.csv

Query with SQL:

csvsql --query "select name from data where age > 30" data.csv > old_folks.csv

Import into PostgreSQL:

csvsql --db postgresql:///database --insert data.csv

Extract data from PostgreSQL::

sql2csv --db postgresql:///database --query "select * from data" > extract.csv

And much more...

CHAPTER 3

Table of contents

Installation

Users

csvkit is works on Python versions 2.6, 2.7, 3.3 and 3.4, as well as PyPy. It is supported on OSX and Linux. It also works—but is tested less frequently—on Windows.

Installing csvkit is simple:

```
pip install csvkit
```

Note: If you are installing on Ubuntu you may need to install the Python development headers prior to install csvkit:

```
sudo apt-get install python-dev python-pip python-setuptools build-essential
```

Note: If the installation appears to be successful but running the tools fails, try updating your version of Python setuptools:

```
pip install --upgrade setuptools
pip install --upgrade csvkit
```

Note: If you are using Python2 and have a recent version of pip, you may need to run pip with the additional arguments --allow-external argparse.

Developers

If you are a developer that also wants to hack on csvkit, install it this way:

```
git clone git://github.com/onyxfish/csvkit.git
cd csvkit
mkvirtualenv csvkit

# If running Python 2
pip install -r requirements-py2.txt

# If running Python 3
pip install -r requirements-py3.txt

python setup.py develop
tox
```

Before writing any code be sure to read the documentation for *Contributing to csvkit*.

Tutorial

The csvkit tutorial walks through processing and analyzing a real dataset:

Getting started

About this tutorial

There is no better way to learn how to use a new tool than to see it applied in a real world situation. This tutorial will explain the workings of most of the csvkit utilities (including some nifty tricks) in the context of analyzing a real dataset.

The data will be using is a subset of the United States Defense Logistic Agency Law Enforcement Support Office's (LESO) 1033 Program dataset, which describes how surplus military arms have been distributed to local police forces. This data was widely cited in the aftermath of the Ferguson, Missouri protests. The particular data we are using comes from an NPR report analyzing the data.

This tutorial assumes you are comfortable in the command line, but does not assume any prior experience doing data processing or analysis.

Installing csvkit

Installing csvkit is easy:

```
$ sudo pip install csvkit
```

If you have problems installing, check out the common issues described in the *Installation* section of the full documentation.

Note: If you're familiar with virtualenv, it's better to install csvkit inside an env, in which case you should leave off the sudo in the previous command.

Getting the data

Let's start by creating a clean workspace:

```
$ mkdir csvkit_tutorial
$ cd csvkit_tutorial
```

Now let's fetch the data:

```
$ curl -L -O https://github.com/onyxfish/csvkit/raw/master/examples/realdata/ne_1033_

→data.xlsx
```

in2csv: the Excel killer

For purposes of this tutorial, I've converted this data to Excel format. (NPR published it in CSV format.) If you have Excel you can open the file and take a look at it, but really, who wants to wait for Excel to load? Instead, let's make it a CSV:

```
$ in2csv ne_1033_data.xlsx
```

You should see a CSV version of the data dumped into your terminal. All csvkit utilities write to the terminal output ("standard out") by default. This isn't very useful, so let's write it to a file instead:

```
$ in2csv ne_1033_data.xlsx > data.csv
```

data.csv will now contain a CSV version of our original file. If you aren't familiar with the > syntax, it literally means "redirect standard out to a file", but it may be more convenient to think of it as "save".

in2csv will convert a variety of common file formats, including xls, xlsx and fixed-width into CSV format.

csvlook: data periscope

Now that we have some data, we probably want to get some idea of what's in it. We couldn't open it in Excel or Google Docs, but wouldn't it be nice if we could just take a look in the command line? Enter csvlook:

```
$ csvlook data.csv
```

Now at first the output of *csvlook* isn't going to appear very promising. You'll see a mess of data, pipe character and dashes. That's because this dataset has many columns and they won't all fit in the terminal at once. To fix this we need to learn how to reduce our dataset before we look at it.

csvcut: data scalpel

csvcut is the original csvkit tool, the one that started the whole thing. With it, we can slice, delete and reorder the columns in our CSV. First, let's just see what columns are in our data:

```
$ csvcut -n data.csv
1: state
2: county
3: fips
4: nsn
5: item_name
6: quantity
7: ui
```

3.2. Tutorial 7

```
8: acquisition_cost
9: total_cost
10: ship_date
11: federal_supply_category
12: federal_supply_category_name
13: federal_supply_class
14: federal_supply_class_name
```

As you'll can see, our dataset has fourteen columns. Let's take a look at just columns 2, 5 and 6:

```
$ csvcut -c 2,5,6 data.csv
```

Now we've reduced our output CSV to only three columns.

We can also refer to columns by their names to make our lives easier:

```
$ csvcut -c county,item_name,quantity data.csv
```

Putting it together with pipes

Now that we understand in2csv, csvlook and csvcut we can demonstrate the power of csvkit's when combined with the standard command line "pipe". Try this command:

```
$ csvcut -c county,item_name,quantity data.csv | csvlook | head
```

All csvkit utilities accept an input file as "standard in", in addition to as a filename. This means that we can make the output of one csvkit utility become the input of the next. In this case, the output of csvcut becomes the input to csvlook. This also means we can use this output with standard unix commands such as head, which prints only the first ten lines of it's input. Here, the output of csvlook becomes the input of head.

Pipeability is a core feature of csvkit. Of course, you can always write your output to a file using >, but many times it makes more sense to use pipes for speed and brevity.

Of course, we can also pipe in2csv, combining all our previous operations into one:

```
$ in2csv ne_1033_data.xlsx | csvcut -c county,item_name,quantity | csvlook | head
```

Summing up

All the csvkit utilities work standard input and output. Any utility can be piped into another and into another and then at some point down the road redirected to a file. In this way they form a data processing "pipeline" of sorts, allowing you to do non-trivial, repeatable work without creating dozens of intermediary files.

Make sense? If you think you've got it figured out, you can move on to Examining the data.

Examining the data

csvstat: statistics without code

In the previous section we saw how we could use csvlook and csvcut to peek at slices of our data. This is a good starting place for diving into a dataset, but in practice we usually want to get the widest possible view before we start diving into specifics.

csvstat is designed to give us just such a broad picture of our data. It is inspired by the summary() function from the computational statistics programming language "R".

Let's examine summary statistics for some selected columns from our data (remember you can use csvcut -n data.csv to see the columns in the data):

```
$ csvcut -c county,acquisition_cost,ship_date data.csv | csvstat
 1. county
        <type 'unicode'>
       Nulls: False
       Unique values: 35
       5 most frequent values:
                               760
               DOUGLAS:
               DAKOTA: 42
               CASS: 37
               HALL: 23
               LANCASTER:
                               18
       Max length: 10
 2. acquisition_cost
       <type 'float'>
       Nulls: False
       Min: 0.0
       Max: 412000.0
       Sum: 5438254.0
       Mean: 5249.27992278
       Median: 6000.0
       Standard Deviation: 13360.1600088
       Unique values: 75
       5 most frequent values:
               6800.0: 304
               10747.0:
                              195
               6000.0: 105
               499.0: 98
               0.0:
 3. ship_date
       <type 'datetime.date'>
       Nulls: False
       Min: 1984-12-31
       Max: 2054-12-31
       Unique values: 84
       5 most frequent values:
               2013-04-25: 495
               2013-04-26:
                              160
               2008-05-20:
                               2.8
               2012-04-16:
                               26
               2006-11-17:
                               20
Row count: 1036
```

csvstat algorithmically infers the type of each column in the data and then performs basic statistics on it. The particular statistics computed depend on the type of the column.

In this example the first column, county was identified as type "unicode" (text). We see that there are 35 counties represented in the dataset and that DOUGLAS is far and away the most frequently occurring. A quick Google search shows that there are 93 counties in Nebraska, so we know that either not every county received equipment or that the data is incomplete. We can also find out that Douglas county contains Omaha, the state's largest city by far.

The acquisition_cost column is type "float" (number including a decimal). We see that the largest individual cost was 412,000. (Probably dollars, but let's not presume.) Total acquisition costs were 5,438,254.

3.2. Tutorial 9

Lastly, the ship_date column shows us that the earliest data is from 1984 and the latest from 2054. From this we know that there is invalid data for at least one value, since presumably the equipment being shipped does not include time travel devices. We may also note that an unusually large amount of equipment was shipped in April, 2013.

As a journalist, this quick glance at the data gave me a tremendous amount of information about the dataset. Although we have to be careful about assuming to much from this quick glance (always double-check the numbers!) it can be an invaluable way to familiarize yourself with a new dataset.

csvgrep: find the data you need

After reviewing the summary statistics you might wonder what equipment was received by a particular county. To get a simple answer to the question we can use *csvgrep* to search for the state's name amongst the rows. Let's also use csvcut to just look at the columns we care about and csvlook to format the output:

```
$ csvcut -c county,item_name,total_cost data.csv | csvgrep -c county -m LANCASTER |...
|------
 LANCASTER | RIFLE,5.56 MILLIMETER | 120
LANCASTER | RIFLE,5.56 MILLIMETER | 120
 LANCASTER | RIFLE, 5.56 MILLIMETER
                               | 120
                                 | 120
 LANCASTER | RIFLE, 5.56 MILLIMETER
                                  | 120
| LANCASTER | RIFLE,5.56 MILLIMETER
| LANCASTER | RIFLE,5.56 MILLIMETER
                                  | 120
                                  | 120
| LANCASTER | RIFLE, 5.56 MILLIMETER
| LANCASTER | RIFLE, 5.56 MILLIMETER
                                  | 120
| LANCASTER | RIFLE, 5.56 MILLIMETER
                                  | 120
                                  | 120
| LANCASTER | RIFLE, 5.56 MILLIMETER
| LANCASTER | LIGHT ARMORED VEHICLE
                                  1 0
                                  | 0
 LANCASTER | LIGHT ARMORED VEHICLE
 LANCASTER | LIGHT ARMORED VEHICLE
 LANCASTER | MINE RESISTANT VEHICLE
                                 | 0
                                   | 412000
 LANCASTER | IMAGE INTENSIFIER, NIGHT VISION | 6800
 LANCASTER | IMAGE INTENSIFIER, NIGHT VISION | 6800
 LANCASTER | IMAGE INTENSIFIER, NIGHT VISION | 6800
| LANCASTER | IMAGE INTENSIFIER, NIGHT VISION | 6800
|-----
```

LANCASTER county contains Lincoln, Nebraska, the capital of the state and it's second-largest city. The -m flag means "match" and will find text anywhere in a given column—in this case the county column. For those who need a more powerful search you can also use -r to search for a regular expression.

csvsort: order matters

Now let's use *csvsort* to sort the rows by the total_cost column, in reverse (descending) order:

```
$ csvcut -c county,item_name,total_cost data.csv | csvgrep -c county -m LANCASTER | csvsort -c total_cost -r | csvlook | county | item_name | total_cost | county | item_name | total_cost | county | item_name | total_cost | county | LANCASTER | MINE RESISTANT VEHICLE | 412000 | cspc | LANCASTER | IMAGE INTENSIFIER,NIGHT VISION | 6800 | cspc | LANCASTER | IMAGE INTENSIFIER,NIGHT VISION | 6800 | cspc | LANCASTER | IMAGE INTENSIFIER,NIGHT VISION | 6800 | cspc | cs
```

```
LANCASTER | IMAGE INTENSIFIER, NIGHT VISION | 6800
LANCASTER | RIFLE, 5.56 MILLIMETER | 120
LANCASTER | RIFLE, 5.56 MILLIMETER
                                      | 120
LANCASTER | RIFLE, 5.56 MILLIMETER
                                       | 120
LANCASTER | RIFLE, 5.56 MILLIMETER
                                       | 120
LANCASTER | RIFLE, 5.56 MILLIMETER
                                       | 120
LANCASTER | RIFLE, 5.56 MILLIMETER
                                       | 120
LANCASTER | RIFLE, 5.56 MILLIMETER
                                       | 120
LANCASTER | RIFLE, 5.56 MILLIMETER
                                       | 120
                                       | 120
LANCASTER | RIFLE, 5.56 MILLIMETER
                                        | 120
LANCASTER | RIFLE, 5.56 MILLIMETER
                                        1 0
LANCASTER | LIGHT ARMORED VEHICLE
LANCASTER | LIGHT ARMORED VEHICLE
                                        | 0
LANCASTER | LIGHT ARMORED VEHICLE
```

Two interesting things should jump out about this sorted data: that LANCASTER county got a very expensive MINE RESISTANT VEHICLE and that it also go three other LIGHT ARMORED VEHICLE.

What commands would you use to figure out if other counties also recieved large numbers of vehicles?

Summing up

At this point you should be able to use csvkit to investigate the basic properties of a dataset. If you understand this section, you should be ready to move onto *Power tools*.

Power tools

csvjoin: merging related data

One of the most common operations that we need to perform on data is "joining" it to other, related data. For instance, given a dataset about equipment supplied to counties in Nebraska, one might reasonably want to merge that with a dataset containing the population of each county. *csvjoin* allows us to take two those two datasets (equipment and population) and merge them, much like you might do with a SQL JOIN query. In order to demonstrate this, let's grab a second dataset:

Now let's see what's in there:

3.2. Tutorial

```
Unique values: 93
       Max length: 23
 3. total_population
       <type 'int'>
       Nulls: False
       Min: 348
       Max: 518271
        Sum: 1827306
       Mean: 19648.4516129
       Median: 6294
        Standard Deviation: 62164.0702096
       Unique values: 93
  4. margin_of_error
        <type 'int'>
       Nulls: False
       Min: 0
       Max: 115
        Sum: 1800
       Mean: 19.3548387097
       Median: 0
        Standard Deviation: 37.6927719494
        Unique values: 15
        5 most frequent values:
                       73
                0:
                115:
                        2
                114: 2
                99:
                        2
                73:
Row count: 93
```

As you can see, this data file contains population estimates for each county in Nebraska from the 2012 5-year ACS estimates. This data was retrieved from Census Reporter and reformatted slightly for this example. Let's join it to our equipment data:

```
$ csvjoin -c fips data.csv acs2012_5yr_population.csv > joined.csv
```

Since both files contain a fips column, we can use that to join the two. In our output you should see the population data appended at the end of each row of data. Let's combine this with what we've learned before to answer the question "What was the lowest population county to receive equipment?":

```
$ csvcut -c county,item_name,total_population joined.csv | csvsort -c total_
→population | csvlook | head
|-----
| county | item_name
→total_population |
______
| MCPHERSON | RIFLE, 5.56 MILLIMETER
                                                               | 348 ...
          WHEELER
          | RIFLE, 5.56 MILLIMETER
                                                               | 725 _
           GREELEY
          | RIFLE, 7.62 MILLIMETER
                                                               | 2515_
           GREELEY
           | RIFLE, 7.62 MILLIMETER
                                                               | 2515_
           | RIFLE, 7.62 MILLIMETER
                                                               | 2515.
  GREELEY
```

Two counties with fewer than one-thousand residents were the recipients of 5.56 millimeter assault rifles. This simple example demonstrates the power of joining datasets. Although SQL will always be a more flexible option, csvjoin will often get you where you need to go faster.

csvstack: combining subsets

Frequently large datasets are distributed in many small files. At some point you will probably want to merge those files for aggregate analysis. *csvstack* allows you to "stack" the rows from CSV files with identical headers. To demonstrate, let's imagine we've decided that Nebraska and Kansas form a "region" and that it would be useful to analyze them in a single dataset. Let's grab the Kansas data:

```
$ curl -L -O https://github.com/onyxfish/csvkit/raw/master/examples/realdata/ks_1033_ 
data.csvstack
```

Now let's stack these two data files:

```
$ csvstack ne_1033_data.csv ks_1033_data.csv > region.csv
```

Using csvstat we cansee that our region.csv contains both datasets:

```
$ csvstat -c state,acquisition_cost region.csv
 1. state
        <type 'unicode'>
       Nulls: False
       Values: KS, NE
 8. acquisition_cost
        <type 'float'>
        Nulls: False
       Min: 0.0
       Max: 658000.0
        Sum: 9447912.36
       Mean: 3618.50339334
       Median: 138.0
        Standard Deviation: 23725.9555723
        Unique values: 127
        5 most frequent values:
                120.0: 649
                499.0: 449
                138.0: 311
                6800.0: 304
                58.71: 218
Row count: 2611
```

If you supply the -g flag then csvstack can also add a "grouping column" to each row, so that you can tell which file each row came from. In this case we don't need this, but you can imagine a situation in which instead of having a county column each of this datasets had simply been named nebraska.csv and kansas.csv. In that case, using a grouping column would prevent us from losing information when we stacked them.

3.2. Tutorial

csvsql and sql2csv: ultimate power

Sometimes (almost always), the command line isn't enough. It would be crazy to try to do all your analysis using command line tools. Often times, the correct tool for data analysis is SQL. *csvsql* and *sql2csv* form a bridge that eases migrating your data into and out of a SQL database. For smaller datasets csvsql can also leverage sqlite to allow execution of ad hoc SQL queries without ever touching a database.

By default, csvsql will generate a create table statement for your data. You can specify what sort of database you are using with the -i flag:

```
$ csvsql -i sqlite joined.csv
CREATE TABLE joined (
        state VARCHAR(2) NOT NULL,
        county VARCHAR (10) NOT NULL,
        fips INTEGER NOT NULL,
        nsn VARCHAR (16) NOT NULL,
        item_name VARCHAR(62) NOT NULL,
        quantity VARCHAR(4) NOT NULL,
        ui VARCHAR(7) NOT NULL,
        acquisition cost FLOAT NOT NULL,
        total_cost VARCHAR(10) NOT NULL,
        ship_date DATE NOT NULL,
        federal_supply_category VARCHAR(34) NOT NULL,
        federal_supply_category_name VARCHAR(35) NOT NULL,
        federal_supply_class VARCHAR(25) NOT NULL,
        federal supply class name VARCHAR(63),
        name VARCHAR(21) NOT NULL,
        total_population INTEGER NOT NULL,
        margin_of_error INTEGER NOT NULL
);
```

Here we have the sqlite "create table" statement for our joined data. You'll see that, like csvstat, csvsql has done it's best to infer the column types.

Often you won't care about storing the SQL statements locally. You can also use csvsql to create the table directly in the database on your local machine. If you add the --insert option the data will also be imported:

```
$ csvsql --db sqlite:///leso.db --insert joined.csv
```

How can we check that our data was imported successfully? We could use the sqlite command line interface, but rather than worry about the specifics of another tool, we can also use sql2csv:

```
$ sql2csv --db sqlite:///leso.db --query "select * from joined"
```

Note that the --query parameter to sql2csv accepts any SQL query. For example, to export Douglas county from the joined table from our sqlite database, we would run:

```
$ sql2csv --db sqlite:///leso.db --query "select * from joined where county='DOUGLAS'; -> " > douglas.csv
```

Sometimes, if you will only be running a single query, even constructing the database is a waste of time. For that case, you can actually skip the database entirely and csvsql will create one in memory for you:

```
$ csvsql --query "select county,item_name from joined where quantity > 5;" joined.csv 

→ | csvlook
```

SQL queries directly on CSVs! Keep in mind when using this that you are loading the entire dataset into an in-memory database, so it is likely to be very slow for large datasets.

Summing up

csvjoin, csvstack, csvsql and sql2csv represent the power tools of csvkit. Using this tools can vastly simplify processes that would otherwise require moving data between other systems. But what about cases where these tools still don't cut it? What if you need to move your data onto the web or into a legacy database system? We've got a few solutions for those problems in our final section, *Going elsewhere with your data*.

Going elsewhere with your data

csvjson: going online

Very frequently one of the last steps in any data analysis is to get the data onto the web for display as a table, map or chart. CSV is rarely the ideal format for this. More often than not what you want is JSON and that's where *csvjson* comes in. csvjson takes an input CSV and outputs neatly formatted JSON. For the sake of illustration, let's use csvcut and csvgrep to convert just a small slice of our data:

A common usage of turning a CSV into a JSON file is for usage as a lookup table in the browser. This can be illustrated with the ACS data we looked at earlier, which contains a unique fips code for each county:

```
$ csvjson --indent 4 --key fips acs2012_5yr_population.csv | head
{
    "31001": {
        "fips": "31001",
            "name": "Adams County, NE",
            "total_population": "31299",
            "margin_of_error": "0"
    },
    "31003": {
        "fips": "31003",
            "name": "Antelope County, NE",
```

For those making maps, csvjson can also output GeoJSON, see its documentation for more details.

csvpy: going into code

For the programmers out there, the command line is rarely as functional as just writing a little bit of code. *csvpy* exists just to make a programmer's life easier. Invoking it simply launches a Python interactive terminal, with the data preloaded into a CSV reader:

3.2. Tutorial

```
$ csvpy data.csv
Welcome! "data.csv" has been loaded in a CSVKitReader object named "reader".
>>> print len(list(reader))
1037
>>> quit()
```

In addition to being a time-saver, because this uses csvkit's internal CSVKitReader the reader is Unicode aware.

csvformat: for legacy systems

It is a foundational principle of csvkit that it always outputs cleanly formatted CSV data. None of the normal csvkit tools can be forced to produce pipe or tab-delimited output, despite these being common formats. This principle is what allows the csvkit tools to chain together so easily and hopefully also reduces the amount of crummy, non-standard CSV files in the world. However, sometimes a legacy system just has to have a pipe-delimited file and it would be crazy to make you use another tool to create it. That's why we've got *csvformat*.

Pipe-delimited:

```
$ csvformat -D \| data.csv
```

Tab-delimited:

```
$ csvformat -T data.csv
```

Quote every cell:

```
$ csvformat -U 1 data.csv
```

Ampersand-delimited, dollar-signs for quotes, quote all strings, and asterisk for line endings:

```
$ csvformat -D \& -Q \$ -U 2 -M \* data.csv
```

You get the picture.

Summing up

Thus concludes the csvkit tutorial. At this point, I hope, you have a sense a breadth of possibilities these tools open up with a relative small number of command line tools. Of course, this tutorial has only scratched the surface of the available options, so remember to check the documentation for each tool as well.

So armed, go forth and expand the empire of the king of tabular file formats.

Command-Line Usage

csvkit is comprised of a number of individual command line utilities that be loosely divided into a few major categories: Input, Processing, and Output. Documentation and examples for each utility are described on the following pages.

Input

in2csv

Description

Converts various tabular data formats into CSV.

Converting fixed width requires that you provide a schema file with the "-s" option. The schema file should have the following format:

```
column, start, length
name, 0, 30
birthday, 30, 10
age, 40, 3
```

The header line is required though the columns may be in any order:

```
usage: in2csv [-h] [-d DELIMITER] [-t] [-q QUOTECHAR] [-u {0,1,2,3}] [-b]
              [-p` ESCAPECHAR] [-e ENCODING] [-f FORMAT] [-s SCHEMA]
              [FILE]
Convert common, but less awesome, tabular data formats to CSV.
positional arguments:
 FILE
                        The CSV file to operate on. If omitted, will accept
                        input on STDIN.
optional arguments:
 -h, --help
                        show this help message and exit
 -f FORMAT, --format FORMAT
                        The format of the input file. If not specified will be
                        inferred from the file type. Supported formats: csv,
                        dbf, fixed, geojson, json, xls, xlsx.
 -s SCHEMA, --schema SCHEMA
                        Specifies a CSV-formatted schema file for converting
                        fixed-width files. See documentation for details.
 -k KEY, --key KEY
                        Specifies a top-level key to use look within for a
                        list of objects to be converted when processing JSON.
 -y SNIFFLIMIT, --snifflimit SNIFFLIMIT
                        Limit CSV dialect sniffing to the specified number of
                        bytes. Specify "0" to disable sniffing entirely.
  --sheet SHEET
                        The name of the XLSX sheet to operate on.
  --no-inference
                        Disable type inference when parsing the input.
```

See also: Arguments common to all utilities.

Note: DBF format is only supported when running on Python 2.

Examples

Convert the 2000 census geo headers file from fixed-width to CSV and from latin-1 encoding to utf8:

```
$ in2csv -e iso-8859-1 -f fixed -s examples/realdata/census_2000/census2000_geo_

-schema.csv examples/realdata/census_2000/usgeo_excerpt.upl > usgeo.csv
```

Note: A library of fixed-width schemas is maintained in the ffs project:

https://github.com/onyxfish/ffs

Convert an Excel .xls file:

```
$ in2csv examples/test.xls
```

Standardize the formatting of a CSV file (quoting, line endings, etc.):

```
$ in2csv examples/realdata/FY09_EDU_Recipients_by_State.csv
```

Fetch csvkit's open issues from the Github API, convert the JSON response into a CSV and write it to a file:

```
$ curl https://api.github.com/repos/onyxfish/csvkit/issues?state=open | in2csv -f_
→json -v > issues.csv
```

Convert a DBase DBF file to an equivalent CSV:

```
$ in2csv examples/testdbf.dbf > testdbf_converted.csv
```

Fetch the ten most recent robberies in Oakland, convert the GeoJSON response into a CSV and write it to a file:

```
$ curl "http://oakland.crimespotting.org/crime-data?format=json&type=robbery&count=10
→" | in2csv -f geojson > robberies.csv
```

sql2csv

Description

Executes arbitrary commands against a SQL database and outputs the results as a CSV:

```
usage: sq12csv [-h] [-v] [-1] [--db CONNECTION_STRING] [-q QUERY] [-H] [FILE]
Execute an SQL query on a database and output the result to a CSV file.
positional arguments:
                        The file to use as SQL query. If both FILE and QUERY
 FILE
                        are omitted, query will be read from STDIN.
optional arguments:
 -h, --help
                        show this help message and exit
 -v, --verbose
                        Print detailed tracebacks when errors occur.
                        Insert a column of line numbers at the front of the
 -1, --linenumbers
                        output. Useful when piping to grep or as a simple
                        primary key.
 --db CONNECTION_STRING
                        An sqlalchemy connection string to connect to a
                        database.
 --query QUERY
                        The SQL query to execute. If specified, it overrides
                        FILE and STDIN.
 -H, --no-header-row
                        Do not output column names.
```

Examples

Load sample data into a table using *csvsql* and then query it using *sql2csv*:

```
$ csvsql --db "sqlite:///dummy.db" --table "test" --insert examples/dummy.csv
$ sql2csv --db "sqlite:///dummy.db" --query "select * from test"
```

Load data about financial aid recipients into Postgresql. Then find the three states that received the most, while also filtering out empty rows:

You can even use it as a simple SQL calculator (in this example an in-memory sqlite database is used as the default):

```
$ sql2csv --query "select 300 * 47 % 14 * 27 + 7000"
```

Processing

csyclean

Description

Cleans a CSV file of common syntax errors. Outputs [basename]_out.csv and [basename]_err.csv, the former containing all valid rows and the latter containing all error rows along with line numbers and descriptions:

See also: Arguments common to all utilities.

Examples

Test a file with known bad rows:

```
$ csvclean -n examples/bad.csv
```

```
Line 3: Expected 3 columns, found 4 columns
Line 4: Expected 3 columns, found 2 columns
```

csvcut

Description

Filters and truncates CSV files. Like unix "cut" command, but for tabular data:

```
usage: csvcut [-h] [-d DELIMITER] [-t] [-q QUOTECHAR] [-u {0,1,2,3}] [-b]
              [-p` ESCAPECHAR] [-e ENCODING] [-n] [-c COLUMNS] [-s] [-1]
              [FILE]
Filter and truncate CSV files. Like unix "cut" command, but for tabular data.
positional arguments:
 FILE
                        The CSV file to operate on. If omitted, will accept
                        input on STDIN.
optional arguments:
 -h, --help
                        show this help message and exit
 -n, --names
                       Display column names and indices from the input CSV
                        and exit.
 -c COLUMNS, --columns COLUMNS
                        A comma separated list of column indices or names to
                        be extracted. Defaults to all columns.
 -C NOT_COLUMNS, --not-columns NOT_COLUMNS
                       A comma separated list of column indices or names to
                        be excluded. Defaults to no columns.
 -x, --delete-empty-rows
                        After cutting, delete rows which are completely empty.
```

See also: Arguments common to all utilities.

Note: csvcut does not implement row filtering, for this you should pipe data to *csvgrep*.

Examples

Print the indices and names of all columns:

```
$ csvcut -n examples/realdata/FY09_EDU_Recipients_by_State.csv

1: State Name

2: State Abbreviate

3: Code

4: Montgomery GI Bill-Active Duty

5: Montgomery GI Bill- Selective Reserve

6: Dependents' Educational Assistance

7: Reserve Educational Assistance Program

8: Post-Vietnam Era Veteran's Educational Assistance Program

9: TOTAL

10:
```

Extract the first and third columns:

```
$ csvcut -c 1,3 examples/realdata/FY09_EDU_Recipients_by_State.csv
```

Extract columns named "TOTAL" and "State Name" (in that order):

```
$ csvcut -c TOTAL, "State Name" examples/realdata/FY09_EDU_Recipients_by_State.csv
```

Add line numbers to a file, making no other changes:

```
$ csvcut -1 examples/realdata/FY09_EDU_Recipients_by_State.csv
```

csvgrep

Description

Filter tabular data to only those rows where certain columns contain a given value or match a regular expression:

```
usage: csvgrep [-h] [-d DELIMITER] [-t] [-q QUOTECHAR] [-u {0,1,2,3}] [-b]
               [-p ESCAPECHAR] [-e ENCODING] [-1] [-n] [-c COLUMNS] [-r]
               [FILE] [PATTERN]
Like the unix "grep" command, but for tabular data.
positional arguments:
 FILE
                        The CSV file to operate on. If omitted, will accept
                        input on STDIN.
optional arguments:
 -h, --help
                       show this help message and exit
 -n, --names
                       Display column names and indices from the input CSV
                        and exit.
 -c COLUMNS, --columns COLUMNS
                        A comma separated list of column indices or names to
                        be searched.
 -m PATTERN, --match PATTERN
                        The string to search for.
 -r REGEX, --regex REGEX
                        If specified, must be followed by a regular expression
                        which will be tested against the specified columns.
 -f MATCHFILE, --file MATCHFILE
                        If specified, must be the path to a file. For each
                        tested row, if any line in the file (stripped of line
                        separators) is an exact match for the cell value, the
                        row will pass.
 -i, --invert-match
                        If specified, select non-matching instead of matching
                        rows.
```

See also: Arguments common to all utilities.

NOTE: Even though '-m', '-r', and '-f' are listed as "optional" arguments, you must specify one of them.

Examples

Search for the row relating to Illinois:

```
$ csvgrep -c 1 -m ILLINOIS examples/realdata/FY09_EDU_Recipients_by_State.csv
```

Search for rows relating to states with names beginning with the letter "I":

```
$ csvgrep -c 1 -r "^I" examples/realdata/FY09_EDU_Recipients_by_State.csv
```

csvjoin

Description

Merges two or more CSV tables together using a method analogous to SQL JOIN operation. By default it performs an inner join, but full outer, left outer, and right outer are also available via flags. Key columns are specified with the -c flag (either a single column which exists in all tables, or a comma-seperated list of columns with one corresponding to each). If the columns flag is not provided then the tables will be merged "sequentially", that is they will be merged in row order with no filtering:

```
usage: csvjoin [-h] [-d DELIMITER] [-t] [-q QUOTECHAR] [-u {0,1,2,3}] [-b]
               [-p` ESCAPECHAR] [-e ENCODING] [-j JOIN] [--outer] [--left]
               [--right]
               FILES [FILES ...]
Execute a SQL-like join to merge CSV files on a specified column or columns.
positional arguments:
 FILES
                        The CSV files to operate on. If only one is specified,
                        it will be copied to STDOUT.
optional arguments:
 -h, --help
                        show this help message and exit
 -c COLUMNS, --columns COLUMNS
                        The column name(s) on which to join. Should be either
                        one name (or index) or a comma-separated list with one
                        name (or index) for each file, in the same order that
                        the files were specified. May also be left
                        unspecified, in which case the two files will be
                        joined sequentially without performing any matching.
  --outer
                        Perform a full outer join, rather than the default
                        inner join.
  --left.
                        Perform a left outer join, rather than the default
                        inner join. If more than two files are provided this
                        will be executed as a sequence of left outer joins,
                        starting at the left.
 --right
                        Perform a right outer join, rather than the default
                        inner join. If more than two files are provided this
                        will be executed as a sequence of right outer joins,
                        starting at the right.
Note that the join operation requires reading all files into memory. Don't try
this on very large files.
```

See also: Arguments common to all utilities.

Examples

```
csvjoin -c "ColumnKey, Column Key" --outer file1.csv file2.csv
```

This command says you have two files to outer join, file1.csv and file2.csv. The key column in file1.csv is ColumnKey, the key column in file2.csv is Column Key.

csvsort

Description

Sort CSV files. Like unix "sort" command, but for tabular data:

```
usage: csvsort [-h] [-d DELIMITER] [-t] [-q QUOTECHAR] [-u {0,1,2,3}] [-b]
               [-p` ESCAPECHAR] [-e ENCODING] [-n] [-c COLUMNS] [-r]
               [FILE]
Sort CSV files. Like unix "sort" command, but for tabular data.
positional arguments:
 FILE
                        The CSV file to operate on. If omitted, will accept
                        input on STDIN.
optional arguments:
 -h, --help
                        show this help message and exit
 -y SNIFFLIMIT, --snifflimit SNIFFLIMIT
                        Limit CSV dialect sniffing to the specified number of
                        bytes. Specify "0" to disable sniffing entirely.
                        Specify the encoding the input file.
 -n, --names
                        Display column names and indices from the input CSV
                        and exit.
 -c COLUMNS, --columns COLUMNS
                        A comma separated list of column indices or names to
                        be extracted. Defaults to all columns.
 -r, --reverse
                       Sort in descending order.
 --no-inference
                       Disable type inference when parsing the input.
```

See also: Arguments common to all utilities.

Examples

Sort the veteran's education benefits table by the "TOTAL" column:

```
$ cat examples/realdata/FY09_EDU_Recipients_by_State.csv | csvsort -c 9
```

View the five states with the most individuals claiming veteran's education benefits:

```
$ cat examples/realdata/FY09_EDU_Recipients_by_State.csv | csvcut -c 1,9 | csvsort -r_ \rightarrow-c 2 | head -n 5
```

csvstack

Description

Stack up the rows from multiple CSV files, optionally adding a grouping value to each row:

```
usage: csvstack [-h] [-d DELIMITER] [-t] [-q QUOTECHAR] [-u {0,1,2,3}] [-b]
                [-p` ESCAPECHAR] [-e ENCODING] [-g GROUPS] [-n GROUP_NAME]
                FILES [FILES ...]
Stack up the rows from multiple CSV files, optionally adding a grouping value.
positional arguments:
 FILES
optional arguments:
 -h, --help
                        show this help message and exit
 -g GROUPS, --groups GROUPS
                        A comma-seperated list of values to add as "grouping
                        factors", one for each CSV being stacked. These will
                        be added to the stacked CSV as a new column. You may
                        specify a name for the grouping column using the -n
                        flag.
 -n GROUP_NAME, --group-name GROUP_NAME
                        A name for the grouping column, e.g. "year". Only used
                        when also specifying -g.
 --filenames
                        Use the filename of each input file as its grouping
                        value. When specified, -g will be ignored.
```

See also: Arguments common to all utilities.

Examples

Contrived example: joining a set of homogoenous files for different years:

```
$ csvstack -g 2009,2010 examples/realdata/FY09_EDU_Recipients_by_State.csv examples/

realdata/Datagov_FY10_EDU_recp_by_State.csv
```

Output (and Analysis)

csvformat

Description

Convert a CSV file to a custom output format.:

```
input on STDIN.
optional arguments:
 -D OUT_DELIMITER, --out-delimiter OUT_DELIMITER
                       Delimiting character of the output CSV file.
                       Specifies that the output CSV file is delimited with
 -T, --out-tabs
                        tabs. Overrides "-D".
 -Q OUT_QUOTECHAR, --out-quotechar OUT_QUOTECHAR
                        Character used to quote strings in the output CSV
                        file.
 -U \{0,1,2,3\}, --out-quoting \{0,1,2,3\}
                        Quoting style used in the output CSV file. 0 = Quote
                        Minimal, 1 = Quote All, 2 = Quote Non-numeric, 3 =
                        Quote None.
 -B, --out-doublequote
                        Whether or not double quotes are doubled in the output
                        CSV file.
 -P OUT_ESCAPECHAR, --out-escapechar OUT_ESCAPECHAR
                        Character used to escape the delimiter in the output
                        CSV file if --quoting 3 ("Quote None") is specified
                        and to escape the QUOTECHAR if --doublequote is not
                        specified.
 -M OUT_LINETERMINATOR, --out-lineterminator OUT_LINETERMINATOR
                        Character used to terminate lines in the output CSV
                        file.
```

See also: Arguments common to all utilities.

Examples

Convert "standard" CSV file to a pipe-delimited one:

```
$ csvformat -D "|" examples/dummy.csv
```

Convert to ridiculous line-endings:

```
$ csvformat -M "\r" examples/dummy.csv
```

csvjson

Description

Converts a CSV file into JSON or GeoJSON (depending on flags):

```
input on STDIN.
optional arguments:
 -i INDENT, --indent INDENT
                        Indent the output JSON this many spaces. Disabled by
                        default.
 -k KEY, --key KEY
                        Output JSON as an array of objects keyed by a given
                        column, KEY, rather than as a list. All values in the
                        column must be unique. If --lat and --lon are also
                        specified, this column will be used as GeoJSON Feature
                        TD.
 --lat LAT
                        A column index or name containing a latitude. Output
                        will be GeoJSON instead of JSON. Only valid if --lon
                        is also specified.
  --lon LON
                        A column index or name containing a longitude. Output
                        will be GeoJSON instead of JSON. Only valid if --lat
                        is also specified.
                        A coordinate reference system string to be included
 --crs CRS
                        with GeoJSON output. Only valid if --lat and --lon are
                        also specified.
```

See also: Arguments common to all utilities.

Examples

Convert veteran's education dataset to JSON keyed by state abbreviation:

```
$ csvjson -k "State Abbreviate" -i 4 examples/realdata/FY09_EDU_Recipients_by_State.

→csv
```

Results in a JSON document like:

```
[...]
"WA":
{
    "": "",
    "Code": "53",
    "Reserve Educational Assistance Program": "549",
    "Dependents' Educational Assistance": "2,192",
    "Montgomery GI Bill-Active Duty": "7,969",
    "State Name": "WASHINGTON",
    "Montgomery GI Bill- Selective Reserve": "769",
    "State Abbreviate": "WA",
    "Post-Vietnam Era Veteran's Educational Assistance Program": "13",
    "TOTAL": "11,492"
},
[...]
}
```

Converting locations of public art into GeoJSON:

```
\ csvjson --lat latitude --lon longitude --k slug --crs EPSG:4269 -i 4 examples/test_ \rightarrow geo.csv
```

Results in a GeoJSON document like:

```
"type": "FeatureCollection",
   "bbox": [
       -95.334619,
       32.299076986939205,
       -95.250699,
       32.351434
   ],
   "crs": {
       "type": "name",
       "properties": {
           "name": "EPSG:4269"
   },
   "features": [
       {
            "geometry": {
                "type": "Point",
                "coordinates": [
                   -95.30181,
                    32.35066
                ]
           },
            "type": "Feature",
            "id": "dcl",
            "properties": {
                "photo_credit": "",
                "description": "In addition to being the only coffee shop in downtown,
→Tyler, DCL also features regular exhibitions of work by local artists.",
                "artist": "",
                "title": "Downtown Coffee Lounge",
                "install_date": "",
                "address": "200 West Erwin Street",
                "last_seen_date": "3/30/12",
                "type": "Gallery",
                "photo_url": ""
       },
   [...]
   ]
```

csvlook

Description

Renders a CSV to the command line in a readable, fixed-width format:

If a table is too wide to display properly try truncating it using *csvcut*.

If the table is too long, try filtering it down with grep or piping the output to less.

See also: Arguments common to all utilities.

Examples

Basic use:

```
$ csvlook examples/testfixed_converted.csv
```

This utility is especially useful as a final operation when piping through other utilities:

```
$ csvcut -c 9,1 examples/realdata/FY09_EDU_Recipients_by_State.csv | csvlook
```

csvpy

Description

Loads a CSV file into a csvkit.CSVKitReader object and then drops into a Python shell so the user can inspect the data however they see fit:

This utility will automatically use the IPython shell if it is installed, otherwise it will use the running Python shell.

Note: Due to platform limitations, csvpy does not accept file input on STDIN.

See also: Arguments common to all utilities.

Examples

Basic use:

```
$ csvpy examples/dummy.csv
Welcome! "examples/dummy.csv" has been loaded in a CSVKitReader object named "reader".
>>> reader.next()
[u'a', u'b', u'c']
```

As a dictionary:

```
$ csvpy --dict examples/dummy.csv -v
Welcome! "examples/dummy.csv" has been loaded in a CSVKitDictReader object named

"reader".
>>> reader.next()
{u'a': u'1', u'c': u'3', u'b': u'2'}
```

csvsql

Description

Generate SQL statements for a CSV file or execute those statements directly on a database. In the latter case supports both creating tables and inserting data:

```
usage: csvsql [-h] [-d DELIMITER] [-t] [-q QUOTECHAR] [-u {0,1,2,3}] [-b]
              [-p ESCAPECHAR] [-z MAXFIELDSIZE] [-e ENCODING] [-H] [-v]
              [-y SNIFFLIMIT]
              [-i {access, sybase, sqlite, informix, firebird, mysql, oracle, maxdb,
→postgresql,mssql}]
              [--db CONNECTION_STRING] [--insert]
              [FILE]
Generate SOL statements for a CSV file or create execute those statements
directly on a database.
Generate a SOL CREATE TABLE statement for a CSV file.
positional arguments:
  FILE
                        The CSV file(s) to operate on. If omitted, will accept
                        input on STDIN.
optional arguments:
                        show this help message and exit
  -h, --help
  -y SNIFFLIMIT, --snifflimit SNIFFLIMIT
                        Limit CSV dialect sniffing to the specified number of
                        bytes. Specify "0" to disable sniffing entirely.
 -i {access, sybase, sqlite, informix, firebird, mysql, oracle, maxdb, postgresql, mssql}, --
→dialect {access, sybase, sqlite, informix, firebird, mysql, oracle, maxdb, postgresql, mssql}
                        Dialect of SQL to generate. Only valid when --db is
                        not specified.
  --db CONNECTION_STRING
                        If present, a sqlalchemy connection string to use to
                        directly execute generated SQL on a database.
                        Execute one or more SQL queries delimited by ";" and
  --query QUERY
                        output the result of the last query as CSV.
                        In addition to creating the table, also insert the
  --insert
                        data into the table. Only valid when --db is
                        specified.
  --table TABLE_NAME
                        Specify a name for the table to be created. If
                        omitted, the filename (minus extension) will be used.
```

```
--no-constraints

Generate a schema without length limits or null checks. Useful when sampling big tables.

--no-create

Skip creating a table. Only valid when --insert is specified.

--blanks

--no-inference

--db-schema

Generate a schema without length limits or null checks. Useful when sampling big tables.

Skip creating a table. Only valid when --insert is specified.

Do not coerce empty strings to NULL values.

Disable type inference when parsing the input.

Optional name of database schema to create table(s) in.
```

See also: Arguments common to all utilities.

For information on connection strings and supported dialects refer to the SQLAlchemy documentation.

Note: Using the —query option may cause rounding (in Python 2) or introduce [Python floating point issues](https://docs.python.org/3.4/tutorial/floatingpoint.html) (in Python 3).

Examples

Generate a statement in the PostgreSQL dialect:

```
$ csvsql -i postgresql examples/realdata/FY09_EDU_Recipients_by_State.csv
```

Create a table and import data from the CSV directly into Postgres:

For large tables it may not be practical to process the entire table. One solution to this is to analyze a sample of the table. In this case it can be useful to turn off length limits and null checks with the no-constraints option:

```
$ head -n 20 examples/realdata/FY09_EDU_Recipients_by_State.csv | csvsql --no-

→constraints --table fy09
```

Create tables for an entire folder of CSVs and import data from those files directly into Postgres:

```
$ createdb test
$ csvsql --db postgresql:///test --insert examples/*.csv
```

You can also use CSVSQL to "directly" query one or more CSV files. Please note that this will create an in-memory SQL database, so it won't be very fast:

```
$ csvsql --query "select m.usda_id, avg(i.sepal_length) as mean_sepal_length from_
iris as i join irismeta as m on (i.species = m.species) group by m.species"

examples/iris.csv examples/irismeta.csv
```

csvstat

Description

Prints descriptive statistics for all columns in a CSV file. Will intelligently determine the type of each column and then print analysis relevant to that type (ranges for dates, mean and median for integers, etc.):

```
usage: csvstat [-h] [-d DELIMITER] [-t] [-q QUOTECHAR] [-u {0,1,2,3}] [-b]
                  [-p` ESCAPECHAR] [-e ENCODING]
                  [FILE]
Print descriptive statistics for all columns in a CSV file.
positional arguments:
 FILE
                        The CSV file to operate on. If omitted, will accept
                        input on STDIN.
optional arguments:
 -h, --help
                        show this help message and exit
 -y SNIFFLIMIT, --snifflimit SNIFFLIMIT
                        Limit CSV dialect sniffing to the specified number of
                        bytes. Specify "0" to disable sniffing entirely.
 -c COLUMNS, --columns COLUMNS
                       A comma separated list of column indices or names to
                       be examined. Defaults to all columns.
 --max
                       Only output max.
 --min
                       Only output min.
 --sum
                       Only output sum.
 --mean
                      Only output mean.
 --median
                      Only output median.
 --stdev
                      Only output standard deviation.
                      Only output whether column contains nulls.
 --nulls
  --unique
                       Only output unique values.
                       Only output frequent values.
  --freq
                       Only output max value length.
  --len
  --count
                       Only output row count
```

See also: Arguments common to all utilities.

Examples

Basic use:

```
$ csvstat examples/realdata/FY09_EDU_Recipients_by_State.csv
```

When an statistic name is passed, only that stat will be printed:

```
$ csvstat --freq examples/realdata/FY09_EDU_Recipients_by_State.csv

1. State Name: None
2. State Abbreviate: None
3. Code: None
4. Montgomery GI Bill-Active Duty: 3548.0
5. Montgomery GI Bill- Selective Reserve: 1019.0
6. Dependents' Educational Assistance: 1261.0
7. Reserve Educational Assistance Program: 715.0
8. Post-Vietnam Era Veteran's Educational Assistance Program: 6.0
9. TOTAL: 6520.0
10. _unnamed: None
```

If a single stat and a single column are requested, only a value will be returned:

```
$ csvstat -c 4 --freq examples/realdata/FY09_EDU_Recipients_by_State.csv 3548.0
```

Appendices

Arguments common to all utilities

All utilities which accept CSV as input share a set of common command-line arguments:

```
-d DELIMITER, --delimiter DELIMITER
                      Delimiting character of the input CSV file.
                      Specifies that the input CSV file is delimited with
-t, --tabs
                      tabs. Overrides "-d".
-q QUOTECHAR, --quotechar QUOTECHAR
                      Character used to quote strings in the input CSV file.
-u \{0,1,2,3\}, --quoting \{0,1,2,3\}
                      Quoting style used in the input CSV file. 0 = Quote
                      Minimal, 1 = Quote All, 2 = Quote Non-numeric, 3 =
                      Quote None.
-b, --doublequote
                      Whether or not double quotes are doubled in the input
                      CSV file.
-p ESCAPECHAR, --escapechar ESCAPECHAR
                      Character used to escape the delimiter if --quoting 3
                      ("Quote None") is specified and to escape the
                      QUOTECHAR if --doublequote is not specified.
-z MAXFIELDSIZE, --maxfieldsize MAXFIELDSIZE
                      Maximum length of a single field in the input CSV
-H, --no-header-row
                      Specifies that the input CSV file has no header row.
-e ENCODING, --encoding ENCODING
-S, --skipinitialspace
                      Ignore whitespace immediately following the delimiter.
-v, --verbose
                      Print detailed tracebacks when errors occur.
                      Specify the encoding the input file.
                      Insert a column of line numbers at the front of the
-1, --linenumbers
                      output. Useful when piping to grep or as a simple
                      primary key.
                      When interpreting or displaying column numbers, use
--zero
                      zero-based numbering instead of the default 1-based
                      numbering.
```

These arguments may be used to override csvkit's default "smart" parsing of CSV files. This is frequently necessary if the input file uses a particularly unusual style of quoting or is an encoding that is not compatible with utf-8. Not every command is supported by every tool, but the majority of them are.

Note that the output of csvkit's utilities is always formatted with "default" formatting options. This means that when executing multiple csvkit commands (either with a pipe or via intermediary files) it is only ever necessary to specify formatting arguments the first time. (And doing so for subsequent commands will likely cause them to fail.)

Tips and Tricks

Reading compressed CSVs

csvkit has builtin support for reading gzip or bz2 compressed input files. This is automatically detected based on the file extension. For example:

```
$ csvstat examples/dummy.csv.gz
$ csvstat examples/dummy.csv.bz2
```

Please note, the files are decompressed in memory, so this is a convenience, not an optimization.

Specifying STDIN as a file

Most tools default to STDIN if no filename is specified, but tools like *csvjoin* and *csvstack* accept multiple files, so this is not possible. To work around this it is also possible to specify STDIN by using – as a filename. For example, these three commands are functionally identical:

```
$ csvstat examples/dummy.csv
$ cat examples/dummy.csv | csvstat
$ cat examples/dummy.csv | csvstat -
```

This specification allows you to, for instance, csvstack input on STDIN with another file:

```
$ cat ~/src/csvkit/examples/dummy.csv | csvstack ~/src/csvkit/examples/dummy3.csv -
```

Using as a Python library

csvkit is designed to be used a replacement for most of Python's csv module. Important parts of the API are documented on the following pages.

Don't!

```
import csv
```

Do!

```
import csvkit
```

csvkit

This module contains csvkit's superpowered replacement for the builtin csv module. For Python 2 users, the greatest improvement over the standard library full unicode support. Python 3's csv module supports unicode internally, so this module is provided primarily for compatability purposes.

```
Python 2: csvkit.py2.Python 3: csvkit.py3.
```

csvkit.py2

Python2-specific classes.

```
class csvkit.py2.CSVKitReader(f, encoding='utf-8', maxfieldsize=None, **kwargs)
     A unicode-aware CSV reader.
     line_num
     next()
class csvkit.py2.CSVKitWriter (f, encoding='utf-8', line numbers=False, **kwargs)
     A unicode-aware CSV writer.
     writerow(row)
     writerows (rows)
class csvkit.py2.CSVKitDictReader(f, fieldnames=None, restkey=None, restval=None, *args,
                                       **kwargs)
     A unicode-aware CSV DictReader.
     fieldnames
     next()
                                                                          line_numbers=False,
class csvkit.py2.CSVKitDictWriter(f, fieldnames,
                                                        encoding='utf-8',
                                       **kwargs)
     A unicode-aware CSV DictWriter.
     writerow(row)
     writerows (rows)
     writeheader()
csvkit.py2.reader(*args, **kwargs)
     A drop-in replacement for Python's csv.reader() that leverages csvkit.py2.CSVKitReader.
csvkit.py2.writer(*args, **kwargs)
     A drop-in replacement for Python's csv.writer() that leverages csvkit.py2.CSVKitWriter.
csvkit.py3
Python3-specific classes.
class csvkit.py3.CSVKitReader(f, **kwargs)
     A wrapper around Python 3's builtin csv.reader().
     dialect
     line_num
     next()
class csvkit.py3.CSVKitWriter(f, line_numbers=False, **kwargs)
     A wrapper around Python 3's builtin csv.writer().
     writerow(row)
     writerows (rows)
class csvkit.py3.CSVKitDictReader(f, fieldnames=None, restkey=None, restval=None,
                                       alect='excel', *args, **kwds)
     A wrapper around Python 3's builtin csv.DictReader.
     fieldnames
     next()
```

```
class csvkit.py3.CSVKitDictWriter(f, fieldnames, line_numbers=False, **kwargs)
    A wrapper around Python 3's builtin csv.DictWriter.

writerow(row)
writeheader()

csvkit.py3.reader(*args, **kwargs)
    A drop-in replacement for Python's csv.reader() that leverages csvkit.py3.CSVKitReader.

csvkit.py3.writer(*args, **kwargs)
    A drop-in replacement for Python's csv.writer() that leverages csvkit.py3.CSVKitWriter.
```

csvkit.unicsv

This module contains unicode aware replacements for csv.reader() and csv.writer(). The implementations are largely copied from examples in the csv module documentation.

These classes are available for Python 2 only. The Python 3 version of csv supports unicode internally.

Note: You probably don't want to use these classes directly. Try the csvkit module. class csvkit.unicsv.UTF8Recoder (f, encoding) Iterator that reads an encoded stream and reencodes the input to UTF-8. next() class csvkit.unicsv.UnicodeCSVReader (f, encoding='utf-8', maxfieldsize=None, **kwargs) A CSV reader which will read rows from a file in a given encoding. next() line_num class csvkit.unicsv.UnicodeCSVWriter(f, encoding='utf-8', **kwargs) A CSV writer which will write rows to a file in the specified encoding. NB: Optimized so that eight-bit encodings skip re-encoding. See: https://github.com/onyxfish/csvkit/ issues/175 writerow(row) writerows (rows) class csvkit.unicsv.UnicodeCSVDictReader (f, fieldnames=None, restkey=None, restval=None, *args, **kwargs) Defer almost all implementation to csv.DictReader, but wraps our unicode reader instead of csv. reader(). fieldnames next() class csvkit.unicsv.UnicodeCSVDictWriter (f, fieldnames, restval='', extrasaction='raise', *args, ***kwds*) Defer almost all implementation to csv.DictWriter, but wraps our unicode writer instead of csv. writer(). writerow(rowdict)

```
writerows (rowdicts)
writeheader()
```

csvkit.sniffer

```
csvkit.sniffer.sniff dialect (sample)
```

A functional version of csv. Sniffer().sniff, that extends the list of possible delimiters to include some seen in the wild.

Contributing to csvkit

Principles

csvkit is to tabular data what the standard Unix text processing suite (grep, sed, cut, sort) is to text. As such, csvkit adheres to the Unix philosophy.

- 1. Small is beautiful.
- 2. Make each program do one thing well.
- 3. Build a prototype as soon as possible.
- 4. Choose portability over efficiency.
- 5. Store data in flat text files.
- 6. Use software leverage to your advantage.
- 7. Use shell scripts to increase leverage and portability.
- 8. Avoid captive user interfaces.
- 9. Make every program a filter.

As there is no formally defined CSV format, csvkit encourages well-known formatting standards:

- Output favors compatability with the widest range of applications. This means that quoting is done with double-quotes and only when necessary, columns are separated with commas, and lines are terminated with unix style line endings ("\n").
- Data that is modified or generated will prefer consistency over brevity. Floats always include at least one decimal place, even if they are round. Dates and times are written in ISO8601 format.

Process for contributing code

Contributors should use the following roadmap to guide them through the process of submitting a contribution:

- 1. Fork the project on Github.
- 2. Check out the issue tracker and find a task that needs to be done and is of a scope you can realistically expect to complete in a few days. Don't worry about the priority of the issues at first, but try to choose something you'll enjoy. You're much more likely to finish something to the point it can be merged if it's something you really enjoy hacking on.
- 3. Comment on the ticket letting everyone know you're going to be hacking on it so that nobody duplicates your effort. It's also good practice to provide some general idea of how you plan on resolving the issue so that other developers can make suggestions.

- 4. Write tests for the feature you're building. Follow the format of the existing tests in the test directory to see how this works. You can run all the tests with the command nosetests. The one exception to testing is command-line scripts. These don't need unit test, though all reusable components should be factored into library modules.
- 5. Write the code. Try to stay consistent with the style and organization of the existing codebase. A good patch won't be refused for stylistic reasons, but large parts of it may be rewritten and nobody wants that.
- 6. As your coding, periodically merge in work from the master branch and verify you haven't broken anything by running the test suite.
- 7. Write documentation for user-facing features (and library features once the API has stabilized).
- 8. Once it works, is tested, and has documentation, submit a pull request on Github.
- 9. Wait for it to either be merged or to recieve a comment about what needs to be fixed.
- 10. Rejoice.

Legalese

To the extent that they care, contributors should keep the following legal mumbo-jumbo in mind:

The source of csvkit and therefore of any contributions are licensed under the permissive MIT license. By submitting a patch or pull request you are agreeing to release your code under this license. You will be acknowledged in the AUTHORS file. As the owner of your specific contributions you retain the right to privately relicense your specific code contributions (and no others), however, the released version of the code can never be retracted or relicensed.

Release process

- 1. Verify no high priority issues are outstanding.
- 2. Run the full test suite with fresh environments for all versions: tox -r (Everything MUST pass.)
- 3. Ensure these files all have the correct version number:
 - CHANGELOG
 - setup.py
 - docs/conf.py
- 4. Tag the release: git tag -a x.y.z; git push --tags
- 5. Roll out to PyPI: python setup.py sdist upload
- 6. Iterate the version number in all files where it is specified. (see list above)
- 7. Flag the new version for building on Read the Docs.
- 8. Wait for the documentation build to finish.
- 9. Flag the new release as the default documentation version.
- 10. Announce the release on Twitter, etc.

CHAPTER 4

Authors

The following individuals have contributed code to csvkit:

- Christopher Groskopf
- Joe Germuska
- Aaron Bycoffe
- Travis Mehlinger
- Alejandro Companioni
- Benjamin Wilson
- Bryan Silverthorn
- Evan Wheeler
- Matt Bone
- Ryan Pitts
- Hari Dara
- Jeff Larson
- Jim Thaxton
- Miguel Gonzalez
- Anton Ian Sipos
- Gregory Temchenko
- Kevin Schaul
- Marc Abramowitz
- Noah Hoffman
- Jan Schulz
- Derek Wilson

- Chris Rosenthal
- Davide Setti
- Gabi Davar
- Sriram Karra
- James McKinney
- aarcro
- Matt Dudys
- Joakim Lundborg
- Federico Scrinzi
- · Chris Rosenthal
- Shane StClair
- raistlin7447
- Alex Dergachev
- Jeff Paine
- · Jeroen Janssens
- Sébastien Fievet
- Travis Swicegood
- Ryan Murphy
- Diego Rabatone Oliveira
- Matt Pettis
- Tasneem Raja
- Richard Low
- Kristina Durivage
- Espartaco Palma
- pnaimoli
- Michael Mior

CHAPTER 6

Changelog

1.0.0

- Add missing docs for csvcut -C. (#227)
- Reorganize docs so TOC works better. (#339)
- Render docs locally with RTD theme.
- Fix header in "tricks" docs.
- Add install instructions to tutorial. (#331)
- Add killer examples to doc index. (#328)
- Reorganize doc index
- Fix broken csvkit module documentation. (#327)

0.9.0

- Write missing sections of the tutorial. (#32)
- Remove -q arg from sql2csv (conflicts with common flag).
- Fix csvjoin in case where left dataset rows without all columns.
- Rewrote tutorial based on LESO data. (#324)
- Don't error in csvjson if lat/lon columns are null. (#326)
- Maintain field order in output of csvjson.
- Add unit test for json in2csv. (#77)
- Maintain key order when converting JSON into CSV. (#325.)
- Upgrade python-dateutil to version 2.2 (#304)

- Fix sorting of columns with null values. (#302)
- · Added release documentation.
- Fill out short rows with null values. (#313)
- Fix unicode output for csvlook and csvstat. (#315)
- Add documentation for –zero. (#323)
- Fix Integrity error when inserting zero rows in database with csvsql. (#299)
- Add Michael Mior to AUTHORS. (#305)
- Add -count option to CSVStat.
- Implement csvformat.
- Fix bug causing CSVKitDictWriter to output 'utf-8' for blank fields.

0.8.0

- Add pnaimoli to AUTHORS.
- Fix column specification in csvstat. (#236)
- Added "Tips and Tricks" documentation. (#297, #298)
- Add Espartaco Palma to AUTHORS.
- Remove unnecessary enumerate calls. (#292)
- Deprecated DBF support for Python 3+.
- Add support for Python 3.3 and 3.4 (#239)

0.7.3

- Fix date handling with openpyxl > 2.0 (#285)
- Add Kristina Durivage to AUTHORS. (#243)
- · Added Richard Low to AUTHORS.
- Support SQL queries "directly" on CSV files. (#276)
- Add Tasneem Raja to AUTHORS.
- Fix off-by-one error in open ended column ranges. (#238)
- Add Matt Pettis to AUTHORS.
- Add line numbers flag to csvlook (#244)
- Only install argparse for Python < 2.7. (#224)
- Add Diego Rabatone Oliveira to AUTHORS.
- Add Ryan Murphy to AUTHORS.
- Fix DBF dependency. (#270)

0.7.2

• Fix CHANGELOG for release.

0.7.1

• Fix homepage url in setup.py.

0.7.0

- Fix XLSX datetime normalization bug. (#223)
- Add raistlin7447 to AUTHORS.
- Merged sql2csv utility (#259).
- Add Jeroen Janssens to AUTHORS.
- Validate csvsql DB connections before parsing CSVs. (#257)
- Clarify install process for Ubuntu. (#249)
- Clarify docs for –escapechar. (#242)
- Make import csvkit API compatible with import csv.
- Update Travis CI link. (#258)
- Add Sébastien Fievet to AUTHORS.
- Use case-sensitive name for SQLAlchemy (#237)
- · Add Travis Swicegood to AUTHORS.

0.6.1

- Add Chris Rosenthal to AUTHORS.
- Fix multi-file input to csvsql. (#193)
- Passing –snifflimit=0 to disable dialect sniffing. (#190)
- Add aarcro to the AUTHORS file.
- Improve performance of csvgrep. (#204)
- Add Matt Dudys to AUTHORS.
- Add support for –skipinitialspace. (#201)
- Add Joakim Lundborg to AUTHORS.
- Add -no-inference option to in2csv and csvsql. (#206)
- Add Federico Scrinzi to AUTHORS file.
- Add –no-header-row to all tools. (#189)
- Fix csvstack blowing up on empty files. (#209)

6.5. 0.7.2

- Add Chris Rosenthal to AUTHORS file.
- Add –db-schema option to csvsql. (#216)
- Add Shane StClair to AUTHORS file.
- Add –no-inference support to csvsort. (#222)

0.5.0

- Implement geojson support in csvjson. (#159)
- Optimize writing of eight bit codecs. (#175)
- Created csvpy. (#44)
- Support –not-columns for excluding columns. (#137)
- · Add Jan Schulz to AUTHORS file.
- Add Windows scripts. (#111, #176)
- csvjoin, csvsql and csvstack will no longer hold open all files. (#178)
- Added Noah Hoffman to AUTHORS.
- Make csvlook output compatible with emacs table markup. (#174)

0.4.4

- Add Derek Wilson to AUTHORS.
- Add Kevin Schaul to AUTHORS.
- Add DBF support to in2csv. (#11, #160)
- Support –zero option for zero-based column indexing. (#144)
- Support mixing nulls and blanks in string columns.
- Add –blanks option to csvsql. (#149)
- Add multi-file (glob) support to csvsql. (#146)
- Add Gregory Temchenko to AUTHORS.
- Add –no-create option to csvsql. (#148)
- Add Anton Ian Sipos to AUTHORS.
- Fix broken pipe errors. (#150)

0.4.3

• Begin CHANGELOG (a bit late, I'll admit).
