Index 27
This is the documentation for cysignals, a package to deal with interrupts and signal handling in Cython code.

When writing Cython code, special care must be taken to ensure that the code can be interrupted with CTRL-C. Since Cython optimizes for speed, Cython normally does not check for interrupts. For example, code like the following cannot be interrupted in Cython:

```python
while True:
    pass
```

While this is running, pressing CTRL-C has no effect. The only way out is to kill the Python process. On certain systems, you can still quit Python by typing CTRL-\ (sending a Quit signal) instead of CTRL-C. The package cysignals provides functionality to deal with this, see Interrupt handling.

Besides this, cysignals also provides Python functions/classes to deal with signals. These are not directly related to interrupts in Cython, but provide some supporting functionality beyond what Python provides, see Signal-related interfaces for Python code.
Dealing with interrupts and other signals using `sig_check` and `sig_on`:

### 1.1 Interrupt handling

cysignals provides two related mechanisms to deal with interrupts:

- Use `sig_check()` if you are writing mixed Cython/Python code. Typically this is code with (nested) loops where every individual statement takes little time.

- Use `sig_on()` and `sig_off()` if you are calling external C libraries or inside pure Cython code (without any Python functions) where even an individual statement, like a library call, can take a long time.

The functions `sig_check()`, `sig_on()` and `sig_off()` can be put in all kinds of Cython functions: `def`, `cdef` or `cpdef`. You cannot put them in pure Python code (files with extension `.py`).

#### 1.1.1 Basic example

The `sig_check()` in the loop below ensures that the loop can be interrupted by CTRL-C:

```cython
def sine_sum(double x, long count):
    cdef double s = 0
    for i in range(count):
        sig_check()
        s += sin(i*x)
    return s
```

See the example directory for this complete working example.

**Note:** Cython `cdef` or `cpdef` functions with a return type (like `cdef int myfunc();`) need to have an `except` value to propagate exceptions. Remember this whenever you write `sig_check()` or `sig_on()` inside such a function, otherwise you will see a message like `Exception KeyboardInterrupt: KeyboardInterrupt()` in `<function name> ignored`. 

---

INTERRUPT/SIGNAL HANDLING

CHAPTER ONE

INTERRUPT/SIGNAL HANDLING
1.1.2 Using sig_check()

sig_check() can be used to check for pending interrupts. If an interrupt happens during the execution of C or Cython code, it will be caught by the next sig_check(), the next sig_on() or possibly the next Python statement. With the latter we mean that certain Python statements also check for interrupts, an example of this is the print statement. The following loop can be interrupted:

```python
>>> while True:
    ...    print("Hello")
```

The typical use case for sig_check() is within tight loops doing complicated stuff (mixed Python and Cython code, potentially raising exceptions). It is reasonably safe to use and gives a lot of control, because in your Cython code, a KeyboardInterrupt can only be raised during sig_check():

```python
from cysignals.signals cimport sig_check
def sig_check_example():
    for x in foo:
        # (one loop iteration which does not take a long time)
        sig_check()
```

This KeyboardInterrupt is treated like any other Python exception and can be handled as usual:

```python
from cysignals.signals cimport sig_check
def catch_interrupts():
    try:
        while some_condition():
            sig_check()
            do_something()
    except KeyboardInterrupt:
        # (handle interrupt)
```

Of course, you can also put the try/except inside the loop in the example above.

The function sig_check() is an extremely fast inline function which should have no measurable effect on performance.

1.1.3 Using sig_on() and sig_off()

Another mechanism for interrupt handling is the pair of functions sig_on() and sig_off(). It is more powerful than sig_check() but also a lot more dangerous. You should put sig_on() before and sig_off() after any Cython code which could potentially take a long time. These two must always be called in pairs, i.e. every sig_on() must be matched by a closing sig_off().

In practice your function will probably look like:

```python
from cysignals.signals cimport sig_on, sig_off
def sig_example():
    # (some harmless initialization)
    sig_on()
    # (a long computation here, potentially calling a C library)
    sig_off()
    # (some harmless post-processing)
    return something
```

It is possible to put sig_on() and sig_off() in different functions, provided that sig_off() is called before the function which calls sig_on() returns. The reason is that sig_on() is implemented using setjmp(), which requires that the stack frame is kept alive. Therefore, the following code is invalid:
# INVALID code because we return from function foo() without calling sig_off() first.

cdef foo():
    sig_on()

def f1():
    foo()
    sig_off()

But the following is valid since you cannot call foo interactively:

from cysignals.signals cimport sig_on, sig_off

cdef int foo():
    sig_off()
    return 2+2

def f1():
    sig_on()
    return foo()

For clarity however, it is best to avoid this.

A common mistake is to put sig_off() towards the end of a function (before the return) when the function has multiple return statements. So make sure there is a sig_off() before every return (and also before every raise).

**Warning:** The code inside sig_on() should be pure C or Cython code. If you call any Python code or manipulate any Python object (even something trivial like x = []), an interrupt can mess up Python’s internal state. When in doubt, try to use sig_check() instead.

Also, when an interrupt occurs inside sig_on(), code execution immediately stops without cleaning up. For example, any memory allocated inside sig_on() is lost. See *Signal handling without exceptions* for ways to deal with this.

When the user presses CTRL-C inside sig_on(), execution will jump back to sig_on() (the first one if there is a stack) and sig_on() will raise KeyboardInterrupt. As with sig_check(), this exception can be handled in the usual way:

from cysignals.signals cimport sig_on, sig_off
def catch_interrupts():
    try:
        sig_on()  # This must be INSIDE the try
        # (some long computation)
        sig_off()
    except KeyboardInterrupt:
        # (handle interrupt)

It is possible to stack sig_on() and sig_off(). If you do this, the effect is exactly the same as if only the outer sig_on()/sig_off() was there. The inner ones will just change a reference counter and otherwise do nothing. Make sure that the number of sig_on() calls equal the number of sig_off() calls:

from cysignals.signals cimport sig_on, sig_off
def f1():

(continues on next page)
Extra care must be taken with exceptions raised inside `sig_on()`. The problem is that, if you do not do anything special, the `sig_off()` will never be called if there is an exception. If you need to `raise` an exception yourself, call a `sig_off()` before it:

```python
from cysignals.signals cimport sig_on, sig_off
def raising_an_exception():
    sig_on()
    # (some long computation)
    if (something_failed):
        sig_off()
        raise RuntimeError("something failed")
    # (some more computation)
    sig_off()
    return something
```

Alternatively, you can use `try/finally` which will also catch exceptions raised by subroutines inside the `try`:

```python
from cysignals.signals cimport sig_on, sig_off
def try_finally_example():
    sig_on()  # This must be OUTSIDE the try
    try:
        # (some long computation, potentially raising exceptions)
        return something
    finally:
        sig_off()
```

If you also want to catch this exception, you need a nested `try`:

```python
from cysignals.signals cimport sig_on, sig_off
def try_finally_and_catch_example():
    try:
        sig_on()
        try:
            # (some long computation, potentially raising exceptions)
        finally:
            sig_off()
    except Exception:
        print("Trouble! Trouble!")
```

`sig_on()` is implemented using the C library call `setjmp()` which takes a very small but still measurable amount of time. In very time-critical code, one can conditionally call `sig_on()` and `sig_off()`:

```python
from cysignals.signals cimport sig_on, sig_off
def conditional_sig_on_example(long n):
    if n > 100:
        sig_on()
```

(continues on next page)
This should only be needed if both the check (n > 100 in the example) and the code inside the `sig_on()` block take very little time.

### 1.2 Handling other signals

Apart from handling interrupts, `sig_on()` provides more general signal handling. For example, it handles `alarm()` time-outs by raising an `AlarmInterrupt` (inherited from `KeyboardInterrupt`) exception.

If the code inside `sig_on()` would generate a segmentation fault or call the C function `abort()` (or more generally, raise any of SIGSEGV, SIGILL, SIGABRT, SIGFPE, SIGBUS), this is caught by the interrupt framework and an exception is raised (`RuntimeError` for SIGABRT, `FloatingPointError` for SIGFPE and the custom exception `SignalError`, based on `BaseException`, otherwise):

```python
from libc.stdlib cimport abort
from cysignals.signals cimport sig_on, sig_off

def abort_example():
    sig_on()
    abort()
    sig_off()

>>> abort_example()
Traceback (most recent call last):
  ...  
RuntimeError: Aborted
```

This exception can be handled by a `try/except` block as explained above. A segmentation fault or `abort()` unguarded by `sig_on()` would simply terminate the Python Interpreter. This applies only to `sig_on()`, the function `sig_check()` only deals with interrupts and alarms.

Instead of `sig_on()`, there is also a function `sig_str(s)`, which takes a C string `s` as argument. It behaves the same as `sig_on()`, except that the string `s` will be used as a string for the exception. `sig_str(s)` should still be closed by `sig_off()`. Example Cython code:

```python
from libc.stdlib cimport abort
from cysignals.signals cimport sig_str, sig_off

def abort_example_with_sig_str():
    sig_str("custom error message")
    abort()
    sig_off()

Executing this gives:

```python
>>> abort_example_with_sig_str()
Traceback (most recent call last):
  ...  
RuntimeError: custom error message
```

With regard to ordinary interrupts (i.e. SIGINT), `sig_str(s)` behaves the same as `sig_on()`: a simple `KeyboardInterrupt` is raised.
1.3 Further topics in interrupt/signal handling

1.3.1 Testing interrupts

When writing documentation, one sometimes wants to check that certain code can be interrupted in a clean way. The best way to do this is to use `cysignals.alarm()`.

The following is an example of a doctest demonstrating that the SageMath function `factor()` can be interrupted:

```python
>>> from cysignals.alarm import alarm, AlarmInterrupt

>>> try:
...    alarm(0.5)
...    factor(10**1000 + 3)
... except AlarmInterrupt:
...    print("alarm!")
alarm!
```

If you use the SageMath doctesting framework, you can instead doctest the exception in the usual way (the Python doctest module exits whenever a `KeyboardInterrupt` is raised in a doctest). To avoid race conditions, make sure that the calls to `alarm()` and the function you want to test are in the same doctest:

```python
>>> alarm(0.5); factor(10**1000 + 3)
Traceback (most recent call last):
...  AlarmInterrupt
```

1.3.2 Signal handling without exceptions

There are several more specialized functions for dealing with interrupts. As mentioned above, `sig_on()` makes no attempt to clean anything up (restore state or freeing memory) when an interrupt occurs. In fact, it would be impossible for `sig_on()` to do that. If you want to add some cleanup code, use `sig_on_no_except()` for this. This function behaves exactly like `sig_on()`, except that any exception raised (like `KeyboardInterrupt` or `RuntimeError`) is not yet passed to Python. Essentially, the exception is there, but we prevent Cython from looking for the exception. Then `cython_check_exception()` can be used to make Cython look for the exception.

Normally, `sig_on_no_except()` returns 1. If a signal was caught and an exception raised, `sig_on_no_except()` instead returns 0. The following example shows how to use `sig_on_no_except()`:

```python
def no_except_example():
    if not sig_on_no_except():
        # (clean up messed up internal state)
        # Make Cython realize that there is an exception.
        # It will look like the exception was actually raised
        # by cython_check_exception().
        cython_check_exception()
        # (some long computation, messing up internal state of objects)
        sig_off()
```

There is also a function `sig_str_no_except(s)` which is analogous to `sig_str(s).

Note: See the file `src/cysignals/tests.pyx` for more examples of how to use the various `sig_*()` functions.
1.3.3 Releasing the Global Interpreter Lock (GIL)

All the functions related to interrupt and signal handling do not require the Python GIL (if you don’t know what this means, you can safely ignore this section), they are declared `nogil`. This means that they can be used in Cython code inside `with nogil` blocks. If `sig_on()` needs to raise an exception, the GIL is temporarily acquired internally.

If you use C libraries without the GIL and you want to raise an exception before calling `sig_error()`, remember to acquire the GIL while raising the exception. Within Cython, you can use a `with gil context`.

---

**Warning:** The GIL should never be released or acquired inside a `sig_on()` block. If you want to use a `with nogil` block, put both `sig_on()` and `sig_off()` inside that block. When in doubt, choose to use `sig_check()` instead, which is always safe to use.

1.4 Debugging Python crashes

If `cysignals` is imported, it sets up a hook which triggers when Python crashes. For example, it would be triggered on a segmentation fault outside a `sig_on()` block.

When a crash happens, first a simple C backtrace is printed if supported by the C library on the system. Then GDB is run to print a much more complete backtrace (except on OS X, where running a debugger requires special privileges). For your convenience, these GDB backtraces are also saved to a logfile.

Finally, this familiar message is shown:

```
This probably occurred because a *compiled* module has a bug
in it and is not properly wrapped with sig_on(), sig_off().
Python will now now terminate.
```
Defining error callbacks for external libraries using \texttt{sig_error}:

### 2.1 Error handling in C libraries

Some C libraries can produce errors and use some sort of callback mechanism to report errors: an external error handling function needs to be set up which will be called by the C library if an error occurs.

The function \texttt{sig\_error()} can be used to deal with these errors. This function may only be called within a \texttt{sig\_on()} block (otherwise the Python interpreter will crash hard) after raising a Python exception. You need to use the Python/C API for this and call \texttt{sig\_error()} after calling some variant of \texttt{PyErr\_SetObject()}. Even within Cython, you cannot use the \texttt{raise} statement, because then the \texttt{sig\_error()} will never be executed. The call to \texttt{sig\_error()} will use the \texttt{sig\_on()} machinery such that the exception will be seen by \texttt{sig\_on()}.

A typical error handler implemented in Cython would look as follows:

```python
from cysignals.signals cimport sig_error
from cpython.exc cimport PyErr_SetString

cdef void error_handler(char *msg):
    PyErr_SetString(RuntimeError, msg)
    sig_error()
```

Exceptions which are raised this way can be handled as usual by putting the \texttt{sig\_on()} in a \texttt{try/except} block. For example, the package \texttt{cypari2} provides a wrapper around the number theory library PARI/GP. The \texttt{error handler} has a callback which turns errors from PARI/GP into Python exceptions of type \texttt{PariError}. This can be handled as follows:

```python
from cysignals.signals cimport sig_on, sig_off
def handle_pari_error():
    try:
        sig_on()  # This must be INSIDE the try
        # (call to PARI)
        sig_off()
    except PariError:
        # (handle error)
```

SageMath uses this mechanism for libGAP, GLPK, NTL and PARI.
cysignals provides further support for system calls related to signals:

### 3.1 Python interface to signal handlers

In this module, we distinguish between the “OS-level” signal handler and the “Python-level” signal handler. The Python function `signal.signal()` sets both of these: it sets the Python-level signal handler to the function specified by the user. It also sets the OS-level signal handler to a specific C function which calls the Python-level signal handler.

The Python `signal` module does not allow access to the OS-level signal handler (in particular, it does not allow one to temporarily change a signal handler if the OS-level handler was not the Python one).

**class** `cysignals.pysignals.SigAction`

An opaque object representing an OS-level signal handler.

The only legal initializers are `signal.SIG_DFL` (the default), `signal.SIG_IGN` and another `SigAction` object (which is copied).

**EXAMPLES:**
```python
>>> from cysignals.pysignals import SigAction
>>> SigAction()
<SigAction with sa_handler=SIG_DFL>
>>> import signal
>>> SigAction(signal.SIG_DFL)
<SigAction with sa_handler=SIG_DFL>
>>> SigAction(signal.SIG_IGN)
<SigAction with sa_handler=SIG_IGN>
>>> A = SigAction(signal.SIG_IGN)
>>> SigAction(A)
<SigAction with sa_handler=SIG_IGN>
>>> SigAction(A) == A
True
```

**TESTS:**
```python
>>> SigAction(42)
Traceback (most recent call last):
  ...
TypeError: cannot initialize SigAction from <... 'int'>
```

**class** `cysignals.pysignals.changesignal`

Context to temporarily change a signal handler.
This should be used as follows:

```python
with changesignal(sig, action):
    ...
```

Inside the context, code behaves as if `signal.signal(sig, action)` was called. When leaving the context, the signal handler is restored to what it was before. Both the Python-level and OS-level signal handlers are restored.

**EXAMPLES:**

```python
>>> from cysignals.pysignals import changesignal
got signal
>>> import os, signal
>>> def handler(*args):
...     print("got signal")
... _ = signal.signal(signal.SIGQUIT, signal.SIG_IGN)
>>> with changesignal(signal.SIGQUIT, handler):
...     os.kill(os.getpid(), signal.SIGQUIT)
got signal
>>> os.kill(os.getpid(), signal.SIGQUIT)
```

```
>>> with changesignal(signal.SIGQUIT, handler):
...     setossignal(signal.SIGQUIT, signal.SIG_DFL)
...     raise
Traceback (most recent call last):
... Exception: just testing
```

### class `cysignals.pysignals.containsignals`

Context to revert any changes to given signal handlers and block those signals.

This should be used as follows:

```python
with containsignals(signals):
    ...
```

where `signals` is a list of signals (by default, all signals numbered from 1 to 31 except for SIGKILL and SIGSTOP, which cannot be handled).

When entering the context, the current handlers of those signals are saved. They are restored when exiting the context. This is mainly meant to prevent unwanted changes to signal handlers that other code may make. Both the Python-level and OS-level signal handlers are saved and restored.

Also, the signals from the list `signals` are blocked. So any newly-installed signal handlers are prevented from being triggered.

**EXAMPLES:**

```python
>>> from cysignals.pysignals import containsignals
got signal
>>> import os, signal
>>> def handler(*args):
...     print("got signal")
... _ = signal.signal(signal.SIGBUS, handler)
>>> with containsignals([signal.SIGBUS]):
...     _ = signal.signal(signal.SIGBUS, signal.SIG_DFL)
...     raise
Traceback (most recent call last):
... Exception: just testing
```

```python
>>> with containsignals([signal.SIGBUS]):
...     # This signal is delivered when exiting the context
...     os.kill(os.getpid(), signal.SIGBUS)
...     print("no signal yet")
no signal yet
```

```python
>>> with containsignals([signal.SIGBUS]):
...     # This signal is delivered when exiting the context
...     os.kill(os.getpid(), signal.SIGBUS)
...     print("no signal yet")
got signal
```
The same example but now containing all signals:

```python
>>> with containsignals() as C:
...     print("blocked {0} signals".format(len(C.oldhandlers)))
...     _ = signal.signal(signal.SIGBUS, signal.SIG_DFL)
...     # This signal is delivered when exiting the context
...     os.kill(os.getpid(), signal.SIGBUS)
...     print("no signal yet")
blocked 29 signals
no signal yet
```

This time, we send a signal which is not contained. We set a new handler, which is not blocked or changed by the context:

```python
def fancyhandler(*args):
    print("fancy!")
>>> with containsignals([signal.SIGINT]):
...     _ = signal.signal(signal.SIGBUS, fancyhandler)
...     os.kill(os.getpid(), signal.SIGBUS)
fancy!
```

cysignals.pysignals.getossignal(sig)

Get the OS-level signal handler.

This returns an opaque object of type `SigAction` which can only be used in a future call to `setossignal()`.

**EXAMPLES:**

```python
>>> from cysignals.pysignals import getossignal
>>> import signal

>>> getossignal(signal.SIGINT)
<SigAction with sa_handler=0x...>

>>> getossignal(signal.SIGUSR1)
<SigAction with sa_handler=SIG_DFL>

>>> def handler(*args):
...     pass

>>> _ = signal.signal(signal.SIGUSR1, handler)

>>> getossignal(signal.SIGUSR1)
<SigAction with sa_handler=0x...>
```

Check whether a signal is handled by the Python signal handler:

```python
>>> from cysignals.pysignals import python_os_handler

>>> getossignal(signal.SIGUSR1) == python_os_handler
True

>>> _ = signal.signal(signal.SIGUSR1, signal.SIG_IGN)

>>> getossignal(signal.SIGUSR1) == python_os_handler
False

>>> getossignal(signal.SIGABRT) == python_os_handler
False
```

**TESTS:**

```python
>>> getossignal(None)
Traceback (most recent call last):
...```

(continues on next page)
cysignals Documentation, Release 1.10.2

(continued from previous page)

```python
>>> getossignal(-1)
Traceback (most recent call last):
...
OSError: [Errno 22] Invalid argument
```

cysignals.pysignals.setossignal(sig, action)

Set the OS-level signal handler to action, which should either be signal.SIG_DFL or signal.SIG_IGN or a SigAction object returned by an earlier call to getossignal() or setossignal().

Return the old signal handler.

**EXAMPLES:**

```python
>>> from cysignals.pysignals import setossignal
>>> import os, signal
>>> def handler(*args):
...    print("got signal")
>>> _, signal.signal(signal.SIGHUP, handler)
got signal
>>> pyhandler = setossignal(signal.SIGHUP, signal.SIG_IGN)
>>> pyhandler
<SigAction with sa_handler=0x...>
>>> os.kill(os.getpid(), signal.SIGHUP)
got signal
>>> setossignal(signal.SIGHUP, signal.SIG_DFL) == pyhandler
True
```

**TESTS:**

```python
>>> setossignal(signal.SIGHUP, None)
Traceback (most recent call last):
...
TypeError: cannot initialize SigAction from <... 'NoneType'>
>>> setossignal(-1, signal.SIG_DFL)
Traceback (most recent call last):
...
OSError: [Errno 22] Invalid argument
```

cysignals.pysignals.setsignal(sig, action, osaction=None)

Set the Python-level signal handler for signal sig to action. If osaction is given, set the OS-level signal handler to osaction. If osaction is None (the default), change only the Python-level handler and keep the OS-level handler.

Return the old Python-level handler.

**EXAMPLES:**

```python
>>> from cysignals.pysignals import *
>>> def handler(*args):
...    print("got signal")
>>> _, signal.signal(signal.SIGSEGV, handler)
>>> A = getossignal(signal.SIGILL)
>>> _, setsignal(signal.SIGILL, getsignal(signal.SIGSEGV))
>>> getossignal(signal.SIGILL) == A
```

(continues on next page)
True
>>> _ = setossignal(signal.SIGILL, getossignal(signal.SIGSEGV))
>>> import os
>>> os.kill(os.getpid(), signal.SIGILL)
got signal
>>> setsignal(signal.SIGILL, signal.SIG_DFL)
<function handler at 0x...>
>>> _ = setsignal(signal.SIGALRM, signal.SIG_DFL, signal.SIG_IGN)
>>> os.kill(os.getpid(), signal.SIGALRM)
>>> _ = setsignal(signal.SIGALRM, handler, getossignal(signal.SIGSEGV))
>>> os.kill(os.getpid(), signal.SIGALRM)
got signal

TESTS:

>>> setsignal(-1, signal.SIG_DFL)
Traceback (most recent call last):
... 
OSError: [Errno 22] Invalid argument

3.2 Interface to the pselect() and sigprocmask() system calls

This module defines a class PSelector which can be used to call the system call pselect() and which can also be used in a with statement to block given signals until PSelector.pselect() is called.

3.2.1 Waiting for subprocesses

One possible use is to wait with a timeout until any child process exits, as opposed to os.wait() which doesn’t have a timeout or multiprocessing.Process.join() which waits for one specific process.

Since SIGCHLD is ignored by default, we first need to install a signal handler for SIGCHLD. It doesn’t matter what it does, as long as the signal isn’t ignored:

>>> import signal
>>> def dummy_handler(sig, frame):
...     pass
>>> _ = signal.signal(signal.SIGCHLD, dummy_handler)

We wait for a child created using the subprocess module:

>>> from cysignals.pselect import PSelector
>>> from subprocess import *
>>> with PSelector([signal.SIGCHLD]) as sel:
...     p = Popen(["sleep", "1"])
...     _ = sel.sleep()
...     p.poll()  # p should be finished
0

Now using the multiprocessing module:

>>> from cysignals.pselect import PSelector
>>> from multiprocessing import *
>>> import time
(continues on next page)
>>> with PSelecter([signal.SIGCHLD]) as sel:
...    p = Process(target=time.sleep, args=(1,))
...    p.start()
...    _ = sel.sleep()
...    p.is_alive()  # p should be finished
False

class cysignals.pselect.PSelecter

This class gives an interface to the pselect system call.

It can be used in a with statement to block given signals such that they can only occur during the pselect() or sleep() calls.

As an example, we block the SIGHUP and SIGALRM signals and then raise a SIGALRM signal. The interrupt will only be seen during the sleep() call:

```python
>>> from cysignals import AlarmInterrupt
>>> from cysignals.pselect import PSelecter
>>> import os, signal, time
>>> with PSelecter([signal.SIGHUP, signal.SIGALRM]) as sel:
...    os.kill(os.getpid(), signal.SIGALRM)
...    time.sleep(0.5)  # Simply sleep, no interrupt detected
...    try:
...        _ = sel.sleep(1)  # Interrupt seen here
...    except AlarmInterrupt:
...        print("Interrupt OK")
```

Warning: If SIGCHLD is blocked inside the with block, then you should not use Popen().wait() or Process().join() because those might block, even if the process has actually exited. Use non-blocking alternatives such as Popen.poll() or multiprocessing.active_children() instead.

__enter__()

Block signals chosen during __init__() in this with block.

OUTPUT: self

TESTS:

Test nesting, where the inner with statements should have no influence, in particular they should not unblock signals which were already blocked upon entering:

```python
>>> from cysignals import AlarmInterrupt
>>> from cysignals.pselect import PSelecter
>>> import os, signal
>>> with PSelecter([signal.SIGALRM]) as sel:
...    os.kill(os.getpid(), signal.SIGALRM)
...    with PSelecter([signal.SIGFPE]) as sel2:
...        _ = sel2.sleep(0.1)
...    with PSelecter([signal.SIGALRM]) as sel3:
...        _ = sel3.sleep(0.1)
...    try:
...        _ = sel1.sleep(0.1)
...    except AlarmInterrupt:
...        print("Interrupt OK")
```

Interrupt OK

18 Chapter 3. Signal-related interfaces for Python code
__exit__(*args)
Reset signal mask to what it was before __enter__().

EXAMPLES:
Install a SIGCHLD handler:

```python
>>> import signal
>>> def child_handler(sig, frame):
...    global got_child
...    got_child = 1
>>> _ = signal.signal(signal.SIGCHLD, child_handler)
>>> got_child = 0
```

Start a process which will cause a SIGCHLD signal:

```python
>>> import time
>>> from multiprocessing import *
>>> from cysignals.pselect import PSelecter, interruptible_sleep

w = PSelecter([signal.SIGCHLD])
with w:
    p = Process(target=time.sleep, args=(0.25,))
    t0 = time.time()
    p.start()
```

This sleep should be interruptible now:

```python
>>> interruptible_sleep(1)
>>> t = time.time() - t0
>>> (0.2 <= t <= 0.9) or t
True
>>> got_child
1
>>> p.join()
```

pselect (rlist, wlist, xlist, timeout)
Wait until one of the given files is ready, or a signal has been received, or until timeout seconds have past.

INPUT:
• rlist – (default: []) a list of files to wait for reading.
• wlist – (default: []) a list of files to wait for writing.
• xlist – (default: []) a list of files to wait for exceptions.
• timeout – (default: None) a timeout in seconds, where None stands for no timeout.

OUTPUT: A 4-tuple (rready, wready, xready, tmout) where the first three are lists of file descriptors which are ready, that is a subset of (rlist, wlist, xlist). The fourth is a boolean which is True if and only if the command timed out. If pselect was interrupted by a signal, the output is ([], [], [], False).

See also:
Use the sleep() method instead if you don’t care about file descriptors.

EXAMPLES:
The file /dev/null should always be available for reading and writing:
A list of various files, all of them should be ready for reading. Also create a pipe, which should be ready for writing, but not reading (since nothing has been written):

```python
>>> import os, sys
>>> f = open(os.devnull, "r")
>>> g = open(sys.executable, "r")
>>> (pr, pw) = os.pipe()
>>> r, w, x, t = PSelecter().pselect([f,g,pr,pw], [pw], [pr,pw])
>>> len(r), len(w), len(x), t
(2, 1, 0, False)
```

Checking for exceptions on the pipe should simply time out:

```python
>>> sel.pselect(xlist=[pr,pw], timeout=0.2)
([], [], [], True)
```

**TESTS:**

It is legal (but silly) to list the same file multiple times:

```python
>>> r, w, x, t = PSelecter().pselect([f,g,f,f,g])
>>> len(r)
5
```

Invalid input:

```python
>>> PSelecter().pselect([None])
Traceback (most recent call last):
... TypeError: an integer is required
```

Open a file and close it, but save the (invalid) file descriptor:

```python
>>> f = open(os.devnull, "r")
>>> n = f.fileno()
>>> f.close()
>>> PSelecter().pselect([n])
Traceback (most recent call last):
... OSError: ...
```

```python
sleep(timeout)
```

Wait until a signal has been received, or until timeout seconds have past.

This is implemented as a special case of `pselect()` with empty lists of file descriptors.

**INPUT:**

- timeout – (default: None) a timeout in seconds, where None stands for no timeout.

**OUTPUT:** A boolean which is True if the call timed out, False if it was interrupted.
EXAMPLES:

A simple wait with timeout:

```python
>>> from cysignals.pselect import PSelecter
>>> sel = PSelecter()
>>> sel.sleep(timeout=0.1)
```

True

0 or negative time-outs are allowed, `sleep` should then return immediately:

```python
>>> sel.sleep(timeout=0)
```

True

```python
>>> sel.sleep(timeout=-123.45)
```

True

cysignals.pselect.get_fileno(f)

Return the file descriptor of `f`.

INPUT:

- `f` – an object with a `.fileno` method or an integer, which is a file descriptor.

OUTPUT: A `C long` representing the file descriptor.

EXAMPLES:

```python
>>> from os import devnull
>>> from cysignals.pselect import get_fileno
>>> get_fileno(open(devnull)) > 2
```

True

```python
>>> get_fileno(42)
```

42

```python
>>> get_fileno(None)
```

Traceback (most recent call last):

```
TypeError: an integer is required
```

```python
>>> get_fileno(-1)
```

Traceback (most recent call last):

```
ValueError: Invalid file descriptor
```

```python
>>> get_fileno(2**30)
```

Traceback (most recent call last):

```
ValueError: Invalid file descriptor
```

cysignals.pselect.interruptible_sleep(seconds)

Sleep for seconds seconds or until a signal arrives. This behaves like `time.sleep` from Python versions <= 3.4 (before PEP 475).

EXAMPLES:

```python
>>> from cysignals.pselect import interruptible_sleep
>>> interruptible_sleep(0.5)
```

We set up an alarm handler doing nothing and check that the alarm interrupts the sleep:

```python
>>> import signal, time
>>> def alarm_handler(sig, frame):
...    pass
```

(continues on next page)
>>> _ = signal.signal(signal.SIGALRM, alarm_handler)
>>> t0 = time.time()
>>> _ = signal.alarm(1)
>>> interruptible_sleep(2)
>>> t = time.time() - t0
>>> (0.9 <= t <= 1.9) or t
True

TESTS:

>>> interruptible_sleep(0)
>>> interruptible_sleep(-1)
Traceback (most recent call last):
...
ValueError: sleep length must be non-negative

Reset the signal handlers:

>>> from cysignals import init_cysignals
>>> _ = init_cysignals()
