dependency_injection.py Documentation

Release 1.0.0

Gittip, LLC

December 18, 2013

Contents

This Python library defines a helper for building a dependency injection framework.

CHAPTER 1

Installation

`dependency_injection` is available on GitHub and on PyPI:

```
$ pip install dependency_injection
```

We test against Python 2.6, 2.7, 3.2, and 3.3.

`dependency_injection` is in the public domain.

CHAPTER 2

What is Dependency Injection?

When you define a function you specify its *parameters*, and when you call the function you pass in *arguments* for those parameters. Dependency injection means dynamically passing arguments to a function based on the parameters it defines. So if you define a function:

```
>>> def foo(bar, baz):
...     pass
```

Then you are advertising to a dependency injection framework that your function wants to have the `bar` and `baz` objects passed into it. What `bar` and `baz` resolve to depends on the dependency injection framework. This library provides a helper, `resolve_dependencies`, for building your own dependency injection framework. It doesn't provide such a framework itself, because that would take away all the fun.

CHAPTER 3

API Reference

dependency_injection.**resolve_dependencies**(*function*, *available*)

Given a function object and a mapping of available dependencies, return a `namedtuple` that has arguments to suit the function's parameters.

Parameters

- **function** – a function object (not just a function name)
- **available** – a `dict` mapping arbitrary names to objects

Returns a `namedtuple` representing the arguments to use in calling the function

The return value of this function is a `namedtuple` with these attributes:

0. `as_args` - a `tuple` of argument values
1. `as_kwargs` - a `dict` of keyword arguments
2. `signature` - a `namedtuple` as returned by `get_signature`

The `as_args` and `as_kwargs` arguments are functionally equivalent. You could call the function using either one and you'd get the same result, and which one you use depends on the needs of the dependency injection framework you're writing, and your personal preference.

This is the main function you want to use from this library. The idea is that in your dependency injection framework, you call this function to resolve the dependencies for a function, and then call the function. So here's a function:

```
>>> def foo(bar, baz):
...     return bar + baz
```

And here's the basics of a dependency injection framework:

```
>>> def inject_dependencies(func):
...     my_state = {'bar': 1, 'baz': 2, 'bloo': 'blee'}
...     dependencies = resolve_dependencies(func, my_state)
...     return func(*dependencies.as_args)
...
```

And here's what it looks like to call it:

```
>>> inject_dependencies(foo)
3
```

dependency_injection.**get_signature**(*function*)

Given a function object, return a `namedtuple` representing the function signature.

Parameters **function** – a function object (not just a function name)

Returns a `namedtuple` representing the function signature

This function returns a `namedtuple` with these items:

0. `parameters` - a `tuple` of all parameters, in the order they were defined
1. `required` - a `tuple` of required parameters, in the order they were defined
2. `optional` - a `dict` of optional parameters mapped to their defaults

For example, if you have this function:

```
>>> def foo(bar, baz=1):
...     pass
...
```

Then `get_signature` will return:

```
>>> get_signature(foo)
Signature(parameters=('bar', 'baz'), required=('bar',), optional={'baz': 1})
```

This function is a helper for `resolve_dependencies`.
