gCloud Documentation

Release 0.8.0

Google Cloud Platform

September 08, 2016

CHAPTER 1

Base Client

Base classes for client used to interact with Google Cloud APIs.

class gcloud.client.**Client**(*credentials=None*, *http=None*)
Bases: gcloud.client._ClientFactoryMixin

Client to bundle configuration needed for API requests.

Assumes that the associated _connection_class only accepts http and credentials in its constructor.

Parameters

- **credentials** (oauth2client.client.OAuth2Credentials or NoneType) – The OAuth2 Credentials to use for the connection owned by this client. If not passed (and if no http object is passed), falls back to the default inferred from the environment.
- **http** (httplib2.Http or class that defines request().) – An optional HTTP object to make requests. If not passed, an http object is created that is bound to the credentials for the current object.

from_service_account_json(*json_credentials_path*, **args*, ***kwargs*)
Factory to retrieve JSON credentials while creating client.

Parameters

- **json_credentials_path** (*string*) – The path to a private key file (this file was given to you when you created the service account). This file must contain a JSON object with a private key and other credentials information (downloaded from the Google APIs console).
- **args** (*tuple*) – Remaining positional arguments to pass to constructor.
- **kwargs** (*dictionary*) – Remaining keyword arguments to pass to constructor.

Return type *gcloud.pubsub.client.Client*

Returns The client created with the retrieved JSON credentials.

Raises class:*TypeError* if there is a conflict with the kwargs and the credentials created by the factory.

from_service_account_p12(*client_email*, *private_key_path*, **args*, ***kwargs*)
Factory to retrieve P12 credentials while creating client.

Note: Unless you have an explicit reason to use a PKCS12 key for your service account, we recommend using a JSON key.

Parameters

- **client_email** (*string*) – The e-mail attached to the service account.
- **private_key_path** (*string*) – The path to a private key file (this file was given to you when you created the service account). This file must be in P12 format.
- **args** (*tuple*) – Remaining positional arguments to pass to constructor.
- **kwargs** (*dictionary*) – Remaining keyword arguments to pass to constructor.

Return type *gcloud.client.Client*

Returns The client created with the retrieved P12 credentials.

Raises class:*TypeError* if there is a conflict with the kwargs and the credentials created by the factory.

class gcloud.client.**JSONClient**(*project=None*, *credentials=None*, *http=None*)

Bases: *gcloud.client.Client*, gcloud.client._ClientProjectMixin

Client to for Google JSON-based API.

Assumes such APIs use the `project` and the client needs to store this value.

Parameters

- **project** (*string*) – the project which the client acts on behalf of. If not passed falls back to the default inferred from the environment.
- **credentials** (`oauth2client.client.OAuth2Credentials` or `NoneType`) – The OAuth2 Credentials to use for the connection owned by this client. If not passed (and if no `http` object is passed), falls back to the default inferred from the environment.
- **http** (`httplib2.Http` or class that defines `request()`.) – An optional HTTP object to make requests. If not passed, an `http` object is created that is bound to the `credentials` for the current object.

Raises `ValueError` if the project is neither passed in nor set in the environment.

from_service_account_json(*json_credentials_path*, **args*, ***kwargs*)

Factory to retrieve JSON credentials while creating client.

Parameters

- **json_credentials_path** (*string*) – The path to a private key file (this file was given to you when you created the service account). This file must contain a JSON object with a private key and other credentials information (downloaded from the Google APIs console).
- **args** (*tuple*) – Remaining positional arguments to pass to constructor.
- **kwargs** (*dictionary*) – Remaining keyword arguments to pass to constructor.

Return type *gcloud.pubsub.client.Client*

Returns The client created with the retrieved JSON credentials.

Raises class:*TypeError* if there is a conflict with the kwargs and the credentials created by the factory.

from_service_account_p12(*client_email*, *private_key_path*, **args*, ***kwargs*)
Factory to retrieve P12 credentials while creating client.

Note: Unless you have an explicit reason to use a PKCS12 key for your service account, we recommend using a JSON key.

Parameters

- **client_email** (*string*) – The e-mail attached to the service account.
- **private_key_path** (*string*) – The path to a private key file (this file was given to you when you created the service account). This file must be in P12 format.
- **args** (*tuple*) – Remaining positional arguments to pass to constructor.
- **kwargs** (*dictionary*) – Remaining keyword arguments to pass to constructor.

Return type *gcloud.client.Client*

Returns The client created with the retrieved P12 credentials.

Raises class:*TypeError* if there is a conflict with the kwargs and the credentials created by the factory.

CHAPTER 2

Credentials Helpers

A simple wrapper around the OAuth2 credentials library.

gcloud.credentials.**generate_signed_url**(*credentials*, *resource*, *expiration*, *api_access_endpoint=''*, *method='GET'*, *content_md5=None*, *content_type=None*)

Generate signed URL to provide query-string auth'n to a resource.

Note: If you are on Google Compute Engine, you can't generate a signed URL. Follow https://github.com/GoogleCloudPlatform/gcloud-python/issues/922 for updates on this. If you'd like to be able to generate a signed URL from GCE, you can use a standard service account from a JSON file rather than a GCE service account.

Parameters

- **credentials** (oauth2client.appengine.AppAssertionCredentials) – Credentials object with an associated private key to sign text.
- **resource** (*string*) – A pointer to a specific resource (typically, /bucket-name/path/to/blob.txt).
- **expiration** (*int, long, datetime.datetime, datetime.timedelta*) – When the signed URL should expire.
- **api_access_endpoint** (*string*) – Optional URI base. Defaults to empty string.
- **method** (*string*) – The HTTP verb that will be used when requesting the URL.
- **content_md5** (*string*) – The MD5 hash of the object referenced by resource.
- **content_type** (*string*) – The content type of the object referenced by resource.

Return type string

Returns A signed URL you can use to access the resource until expiration.

gcloud.credentials.**get_credentials**()

Gets credentials implicitly from the current environment.

Note: You should not need to use this function directly. Instead, use the helper method gcloud.datastore.__init__.get_connection() which uses this method under the hood.

Checks environment in order of precedence:

- Google App Engine (production and testing)
- Environment variable GOOGLE_APPLICATION_CREDENTIALS pointing to a file with stored credentials information.
- Stored "well known" file associated with `gcloud` command line tool.
- Google Compute Engine production environment.

The file referred to in GOOGLE_APPLICATION_CREDENTIALS is expected to contain information about credentials that are ready to use. This means either service account information or user account information with a ready-to-use refresh token:

```
{                                       {
    'type': 'authorized_user',              'type': 'service_account',
    'client_id': '...',                     'client_id': '...',
    'client_secret': '...',       OR        'client_email': '...',
    'refresh_token': '...,                  'private_key_id': '...',
}                                           'private_key': '...',
                                        }
```

The second of these is simply a JSON key downloaded from the Google APIs console. The first is a close cousin of the "client secrets" JSON file used by `oauth2client.clientsecrets` but differs in formatting.

Return type `oauth2client.client.GoogleCredentials`, `oauth2client.appengine.AppAssertionCredentials`, `oauth2client.gce.AppAssertionCredentials`, `oauth2client.service_account._ServiceAc`

Returns A new credentials instance corresponding to the implicit environment.

`gcloud.credentials.`**`get_for_service_account_json`**(*json_credentials_path*, *scope=None*)

Gets the credentials for a service account with JSON key.

Parameters

- **`json_credentials_path`** (*`string`*) – The path to a private key file (this file was given to you when you created the service account). This file must contain a JSON object with a private key and other credentials information (downloaded from the Google APIs console).
- **`scope`** (*`string or tuple of string`*) – The scope against which to authenticate. (Different services require different scopes, check the documentation for which scope is required for the different levels of access to any particular API.)

Return type `oauth2client.client.GoogleCredentials`, `oauth2client.service_account._ServiceAccountCredentials`

Returns New service account or Google (for a user JSON key file) credentials object.

`gcloud.credentials.`**`get_for_service_account_p12`**(*client_email*, *private_key_path*, *scope=None*)

Gets the credentials for a service account with PKCS12 / p12 key.

Note: This method is not used by default, instead *`get_credentials()`* is used. This method is intended to be used when the environments is known explicitly and detecting the environment implicitly would be superfluous.

Parameters

- **`client_email`** (*`string`*) – The e-mail attached to the service account.

- **private_key_path** (*string*) – The path to a private key file (this file was given to you when you created the service account). This file must be in P12 format.
- **scope** (*string or tuple of string*) – The scope against which to authenticate. (Different services require different scopes, check the documentation for which scope is required for the different levels of access to any particular API.)

Return type `oauth2client.client.SignedJwtAssertionCredentials`

Returns A new `SignedJwtAssertionCredentials` instance with the needed service account settings.

CHAPTER 3

Base Connections

Shared implementation of connections to API servers.

gcloud.connection.**API_BASE_URL = 'https://www.googleapis.com'**
The base of the API call URL.

class gcloud.connection.**Connection**(*credentials=None*, *http=None*)
Bases: object

A generic connection to Google Cloud Platform.

Subclasses should understand only the basic types in method arguments, however they should be capable of returning advanced types.

If no value is passed in for http, a httplib2.Http object will be created and authorized with the credentials. If not, the credentials and http need not be related.

Subclasses may seek to use the private key from credentials to sign data.

A custom (non-httplib2) HTTP object must have a request method which accepts the following arguments:

- uri
- method
- body
- headers

In addition, redirections and connection_type may be used.

Without the use of credentials.authorize(http), a custom http object will also need to be able to add a bearer token to API requests and handle token refresh on 401 errors.

Parameters

- **credentials** (oauth2client.client.OAuth2Credentials or NoneType) – The OAuth2 Credentials to use for this connection.
- **http** (httplib2.Http or class that defines request().) – An optional HTTP object to make requests.

SCOPE = None
The scopes required for authenticating with a service.

Needs to be set by subclasses.

USER_AGENT = 'gcloud-python/0.8.0'
The user agent for gcloud-python requests.

credentials
Getter for current credentials.

Return type oauth2client.client.OAuth2Credentials or NoneType

Returns The credentials object associated with this connection.

http
A getter for the HTTP transport used in talking to the API.

Return type httplib2.Http

Returns A Http object used to transport data.

class gcloud.connection.**JSONConnection**(*credentials=None*, *http=None*)
Bases: *gcloud.connection.Connection*

A connection to a Google JSON-based API.

These APIs are discovery based. For reference: https://developers.google.com/discovery/

This defines Connection.api_request() for making a generic JSON API request and API requests are created elsewhere.

The class constants * API_BASE_URL * API_VERSION * API_URL_TEMPLATE must be updated by subclasses.

API_BASE_URL = None
The base of the API call URL.

API_URL_TEMPLATE = None
A template for the URL of a particular API call.

API_VERSION = None
The version of the API, used in building the API call's URL.

api_request(*method*, *path*, *query_params=None*, *data=None*, *content_type=None*, *api_base_url=None*, *api_version=None*, *expect_json=True*, *_target_object=None*)
Make a request over the HTTP transport to the API.

You shouldn't need to use this method, but if you plan to interact with the API using these primitives, this is the correct one to use.

Parameters

- **method** (*string*) – The HTTP method name (ie, GET, POST, etc). Required.
- **path** (*string*) – The path to the resource (ie, '/b/bucket-name'). Required.
- **query_params** (*dict*) – A dictionary of keys and values to insert into the query string of the URL. Default is empty dict.
- **data** (*string*) – The data to send as the body of the request. Default is the empty string.
- **content_type** (*string*) – The proper MIME type of the data provided. Default is None.
- **api_base_url** (*string*) – The base URL for the API endpoint. Typically you won't have to provide this. Default is the standard API base URL.
- **api_version** (*string*) – The version of the API to call. Typically you shouldn't provide this and instead use the default for the library. Default is the latest API version supported by gcloud-python.
- **expect_json** (*boolean*) – If True, this method will try to parse the response as JSON and raise an exception if that cannot be done. Default is True.

- **_target_object** (object or NoneType) – Protected argument to be used by library callers. This can allow custom behavior, for example, to defer an HTTP request and complete initialization of the object at a later time.

Raises Exception if the response code is not 200 OK.

classmethod build_api_url(*path*, *query_params=None*, *api_base_url=None*, *api_version=None*)

Construct an API url given a few components, some optional.

Typically, you shouldn't need to use this method.

Parameters

- **path** (*string*) – The path to the resource (ie, '/b/bucket-name').
- **query_params** (*dict*) – A dictionary of keys and values to insert into the query string of the URL.
- **api_base_url** (*string*) – The base URL for the API endpoint. Typically you won't have to provide this.
- **api_version** (*string*) – The version of the API to call. Typically you shouldn't provide this and instead use the default for the library.

Return type string

Returns The URL assembled from the pieces provided.

CHAPTER 4

Exceptions

Custom exceptions for gcloud.storage package.

See: https://cloud.google.com/storage/docs/json_api/v1/status-codes

exception gcloud.exceptions.**BadRequest**(*message*, *errors=()*)
Bases: *gcloud.exceptions.ClientError*

Exception mapping a '400 Bad Request' response.

code = 400

exception gcloud.exceptions.**ClientError**(*message*, *errors=()*)
Bases: *gcloud.exceptions.GCloudError*

Base for 4xx responses

This class is abstract

exception gcloud.exceptions.**Conflict**(*message*, *errors=()*)
Bases: *gcloud.exceptions.ClientError*

Exception mapping a '409 Conflict' response.

code = 409

exception gcloud.exceptions.**Forbidden**(*message*, *errors=()*)
Bases: *gcloud.exceptions.ClientError*

Exception mapping a '403 Forbidden' response.

code = 403

exception gcloud.exceptions.**GCloudError**(*message*, *errors=()*)
Bases: exceptions.Exception

Base error class for gcloud errors (abstract).

Each subclass represents a single type of HTTP error response.

code = None
HTTP status code. Concrete subclasses *must* define.

See: http://www.w3.org/Protocols/rfc2616/rfc2616-sec10.html

errors
Detailed error information.

Return type list(dict)

Returns a list of mappings describing each error.

exception gcloud.exceptions.**InternalServerError**(*message*, *errors=()*)
Bases: *gcloud.exceptions.ServerError*

Exception mapping a '500 Internal Server Error' response.

code = 500

exception gcloud.exceptions.**LengthRequired**(*message*, *errors=()*)
Bases: *gcloud.exceptions.ClientError*

Exception mapping a '411 Length Required' response.

code = 411

exception gcloud.exceptions.**MethodNotAllowed**(*message*, *errors=()*)
Bases: *gcloud.exceptions.ClientError*

Exception mapping a '405 Method Not Allowed' response.

code = 405

exception gcloud.exceptions.**MovedPermanently**(*message*, *errors=()*)
Bases: *gcloud.exceptions.Redirection*

Exception mapping a '301 Moved Permanently' response.

code = 301

exception gcloud.exceptions.**NotFound**(*message*, *errors=()*)
Bases: *gcloud.exceptions.ClientError*

Exception mapping a '404 Not Found' response.

code = 404

exception gcloud.exceptions.**NotImplemented**(*message*, *errors=()*)
Bases: *gcloud.exceptions.ServerError*

Exception mapping a '501 Not Implemented' response.

code = 501

exception gcloud.exceptions.**NotModified**(*message*, *errors=()*)
Bases: *gcloud.exceptions.Redirection*

Exception mapping a '304 Not Modified' response.

code = 304

exception gcloud.exceptions.**PreconditionFailed**(*message*, *errors=()*)
Bases: *gcloud.exceptions.ClientError*

Exception mapping a '412 Precondition Failed' response.

code = 412

exception gcloud.exceptions.**Redirection**(*message*, *errors=()*)
Bases: *gcloud.exceptions.GCloudError*

Base for 3xx responses

This class is abstract.

exception gcloud.exceptions.**RequestRangeNotSatisfiable**(*message*, *errors=()*)
Bases: *gcloud.exceptions.ClientError*

Exception mapping a '416 Request Range Not Satisfiable' response.

code = 416

exception gcloud.exceptions.**ResumeIncomplete**(*message*, *errors=()*)
Bases: *gcloud.exceptions.Redirection*

Exception mapping a '308 Resume Incomplete' response.

code = 308

exception gcloud.exceptions.**ServerError**(*message*, *errors=()*)
Bases: *gcloud.exceptions.GCloudError*

Base for 5xx responses: (abstract)

exception gcloud.exceptions.**ServiceUnavailable**(*message*, *errors=()*)
Bases: *gcloud.exceptions.ServerError*

Exception mapping a '503 Service Unavailable' response.

code = 503

exception gcloud.exceptions.**TemporaryRedirect**(*message*, *errors=()*)
Bases: *gcloud.exceptions.Redirection*

Exception mapping a '307 Temporary Redirect' response.

code = 307

exception gcloud.exceptions.**TooManyRequests**(*message*, *errors=()*)
Bases: *gcloud.exceptions.ClientError*

Exception mapping a '429 Too Many Requests' response.

code = 429

exception gcloud.exceptions.**Unauthorized**(*message*, *errors=()*)
Bases: *gcloud.exceptions.ClientError*

Exception mapping a '401 Unauthorized' response.

code = 401

gcloud.exceptions.**eklass**
alias of *ServiceUnavailable*

gcloud.exceptions.**make_exception**(*response*, *content*, *error_info=None*, *use_json=True*)
Factory: create exception based on HTTP response code.

Parameters

- **response** (httplib2.Response or other HTTP response object) – A response object that defines a status code as the status attribute.
- **content** (*string or dictionary*) – The body of the HTTP error response.
- **error_info** (*string*) – Optional string giving extra information about the failed request.
- **use_json** (*boolean*) – Flag indicating if content is expected to be JSON.

Return type instance of *GCloudError*, or a concrete subclass.

Returns Exception specific to the error response.

CHAPTER 5

Authentication

5.1 Overview

- **If you're running in Compute Engine or App Engine**, authentication should "just work".
- **If you're developing locally**, the easiest way to authenticate is using the Google Cloud SDK:

```
$ gcloud auth login
```

- **If you're running your application elsewhere**, you should download a service account JSON keyfile and point to it using an environment variable:

```
$ export GOOGLE_APPLICATION_CREDENTIALS="/path/to/keyfile.json"
```

5.2 Client-Provided Authentication

Every package uses a *Client* as a base for interacting with an API. For example:

```
from gcloud import datastore
client = datastore.Client()
```

Passing no arguments at all will "just work" if you've followed the instructions in the *Overview*. The credentials are inferred from your local environment by using Google Application Default Credentials.

5.2.1 Credential Discovery Precedence

When loading the Application Default Credentials, the library will check properties of your local environment in the following order:

1. Application running in Google App Engine
2. JSON or PKCS12/P12 keyfile pointed to by `GOOGLE_APPLICATION_CREDENTIALS` environment variable
3. Credentials provided by the Google Cloud SDK (via `gcloud auth login`)
4. Application running in Google Compute Engine

5.3 Explicit Credentials

The Application Default Credentials discussed above can be useful if your code needs to run in many different environments or if you just don't want authentication to be a focus in your code.

However, you may want to be explicit because

- your code will only run in one place
- you may have code which needs to be run as a specific service account every time (rather than with the locally inferred credentials)
- you may want to use two separate accounts to simultaneously access data from different projects

In these situations, you can create an explicit `Credentials` object suited to your environment. After creation, you can pass it directly to a *`Client`*:

```
client = Client(credentials=credentials)
```

5.3.1 Google App Engine Environment

To create `credentials` just for Google App Engine:

```
from oauth2client.appengine import AppAssertionCredentials
credentials = AppAssertionCredentials([])
```

5.3.2 Google Compute Engine Environment

To create `credentials` just for Google Compute Engine:

```
from oauth2client.gce import AppAssertionCredentials
credentials = AppAssertionCredentials([])
```

5.3.3 Service Accounts

A service account can be used with both a JSON keyfile and a PKCS12/P12 keyfile.

Directly creating `credentials` in oauth2client for a service account is a rather complex process, so as a convenience, the *`from_service_account_json()`* and *`from_service_account_p12()`* factories are provided to create a *`Client`* with service account credentials.

For example, with a JSON keyfile:

```
client = Client.from_service_account_json('/path/to/keyfile.json')
```

Tip: Unless you have a specific reason to use a PKCS12/P12 key for your service account, we recommend using a JSON key.

5.3.4 User Accounts (3-legged OAuth 2.0) with a refresh token

The majority of cases are intended to authenticate machines or workers rather than actual user accounts. However, it's also possible to call Google Cloud APIs with a user account via OAuth 2.0.

Tip: A production application should **use a service account**, but you may wish to use your own personal user account when first getting started with the `gcloud-python` library.

The simplest way to use credentials from a user account is via Application Default Credentials using `gcloud auth login` (as mentioned above):

```
from oauth2client.client import GoogleCredentials
credentials = GoogleCredentials.get_application_default()
```

This will still follow the *precedence* described above, so be sure none of the other possible environments conflict with your user provided credentials.

Advanced users of oauth2client can also use custom flows to create credentials using client secrets or using a webserver flow. After creation, `Credentials` can be serialized with `to_json()` and stored in a file and then and deserialized with `from_json()`.

5.4 Troubleshooting

5.4.1 Setting up a Service Account

If your application is not running on Google Compute Engine, you need a Google Developers Service Account.

1. Visit the Google Developers Console.
2. Create a new project or click on an existing project.
3. Navigate to **APIs & auth > APIs** and enable the APIs that your application requires.

   Note: You may need to enable billing in order to use these services.

   - **BigQuery**
     - BigQuery API
   - **Datastore**
     - Google Cloud Datastore API
   - **Pub/Sub**
     - Google Cloud Pub/Sub
   - **Search**
     - Google Cloud Search API
   - **Storage**
     - Google Cloud Storage
     - Google Cloud Storage JSON API

1. Navigate to **APIs & auth > Credentials**.

   You should see a screen like one of the following:

Find the "Add credentials" drop down and select "Service account" to be guided through downloading a new JSON keyfile.

If you want to re-use an existing service account, you can easily generate a new keyfile. Just select the account you wish to re-use, and click **Generate new JSON key**:

5.4.2 Using Google Compute Engine

If your code is running on Google Compute Engine, using the inferred Google Application Default Credentials will be sufficient for retrieving credentials.

However, by default your credentials may not grant you access to the services you intend to use. Be sure when you set up the GCE instance, you add the correct scopes for the APIs you want to access:

- **All APIs**
  - `https://www.googleapis.com/auth/cloud-platform`
  - `https://www.googleapis.com/auth/cloud-platform.read-only`
- **BigQuery**
  - `https://www.googleapis.com/auth/bigquery`
  - `https://www.googleapis.com/auth/bigquery.insertdata`
- **Datastore**
  - `https://www.googleapis.com/auth/datastore`
  - `https://www.googleapis.com/auth/userinfo.email`
- **Pub/Sub**
  - `https://www.googleapis.com/auth/pubsub`
- **Storage**
  - `https://www.googleapis.com/auth/devstorage.full_control`
  - `https://www.googleapis.com/auth/devstorage.read_only`
  - `https://www.googleapis.com/auth/devstorage.read_write`

5.5 Advanced Customization

Though the `gcloud-python` library defaults to using oauth2client to sign requests and `httplib2` for sending requests, it is not a strict requirement.

The *`Client`* constructor accepts an optional `http` argument in place of a `credentials` object. If passed, all HTTP requests made by the client will use your custom HTTP object.

In order for this to be possible, the `http` object must do two things:

- Handle authentication on its own
- Define a method `request()` that can subsitute for `httplib2.Http.request()`.

The entire signature from `httplib2` need not be implemented, we only use it as

```
http.request(uri, method=method_name, body=body, headers=headers)
```

For an example of such an implementation, a `gcloud-python` user created a custom HTTP class using the requests library.

As for handling authentication on your own, it may be easiest just to re-use bits from `oauth2client`. Unfortunately, these parts have a hard dependency on `httplib2`. We hope to enable using custom HTTP libraries with `oauth2client` at some point.

CHAPTER 6

Datastore Client

Convenience wrapper for invoking APIs/factories w/ a dataset ID.

class gcloud.datastore.client.**Client**(*dataset_id=None*, *namespace=None*, *credentials=None*, *http=None*)

Bases: *gcloud.client.Client*

Convenience wrapper for invoking APIs/factories w/ a dataset ID.

Parameters

- **dataset_id** (*string*) – (optional) dataset ID to pass to proxied API methods.
- **namespace** (*string*) – (optional) namespace to pass to proxied API methods.
- **credentials** (oauth2client.client.OAuth2Credentials or NoneType) – The OAuth2 Credentials to use for the connection owned by this client. If not passed (and if no http object is passed), falls back to the default inferred from the environment.
- **http** (httplib2.Http or class that defines request().) – An optional HTTP object to make requests. If not passed, an http object is created that is bound to the credentials for the current object.

allocate_ids(*incomplete_key*, *num_ids*)

Allocate a list of IDs from a partial key.

Parameters

- **incomplete_key** (A *gcloud.datastore.key.Key*) – Partial key to use as base for allocated IDs.
- **num_ids** (*integer*) – The number of IDs to allocate.

Return type list of *gcloud.datastore.key.Key*

Returns The (complete) keys allocated with incomplete_key as root.

Raises ValueError if incomplete_key is not a partial key.

batch()

Proxy to *gcloud.datastore.batch.Batch*.

Passes our dataset_id.

current_batch

Currently-active batch.

Return type *gcloud.datastore.batch.Batch*, or an object implementing its API, or NoneType (if no batch is active).

Returns The batch/transaction at the top of the batch stack.

current_transaction
Currently-active transaction.

Return type *gcloud.datastore.transaction.Transaction*, or an object implementing its API, or NoneType (if no transaction is active).

Returns The transaction at the top of the batch stack.

delete(*key*)
Delete the key in the Cloud Datastore.

Note: This is just a thin wrapper over *delete_multi()*. The backend API does not make a distinction between a single key or multiple keys in a commit request.

Parameters **key** (*gcloud.datastore.key.Key*) – The key to be deleted from the datastore.

delete_multi(*keys*)
Delete keys from the Cloud Datastore.

Parameters **keys** (list of *gcloud.datastore.key.Key*) – The keys to be deleted from the datastore.

get(*key*, *missing=None*, *deferred=None*)
Retrieve an entity from a single key (if it exists).

Note: This is just a thin wrapper over *get_multi()*. The backend API does not make a distinction between a single key or multiple keys in a lookup request.

Parameters

- **key** (*gcloud.datastore.key.Key*) – The key to be retrieved from the datastore.
- **missing** (*an empty list or None.*) – If a list is passed, the key-only entities returned by the backend as "missing" will be copied into it. Use only as a keyword param.
- **deferred** (*an empty list or None.*) – If a list is passed, the keys returned by the backend as "deferred" will be copied into it. Use only as a keyword param.

Return type *gcloud.datastore.entity.Entity* or NoneType

Returns The requested entity if it exists.

get_multi(*keys*, *missing=None*, *deferred=None*)
Retrieve entities, along with their attributes.

Parameters

- **keys** (list of *gcloud.datastore.key.Key*) – The keys to be retrieved from the datastore.
- **missing** (*an empty list or None.*) – If a list is passed, the key-only entities returned by the backend as "missing" will be copied into it. Use only as a keyword param.
- **deferred** (*an empty list or None.*) – If a list is passed, the keys returned by the backend as "deferred" will be copied into it. Use only as a keyword param.

Return type list of *gcloud.datastore.entity.Entity*

Returns The requested entities.

Raises ValueError if `keys` has a dataset ID which does not match our dataset ID.

key(**path_args*, ***kwargs*)
Proxy to *gcloud.datastore.key.Key*.

Passes our `dataset_id`.

put(*entity*)
Save an entity in the Cloud Datastore.

Note: This is just a thin wrapper over *put_multi()*. The backend API does not make a distinction between a single entity or multiple entities in a commit request.

Parameters **entity** (*gcloud.datastore.entity.Entity*) – The entity to be saved to the datastore.

put_multi(*entities*)
Save entities in the Cloud Datastore.

Parameters **entities** (list of *gcloud.datastore.entity.Entity*) – The entities to be saved to the datastore.

Raises ValueError if `entities` is a single entity.

query(***kwargs*)
Proxy to *gcloud.datastore.query.Query*.

Passes our `dataset_id`.

transaction()
Proxy to *gcloud.datastore.transaction.Transaction*.

Passes our `dataset_id`.

6.1 Connection

Connections to gcloud datastore API servers.

class gcloud.datastore.connection.**Connection**(*credentials=None*, *http=None*, *api_base_url=None*)
Bases: *gcloud.connection.Connection*

A connection to the Google Cloud Datastore via the Protobuf API.

This class should understand only the basic types (and protobufs) in method arguments, however should be capable of returning advanced types.

Parameters

- **credentials** (`oauth2client.client.OAuth2Credentials`) – The OAuth2 Credentials to use for this connection.
- **http** (`httplib2.Http` or class that defines `request()`.) – An optional HTTP object to make requests.

- **api_base_url** (*string*) – The base of the API call URL. Defaults to the value from *gcloud.connection*.

API_URL_TEMPLATE = '{api_base}/datastore/{api_version}/datasets/{dataset_id}/{method}'
A template for the URL of a particular API call.

API_VERSION = 'v1beta2'
The version of the API, used in building the API call's URL.

SCOPE = ('https://www.googleapis.com/auth/datastore', 'https://www.googleapis.com/auth/userinfo.email')
The scopes required for authenticating as a Cloud Datastore consumer.

allocate_ids(*dataset_id*, *key_pbs*)
Obtain backend-generated IDs for a set of keys.

Maps the `DatastoreService.AllocateIds` protobuf RPC.

Parameters

- **dataset_id** (*string*) – The ID of the dataset to which the transaction belongs.
- **key_pbs** (list of `gcloud.datastore._datastore_v1_pb2.Key`) – The keys for which the backend should allocate IDs.

Return type list of `gcloud.datastore._datastore_v1_pb2.Key`

Returns An equal number of keys, with IDs filled in by the backend.

begin_transaction(*dataset_id*, *serializable=False*)
Begin a transaction.

Maps the `DatastoreService.BeginTransaction` protobuf RPC.

Parameters

- **dataset_id** (*string*) – The ID dataset to which the transaction applies.
- **serializable** (*boolean*) – Boolean indicating if the isolation level of the transaction should be SERIALIZABLE (True) or SNAPSHOT (False).

Return type `_datastore_v1_pb2.BeginTransactionResponse`

Returns' the result protobuf for the begin transaction request.

build_api_url(*dataset_id*, *method*, *base_url=None*, *api_version=None*)
Construct the URL for a particular API call.

This method is used internally to come up with the URL to use when making RPCs to the Cloud Datastore API.

Parameters

- **dataset_id** (*string*) – The ID of the dataset to connect to. This is usually your project name in the cloud console.
- **method** (*string*) – The API method to call (ie, runQuery, lookup, ...).
- **base_url** (*string*) – The base URL where the API lives. You shouldn't have to provide this.
- **api_version** (*string*) – The version of the API to connect to. You shouldn't have to provide this.

commit(*dataset_id*, *mutation_pb*, *transaction_id*)
Commit dataset mutations in context of current transation (if any).

Maps the `DatastoreService.Commit` protobuf RPC.

Parameters

- **dataset_id** (*string*) – The ID dataset to which the transaction applies.
- **mutation_pb** (datastore_pb.Mutation.) – The protobuf for the mutations being saved.
- **transaction_id** (*string or None*) – The transaction ID returned from *begin_transaction()*. Non-transactional batches must pass None.

Return type gcloud.datastore._datastore_v1_pb2.MutationResult.

Returns' the result protobuf for the mutation.

lookup(*dataset_id*, *key_pbs*, *eventual=False*, *transaction_id=None*)

Lookup keys from a dataset in the Cloud Datastore.

Maps the DatastoreService.Lookup protobuf RPC.

This method deals only with protobufs (gcloud.datastore._datastore_v1_pb2.Key and gcloud.datastore._datastore_v1_pb2.Entity) and is used under the hood in gcloud.datastore.get():

```
>>> from gcloud import datastore
>>> key = datastore.Key('MyKind', 1234, dataset_id='dataset-id')
>>> datastore.get(key)
[<Entity object>]
```

Using the connection class directly:

```
>>> connection.lookup('dataset-id', [key.to_protobuf()])
[<Entity protobuf>]
```

Parameters

- **dataset_id** (*string*) – The ID of the dataset to look up the keys.
- **key_pbs** (list of gcloud.datastore._datastore_v1_pb2.Key) – The keys to retrieve from the datastore.
- **eventual** (*boolean*) – If False (the default), request STRONG read consistency. If True, request EVENTUAL read consistency.
- **transaction_id** (*string*) – If passed, make the request in the scope of the given transaction. Incompatible with eventual==True.

Return type tuple

Returns A triple of (results, missing, deferred) where both results and missing are lists of gcloud.datastore._datastore_v1_pb2.Entity and deferred is a list of gcloud.datastore._datastore_v1_pb2.Key.

rollback(*dataset_id*, *transaction_id*)

Rollback the connection's existing transaction.

Maps the DatastoreService.Rollback protobuf RPC.

Parameters

- **dataset_id** (*string*) – The ID of the dataset to which the transaction belongs.
- **transaction_id** (*string*) – The transaction ID returned from *begin_transaction()*.

run_query(*dataset_id*, *query_pb*, *namespace=None*, *eventual=False*, *transaction_id=None*)

Run a query on the Cloud Datastore.

Maps the `DatastoreService.RunQuery` protobuf RPC.

Given a Query protobuf, sends a `runQuery` request to the Cloud Datastore API and returns a list of entity protobufs matching the query.

You typically wouldn't use this method directly, in favor of the *gcloud.datastore.query.Query.fetch()* method.

Under the hood, the *gcloud.datastore.query.Query* class uses this method to fetch data:

```
>>> from gcloud import datastore
```

```
>>> query = datastore.Query(kind='MyKind')
>>> query.add_filter('property', '=', 'val')
```

Using the query's `fetch_page` method...

```
>>> entities, cursor, more_results = query.fetch_page()
>>> entities
[<list of Entity unmarshalled from protobuf>]
>>> cursor
<string containing cursor where fetch stopped>
>>> more_results
<boolean of more results>
```

Under the hood this is doing...

```
>>> connection.run_query('dataset-id', query.to_protobuf())
[<list of Entity Protobufs>], cursor, more_results, skipped_results
```

Parameters

- **dataset_id** (*string*) – The ID of the dataset over which to run the query.
- **query_pb** (`gcloud.datastore._datastore_v1_pb2.Query`) – The Protobuf representing the query to run.
- **namespace** (*string*) – The namespace over which to run the query.
- **eventual** (*boolean*) – If False (the default), request `STRONG` read consistency. If True, request `EVENTUAL` read consistency.
- **transaction_id** (*string*) – If passed, make the request in the scope of the given transaction. Incompatible with `eventual==True`.

CHAPTER 7

Entities

Class for representing a single entity in the Cloud Datastore.

class `gcloud.datastore.entity.`**`Entity`**(*key=None*, *exclude_from_indexes=()*)

Bases: `dict`

Entities are akin to rows in a relational database

An entity storing the actual instance of data.

Each entity is officially represented with a *`gcloud.datastore.key.Key`* class, however it is possible that you might create an Entity with only a partial Key (that is, a Key with a Kind, and possibly a parent, but without an ID). In such a case, the datastore service will automatically assign an ID to the partial key.

Entities in this API act like dictionaries with extras built in that allow you to delete or persist the data stored on the entity.

Entities are mutable and act like a subclass of a dictionary. This means you could take an existing entity and change the key to duplicate the object.

Use `gcloud.datastore.get()` to retrieve an existing entity.

```
>>> datastore.get(key)
<Entity[{'kind': 'EntityKind', id: 1234}] {'property': 'value'}>
```

You can the set values on the entity just like you would on any other dictionary.

```
>>> entity['age'] = 20
>>> entity['name'] = 'JJ'
>>> entity
<Entity[{'kind': 'EntityKind', id: 1234}] {'age': 20, 'name': 'JJ'}>
```

And you can convert an entity to a regular Python dictionary with the `dict` builtin:

```
>>> dict(entity)
{'age': 20, 'name': 'JJ'}
```

Note: When saving an entity to the backend, values which are "text" (`unicode` in Python2, `str` in Python3) will be saved using the 'text_value' field, after being encoded to UTF-8. When retrieved from the back-end, such values will be decoded to "text" again. Values which are "bytes" (`str` in Python2, `bytes` in Python3), will be saved using the 'blob_value' field, without any decoding / encoding step.

Parameters

- **key** (*gcloud.datastore.key.Key*) – Optional key to be set on entity. Required for `gcloud.datastore.put()` and `gcloud.datastore.put_multi()`
- **exclude_from_indexes** (*tuple of string*) – Names of fields whose values are not to be indexed for this entity.

exclude_from_indexes

Names of fields which are *not* to be indexed for this entity.

Return type sequence of field names

kind

Get the kind of the current entity.

Note: This relies entirely on the *gcloud.datastore.key.Key* set on the entity. That means that we're not storing the kind of the entity at all, just the properties and a pointer to a Key which knows its Kind.

CHAPTER 8

Keys

Create / interact with gcloud datastore keys.

class gcloud.datastore.key.**Key**(**path_args*, ***kwargs*)

Bases: object

An immutable representation of a datastore Key.

To create a basic key:

```
>>> Key('EntityKind', 1234)
<Key[{'kind': 'EntityKind', 'id': 1234}]>
>>> Key('EntityKind', 'foo')
<Key[{'kind': 'EntityKind', 'name': 'foo'}]>
```

To create a key with a parent:

```
>>> Key('Parent', 'foo', 'Child', 1234)
<Key[{'kind': 'Parent', 'name': 'foo'}, {'kind': 'Child', 'id': 1234}]>
>>> Key('Child', 1234, parent=parent_key)
<Key[{'kind': 'Parent', 'name': 'foo'}, {'kind': 'Child', 'id': 1234}]>
```

To create a partial key:

```
>>> Key('Parent', 'foo', 'Child')
<Key[{'kind': 'Parent', 'name': 'foo'}, {'kind': 'Child'}]>
```

Parameters

- **path_args** (*tuple of string and integer*) – May represent a partial (odd length) or full (even length) key path.
- **kwargs** (*dictionary*) – Keyword arguments to be passed in.

Accepted keyword arguments are * namespace (string): A namespace identifier for the key. * dataset_id (string): The dataset ID associated with the key. * parent (*gcloud.datastore.key.Key*): The parent of the key.

The dataset ID argument is required unless it has been set implicitly.

completed_key(*id_or_name*)

Creates new key from existing partial key by adding final ID/name.

Parameters **id_or_name** (*string or integer*) – ID or name to be added to the key.

Return type *gcloud.datastore.key.Key*

Returns A new `Key` instance with the same data as the current one and an extra ID or name added.

Raises `ValueError` if the current key is not partial or if `id_or_name` is not a string or integer.

dataset_id
Dataset ID getter.

Return type string

Returns The key's dataset ID.

flat_path
Getter for the key path as a tuple.

Return type tuple of string and integer

Returns The tuple of elements in the path.

id
ID getter. Based on the last element of path.

Return type integer

Returns The (integer) ID of the key.

id_or_name
Getter. Based on the last element of path.

Return type integer (if `id`) or string (if `name`)

Returns The last element of the key's path if it is either an `id` or a `name`.

is_partial
Boolean indicating if the key has an ID (or name).

Return type boolean

Returns `True` if the last element of the key's path does not have an `id` or a `name`.

kind
Kind getter. Based on the last element of path.

Return type string

Returns The kind of the current key.

name
Name getter. Based on the last element of path.

Return type string

Returns The (string) name of the key.

namespace
Namespace getter.

Return type string

Returns The namespace of the current key.

parent
The parent of the current key.

Return type *gcloud.datastore.key.Key* or `NoneType`

Returns A new `Key` instance, whose path consists of all but the last element of current path. If the current key has only one path element, returns `None`.

path

Path getter.

Returns a copy so that the key remains immutable.

Return type `list` of `dict`

Returns The (key) path of the current key.

to_protobuf()

Return a protobuf corresponding to the key.

Return type `gcloud.datastore._datastore_v1_pb2.Key`

Returns The protobuf representing the key.

CHAPTER 9

Queries

Create / interact with gcloud datastore queries.

class gcloud.datastore.query.**Iterator**(*query*, *client*, *limit=None*, *offset=0*, *start_cursor=None*, *end_cursor=None*)

Bases: object

Represent the state of a given execution of a Query.

Parameters

- **query** (*gcloud.datastore.query.Query*) – Query object holding permanent configuration (i.e. things that don't change on with each page in a results set).
- **client** (*gcloud.datastore.client.Client*) – The client used to make a request.
- **limit** (*integer*) – (Optional) Limit the number of results returned.
- **offset** (*integer*) – (Optional) Defaults to 0. Offset used to begin a query.
- **start_cursor** (*bytes*) – (Optional) Cursor to begin paging through query results.
- **end_cursor** (*bytes*) – (Optional) Cursor to end paging through query results.

next_page()

Fetch a single "page" of query results.

Low-level API for fine control: the more convenient API is to iterate on the current Iterator.

Return type tuple, (entities, more_results, cursor)

class gcloud.datastore.query.**Query**(*client*, *kind=None*, *dataset_id=None*, *namespace=None*, *ancestor=None*, *filters=()*, *projection=()*, *order=()*, *group_by=()*)

Bases: object

A Query against the Cloud Datastore.

This class serves as an abstraction for creating a query over data stored in the Cloud Datastore.

Parameters

- **client** (*gcloud.datastore.client.Client*) – The client used to connect to datastore.
- **kind** (*string*) – The kind to query.
- **dataset_id** (*string*) – The ID of the dataset to query. If not passed, uses the client's value.

- **namespace** (*string or None*) – The namespace to which to restrict results. If not passed, uses the client's value.
- **ancestor** (*gcloud.datastore.key.Key* or None) – key of the ancestor to which this query's results are restricted.
- **filters** (*sequence of (property_name, operator, value) tuples*) – property filters applied by this query.
- **projection** (*sequence of string*) – fields returned as part of query results.
- **order** (*sequence of string*) – field names used to order query results. Prepend '-' to a field name to sort it in descending order.
- **group_by** (*sequence of string*) – field names used to group query results.

Raises ValueError if `dataset_id` is not passed and no implicit default is set.

OPERATORS = {'>': 3, '<=': 2, '=': 5, '>=': 4, '<': 1}
Mapping of operator strings and their protobuf equivalents.

add_filter(*property_name*, *operator*, *value*)
Filter the query based on a property name, operator and a value.

Expressions take the form of:

```
.add_filter('<property>', '<operator>', <value>)
```

where property is a property stored on the entity in the datastore and operator is one of `OPERATORS` (ie, =, <, <=, >, >=):

```
>>> from gcloud import datastore
>>> query = datastore.Query('Person')
>>> query.add_filter('name', '=', 'James')
>>> query.add_filter('age', '>', 50)
```

Parameters

- **property_name** (*string*) – A property name.
- **operator** (*string*) – One of =, <, <=, >, >=.
- **value** (*integer, string, boolean, float, None, datetime*) – The value to filter on.

Raises `ValueError` if `operation` is not one of the specified values, or if a filter names `'__key__'` but passes invalid operator (== is required) or value (a key is required).

ancestor
The ancestor key for the query.

Return type Key or None

dataset_id
Get the dataset ID for this Query.

Return type str

fetch(*limit=None*, *offset=0*, *start_cursor=None*, *end_cursor=None*, *client=None*)
Execute the Query; return an iterator for the matching entities.

For example:

```
>>> from gcloud import datastore
>>> query = datastore.Query('Person')
>>> query.add_filter('name', '=', 'Sally')
>>> list(query.fetch())
[<Entity object>, <Entity object>, ...]
>>> list(query.fetch(1))
[<Entity object>]
```

Parameters

- **limit** (*integer or None*) – An optional limit passed through to the iterator.
- **offset** (*integer*) – An optional offset passed through to the iterator.
- **start_cursor** (*bytes*) – An optional cursor passed through to the iterator.
- **end_cursor** (*bytes*) – An optional cursor passed through to the iterator.
- **client** (*gcloud.datastore.client.Client*) – client used to connect to datastore. If not supplied, uses the query's value.

Return type *Iterator*

Raises ValueError if `connection` is not passed and no implicit default has been set.

filters
Filters set on the query.

Return type sequence of (property_name, operator, value) tuples.

group_by
Names of fields used to group query results.

Return type sequence of string

keys_only()
Set the projection to include only keys.

kind
Get the Kind of the Query.

Return type string

namespace
This query's namespace

Return type string or None

Returns the namespace assigned to this query

order
Names of fields used to sort query results.

Return type sequence of string

projection
Fields names returned by the query.

Return type sequence of string

Returns Names of fields in query results.

CHAPTER 10

Transactions

Create / interact with gcloud datastore transactions.

class gcloud.datastore.transaction.**Transaction**(*client*)

Bases: *gcloud.datastore.batch.Batch*

An abstraction representing datastore Transactions.

Transactions can be used to build up a bulk mutuation as well as provide isolation.

For example, the following snippet of code will put the two `save` operations (either `insert_auto_id` or `upsert`) into the same mutation, and execute those within a transaction:

```
>>> from gcloud import datastore

>>> with datastore.Transaction():
...     datastore.put_multi([entity1, entity2])
```

Because it derives from `Batch`, :class‘Transaction‘ also provides `put()` and `delete()` methods:

```
>>> with datastore.Transaction() as xact:
...     xact.put(entity1)
...     xact.delete(entity2.key)
```

By default, the transaction is rolled back if the transaction block exits with an error:

```
>>> with datastore.Transaction():
...     do_some_work()
...     raise SomeException()  # rolls back
```

If the transaction block exists without an exception, it will commit by default.

Warning: Inside a transaction, automatically assigned IDs for entities will not be available at save time! That means, if you try:

```
>>> with datastore.Transaction():
...     entity = datastore.Entity(key=Key('Thing'))
...     datastore.put(entity)
```

`entity` won't have a complete Key until the transaction is committed.
Once you exit the transaction (or call `commit()`), the automatically generated ID will be assigned to the entity:

```
>>> with datastore.Transaction():
...     entity = datastore.Entity(key=Key('Thing'))
...     datastore.put(entity)
...     assert entity.key.is_partial  # There is no ID on this key.
...
>>> assert not entity.key.is_partial  # There *is* an ID.
```

If you don't want to use the context manager you can initialize a transaction manually:

```
>>> transaction = datastore.Transaction()
>>> transaction.begin()

>>> entity = datastore.Entity(key=Key('Thing'))
>>> transaction.put(entity)

>>> if error:
...     transaction.rollback()
... else:
...     transaction.commit()
```

Parameters **client** (*gcloud.datastore.client.Client*) – The client used to connect to datastore.

begin()
Begins a transaction.

This method is called automatically when entering a with statement, however it can be called explicitly if you don't want to use a context manager.

Raises `ValueError` if the transaction has already begun.

commit()
Commits the transaction.

This is called automatically upon exiting a with statement, however it can be called explicitly if you don't want to use a context manager.

This method has necessary side-effects:

- Sets the current transaction's ID to None.

current()
Return the topmost transaction.

Note: if the topmost element on the stack is not a transaction, returns None.

Return type *gcloud.datastore.transaction.Transaction* or None

id

Getter for the transaction ID.

Return type string

Returns The ID of the current transaction.

rollback()

Rolls back the current transaction.

This method has necessary side-effects:

- Sets the current connection's transaction reference to None.
- Sets the current transaction's ID to None.

CHAPTER 11

Batches

Create / interact with a batch of updates / deletes.

Batches provide the ability to execute multiple operations in a single request to the Cloud Datastore API.

See https://cloud.google.com/datastore/docs/concepts/entities#Datastore_Batch_operations

class gcloud.datastore.batch.**Batch**(*client*)

Bases: object

An abstraction representing a collected group of updates / deletes.

Used to build up a bulk mutuation.

For example, the following snippet of code will put the two `save` operations and the delete operatiuon into the same mutation, and send them to the server in a single API request:

```
>>> from gcloud.datastore.batch import Batch
>>> batch = Batch()
>>> batch.put(entity1)
>>> batch.put(entity2)
>>> batch.delete(key3)
>>> batch.commit()
```

You can also use a batch as a context manager, in which case the `commit` will be called automatically if its block exits without raising an exception:

```
>>> with Batch() as batch:
...     batch.put(entity1)
...     batch.put(entity2)
...     batch.delete(key3)
```

By default, no updates will be sent if the block exits with an error:

```
>>> with Batch() as batch:
...   do_some_work(batch)
...   raise Exception() # rolls back
```

Parameters **client** (*gcloud.datastore.client.Client*) – The client used to connect to datastore.

add_auto_id_entity(*entity*)

Adds an entity to the list of entities to update with IDs.

When an entity has a partial key, calling `save()` adds an insert_auto_id entry in the mutation. In order to make sure we update the Entity once the transaction is committed, we need to keep track of which entities to update (and the order is important).

When you call `save()` on an entity inside a transaction, if the entity has a partial key, it adds itself to the list of entities to be updated once the transaction is committed by calling this method.

Parameters **entity** (*gcloud.datastore.entity.Entity*) – The entity to be updated with a completed key.

Raises ValueError if the entity's key is alread completed.

begin()
No-op

Overridden by *gcloud.datastore.transaction.Transaction*.

commit()
Commits the batch.

This is called automatically upon exiting a with statement, however it can be called explicitly if you don't want to use a context manager.

connection
Getter for connection over which the batch will run.

Return type *gcloud.datastore.connection.Connection*

Returns The connection over which the batch will run.

current()
Return the topmost batch / transaction, or None.

dataset_id
Getter for dataset ID in which the batch will run.

Return type `str`

Returns The dataset ID in which the batch will run.

delete(*key*)
Remember a key to be deleted durring `commit`.

Parameters **key** (*gcloud.datastore.key.Key*) – the key to be deleted.

Raises ValueError if key is not complete, or if the key's `dataset_id` does not match ours.

mutation
Getter for the current mutation.

Every batch is committed with a single Mutation representing the 'work' to be done as part of the batch. Inside a batch, calling `batch.put()` with an entity, or `batch.delete` with a key, builds up the mutation. This getter returns the Mutation protobuf that has been built-up so far.

Return type `gcloud.datastore._datastore_v1_pb2.Mutation`

Returns The Mutation protobuf to be sent in the commit request.

namespace
Getter for namespace in which the batch will run.

Return type `str`

Returns The namespace in which the batch will run.

put(*entity*)
Remember an entity's state to be saved during `commit`.

Note: Any existing properties for the entity will be replaced by those currently set on this instance. Already-stored properties which do not correspond to keys set on this instance will be removed from the datastore.

Note: Property values which are "text" ('unicode' in Python2, 'str' in Python3) map to 'string_value' in the datastore; values which are "bytes" ('str' in Python2, 'bytes' in Python3) map to 'blob_value'.

Parameters **entity** (*gcloud.datastore.entity.Entity*) – the entity to be saved.

Raises ValueError if entity has no key assigned, or if the key's `dataset_id` does not match ours.

rollback()
No-op

Overridden by *gcloud.datastore.transaction.Transaction*.

CHAPTER 12

Storage Client

Client for interacting with the Google Cloud Storage API.

class gcloud.storage.client.**Client**(*project=None*, *credentials=None*, *http=None*)
Bases: *gcloud.client.JSONClient*

Client to bundle configuration needed for API requests.

Parameters

- **project** (*string*) – the project which the client acts on behalf of. Will be passed when creating a topic. If not passed, falls back to the default inferred from the environment.
- **credentials** (oauth2client.client.OAuth2Credentials or NoneType) – The OAuth2 Credentials to use for the connection owned by this client. If not passed (and if no http object is passed), falls back to the default inferred from the environment.
- **http** (httplib2.Http or class that defines request().) – An optional HTTP object to make requests. If not passed, an http object is created that is bound to the credentials for the current object.

batch()
Factory constructor for batch object.

Note: This will not make an HTTP request; it simply instantiates a batch object owned by this client.

Return type gcloud.storage.batch.Batch

Returns The batch object created.

bucket(*bucket_name*)
Factory constructor for bucket object.

Note: This will not make an HTTP request; it simply instantiates a bucket object owned by this client.

Parameters **bucket_name** (*string*) – The name of the bucket to be instantiated.

Return type *gcloud.storage.bucket.Bucket*

Returns The bucket object created.

connection
Get connection or batch on the client.

Return type *gcloud.storage.connection.Connection*

Returns The connection set on the client, or the batch if one is set.

create_bucket(*bucket_name*)
Create a new bucket.

For example:

```
>>> bucket = client.create_bucket('my-bucket')
>>> print bucket
<Bucket: my-bucket>
```

This implements "storage.buckets.insert".

If the bucket already exists, will raise *gcloud.exceptions.Conflict*.

Parameters **bucket_name** (*string*) – The bucket name to create.

Return type *gcloud.storage.bucket.Bucket*

Returns The newly created bucket.

current_batch
Currently-active batch.

Return type `gcloud.storage.batch.Batch` or `NoneType` (if no batch is active).

Returns The batch at the top of the batch stack.

get_bucket(*bucket_name*)
Get a bucket by name.

If the bucket isn't found, this will raise a `gcloud.storage.exceptions.NotFound`.

For example:

```
>>> try:
>>>   bucket = client.get_bucket('my-bucket')
>>> except gcloud.exceptions.NotFound:
>>>   print 'Sorry, that bucket does not exist!'
```

This implements "storage.buckets.get".

Parameters **bucket_name** (*string*) – The name of the bucket to get.

Return type *gcloud.storage.bucket.Bucket*

Returns The bucket matching the name provided.

Raises *gcloud.exceptions.NotFound*

list_buckets(*max_results=None*, *page_token=None*, *prefix=None*, *projection='noAcl'*, *fields=None*)
Get all buckets in the project associated to the client.

This will not populate the list of blobs available in each bucket.

```
>>> for bucket in client.list_buckets():
>>>   print bucket
```

This implements "storage.buckets.list".

Parameters

- **max_results** (integer or NoneType) – Optional. Maximum number of buckets to return.
- **page_token** (string or NoneType) – Optional. Opaque marker for the next "page" of buckets. If not passed, will return the first page of buckets.
- **prefix** (string or NoneType) – Optional. Filter results to buckets whose names begin with this prefix.
- **projection** (string or NoneType) – If used, must be 'full' or 'noAcl'. Defaults to 'noAcl'. Specifies the set of properties to return.
- **fields** (string or NoneType) – Selector specifying which fields to include in a partial response. Must be a list of fields. For example to get a partial response with just the next page token and the language of each bucket returned: 'items/id,nextPageToken'

Return type iterable of *gcloud.storage.bucket.Bucket* objects.

Returns All buckets belonging to this project.

lookup_bucket(*bucket_name*)

Get a bucket by name, returning None if not found.

You can use this if you would rather check for a None value than catching an exception:

```
>>> bucket = client.lookup_bucket('doesnt-exist')
>>> print bucket
None
>>> bucket = client.lookup_bucket('my-bucket')
>>> print bucket
<Bucket: my-bucket>
```

Parameters **bucket_name** (*string*) – The name of the bucket to get.

Return type *gcloud.storage.bucket.Bucket*

Returns The bucket matching the name provided or None if not found.

12.1 Connection

Create / interact with gcloud storage connections.

class gcloud.storage.connection.**Connection**(*credentials=None*, *http=None*)

Bases: *gcloud.connection.JSONConnection*

A connection to Google Cloud Storage via the JSON REST API.

Parameters

- **credentials** (oauth2client.client.OAuth2Credentials) – (Optional) The OAuth2 Credentials to use for this connection.
- **http** (httplib2.Http or class that defines request().) – (Optional) HTTP object to make requests.

API_BASE_URL = 'https://www.googleapis.com'

The base of the API call URL.

API_URL_TEMPLATE = '{api_base_url}/storage/{api_version}{path}'

A template for the URL of a particular API call.

API_VERSION = 'v1'
The version of the API, used in building the API call's URL.

SCOPE = ('https://www.googleapis.com/auth/devstorage.full_control', 'https://www.googleapis.com/auth/devstorage.read_
The scopes required for authenticating as a Cloud Storage consumer.

CHAPTER 13

Blobs / Objects

Create / interact with Google Cloud Storage blobs.

class gcloud.storage.blob.**Blob**(*name*, *bucket*, *chunk_size=None*)
Bases: gcloud.storage._helpers._PropertyMixin

A wrapper around Cloud Storage's concept of an Object.

Parameters

- **name** (*string*) – The name of the blob. This corresponds to the unique path of the object in the bucket.
- **bucket** (*gcloud.storage.bucket.Bucket*) – The bucket to which this blob belongs.
- **chunk_size** (*integer*) – The size of a chunk of data whenever iterating (1 MB). This must be a multiple of 256 KB per the API specification.

acl
Create our ACL on demand.

cache_control
HTTP 'Cache-Control' header for this object.

See: https://tools.ietf.org/html/rfc7234#section-5.2 and https://cloud.google.com/storage/docs/json_api/v1/objects

If the property is not set locally, returns None.

Return type string or NoneType

chunk_size
Get the blob's default chunk size.

Return type integer or NoneType

Returns The current blob's chunk size, if it is set.

client
The client bound to this blob.

component_count
Number of underlying components that make up this object.

See: https://cloud.google.com/storage/docs/json_api/v1/objects

Return type integer or NoneType

Returns The component count (in case of a composed object) or None if the property is not set locally. This property will not be set on objects not created via compose.

content_disposition
HTTP 'Content-Disposition' header for this object.

See: https://tools.ietf.org/html/rfc6266 **and** https://cloud.google.com/storage/docs/json_api/v1/objects

If the property is not set locally, returns `None`.

Return type string or `NoneType`

content_encoding
HTTP 'Content-Encoding' header for this object.

See: https://tools.ietf.org/html/rfc7231#section-3.1.2.2 **and** https://cloud.google.com/storage/docs/json_api/v1/objects

If the property is not set locally, returns `None`.

Return type string or `NoneType`

content_language
HTTP 'Content-Language' header for this object.

See: http://tools.ietf.org/html/bcp47 **and** https://cloud.google.com/storage/docs/json_api/v1/objects

If the property is not set locally, returns `None`.

Return type string or `NoneType`

content_type
HTTP 'Content-Type' header for this object.

See: https://tools.ietf.org/html/rfc2616#section-14.17 **and** https://cloud.google.com/storage/docs/json_api/v1/objects

If the property is not set locally, returns `None`.

Return type string or `NoneType`

crc32c
CRC32C checksum for this object.

See: http://tools.ietf.org/html/rfc4960#appendix-B **and** https://cloud.google.com/storage/docs/json_api/v1/objects

If the property is not set locally, returns `None`.

Return type string or `NoneType`

delete(*client=None*)
Deletes a blob from Cloud Storage.

Parameters **client** (*gcloud.storage.client.Client* or `NoneType`) – Optional. The client to use. If not passed, falls back to the `client` stored on the blob's bucket.

Return type *Blob*

Returns The blob that was just deleted.

Raises *gcloud.exceptions.NotFound* (propagated from *gcloud.storage.bucket.Bucket.delete_blob()*).

download_as_string(*client=None*)
Download the contents of this blob as a string.

Parameters **client** (*gcloud.storage.client.Client* or `NoneType`) – Optional. The client to use. If not passed, falls back to the `client` stored on the blob's bucket.

Return type bytes

Returns The data stored in this blob.

Raises *gcloud.exceptions.NotFound*

download_to_file(*file_obj*, *client=None*)
Download the contents of this blob into a file-like object.

Parameters

- **file_obj** (*file*) – A file handle to which to write the blob's data.
- **client** (*gcloud.storage.client.Client* or NoneType) – Optional. The client to use. If not passed, falls back to the client stored on the blob's bucket.

Raises *gcloud.exceptions.NotFound*

download_to_filename(*filename*, *client=None*)
Download the contents of this blob into a named file.

Parameters

- **filename** (*string*) – A filename to be passed to open.
- **client** (*gcloud.storage.client.Client* or NoneType) – Optional. The client to use. If not passed, falls back to the client stored on the blob's bucket.

Raises *gcloud.exceptions.NotFound*

etag
Retrieve the ETag for the object.

See: http://tools.ietf.org/html/rfc2616#section-3.11 and https://cloud.google.com/storage/docs/json_api/v1/objects

Return type string or NoneType

Returns The blob etag or None if the property is not set locally.

exists(*client=None*)
Determines whether or not this blob exists.

Parameters **client** (*gcloud.storage.client.Client* or NoneType) – Optional. The client to use. If not passed, falls back to the client stored on the blob's bucket.

Return type boolean

Returns True if the blob exists in Cloud Storage.

generate_signed_url(*expiration*, *method='GET'*, *client=None*, *credentials=None*)
Generates a signed URL for this blob.

Note: If you are on Google Compute Engine, you can't generate a signed URL. Follow https://github.com/GoogleCloudPlatform/gcloud-python/issues/922 for updates on this. If you'd like to be able to generate a signed URL from GCE, you can use a standard service account from a JSON file rather than a GCE service account.

If you have a blob that you want to allow access to for a set amount of time, you can use this method to generate a URL that is only valid within a certain time period.

This is particularly useful if you don't want publicly accessible blobs, but don't want to require users to explicitly log in.

Parameters

- **expiration** (*int, long, datetime.datetime, datetime.timedelta*) – When the signed URL should expire.

- **method** (*string*) – The HTTP verb that will be used when requesting the URL.
- **client** (*gcloud.storage.client.Client* or NoneType) – Optional. The client to use. If not passed, falls back to the client stored on the blob's bucket.
- **credentials** (oauth2client.client.OAuth2Credentials or NoneType) – The OAuth2 credentials to use to sign the URL.

Return type string

Returns A signed URL you can use to access the resource until expiration.

generation

Retrieve the generation for the object.

See: https://cloud.google.com/storage/docs/json_api/v1/objects

Return type integer or NoneType

Returns The generation of the blob or None if the property is not set locally.

id

Retrieve the ID for the object.

See: https://cloud.google.com/storage/docs/json_api/v1/objects

Return type string or NoneType

Returns The ID of the blob or None if the property is not set locally.

make_public(*client=None*)

Make this blob public giving all users read access.

Parameters **client** (*gcloud.storage.client.Client* or NoneType) – Optional. The client to use. If not passed, falls back to the client stored on the blob's bucket.

md5_hash

MD5 hash for this object.

See: http://tools.ietf.org/html/rfc4960#appendix-B and https://cloud.google.com/storage/docs/json_api/v1/objects

If the property is not set locally, returns None.

Return type string or NoneType

media_link

Retrieve the media download URI for the object.

See: https://cloud.google.com/storage/docs/json_api/v1/objects

Return type string or NoneType

Returns The media link for the blob or None if the property is not set locally.

metadata

Retrieve arbitrary/application specific metadata for the object.

See: https://cloud.google.com/storage/docs/json_api/v1/objects

Return type dict or NoneType

Returns The metadata associated with the blob or None if the property is not set locally.

metageneration

Retrieve the metageneration for the object.

See: https://cloud.google.com/storage/docs/json_api/v1/objects

Return type integer or `NoneType`

Returns The metageneration of the blob or `None` if the property is not set locally.

owner
Retrieve info about the owner of the object.

See: https://cloud.google.com/storage/docs/json_api/v1/objects

Return type dict or `NoneType`

Returns Mapping of owner's role/ID. If the property is not set locally, returns `None`.

path
Getter property for the URL path to this Blob.

Return type string

Returns The URL path to this Blob.

static **path_helper**(*bucket_path*, *blob_name*)
Relative URL path for a blob.

Parameters

- **bucket_path** (*string*) – The URL path for a bucket.
- **blob_name** (*string*) – The name of the blob.

Return type string

Returns The relative URL path for `blob_name`.

public_url
The public URL for this blob's object.

Return type *string*

Returns The public URL for this blob.

self_link
Retrieve the URI for the object.

See: https://cloud.google.com/storage/docs/json_api/v1/objects

Return type string or `NoneType`

Returns The self link for the blob or `None` if the property is not set locally.

size
Size of the object, in bytes.

See: https://cloud.google.com/storage/docs/json_api/v1/objects

Return type integer or `NoneType`

Returns The size of the blob or `None` if the property is not set locally.

storage_class
Retrieve the storage class for the object.

See: https://cloud.google.com/storage/docs/storage-classes https://cloud.google.com/storage/docs/nearline-storage https://cloud.google.com/storage/docs/durable-reduced-availability

Return type string or `NoneType`

Returns If set, one of "STANDARD", "NEARLINE", or "DURABLE_REDUCED_AVAILABILITY", else `None`.

time_deleted
Retrieve the timestamp at which the object was deleted.

See: https://cloud.google.com/storage/docs/json_api/v1/objects

Return type datetime.datetime or NoneType

Returns Datetime object parsed from RFC3339 valid timestamp, or None if the property is not set locally. If the blob has not been deleted, this will never be set.

updated
Retrieve the timestamp at which the object was updated.

See: https://cloud.google.com/storage/docs/json_api/v1/objects

Return type datetime.datetime or NoneType

Returns Datetime object parsed from RFC3339 valid timestamp, or None if the property is not set locally.

upload_from_file(*file_obj*, *rewind=False*, *size=None*, *content_type=None*, *num_retries=6*, *client=None*)
Upload the contents of this blob from a file-like object.

The content type of the upload will either be - The value passed in to the function (if any) - The value stored on the current blob - The default value of 'application/octet-stream'

Note: The effect of uploading to an existing blob depends on the "versioning" and "lifecycle" policies defined on the blob's bucket. In the absence of those policies, upload will overwrite any existing contents.

See the object versioning and lifecycle API documents for details.

Parameters

- **file_obj** (*file*) – A file handle open for reading.
- **rewind** (*boolean*) – If True, seek to the beginning of the file handle before writing the file to Cloud Storage.
- **size** (*int*) – The number of bytes to read from the file handle. If not provided, we'll try to guess the size using os.fstat(). (If the file handle is not from the filesystem this won't be possible.)
- **content_type** (string or NoneType) – Optional type of content being uploaded.
- **num_retries** (*integer*) – Number of upload retries. Defaults to 6.
- **client** (*gcloud.storage.client.Client* or NoneType) – Optional. The client to use. If not passed, falls back to the client stored on the blob's bucket.

Raises ValueError if size is not passed in and can not be determined

upload_from_filename(*filename*, *content_type=None*, *client=None*)
Upload this blob's contents from the content of a named file.

The content type of the upload will either be - The value passed in to the function (if any) - The value stored on the current blob - The value given by mimetypes.guess_type

---

Note: The effect of uploading to an existing blob depends on the "versioning" and "lifecycle" policies defined on the blob's bucket. In the absence of those policies, upload will overwrite any existing contents.

See the object versioning and lifecycle API documents for details.

Parameters

- **filename** (*string*) – The path to the file.
- **content_type** (string or NoneType) – Optional type of content being uploaded.
- **client** (*gcloud.storage.client.Client* or NoneType) – Optional. The client to use. If not passed, falls back to the client stored on the blob's bucket.

upload_from_string(*data*, *content_type='text/plain'*, *client=None*)

Upload contents of this blob from the provided string.

Note: The effect of uploading to an existing blob depends on the "versioning" and "lifecycle" policies defined on the blob's bucket. In the absence of those policies, upload will overwrite any existing contents.

See the object versioning and lifecycle API documents for details.

Parameters

- **data** (*bytes or text*) – The data to store in this blob. If the value is text, it will be encoded as UTF-8.
- **content_type** (*string*) – Optional type of content being uploaded. Defaults to 'text/plain'.
- **client** (*gcloud.storage.client.Client* or NoneType) – Optional. The client to use. If not passed, falls back to the client stored on the blob's bucket.

CHAPTER 14

Buckets

Create / interact with gcloud storage buckets.

class `gcloud.storage.bucket.`**`Bucket`**(*client*, *name=None*)
Bases: `gcloud.storage._helpers._PropertyMixin`

A class representing a Bucket on Cloud Storage.

Parameters

- **`client`** (*`gcloud.storage.client.Client`*) – A client which holds credentials and project configuration for the bucket (which requires a project).
- **`name`** (*`string`*) – The name of the bucket.

`acl`
Create our ACL on demand.

`blob`(*blob_name*, *chunk_size=None*)
Factory constructor for blob object.

Note: This will not make an HTTP request; it simply instantiates a blob object owned by this bucket.

Parameters

- **`blob_name`** (*`string`*) – The name of the blob to be instantiated.
- **`chunk_size`** (*`integer`*) – The size of a chunk of data whenever iterating (1 MB). This must be a multiple of 256 KB per the API specification.

Return type *`gcloud.storage.blob.Blob`*

Returns The blob object created.

`client`
The client bound to this bucket.

`configure_website`(*main_page_suffix=None*, *not_found_page=None*)
Configure website-related properties.

See: https://developers.google.com/storage/docs/website-configuration

Note: This (apparently) only works if your bucket name is a domain name (and to do that, you need to get approved somehow...).

If you want this bucket to host a website, just provide the name of an index page and a page to use when a blob isn't found:

```
>>> from gcloud import storage
>>> client = storage.Client()
>>> bucket = client.get_bucket(bucket_name)
>>> bucket.configure_website('index.html', '404.html')
```

You probably should also make the whole bucket public:

```
>>> bucket.make_public(recursive=True, future=True)
```

This says: "Make the bucket public, and all the stuff already in the bucket, and anything else I add to the bucket. Just make it all public."

Parameters

- **main_page_suffix** (*string*) – The page to use as the main page of a directory. Typically something like index.html.
- **not_found_page** (*string*) – The file to use when a page isn't found.

copy_blob(*blob*, *destination_bucket*, *new_name=None*, *client=None*)

Copy the given blob to the given bucket, optionally with a new name.

Parameters

- **blob** (*gcloud.storage.blob.Blob*) – The blob to be copied.
- **destination_bucket** (*gcloud.storage.bucket.Bucket*) – The bucket into which the blob should be copied.
- **new_name** (*string*) – (optional) the new name for the copied file.
- **client** (*gcloud.storage.client.Client* or `NoneType`) – Optional. The client to use. If not passed, falls back to the `client` stored on the current bucket.

Return type *gcloud.storage.blob.Blob*

Returns The new Blob.

cors

Retrieve CORS policies configured for this bucket.

See: http://www.w3.org/TR/cors/ and https://cloud.google.com/storage/docs/json_api/v1/buckets

Return type list of dictionaries

Returns A sequence of mappings describing each CORS policy.

create(*client=None*)

Creates current bucket.

If the bucket already exists, will raise *gcloud.exceptions.Conflict*.

This implements "storage.buckets.insert".

Parameters **client** (*gcloud.storage.client.Client* or `NoneType`) – Optional. The client to use. If not passed, falls back to the `client` stored on the current bucket.

Return type *gcloud.storage.bucket.Bucket*

Returns The newly created bucket.

default_object_acl
Create our defaultObjectACL on demand.

delete(*force=False*, *client=None*)
Delete this bucket.

The bucket **must** be empty in order to submit a delete request. If `force=True` is passed, this will first attempt to delete all the objects / blobs in the bucket (i.e. try to empty the bucket).

If the bucket doesn't exist, this will raise *gcloud.exceptions.NotFound*. If the bucket is not empty (and `force=False`), will raise *gcloud.exceptions.Conflict*.

If `force=True` and the bucket contains more than 256 objects / blobs this will cowardly refuse to delete the objects (or the bucket). This is to prevent accidental bucket deletion and to prevent extremely long runtime of this method.

Parameters

- **force** (*boolean*) – If True, empties the bucket's objects then deletes it.
- **client** (*gcloud.storage.client.Client* or `NoneType`) – Optional. The client to use. If not passed, falls back to the `client` stored on the current bucket.

Raises `ValueError` if `force` is `True` and the bucket contains more than 256 objects / blobs.

delete_blob(*blob_name*, *client=None*)
Deletes a blob from the current bucket.

If the blob isn't found (backend 404), raises a *gcloud.exceptions.NotFound*.

For example:

```
>>> from gcloud.exceptions import NotFound
>>> from gcloud import storage
>>> client = storage.Client()
>>> bucket = client.get_bucket('my-bucket')
>>> print bucket.list_blobs()
[<Blob: my-bucket, my-file.txt>]
>>> bucket.delete_blob('my-file.txt')
>>> try:
...   bucket.delete_blob('doesnt-exist')
... except NotFound:
...   pass
```

Parameters

- **blob_name** (*string*) – A blob name to delete.
- **client** (*gcloud.storage.client.Client* or `NoneType`) – Optional. The client to use. If not passed, falls back to the `client` stored on the current bucket.

Raises *gcloud.exceptions.NotFound* (to suppress the exception, call `delete_blobs`, passing a no-op `on_error` callback, e.g.:

```
>>> bucket.delete_blobs([blob], on_error=lambda blob: None)
```

delete_blobs(*blobs*, *on_error=None*, *client=None*)
Deletes a list of blobs from the current bucket.

Uses *Bucket.delete_blob()* to delete each individual blob.

Parameters

- **blobs** (list of string or *gcloud.storage.blob.Blob*) – A list of blob names or Blob objects to delete.
- **on_error** (*a callable taking (blob)*) – If not `None`, called once for each blob raising *gcloud.exceptions.NotFound*; otherwise, the exception is propagated.
- **client** (*gcloud.storage.client.Client* or `NoneType`) – Optional. The client to use. If not passed, falls back to the `client` stored on the current bucket.

Raises *gcloud.exceptions.NotFound* (if *on_error* is not passed).

disable_logging()
Disable access logging for this bucket.

See: https://cloud.google.com/storage/docs/accesslogs#disabling

disable_website()
Disable the website configuration for this bucket.

This is really just a shortcut for setting the website-related attributes to `None`.

enable_logging(*bucket_name*, *object_prefix=''*)
Enable access logging for this bucket.

See: https://cloud.google.com/storage/docs/accesslogs#delivery

Parameters

- **bucket_name** (*string*) – name of bucket in which to store access logs
- **object_prefix** (*string*) – prefix for access log filenames

etag
Retrieve the ETag for the bucket.

See: http://tools.ietf.org/html/rfc2616#section-3.11 and https://cloud.google.com/storage/docs/json_api/v1/buckets

Return type string or `NoneType`

Returns The bucket etag or `None` if the property is not set locally.

exists(*client=None*)
Determines whether or not this bucket exists.

Parameters **client** (*gcloud.storage.client.Client* or `NoneType`) – Optional. The client to use. If not passed, falls back to the `client` stored on the current bucket.

Return type boolean

Returns True if the bucket exists in Cloud Storage.

get_blob(*blob_name*, *client=None*)
Get a blob object by name.

This will return None if the blob doesn't exist:

```
>>> from gcloud import storage
>>> client = storage.Client()
>>> bucket = client.get_bucket('my-bucket')
>>> print bucket.get_blob('/path/to/blob.txt')
<Blob: my-bucket, /path/to/blob.txt>
>>> print bucket.get_blob('/does-not-exist.txt')
None
```

Parameters

- **blob_name** (*string*) – The name of the blob to retrieve.
- **client** (*gcloud.storage.client.Client* or NoneType) – Optional. The client to use. If not passed, falls back to the client stored on the current bucket.

Return type *gcloud.storage.blob.Blob* or None

Returns The blob object if it exists, otherwise None.

get_logging()
Return info about access logging for this bucket.

See: https://cloud.google.com/storage/docs/accesslogs#status

Return type dict or None

Returns a dict w/ keys, logBucket and logObjectPrefix (if logging is enabled), or None (if not).

id
Retrieve the ID for the bucket.

See: https://cloud.google.com/storage/docs/json_api/v1/buckets

Return type string or NoneType

Returns The ID of the bucket or None if the property is not set locally.

lifecycle_rules
Lifecycle rules configured for this bucket.

See: https://cloud.google.com/storage/docs/lifecycle and https://cloud.google.com/storage/docs/json_api/v1/buckets

Return type list(dict)

Returns A sequence of mappings describing each lifecycle rule.

list_blobs(*max_results=None*, *page_token=None*, *prefix=None*, *delimiter=None*, *versions=None*, *projection='noAcl'*, *fields=None*, *client=None*)
Return an iterator used to find blobs in the bucket.

Parameters

- **max_results** (integer or NoneType) – maximum number of blobs to return.
- **page_token** (*string*) – opaque marker for the next "page" of blobs. If not passed, will return the first page of blobs.
- **prefix** (string or NoneType) – optional prefix used to filter blobs.
- **delimiter** (string or NoneType) – optional delimter, used with prefix to emulate hierarchy.
- **versions** (boolean or NoneType) – whether object versions should be returned as separate blobs.
- **projection** (string or NoneType) – If used, must be 'full' or 'noAcl'. Defaults to 'noAcl'. Specifies the set of properties to return.
- **fields** (string or NoneType) – Selector specifying which fields to include in a partial response. Must be a list of fields. For example to get a partial response with just the next page token and the language of each blob returned: 'items/contentLanguage,nextPageToken'

- **client** (*gcloud.storage.client.Client* or NoneType) – Optional. The client to use. If not passed, falls back to the client stored on the current bucket.

Return type _BlobIterator.

Returns An iterator of blobs.

location
Retrieve location configured for this bucket.

See: https://cloud.google.com/storage/docs/json_api/v1/buckets and https://cloud.google.com/storage/docs/concepts-techniques#specifyinglocations

If the property is not set locally, returns None.

Return type string or NoneType

make_public(*recursive=False*, *future=False*, *client=None*)
Make a bucket public.

If recursive=True and the bucket contains more than 256 objects / blobs this will cowardly refuse to make the objects public. This is to prevent extremely long runtime of this method.

Parameters

- **recursive** (*boolean*) – If True, this will make all blobs inside the bucket public as well.
- **future** (*boolean*) – If True, this will make all objects created in the future public as well.
- **client** (*gcloud.storage.client.Client* or NoneType) – Optional. The client to use. If not passed, falls back to the client stored on the current bucket.

metageneration
Retrieve the metageneration for the bucket.

See: https://cloud.google.com/storage/docs/json_api/v1/buckets

Return type integer or NoneType

Returns The metageneration of the bucket or None if the property is not set locally.

owner
Retrieve info about the owner of the bucket.

See: https://cloud.google.com/storage/docs/json_api/v1/buckets

Return type dict or NoneType

Returns Mapping of owner's role/ID. If the property is not set locally, returns None.

path
The URL path to this bucket.

static **path_helper**(*bucket_name*)
Relative URL path for a bucket.

Parameters **bucket_name** (*string*) – The bucket name in the path.

Return type string

Returns The relative URL path for bucket_name.

project_number
Retrieve the number of the project to which the bucket is assigned.

See: https://cloud.google.com/storage/docs/json_api/v1/buckets

Return type integer or `NoneType`

Returns The project number that owns the bucket or `None` if the property is not set locally.

rename_blob(*blob*, *new_name*, *client=None*)
Rename the given blob using copy and delete operations.

Effectively, copies blob to the same bucket with a new name, then deletes the blob.

Warning: This method will first duplicate the data and then delete the old blob. This means that with very large objects renaming could be a very (temporarily) costly or a very slow operation.

Parameters

- **blob** (*gcloud.storage.blob.Blob*) – The blob to be renamed.
- **new_name** (*string*) – The new name for this blob.
- **client** (*gcloud.storage.client.Client* or `NoneType`) – Optional. The client to use. If not passed, falls back to the `client` stored on the current bucket.

Return type `Blob`

Returns The newly-renamed blob.

self_link
Retrieve the URI for the bucket.

See: https://cloud.google.com/storage/docs/json_api/v1/buckets

Return type string or `NoneType`

Returns The self link for the bucket or `None` if the property is not set locally.

storage_class
Retrieve the storage class for the bucket.

See: https://cloud.google.com/storage/docs/storage-classes https://cloud.google.com/storage/docs/nearline-storage https://cloud.google.com/storage/docs/durable-reduced-availability

Return type string or `NoneType`

Returns If set, one of "STANDARD", "NEARLINE", or "DURABLE_REDUCED_AVAILABILITY", else `None`.

time_created
Retrieve the timestamp at which the bucket was created.

See: https://cloud.google.com/storage/docs/json_api/v1/buckets

Return type `datetime.datetime` or `NoneType`

Returns Datetime object parsed from RFC3339 valid timestamp, or `None` if the property is not set locally.

versioning_enabled
Is versioning enabled for this bucket?

See: https://cloud.google.com/storage/docs/object-versioning for details.

Return type boolean

Returns True if enabled, else False.

CHAPTER 15

ACL

Manipulate access control lists that Cloud Storage provides.

gcloud.storage.bucket.Bucket has a getting method that creates an ACL object under the hood, and you can interact with that using *gcloud.storage.bucket.Bucket.acl()*:

```
>>> from gcloud import storage
>>> client = storage.Client()
>>> bucket = client.get_bucket(bucket_name)
>>> acl = bucket.acl
```

Adding and removing permissions can be done with the following methods (in increasing order of granularity):

- *ACL.all()* corresponds to access for all users.
- *ACL.all_authenticated()* corresponds to access for all users that are signed into a Google account.
- *ACL.domain()* corresponds to access on a per Google Apps domain (ie, `example.com`).
- *ACL.group()* corresponds to access on a per group basis (either by ID or e-mail address).
- *ACL.user()* corresponds to access on a per user basis (either by ID or e-mail address).

And you are able to `grant` and `revoke` the following roles:

- **Reading**: `_ACLEntity.grant_read()` and `_ACLEntity.revoke_read()`
- **Writing**: `_ACLEntity.grant_write()` and `_ACLEntity.revoke_write()`
- **Owning**: `_ACLEntity.grant_owner()` and `_ACLEntity.revoke_owner()`

You can use any of these like any other factory method (these happen to be `_ACLEntity` factories):

```
>>> acl.user('me@example.org').grant_read()
>>> acl.all_authenticated().grant_write()
```

You can also chain these `grant_*` and `revoke_*` methods together for brevity:

```
>>> acl.all().grant_read().revoke_write()
```

After that, you can save any changes you make with the *gcloud.storage.acl.ACL.save()* method:

```
>>> acl.save()
```

You can alternatively save any existing *gcloud.storage.acl.ACL* object (whether it was created by a factory method or not) from a *gcloud.storage.bucket.Bucket*:

```
>>> bucket.acl.save(acl=acl)
```

To get the list of `entity` and `role` for each unique pair, the *ACL* class is iterable:

```
>>> print list(ACL)
[{'role': 'OWNER', 'entity': 'allUsers'}, ...]
```

This list of tuples can be used as the `entity` and `role` fields when sending metadata for ACLs to the API.

class gcloud.storage.acl.**ACL**
Bases: object

Container class representing a list of access controls.

add_entity(*entity*)
Add an entity to the ACL.

Parameters **entity** (_ACLEntity) – The entity to add to this ACL.

all()
Factory method for an Entity representing all users.

Return type _ACLEntity

Returns An entity representing all users.

all_authenticated()
Factory method for an Entity representing all authenticated users.

Return type _ACLEntity

Returns An entity representing all authenticated users.

clear(*client=None*)
Remove all ACL entries.

Note that this won't actually remove *ALL* the rules, but it will remove all the non-default rules. In short, you'll still have access to a bucket that you created even after you clear ACL rules with this method.

Parameters **client** (*gcloud.storage.client.Client* or NoneType) – Optional. The client to use. If not passed, falls back to the `client` stored on the ACL's parent.

client
Abstract getter for the object client.

domain(*domain*)
Factory method for a domain Entity.

Parameters **domain** (*string*) – The domain for this entity.

Return type _ACLEntity

Returns An entity corresponding to this domain.

entity(*entity_type*, *identifier=None*)
Factory method for creating an Entity.

If an entity with the same type and identifier already exists, this will return a reference to that entity. If not, it will create a new one and add it to the list of known entities for this ACL.

Parameters

- **entity_type** (*string*) – The type of entity to create (ie, `user`, `group`, etc)
- **identifier** (*string*) – The ID of the entity (if applicable). This can be either an ID or an e-mail address.

Return type _ACLEntity

Returns A new Entity or a reference to an existing identical entity.

entity_from_dict(*entity_dict*)
Build an _ACLEntity object from a dictionary of data.

An entity is a mutable object that represents a list of roles belonging to either a user or group or the special types for all users and all authenticated users.

Parameters **entity_dict** (*dict*) – Dictionary full of data from an ACL lookup.

Return type _ACLEntity

Returns An Entity constructed from the dictionary.

get_entities()
Get a list of all Entity objects.

Return type list of _ACLEntity objects

Returns A list of all Entity objects.

get_entity(*entity*, *default=None*)
Gets an entity object from the ACL.

Parameters

- **entity** (_ACLEntity or string) – The entity to get lookup in the ACL.
- **default** (*anything*) – This value will be returned if the entity doesn't exist.

Return type _ACLEntity

Returns The corresponding entity or the value provided to default.

group(*identifier*)
Factory method for a group Entity.

Parameters **identifier** (*string*) – An id or e-mail for this particular group.

Return type _ACLEntity

Returns An Entity corresponding to this group.

has_entity(*entity*)
Returns whether or not this ACL has any entries for an entity.

Parameters **entity** (_ACLEntity) – The entity to check for existence in this ACL.

Return type boolean

Returns True of the entity exists in the ACL.

loaded = False

reload(*client=None*)
Reload the ACL data from Cloud Storage.

Parameters **client** (*gcloud.storage.client.Client* or NoneType) – Optional. The client to use. If not passed, falls back to the client stored on the ACL's parent.

reload_path = None

reset()
Remove all entities from the ACL, and clear the loaded flag.

save(*acl=None*, *client=None*)
Save this ACL for the current bucket.

Parameters

- **acl** (*gcloud.storage.acl.ACL*, or a compatible list.) – The ACL object to save. If left blank, this will save current entries.
- **client** (*gcloud.storage.client.Client* or `NoneType`) – Optional. The client to use. If not passed, falls back to the `client` stored on the ACL's parent.

save_path = None

user(*identifier*)
Factory method for a user Entity.

Parameters **identifier** (*string*) – An id or e-mail for this particular user.

Return type `_ACLEntity`

Returns An Entity corresponding to this user.

class gcloud.storage.acl.**BucketACL**(*bucket*)
Bases: *gcloud.storage.acl.ACL*

An ACL specifically for a bucket.

Parameters **bucket** (*gcloud.storage.bucket.Bucket*) – The bucket to which this ACL relates.

client
The client bound to this ACL's bucket.

reload_path
Compute the path for GET API requests for this ACL.

save_path
Compute the path for PATCH API requests for this ACL.

class gcloud.storage.acl.**DefaultObjectACL**(*bucket*)
Bases: *gcloud.storage.acl.BucketACL*

A class representing the default object ACL for a bucket.

class gcloud.storage.acl.**ObjectACL**(*blob*)
Bases: *gcloud.storage.acl.ACL*

An ACL specifically for a Cloud Storage object / blob.

Parameters **blob** (*gcloud.storage.blob.Blob*) – The blob that this ACL corresponds to.

client
The client bound to this ACL's blob.

reload_path
Compute the path for GET API requests for this ACL.

save_path
Compute the path for PATCH API requests for this ACL.

CHAPTER 16

Using the API

16.1 Authentication / Configuration

- Use *Client* objects to configure your applications.
- *Client* objects hold both a `project` and an authenticated connection to the PubSub service.
- The authentication credentials can be implicitly determined from the environment or directly via `from_service_account_json` and `from_service_account_p12`.
- After setting `GOOGLE_APPLICATION_CREDENTIALS` and `GCLOUD_PROJECT` environment variables, create a *Client*

```
>>> from gcloud import pubsub
>>> client = pubsub.Client()
```

16.2 Manage topics for a project

Create a new topic for the default project:

```
>>> from gcloud import pubsub
>>> client = pubsub.Client()
>>> topic = client.topic('topic_name')
>>> topic.create()  # API request
```

Check for the existence of a topic:

```
>>> from gcloud import pubsub
>>> client = pubsub.Client()
>>> topic = client.topic('topic_name')
>>> topic.exists()  # API request
True
```

List topics for the default project:

```
>>> from gcloud import pubsub
>>> client = pubsub.Client()
>>> topics, next_page_token = client.list_topics()  # API request
>>> [topic.name for topic in topics]
['topic_name']
```

Delete a topic:

```
>>> from gcloud import pubsub
>>> client = pubsub.Client()
>>> topic = client.topic('topic_name')
>>> topic.delete()  # API request
```

16.3 Publish messages to a topic

Publish a single message to a topic, without attributes:

```
>>> from gcloud import pubsub
>>> client = pubsub.Client()
>>> topic = client.topic('topic_name')
>>> topic.publish('this is the message_payload')  # API request
<message_id>
```

Publish a single message to a topic, with attributes:

```
>>> from gcloud import pubsub
>>> client = pubsub.Client()
>>> topic = client.topic('topic_name')
>>> topic.publish('this is another message_payload',
...               attr1='value1', attr2='value2')  # API request
<message_id>
```

Publish a set of messages to a topic (as a single request):

```
>>> from gcloud import pubsub
>>> client = pubsub.Client()
>>> topic = client.topic('topic_name')
>>> with topic.batch() as batch:
...     batch.publish('this is the first message_payload')
...     batch.publish('this is the second message_payload',
...                   attr1='value1', attr2='value2')
>>> list(batch)
[<message_id1>, <message_id2>]
```

Note: The only API request happens during the `__exit__()` of the topic used as a context manager.

16.4 Manage subscriptions to topics

Create a new pull subscription for a topic:

```
>>> from gcloud import pubsub
>>> client = pubsub.Client()
>>> topic = client.topic('topic_name')
>>> subscription = topic.subscription('subscription_name')
>>> subscription.create()  # API request
```

Create a new pull subscription for a topic with a non-default ACK deadline:

```
>>> from gcloud import pubsub
>>> client = pubsub.Client()
>>> topic = client.topic('topic_name')
```

```
>>> subscription = topic.subscription('subscription_name', ack_deadline=90)
>>> subscription.create()  # API request
```

Create a new push subscription for a topic:

```
>>> from gcloud import pubsub
>>> ENDPOINT = 'https://example.com/hook'
>>> client = pubsub.Client()
>>> topic = client.topic('topic_name')
>>> subscription = topic.subscription('subscription_name',
...                                   push_endpoint=ENDPOINT)
>>> subscription.create()  # API request
```

Check for the existence of a subscription:

```
>>> from gcloud import pubsub
>>> client = pubsub.Client()
>>> topic = client.topic('topic_name')
>>> subscription = topic.subscription('subscription_name')
>>> subscription.exists()  # API request
True
```

Convert a pull subscription to push:

```
>>> from gcloud import pubsub
>>> ENDPOINT = 'https://example.com/hook'
>>> client = pubsub.Client()
>>> topic = client.topic('topic_name')
>>> subscription = topic.subscription('subscription_name')
>>> subscription.modify_push_configuration(push_endpoint=ENDPOINT)  # API request
```

Convert a push subscription to pull:

```
>>> from gcloud import pubsub
>>> ENDPOINT = 'https://example.com/hook'
>>> client = pubsub.Client()
>>> topic = client.topic('topic_name')
>>> subscription = topic.subscription('subscription_name',
...                                   push_endpoint=ENDPOINT)
>>> subscription.modify_push_configuration(push_endpoint=None)  # API request
```

List subscriptions for a topic:

```
>>> from gcloud import pubsub
>>> client = pubsub.Client()
>>> subscriptions, next_page_token = client.list_subscriptions(
...     topic_name='topic_name')  # API request
>>> [subscription.name for subscription in subscriptions]
['subscription_name']
```

List all subscriptions for the default project:

```
>>> from gcloud import pubsub
>>> client = pubsub.Client()
>>> subscription, next_page_tokens = client.list_subscriptions()  # API request
>>> [subscription.name for subscription in subscriptions]
['subscription_name']
```

Delete a subscription:

```
>>> from gcloud import pubsub
>>> client = pubsub.Client()
>>> topic = client.topic('topic_name')
>>> subscription = topic.subscription('subscription_name')
>>> subscription.delete()  # API request
```

16.5 Pull messages from a subscription

Fetch pending messages for a pull subscription:

```
>>> from gcloud import pubsub
>>> client = pubsub.Client()
>>> topic = client.topic('topic_name')
>>> subscription = topic.subscription('subscription_name')
>>> with topic.batch() as batch:
...     batch.publish('this is the first message_payload')
...     batch.publish('this is the second message_payload',
...                   attr1='value1', attr2='value2')
>>> received = subscription.pull()  # API request
>>> messages = [recv[1] for recv in received]
>>> [message.id for message in messages]
[<message_id1>, <message_id2>]
>>> [message.data for message in messages]
['this is the first message_payload', 'this is the second message_payload']
>>> [message.attributes for message in messages]
[{}, {'attr1': 'value1', 'attr2': 'value2'}]
```

Note that received messages must be acknowledged, or else the back-end will re-send them later:

```
>>> ack_ids = [recv[0] for recv in received]
>>> subscription.acknowledge(ack_ids)
```

Fetch a limited number of pending messages for a pull subscription:

```
>>> from gcloud import pubsub
>>> client = pubsub.Client()
>>> topic = client.topic('topic_name')
>>> subscription = topic.subscription('subscription_name')
>>> with topic.batch() as batch:
...     batch.publish('this is the first message_payload')
...     batch.publish('this is the second message_payload',
...                   attr1='value1', attr2='value2')
>>> received = subscription.pull(max_messages=1)  # API request
>>> messages = [recv[1] for recv in received]
>>> [message.id for message in messages]
```

Fetch messages for a pull subscription without blocking (none pending):

```
>>> from gcloud import pubsub
>>> client = pubsub.Client()
>>> topic = client.topic('topic_name')
>>> subscription = topic.subscription('subscription_name')
>>> received = subscription.pull(return_immediately=True)  # API request
>>> messages = [recv[1] for recv in received]
>>> [message.id for message in messages]
[]
```

CHAPTER 17

Pub/Sub Client

Client for interacting with the Google Cloud Pub/Sub API.

class gcloud.pubsub.client.**Client**(*project=None*, *credentials=None*, *http=None*)
Bases: *gcloud.client.JSONClient*

Client to bundle configuration needed for API requests.

Parameters

- **project** (*string*) – the project which the client acts on behalf of. Will be passed when creating a topic. If not passed, falls back to the default inferred from the environment.
- **credentials** (oauth2client.client.OAuth2Credentials or NoneType) – The OAuth2 Credentials to use for the connection owned by this client. If not passed (and if no http object is passed), falls back to the default inferred from the environment.
- **http** (httplib2.Http or class that defines request().) – An optional HTTP object to make requests. If not passed, an http object is created that is bound to the credentials for the current object.

list_subscriptions(*page_size=None*, *page_token=None*, *topic_name=None*)
List subscriptions for the project associated with this client.

See: https://cloud.google.com/pubsub/reference/rest/v1beta2/projects/topics/list

and (where topic_name is passed): https://cloud.google.com/pubsub/reference/rest/v1beta2/projects/topics/subscriptions/

Parameters

- **page_size** (*int*) – maximum number of topics to return, If not passed, defaults to a value set by the API.
- **page_token** (*string*) – opaque marker for the next "page" of topics. If not passed, the API will return the first page of topics.
- **topic_name** (*string*) – limit results to subscriptions bound to the given topic.

Return type tuple, (list, str)

Returns list of *gcloud.pubsub.subscription.Subscription*, plus a "next page token" string: if not None, indicates that more topics can be retrieved with another call (pass that value as page_token).

list_topics(*page_size=None*, *page_token=None*)
List topics for the project associated with this client.

See: https://cloud.google.com/pubsub/reference/rest/v1beta2/projects/topics/list

Parameters

- **page_size** (*int*) – maximum number of topics to return, If not passed, defaults to a value set by the API.
- **page_token** (*string*) – opaque marker for the next "page" of topics. If not passed, the API will return the first page of topics.

Return type tuple, (list, str)

Returns list of *gcloud.pubsub.topic.Topic*, plus a "next page token" string: if not None, indicates that more topics can be retrieved with another call (pass that value as `page_token`).

topic(*name*, *timestamp_messages=False*)
Creates a topic bound to the current client.

Parameters

- **name** (*string*) – the name of the topic to be constructed.
- **timestamp_messages** (*boolean*) – To be passed to `Topic` constructor.

Return type *gcloud.pubsub.topic.Topic*

Returns Topic created with the current client.

17.1 Connection

Create / interact with gcloud pubsub connections.

class `gcloud.pubsub.connection.`**Connection**(*credentials=None*, *http=None*)
Bases: *gcloud.connection.JSONConnection*

A connection to Google Cloud Pubsub via the JSON REST API.

Parameters

- **credentials** (`oauth2client.client.OAuth2Credentials`) – (Optional) The OAuth2 Credentials to use for this connection.
- **http** (`httplib2.Http` or class that defines `request()`.) – (Optional) HTTP object to make requests.

API_BASE_URL = 'https://pubsub.googleapis.com'
The base of the API call URL.

API_URL_TEMPLATE = '{api_base_url}/{api_version}{path}'
A template for the URL of a particular API call.

API_VERSION = 'v1'
The version of the API, used in building the API call's URL.

SCOPE = ('https://www.googleapis.com/auth/pubsub', 'https://www.googleapis.com/auth/cloud-platform')
The scopes required for authenticating as a Cloud Pub/Sub consumer.

CHAPTER 18

Topics

Define API Topics.

class gcloud.pubsub.topic.**Batch**(*topic*, *client*)
Bases: object

Context manager: collect messages to publish via a single API call.

Helper returned by :meth:Topic.batch

Parameters

- **topic** (*gcloud.pubsub.topic.Topic*) – the topic being published
- **client** (*gcloud.pubsub.client.Client*) – The client to use.

commit(*client=None*)
Send saved messages as a single API call.

Parameters **client** (*gcloud.pubsub.client.Client* or NoneType) – the client to use. If not passed, falls back to the client stored on the current batch.

publish(*message*, ***attrs*)
Emulate publishing a message, but save it.

Parameters

- **message** (*bytes*) – the message payload
- **attrs** (*dict (string -> string)*) – key-value pairs to send as message attributes

class gcloud.pubsub.topic.**Topic**(*name*, *client*, *timestamp_messages=False*)
Bases: object

Topics are targets to which messages can be published.

Subscribers then receive those messages.

See: https://cloud.google.com/pubsub/reference/rest/v1beta2/projects/topics

Parameters

- **name** (*string*) – the name of the topic
- **client** (*gcloud.pubsub.client.Client*) – A client which holds credentials and project configuration for the topic (which requires a project).
- **timestamp_messages** (*boolean*) – If true, the topic will add a timestamp key to the attributes of each published message: the value will be an RFC 3339 timestamp.

batch(*client=None*)
Return a batch to use as a context manager.

Parameters **client** (*gcloud.pubsub.client.Client* or NoneType) – the client to use. If not passed, falls back to the client stored on the current topic.

Return type *Batch*

Returns A batch to use as a context manager.

create(*client=None*)
API call: create the topic via a PUT request

See: https://cloud.google.com/pubsub/reference/rest/v1beta2/projects/topics/create

Parameters **client** (*gcloud.pubsub.client.Client* or NoneType) – the client to use. If not passed, falls back to the client stored on the current topic.

delete(*client=None*)
API call: delete the topic via a DELETE request

See: https://cloud.google.com/pubsub/reference/rest/v1beta2/projects/topics/delete

Parameters **client** (*gcloud.pubsub.client.Client* or NoneType) – the client to use. If not passed, falls back to the client stored on the current topic.

exists(*client=None*)
API call: test for the existence of the topic via a GET request

See https://cloud.google.com/pubsub/reference/rest/v1beta2/projects/topics/get

Parameters **client** (*gcloud.pubsub.client.Client* or NoneType) – the client to use. If not passed, falls back to the client stored on the current topic.

classmethod **from_api_repr**(*resource*, *client*)
Factory: construct a topic given its API representation

Parameters

- **resource** (*dict*) – topic resource representation returned from the API
- **client** (*gcloud.pubsub.client.Client*) – Client which holds credentials and project configuration for the topic.

Return type *gcloud.pubsub.topic.Topic*

Returns Topic parsed from resource.

Raises ValueError if client is not None and the project from the resource does not agree with the project from the client.

full_name
Fully-qualified name used in topic / subscription APIs

path
URL path for the topic's APIs

project
Project bound to the topic.

publish(*message*, *client=None*, ***attrs*)
API call: publish a message to a topic via a POST request

See: https://cloud.google.com/pubsub/reference/rest/v1beta2/projects/topics/publish

Parameters

- **message** (*bytes*) – the message payload
- **client** (*gcloud.pubsub.client.Client* or NoneType) – the client to use. If not passed, falls back to the client stored on the current topic.
- **attrs** (*dict (string -> string)*) – key-value pairs to send as message attributes

Return type str

Returns message ID assigned by the server to the published message

subscription(*name*, *ack_deadline=None*, *push_endpoint=None*)

Creates a subscription bound to the current topic.

Parameters

- **name** (*string*) – the name of the subscription
- **ack_deadline** (*int*) – the deadline (in seconds) by which messages pulled from the back-end must be acknowledged.
- **push_endpoint** (*string*) – URL to which messages will be pushed by the back-end. If not set, the application must pull messages.

CHAPTER 19

Subscriptions

Define API Subscriptions.

class gcloud.pubsub.subscription.**Subscription**(*name*, *topic*, *ack_deadline=None*, *push_endpoint=None*)

Bases: object

Subscriptions receive messages published to their topics.

See: https://cloud.google.com/pubsub/reference/rest/v1beta2/projects/subscriptions

Parameters

- **name** (*string*) – the name of the subscription
- **topic** (*gcloud.pubsub.topic.Topic*) – the topic to which the subscription belongs..
- **ack_deadline** (*int*) – the deadline (in seconds) by which messages pulled from the back-end must be acknowledged.
- **push_endpoint** (*string*) – URL to which messages will be pushed by the back-end. If not set, the application must pull messages.

acknowledge(*ack_ids*, *client=None*)

API call: acknowledge retrieved messages for the subscription.

See: https://cloud.google.com/pubsub/reference/rest/v1beta2/projects/subscriptions/acknowledge

Parameters

- **ack_ids** (*list of string*) – ack IDs of messages being acknowledged
- **client** (*gcloud.pubsub.client.Client* or NoneType) – the client to use. If not passed, falls back to the client stored on the current subscription's topic.

create(*client=None*)

API call: create the subscription via a PUT request

See: https://cloud.google.com/pubsub/reference/rest/v1beta2/projects/subscriptions/create

Parameters **client** (*gcloud.pubsub.client.Client* or NoneType) – the client to use. If not passed, falls back to the client stored on the current subscription's topic.

delete(*client=None*)

API call: delete the subscription via a DELETE request.

See: https://cloud.google.com/pubsub/reference/rest/v1beta2/projects/subscriptions/delete

Parameters **client** (*gcloud.pubsub.client.Client* or NoneType) – the client to use. If not passed, falls back to the client stored on the current subscription's topic.

exists(*client=None*)
API call: test existence of the subscription via a GET request

See https://cloud.google.com/pubsub/reference/rest/v1beta2/projects/subscriptions/get

Parameters **client** (*gcloud.pubsub.client.Client* or NoneType) – the client to use. If not passed, falls back to the client stored on the current subscription's topic.

classmethod from_api_repr(*resource*, *client*, *topics=None*)
Factory: construct a topic given its API representation

Parameters

- **resource** (*dict*) – topic resource representation returned from the API
- **client** (*gcloud.pubsub.client.Client*) – Client which holds credentials and project configuration for a topic.
- **topics** (*dict or None*) – A mapping of topic names -> topics. If not passed, the subscription will have a newly-created topic.

Return type *gcloud.pubsub.subscription.Subscription*

Returns Subscription parsed from resource.

modify_ack_deadline(*ack_id*, *ack_deadline*, *client=None*)
API call: update acknowledgement deadline for a retrieved message.

See: https://cloud.google.com/pubsub/reference/rest/v1beta2/projects/subscriptions/acknowledge

Parameters

- **ack_id** (*string*) – ack ID of message being updated
- **ack_deadline** (*int*) – new deadline for the message, in seconds
- **client** (*gcloud.pubsub.client.Client* or NoneType) – the client to use. If not passed, falls back to the client stored on the current subscription's topic.

modify_push_configuration(*push_endpoint*, *client=None*)
API call: update the push endpoint for the subscription.

See: https://cloud.google.com/pubsub/reference/rest/v1beta2/projects/subscriptions/modifyPushConfig

Parameters

- **push_endpoint** (*string*) – URL to which messages will be pushed by the back-end. If None, the application must pull messages.
- **client** (*gcloud.pubsub.client.Client* or NoneType) – the client to use. If not passed, falls back to the client stored on the current subscription's topic.

path
URL path for the subscription's APIs

pull(*return_immediately=False*, *max_messages=1*, *client=None*)
API call: retrieve messages for the subscription.

See: https://cloud.google.com/pubsub/reference/rest/v1beta2/projects/subscriptions/pull

Parameters

- **return_immediately** (*boolean*) – if True, the back-end returns even if no messages are available; if False, the API call blocks until one or more messages are available.

- **max_messages** (*int*) – the maximum number of messages to return.
- **client** (*gcloud.pubsub.client.Client* or NoneType) – the client to use. If not passed, falls back to the client stored on the current subscription's topic.

Return type list of (ack_id, message) tuples

Returns sequence of tuples: ack_id is the ID to be used in a subsequent call to *acknowledge()*, and message is an instance of gcloud.pubsub.message.Message.

reload(*client=None*)

API call: sync local subscription configuration via a GET request

See https://cloud.google.com/pubsub/reference/rest/v1beta2/projects/subscriptions/get

Parameters **client** (*gcloud.pubsub.client.Client* or NoneType) – the client to use. If not passed, falls back to the client stored on the current subscription's topic.

CHAPTER 20

Using the API

20.1 Authentication / Configuration

- Use *Client* objects to configure your applications.
- *Client* objects hold both a `project` and an authenticated connection to the BigQuery service.
- The authentication credentials can be implicitly determined from the environment or directly via `from_service_account_json` and `from_service_account_p12`.
- After setting `GOOGLE_APPLICATION_CREDENTIALS` and `GCLOUD_PROJECT` environment variables, create an instance of *Client*.

```
>>> from gcloud import bigquery
>>> client = bigquery.Client()
```

- Override the credentials inferred from the environment by passing explicit `credentials` to one of the alternative `classmethod` factories, *:meth:gcloud.bigquery.client.Client.from_service_account_json*:

```
>>> from gcloud import bigquery
>>> client = bigquery.Client.from_service_account_json('/path/to/creds.json')
```

or *:meth:gcloud.bigquery.client.Client.from_service_account_p12*:

```
>>> from gcloud import bigquery
>>> client = bigquery.Client.from_service_account_p12('/path/to/creds.p12', 'jrandom@example.com
```

20.2 Projects

A project is the top-level container in the `BigQuery` API: it is tied closely to billing, and can provide default access control across all its datasets. If no `project` is passed to the client container, the library attempts to infer a project using the environment (including explicit environment variables, GAE, and GCE).

To override the project inferred from the environment, pass an explicit `project` to the constructor, or to either of the alternative `classmethod` factories:

```
>>> from gcloud import bigquery
>>> client = bigquery.Client(project='PROJECT_ID')
```

20.2.1 Project ACLs

Each project has an access control list granting reader / writer / owner permission to one or more entities. This list cannot be queried or set via the API: it must be managed using the Google Developer Console.

20.3 Datasets

A dataset represents a collection of tables, and applies several default policies to tables as they are created:

- An access control list (ACL). When created, a dataset has an ACL which maps to the ACL inherited from its project.
- A default table expiration period. If set, tables created within the dataset will have the value as their expiration period.

20.3.1 Dataset operations

Create a new dataset for the client's project:

```
>>> from gcloud import bigquery
>>> client = bigquery.Client()
>>> dataset = client.dataset('dataset_name')
>>> dataset.create()  # API request
```

Check for the existence of a dataset:

```
>>> from gcloud import bigquery
>>> client = bigquery.Client()
>>> dataset = client.dataset('dataset_name')
>>> dataset.exists()  # API request
True
```

List datasets for the client's project:

```
>>> from gcloud import bigquery
>>> client = bigquery.Client()
>>> datasets, next_page_token = client.list_datasets()  # API request
>>> [dataset.name for dataset in datasets]
['dataset_name']
```

Refresh metadata for a dataset (to pick up changes made by another client):

```
>>> from gcloud import bigquery
>>> client = bigquery.Client()
>>> dataset = client.dataset('dataset_name')
>>> dataset.reload()  # API request
```

Patch metadata for a dataset:

```
>>> from gcloud import bigquery
>>> client = bigquery.Client()
>>> dataset = client.dataset('dataset_name')
>>> one_day_ms = 24 * 60 * 60 * 1000
>>> dataset.patch(description='Description goes here',
...               default_table_expiration_ms=one_day_ms)  # API request
```

Replace the ACL for a dataset, and update all writeable fields:

```
>>> from gcloud import bigquery
>>> client = bigquery.Client()
>>> dataset = client.dataset('dataset_name')
>>> dataset.get()  # API request
>>> acl = list(dataset.acl)
>>> acl.append(bigquery.Access(role='READER', entity_type='domain', entity='example.com'))
>>> dataset.acl = acl
>>> dataset.update()  # API request
```

Delete a dataset:

```
>>> from gcloud import bigquery
>>> client = bigquery.Client()
>>> dataset = client.dataset('dataset_name')
>>> dataset.delete()  # API request
```

20.4 Tables

Tables exist within datasets. List tables for the dataset:

```
>>> from gcloud import bigquery
>>> client = bigquery.Client()
>>> dataset = client.dataset('dataset_name')
>>> tables, next_page_token = dataset.list_tables()  # API request
>>> [table.name for table in tables]
['table_name']
```

Create a table:

```
>>> from gcloud import bigquery
>>> client = bigquery.Client()
>>> dataset = client.dataset('dataset_name')
>>> table = dataset.table(name='person_ages')
>>> table.create()  # API request
```

Check for the existence of a table:

```
>>> from gcloud import bigquery
>>> client = bigquery.Client()
>>> dataset = client.dataset('dataset_name')
>>> table = dataset.table(name='person_ages')
>>> table.exists()  # API request
True
```

Refresh metadata for a table (to pick up changes made by another client):

```
>>> from gcloud import bigquery
>>> client = bigquery.Client()
>>> dataset = client.dataset('dataset_name')
>>> dataset.reload()  # API request
```

Patch specific properties for a table:

```
>>> from gcloud import bigquery
>>> client = bigquery.Client()
>>> dataset = client.dataset('dataset_name')
>>> table = dataset.table(name='person_ages')
```

```
>>> table.patch(friendly_name='Person Ages',
...             description='Ages of persons')  # API request
```

Update all writable metadata for a table

```
>>> from gcloud import bigquery
>>> from gcloud.bigquery import SchemaField
>>> client = bigquery.Client()
>>> dataset = client.dataset('dataset_name')
>>> table = dataset.table(name='person_ages')
>>> table.schema = [
...     SchemaField(name='full_name', type='string', mode='required'),
...     SchemaField(name='age', type='int', mode='required)]
>>> table.update()  # API request
```

Get rows from a table's data:

```
>>> from gcloud import bigquery
>>> client = bigquery.Client()
>>> dataset = client.dataset('dataset_name')
>>> table = dataset.table(name='person_ages')
>>> rows, next_page_token = table.data(max_results=100)  # API request
>>> rows.csv.headers
('full_name', 'age')
>>> list(rows.csv)
[('Abel Adamson', 27), ('Beverly Bowman', 33)]
>>> for row in rows:
...     for field, value in zip(table.schema, row):
...         do_something(field, value)
```

Delete a table:

```
>>> from gcloud import bigquery
>>> client = bigquery.Client()
>>> dataset = client.dataset('dataset_name')
>>> table = dataset.table(name='person_ages')
>>> table.delete()  # API request
```

20.5 Jobs

Jobs describe actions peformed on data in BigQuery tables:

- Load data into a table
- Run a query against data in one or more tables
- Extract data from a table
- Copy a table

List jobs for a project:

```
>>> from gcloud import bigquery
>>> client = bigquery.Client()
>>> jobs = client.jobs()  # API request
>>> [(job.job_id, job.type, job.created, job.state) for job in jobs]
['e3344fba-09df-4ae0-8337-fddee34b3840', 'insert', (datetime.datetime(2015, 7, 23, 9, 30, 20, 268260,
```

20.5.1 Querying data (synchronous)

Run a query which can be expected to complete within bounded time:

```
>>> from gcloud import bigquery
>>> client = bigquery.Client()
>>> query = """\
SELECT count(*) AS age_count FROM dataset_name.person_ages
"""
>>> results = client.query(query, timeout_ms=1000)
>>> retry_count = 100
>>> while retry_count > 0 and not results.job_complete:
...     retry_count -= 1
...     time.sleep(10)
...     results.reload()  # API request
>>> results.schema
[{'name': 'age_count', 'type': 'integer', 'mode': 'nullable'}]
>>> results.rows
[(15,)]
```

Note: If the query takes longer than the timeout allowed, `results.job_complete` will be `False`: we therefore poll until it is completed.

20.5.2 Querying data (asynchronous)

Background a query, loading the results into a table:

```
>>> from gcloud import bigquery
>>> client = bigquery.Client()
>>> query = """\
SELECT firstname + ' ' + last_name AS full_name,
       FLOOR(DATEDIFF(CURRENT_DATE(), birth_date) / 365) AS age
 FROM dataset_name.persons
"""
>>> dataset = client.dataset('dataset_name')
>>> table = dataset.table(name='person_ages')
>>> job = client.query_async(query,
...                          destination=table,
...                          write_disposition='truncate')
>>> job.job_id
'e3344fba-09df-4ae0-8337-fddee34b3840'
>>> job.type
'query'
>>> job.created
None
>>> job.state
None
```

Note:

- `gcloud.bigquery` generates a UUID for each job.
- The `created` and `state` fields are not set until the job is submitted to the BigQuery back-end.

Then, begin executing the job on the server:

```
>>> job.submit()  # API call
>>> job.created
datetime.datetime(2015, 7, 23, 9, 30, 20, 268260, tzinfo=<UTC>)
>>> job.state
'running'
```

Poll until the job is complete:

```
>>> import time
>>> retry_count = 100
>>> while retry_count > 0 and job.state == 'running':
...     retry_count -= 1
...     time.sleep(10)
...     job.reload()  # API call
>>> job.state
'done'
>>> job.ended
datetime.datetime(2015, 7, 23, 9, 30, 21, 334792, tzinfo=<UTC>)
```

20.5.3 Inserting data (synchronous)

Load data synchronously from a local CSV file into a new table. First, create the job locally:

```
>>> from gcloud import bigquery
>>> client = bigquery.Client()
>>> table = dataset.table(name='person_ages')
>>> with open('/path/to/person_ages.csv', 'rb') as file_obj:
...     job = table.load_from_file(
...         file_obj,
...         source_format='CSV',
...         skip_leading_rows=1
...         write_disposition='truncate',
...         )  # API request
>>> job.job_id
'e3344fba-09df-4ae0-8337-fddee34b3840'
>>> job.type
'load'
>>> job.created
datetime.datetime(2015, 7, 23, 9, 30, 20, 268260, tzinfo=<UTC>)
>>> job.state
'done'
>>> job.ended
datetime.datetime(2015, 7, 23, 9, 30, 21, 334792, tzinfo=<UTC>)
```

20.5.4 Inserting data (asynchronous)

Start a job loading data asynchronously from a set of CSV files, located on Google Cloud Storage, appending rows into an existing table. First, create the job locally:

```
>>> from gcloud import bigquery
>>> client = bigquery.Client()
>>> table = dataset.table(name='person_ages')
>>> job = table.load_from_storage(bucket_name='bucket-name',
...                               object_name_glob='object-prefix*',
...                               source_format='CSV',
...                               skip_leading_rows=1,
```

```
...                                 write_disposition='truncate')
>>> job.job_id
'e3344fba-09df-4ae0-8337-fddee34b3840'
>>> job.type
'load'
>>> job.created
None
>>> job.state
None
```

Note:

- `gcloud.bigquery` generates a UUID for each job.
- The `created` and `state` fields are not set until the job is submitted to the BigQuery back-end.

Then, begin executing the job on the server:

```
>>> job.submit()  # API call
>>> job.created
datetime.datetime(2015, 7, 23, 9, 30, 20, 268260, tzinfo=<UTC>)
>>> job.state
'running'
```

Poll until the job is complete:

```
>>> import time
>>> retry_count = 100
>>> while retry_count > 0 and job.state == 'running':
...     retry_count -= 1
...     time.sleep(10)
...     job.reload()  # API call
>>> job.state
'done'
>>> job.ended
datetime.datetime(2015, 7, 23, 9, 30, 21, 334792, tzinfo=<UTC>)
```

20.5.5 Exporting data (async)

Start a job exporting a table's data asynchronously to a set of CSV files, located on Google Cloud Storage. First, create the job locally:

```
>>> from gcloud import bigquery
>>> client = bigquery.Client()
>>> table = dataset.table(name='person_ages')
>>> job = table.export_to_storage(bucket_name='bucket-name',
...                               object_name_glob='export-prefix*.csv',
...                               destination_format='CSV',
...                               print_header=1,
...                               write_disposition='truncate')
>>> job.job_id
'e3344fba-09df-4ae0-8337-fddee34b3840'
>>> job.type
'load'
>>> job.created
None
```

```
>>> job.state
None
```

Note:

- `gcloud.bigquery` generates a UUID for each job.
- The `created` and `state` fields are not set until the job is submitted to the BigQuery back-end.

Then, begin executing the job on the server:

```
>>> job.submit()  # API call
>>> job.created
datetime.datetime(2015, 7, 23, 9, 30, 20, 268260, tzinfo=<UTC>)
>>> job.state
'running'
```

Poll until the job is complete:

```
>>> import time
>>> retry_count = 100
>>> while retry_count > 0 and job.state == 'running':
...     retry_count -= 1
...     time.sleep(10)
...     job.reload()  # API call
>>> job.state
'done'
>>> job.ended
datetime.datetime(2015, 7, 23, 9, 30, 21, 334792, tzinfo=<UTC>)
```

20.5.6 Copy tables (async)

First, create the job locally:

```
>>> from gcloud import bigquery
>>> client = bigquery.Client()
>>> source_table = dataset.table(name='person_ages')
>>> destination_table = dataset.table(name='person_ages_copy')
>>> job = source_table.copy_to(destination_table)  # API request
>>> job.job_id
'e3344fba-09df-4ae0-8337-fddee34b3840'
>>> job.type
'copy'
>>> job.created
None
>>> job.state
None
```

Note:

- `gcloud.bigquery` generates a UUID for each job.
- The `created` and `state` fields are not set until the job is submitted to the BigQuery back-end.

Then, begin executing the job on the server:

```
>>> job.submit()  # API call
>>> job.created
datetime.datetime(2015, 7, 23, 9, 30, 20, 268260, tzinfo=<UTC>)
>>> job.state
'running'
```

Poll until the job is complete:

```
>>> import time
>>> retry_count = 100
>>> while retry_count > 0 and job.state == 'running':
...     retry_count -= 1
...     time.sleep(10)
...     job.reload()  # API call
>>> job.state
'done'
>>> job.ended
datetime.datetime(2015, 7, 23, 9, 30, 21, 334792, tzinfo=<UTC>)
```

CHAPTER 21

BigQuery Client

Client for interacting with the Google BigQuery API.

class gcloud.bigquery.client.**Client**(*project=None*, *credentials=None*, *http=None*)
Bases: *gcloud.client.JSONClient*

Client to bundle configuration needed for API requests.

Parameters

- **project** (*string*) – the project which the client acts on behalf of. Will be passed when creating a dataset / job. If not passed, falls back to the default inferred from the environment.
- **credentials** (oauth2client.client.OAuth2Credentials or NoneType) – The OAuth2 Credentials to use for the connection owned by this client. If not passed (and if no http object is passed), falls back to the default inferred from the environment.
- **http** (httplib2.Http or class that defines request().) – An optional HTTP object to make requests. If not passed, an http object is created that is bound to the credentials for the current object.

copy_table(*name*, *destination*, **sources*)
Construct a job for copying one or more tables into another table.

Parameters

- **name** (*string*) – Name of the job.
- **destination** (*gcloud.bigquery.table.Table*) – Table into which data is to be copied.
- **sources** (sequence of *gcloud.bigquery.table.Table*) – tables to be copied.

Return type *gcloud.bigquery.job.CopyJob*

Returns a new CopyJob instance

dataset(*name*)
Construct a dataset bound to this client.

Parameters **name** (*string*) – Name of the dataset.

Return type *gcloud.bigquery.dataset.Dataset*

Returns a new Dataset instance

extract_table_to_storage(*name*, *source*, **destination_uris*)
Construct a job for extracting a table into Cloud Storage files.

Parameters

- **name** (*string*) – Name of the job.
- **source** (*gcloud.bigquery.table.Table*) – table to be extracted.
- **destination_uris** (*sequence of string*) – URIs of CloudStorage file(s) into which table data is to be extracted.

Return type *gcloud.bigquery.job.ExtractTableToStorageJob*

Returns a new `ExtractTableToStorageJob` instance

list_datasets(*include_all=False*, *max_results=None*, *page_token=None*)
List datasets for the project associated with this client.

See: https://cloud.google.com/bigquery/docs/reference/v2/datasets/list

Parameters

- **include_all** (*boolean*) – True if results include hidden datasets.
- **max_results** (*int*) – maximum number of datasets to return, If not passed, defaults to a value set by the API.
- **page_token** (*string*) – opaque marker for the next "page" of datasets. If not passed, the API will return the first page of datasets.

Return type tuple, (list, str)

Returns list of *gcloud.bigquery.dataset.Dataset*, plus a "next page token" string: if the token is not None, indicates that more datasets can be retrieved with another call (pass that value as `page_token`).

load_table_from_storage(*name*, *destination*, **source_uris*)
Construct a job for loading data into a table from CloudStorage.

Parameters

- **name** (*string*) – Name of the job.
- **destination** (*gcloud.bigquery.table.Table*) – Table into which data is to be loaded.
- **source_uris** (*sequence of string*) – URIs of data files to be loaded.

Return type *gcloud.bigquery.job.LoadTableFromStorageJob*

Returns a new `LoadTableFromStorageJob` instance

run_async_query(*name*, *query*)
Construct a job for running a SQL query asynchronously.

Parameters

- **name** (*string*) – Name of the job.
- **query** (*string*) – SQL query to be executed

Return type *gcloud.bigquery.job.RunAsyncQueryJob*

Returns a new `RunAsyncQueryJob` instance

run_sync_query(*query*)
Construct a job for running a SQL query synchronously.

Parameters **query** (*string*) – SQL query to be executed

Return type *gcloud.bigquery.job.RunSyncQueryJob*

Returns a new `RunSyncQueryJob` instance

21.1 Connection

Create / interact with gcloud bigquery connections.

class `gcloud.bigquery.connection.`**`Connection`**(*credentials=None*, *http=None*)
Bases: *gcloud.connection.JSONConnection*

A connection to Google Cloud BigQuery via the JSON REST API.

`API_BASE_URL` = **'https://www.googleapis.com'**
The base of the API call URL.

`API_URL_TEMPLATE` = **'{api_base_url}/bigquery/{api_version}{path}'**
A template for the URL of a particular API call.

`API_VERSION` = **'v2'**
The version of the API, used in building the API call's URL.

`SCOPE` = **('https://www.googleapis.com/auth/bigquery', 'https://www.googleapis.com/auth/cloud-platform')**
The scopes required for authenticating as a Cloud BigQuery consumer.

CHAPTER 22

Datasets

Define API Datasets.

class gcloud.bigquery.dataset.**AccessGrant**(*role*, *entity_type*, *entity_id*)
Bases: object

Represent grant of an access role to an entity.

Parameters

- **role** (*string (one of 'OWNER', 'WRITER', 'READER').*) – role granted to the entity.
- **entity_type** (*string (one of 'specialGroup', 'groupByEmail', or 'userByEmail')*) – type of entity being granted the role.
- **entity_id** (*string*) – ID of entity being granted the role.

class gcloud.bigquery.dataset.**Dataset**(*name*, *client*, *access_grants=()*)
Bases: object

Datasets are containers for tables.

See: https://cloud.google.com/bigquery/docs/reference/v2/datasets

Parameters

- **name** (*string*) – the name of the dataset
- **client** (*gcloud.bigquery.client.Client*) – A client which holds credentials and project configuration for the dataset (which requires a project).
- **access_grants** (list of *AccessGrant*) – roles granted to entities for this dataset

access_grants
Dataset's access grants.

Return type list of *AccessGrant*

Returns roles granted to entities for this dataset

create(*client=None*)
API call: create the dataset via a PUT request

See: https://cloud.google.com/bigquery/reference/rest/v2/tables/insert

Parameters **client** (*gcloud.bigquery.client.Client* or NoneType) – the client to use. If not passed, falls back to the client stored on the current dataset.

created
Datetime at which the dataset was created.

Return type `datetime.datetime`, or `NoneType`

Returns the creation time (None until set from the server).

dataset_id
ID for the dataset resource.

Return type string, or `NoneType`

Returns the ID (None until set from the server).

default_table_expiration_ms
Default expiration time for tables in the dataset.

Return type integer, or `NoneType`

Returns The time in milliseconds, or None (the default).

delete(*client=None*)
API call: delete the dataset via a DELETE request

See: https://cloud.google.com/bigquery/reference/rest/v2/datasets/delete

Parameters **client** (*gcloud.bigquery.client.Client* or `NoneType`) – the client to use. If not passed, falls back to the `client` stored on the current dataset.

description
Description of the dataset.

Return type string, or `NoneType`

Returns The description as set by the user, or None (the default).

etag
ETag for the dataset resource.

Return type string, or `NoneType`

Returns the ETag (None until set from the server).

exists(*client=None*)
API call: test for the existence of the dataset via a GET request

See https://cloud.google.com/bigquery/docs/reference/v2/datasets/get

Parameters **client** (*gcloud.bigquery.client.Client* or `NoneType`) – the client to use. If not passed, falls back to the `client` stored on the current dataset.

friendly_name
Title of the dataset.

Return type string, or `NoneType`

Returns The name as set by the user, or None (the default).

classmethod from_api_repr(*resource*, *client*)
Factory: construct a dataset given its API representation

Parameters

- **resource** (*dict*) – dataset resource representation returned from the API
- **client** (*gcloud.bigquery.client.Client*) – Client which holds credentials and project configuration for the dataset.

Return type *gcloud.bigquery.dataset.Dataset*

Returns Dataset parsed from `resource`.

list_tables(*max_results=None*, *page_token=None*)
List tables for the project associated with this client.

See: https://cloud.google.com/bigquery/docs/reference/v2/tables/list

Parameters

- **max_results** (*int*) – maximum number of tables to return, If not passed, defaults to a value set by the API.
- **page_token** (*string*) – opaque marker for the next "page" of datasets. If not passed, the API will return the first page of datasets.

Return type tuple, (list, str)

Returns list of *gcloud.bigquery.table.Table*, plus a "next page token" string: if not None, indicates that more tables can be retrieved with another call (pass that value as `page_token`).

location
Location in which the dataset is hosted.

Return type string, or `NoneType`

Returns The location as set by the user, or None (the default).

modified
Datetime at which the dataset was last modified.

Return type `datetime.datetime`, or `NoneType`

Returns the modification time (None until set from the server).

patch(*client=None*, ***kw*)
API call: update individual dataset properties via a PATCH request

See https://cloud.google.com/bigquery/docs/reference/v2/datasets/patch

Parameters

- **client** (*gcloud.bigquery.client.Client* or `NoneType`) – the client to use. If not passed, falls back to the `client` stored on the current dataset.
- **kw** (`dict`) – properties to be patched.

Raises ValueError for invalid value types.

path
URL path for the dataset's APIs.

Return type string

Returns the path based on project and dataste name.

project
Project bound to the dataset.

Return type string

Returns the project (derived from the client).

reload(*client=None*)
API call: refresh dataset properties via a GET request

See https://cloud.google.com/bigquery/docs/reference/v2/datasets/get

Parameters **client** (*gcloud.bigquery.client.Client* or NoneType) – the client to use. If not passed, falls back to the client stored on the current dataset.

self_link
URL for the dataset resource.

Return type string, or NoneType

Returns the URL (None until set from the server).

table(*name*, *schema=()*)
Construct a table bound to this dataset.

Parameters

- **name** (*string*) – Name of the table.
- **schema** (list of *gcloud.bigquery.table.SchemaField*) – The table's schema

Return type *gcloud.bigquery.table.Table*

Returns a new Table instance

update(*client=None*)
API call: update dataset properties via a PUT request

See https://cloud.google.com/bigquery/docs/reference/v2/datasets/update

Parameters **client** (*gcloud.bigquery.client.Client* or NoneType) – the client to use. If not passed, falls back to the client stored on the current dataset.

CHAPTER 23

Jobs

Define API Jobs.

class gcloud.bigquery.job.**Compression**(*name*)
Bases: gcloud.bigquery.job._EnumProperty

Pseudo-enum for compression properties.

ALLOWED = ('GZIP', 'NONE')

GZIP = 'GZIP'

NONE = 'NONE'

class gcloud.bigquery.job.**CopyJob**(*name*, *destination*, *sources*, *client*)
Bases: gcloud.bigquery.job._AsyncJob

Asynchronous job: copy data into a table from other tables.

Parameters

- **name** (*string*) – the name of the job
- **destination** (*gcloud.bigquery.table.Table*) – Table into which data is to be loaded.
- **sources** (list of *gcloud.bigquery.table.Table*) – Table into which data is to be loaded.
- **client** (*gcloud.bigquery.client.Client*) – A client which holds credentials and project configuration for the dataset (which requires a project).

create_disposition
See: https://cloud.google.com/bigquery/docs/reference/v2/jobs#configuration.copy.createDisposition

write_disposition
See: https://cloud.google.com/bigquery/docs/reference/v2/jobs#configuration.copy.writeDisposition

class gcloud.bigquery.job.**CreateDisposition**(*name*)
Bases: gcloud.bigquery.job._EnumProperty

Pseudo-enum for create_disposition properties.

ALLOWED = ('CREATE_IF_NEEDED', 'CREATE_NEVER')

CREATE_IF_NEEDED = 'CREATE_IF_NEEDED'

CREATE_NEVER = 'CREATE_NEVER'

class gcloud.bigquery.job.**DestinationFormat**(*name*)
Bases: gcloud.bigquery.job._EnumProperty

Pseudo-enum for destination_format properties.

ALLOWED = ('CSV', 'NEWLINE_DELIMITED_JSON', 'AVRO')

AVRO = 'AVRO'

CSV = 'CSV'

NEWLINE_DELIMITED_JSON = 'NEWLINE_DELIMITED_JSON'

class gcloud.bigquery.job.**Encoding**(*name*)
Bases: gcloud.bigquery.job._EnumProperty

Pseudo-enum for encoding properties.

ALLOWED = ('UTF-8', 'ISO-8559-1')

ISO_8559_1 = 'ISO-8559-1'

UTF_8 = 'UTF-8'

class gcloud.bigquery.job.**ExtractTableToStorageJob**(*name*, *source*, *destination_uris*, *client*)
Bases: gcloud.bigquery.job._AsyncJob

Asynchronous job: extract data from a table into Cloud Storage.

Parameters

- **name** (*string*) – the name of the job
- **source** (*gcloud.bigquery.table.Table*) – Table into which data is to be loaded.
- **destination_uris** (*list of string*) – URIs describing Cloud Storage blobs into which extracted data will be written.
- **client** (*gcloud.bigquery.client.Client*) – A client which holds credentials and project configuration for the dataset (which requires a project).

compression
See: https://cloud.google.com/bigquery/docs/reference/v2/jobs#configuration.extracted.compression

destination_format
See: https://cloud.google.com/bigquery/docs/reference/v2/jobs#configuration.extracted.destinationFormat

field_delimiter
See: https://cloud.google.com/bigquery/docs/reference/v2/jobs#configuration.extracted.fieldDelimiter

print_header
See: https://cloud.google.com/bigquery/docs/reference/v2/jobs#configuration.extracted.printHeader

class gcloud.bigquery.job.**LoadTableFromStorageJob**(*name*, *destination*, *source_uris*, *client*, *schema=()*)
Bases: gcloud.bigquery.job._AsyncJob

Asynchronous job for loading data into a table from CloudStorage.

Parameters

- **name** (*string*) – the name of the job
- **destination** (*gcloud.bigquery.table.Table*) – Table into which data is to be loaded.
- **source_uris** (*sequence of string*) – URIs of data files to be loaded.

- **client** (*gcloud.bigquery.client.Client*) – A client which holds credentials and project configuration for the dataset (which requires a project).
- **schema** (list of *gcloud.bigquery.table.SchemaField*) – The job's schema

allow_jagged_rows
See: https://cloud.google.com/bigquery/docs/reference/v2/jobs#configuration.load.allowJaggedRows

allow_quoted_newlines
See: https://cloud.google.com/bigquery/docs/reference/v2/jobs#configuration.load.allowQuotedNewlines

create_disposition
See: https://cloud.google.com/bigquery/docs/reference/v2/jobs#configuration.load.createDisposition

encoding
See: https://cloud.google.com/bigquery/docs/reference/v2/jobs#configuration.load.encoding

field_delimiter
See: https://cloud.google.com/bigquery/docs/reference/v2/jobs#configuration.load.fieldDelimiter

ignore_unknown_values
See: https://cloud.google.com/bigquery/docs/reference/v2/jobs#configuration.load.ignoreUnknownValues

input_file_bytes
Count of bytes loaded from source files.

Return type integer, or `NoneType`

Returns the count (None until set from the server).

input_files
Count of source files.

Return type integer, or `NoneType`

Returns the count (None until set from the server).

max_bad_records
See: https://cloud.google.com/bigquery/docs/reference/v2/jobs#configuration.load.maxBadRecords

output_bytes
Count of bytes saved to destination table.

Return type integer, or `NoneType`

Returns the count (None until set from the server).

output_rows
Count of rows saved to destination table.

Return type integer, or `NoneType`

Returns the count (None until set from the server).

quote_character
See: https://cloud.google.com/bigquery/docs/reference/v2/jobs#configuration.load.quote

schema
Table's schema.

Return type list of `SchemaField`

Returns fields describing the schema

skip_leading_rows
See: https://cloud.google.com/bigquery/docs/reference/v2/jobs#configuration.load.skipLeadingRows

source_format
See: https://cloud.google.com/bigquery/docs/reference/v2/jobs#configuration.load.sourceFormat

write_disposition
See: https://cloud.google.com/bigquery/docs/reference/v2/jobs#configuration.load.writeDisposition

class gcloud.bigquery.job.**QueryPriority**(*name*)
Bases: gcloud.bigquery.job._EnumProperty

Pseudo-enum for RunAsyncQueryJob.priority property.

ALLOWED = ('INTERACTIVE', 'BATCH')

BATCH = 'BATCH'

INTERACTIVE = 'INTERACTIVE'

class gcloud.bigquery.job.**RunAsyncQueryJob**(*name*, *query*, *client*)
Bases: gcloud.bigquery.job._AsyncJob

Asynchronous job: query tables.

Parameters

- **name** (*string*) – the name of the job
- **query** (*string*) – SQL query string
- **client** (*gcloud.bigquery.client.Client*) – A client which holds credentials and project configuration for the dataset (which requires a project).

allow_large_results
See: https://cloud.google.com/bigquery/docs/reference/v2/jobs#configuration.query.allowLargeResults

create_disposition
See: https://cloud.google.com/bigquery/docs/reference/v2/jobs#configuration.query.createDisposition

default_dataset
See: https://cloud.google.com/bigquery/docs/reference/v2/jobs#configuration.query.defaultDataset

destination_table
See: https://cloud.google.com/bigquery/docs/reference/v2/jobs#configuration.query.destinationTable

flatten_results
See: https://cloud.google.com/bigquery/docs/reference/v2/jobs#configuration.query.flattenResults

priority
See: https://cloud.google.com/bigquery/docs/reference/v2/jobs#configuration.query.priority

use_query_cache
See: https://cloud.google.com/bigquery/docs/reference/v2/jobs#configuration.query.useQueryCache

write_disposition
See: https://cloud.google.com/bigquery/docs/reference/v2/jobs#configuration.query.writeDisposition

class gcloud.bigquery.job.**RunSyncQueryJob**(*query*, *client*)
Bases: gcloud.bigquery.job._BaseJob

Synchronous job: query tables.

Parameters

- **query** (*string*) – SQL query string
- **client** (*gcloud.bigquery.client.Client*) – A client which holds credentials and project configuration for the dataset (which requires a project).

cache_hit
Query results served from cache.

See: https://cloud.google.com/bigquery/docs/reference/v2/jobs/query#cacheHit

Return type boolean or `NoneType`

Returns True if the query results were served from cache (None until set by the server).

complete
Server completed query.

See: https://cloud.google.com/bigquery/docs/reference/v2/jobs/query#jobComplete

Return type boolean or `NoneType`

Returns True if the query completed on the server (None until set by the server).

default_dataset
See: https://cloud.google.com/bigquery/docs/reference/v2/jobs/query#defaultDataset

errors
Errors generated by the query.

See: https://cloud.google.com/bigquery/docs/reference/v2/jobs/query#errors

Return type list of mapping, or `NoneType`

Returns Mappings describing errors generated on the server (None until set by the server).

fetch_data(*max_results=None*, *page_token=None*, *start_index=None*, *timeout_ms=None*, *client=None*)
API call: fetch a page of query result data via a GET request

See: https://cloud.google.com/bigquery/docs/reference/v2/jobs/getQueryResults

Parameters

- **max_results** (integer or `NoneType`) – maximum number of rows to return.
- **page_token** (string or `NoneType`) – token representing a cursor into the table's rows.
- **start_index** (integer or `NoneType`) – zero-based index of starting row
- **timeout_ms** (integer or `NoneType`) – timeout, in milliseconds, to wait for query to complete
- **client** (*gcloud.bigquery.client.Client* or `NoneType`) – the client to use. If not passed, falls back to the `client` stored on the current dataset.

Return type tuple

Returns `(row_data, total_rows, page_token)`, where `row_data` is a list of tuples, one per result row, containing only the values; `total_rows` is a count of the total number of rows in the table; and `page_token` is an opaque string which can be used to fetch the next batch of rows (`None` if no further batches can be fetched).

Raises ValueError if the query has not yet been executed.

max_results
See: https://cloud.google.com/bigquery/docs/reference/v2/jobs/query#maxResults

name
Job name, generated by the back-end.

See: https://cloud.google.com/bigquery/docs/reference/v2/jobs/query#jobReference

Return type list of mapping, or `NoneType`

Returns Mappings describing errors generated on the server (None until set by the server).

page_token
Token for fetching next bach of results.

See: https://cloud.google.com/bigquery/docs/reference/v2/jobs/query#pageToken

Return type string, or `NoneType`

Returns Token generated on the server (None until set by the server).

preserve_nulls
See: https://cloud.google.com/bigquery/docs/reference/v2/jobs/query#preserveNulls

rows
Query results.

See: https://cloud.google.com/bigquery/docs/reference/v2/jobs/query#rows

Return type list of tuples of row values, or `NoneType`

Returns fields describing the schema (None until set by the server).

run(*client=None*)
API call: run the query via a POST request

See: https://cloud.google.com/bigquery/docs/reference/v2/jobs/query

Parameters **client** (*gcloud.bigquery.client.Client* or `NoneType`) – the client to use. If not passed, falls back to the `client` stored on the current dataset.

schema
Schema for query results.

See: https://cloud.google.com/bigquery/docs/reference/v2/jobs/query#schema

Return type list of `SchemaField`, or `NoneType`

Returns fields describing the schema (None until set by the server).

timeout_ms
See: https://cloud.google.com/bigquery/docs/reference/v2/jobs/query#timeoutMs

total_bytes_processed
Total number of bytes processed by the query

See: https://cloud.google.com/bigquery/docs/reference/v2/jobs/query#totalBytesProcessed

Return type integer, or `NoneType`

Returns Count generated on the server (None until set by the server).

total_rows
Total number of rows returned by the query

See: https://cloud.google.com/bigquery/docs/reference/v2/jobs/query#totalRows

Return type integer, or `NoneType`

Returns Count generated on the server (None until set by the server).

use_query_cache
See: https://cloud.google.com/bigquery/docs/reference/v2/jobs/query#useQueryCache

class `gcloud.bigquery.job.`**SourceFormat**(*name*)
Bases: `gcloud.bigquery.job._EnumProperty`

Pseudo-enum for `source_format` properties.

ALLOWED = (‘CSV’, ‘DATASTORE_BACKUP’, ‘NEWLINE_DELIMITED_JSON’)

CSV = ‘CSV’

DATASTORE_BACKUP = ‘DATASTORE_BACKUP’

NEWLINE_DELIMITED_JSON = ‘NEWLINE_DELIMITED_JSON’

class gcloud.bigquery.job.**WriteDisposition**(*name*)

Bases: gcloud.bigquery.job._EnumProperty

Pseudo-enum for write_disposition properties.

ALLOWED = (‘WRITE_APPEND’, ‘WRITE_TRUNCATE’, ‘WRITE_EMPTY’)

WRITE_APPEND = ‘WRITE_APPEND’

WRITE_EMPTY = ‘WRITE_EMPTY’

WRITE_TRUNCATE = ‘WRITE_TRUNCATE’

CHAPTER 24

Tables

Define API Datasets.

class gcloud.bigquery.table.**SchemaField**(*name*, *field_type*, *mode='NULLABLE'*, *description=None*, *fields=None*)

Bases: object

Describe a single field within a table schema.

Parameters

- **name** (*string*) – the name of the field
- **field_type** (*string*) – the type of the field (one of 'STRING', 'INTEGER', 'FLOAT', 'BOOLEAN', 'TIMESTAMP' or 'RECORD')
- **mode** (*string*) – the type of the field (one of 'NULLABLE', 'REQUIRED', or 'REPEATED')
- **description** (*string*) – optional description for the field
- **fields** (list of *SchemaField*, or None) – subfields (requires field_type of 'RECORD').

class gcloud.bigquery.table.**Table**(*name*, *dataset*, *schema=()*)

Bases: object

Tables represent a set of rows whose values correspond to a schema.

See: https://cloud.google.com/bigquery/docs/reference/v2/tables

Parameters

- **name** (*string*) – the name of the table
- **dataset** (*gcloud.bigquery.dataset.Dataset*) – The dataset which contains the table.
- **schema** (list of *SchemaField*) – The table's schema

create(*client=None*)

API call: create the dataset via a PUT request

See: https://cloud.google.com/bigquery/docs/reference/v2/tables/insert

Parameters **client** (*gcloud.bigquery.client.Client* or NoneType) – the client to use. If not passed, falls back to the client stored on the current dataset.

created

Datetime at which the table was created.

Return type `datetime.datetime`, or `NoneType`

Returns the creation time (None until set from the server).

dataset_name
Name of dataset containing the table.

Return type string

Returns the ID (derived from the dataset).

delete(*client=None*)
API call: delete the table via a DELETE request

See: https://cloud.google.com/bigquery/docs/reference/v2/tables/delete

Parameters **client** (*gcloud.bigquery.client.Client* or `NoneType`) – the client to use. If not passed, falls back to the `client` stored on the current dataset.

description
Description of the table.

Return type string, or `NoneType`

Returns The description as set by the user, or None (the default).

etag
ETag for the table resource.

Return type string, or `NoneType`

Returns the ETag (None until set from the server).

exists(*client=None*)
API call: test for the existence of the table via a GET request

See https://cloud.google.com/bigquery/docs/reference/v2/tables/get

Parameters **client** (*gcloud.bigquery.client.Client* or `NoneType`) – the client to use. If not passed, falls back to the `client` stored on the current dataset.

expires
Datetime at which the table will be removed.

Return type `datetime.datetime`, or `NoneType`

Returns the expiration time, or None

fetch_data(*max_results=None*, *page_token=None*, *client=None*)
API call: fetch the table data via a GET request

See: https://cloud.google.com/bigquery/docs/reference/v2/tabledata/list

---

Note: This method assumes that its instance's `schema` attribute is up-to-date with the schema as defined on the back-end: if the two schemas are not identical, the values returned may be incomplete. To ensure that the local copy of the schema is up-to-date, call the table's `reload` method.

Parameters

- **max_results** (integer or `NoneType`) – maximum number of rows to return.
- **page_token** (string or `NoneType`) – token representing a cursor into the table's rows.

- **client** (*gcloud.bigquery.client.Client* or NoneType) – the client to use. If not passed, falls back to the client stored on the current dataset.

Return type tuple

Returns (row_data, total_rows, page_token), where row_data is a list of tuples, one per result row, containing only the values; total_rows is a count of the total number of rows in the table; and page_token is an opaque string which can be used to fetch the next batch of rows (None if no further batches can be fetched).

friendly_name
Title of the table.

Return type string, or NoneType

Returns The name as set by the user, or None (the default).

classmethod **from_api_repr**(*resource*, *dataset*)
Factory: construct a table given its API representation

Parameters

- **resource** (*dict*) – table resource representation returned from the API
- **dataset** (*gcloud.bigquery.dataset.Dataset*) – The dataset containing the table.

Return type *gcloud.bigquery.table.Table*

Returns Table parsed from resource.

insert_data(*rows*, *row_ids=None*, *skip_invalid_rows=None*, *ignore_unknown_values=None*, *client=None*)
API call: insert table data via a POST request

See: https://cloud.google.com/bigquery/docs/reference/v2/tabledata/insertAll

Parameters

- **rows** (*list of tuples*) – row data to be inserted
- **row_ids** (*list of string*) – Unique ids, one per row being inserted. If not passed, no de-duplication occurs.
- **skip_invalid_rows** (boolean or NoneType) – skip rows w/ invalid data?
- **ignore_unknown_values** (boolean or NoneType) – ignore columns beyond schema?
- **client** (*gcloud.bigquery.client.Client* or NoneType) – the client to use. If not passed, falls back to the client stored on the current dataset.

Return type list of mappings

Returns One mapping per row with insert errors: the "index" key identifies the row, and the "errors" key contains a list of the mappings describing one or more problems with the row.

location
Location in which the table is hosted.

Return type string, or NoneType

Returns The location as set by the user, or None (the default).

modified
Datetime at which the table was last modified.

Return type `datetime.datetime`, or `NoneType`

Returns the modification time (None until set from the server).

num_bytes
The size of the table in bytes.

Return type integer, or `NoneType`

Returns the byte count (None until set from the server).

num_rows
The number of rows in the table.

Return type integer, or `NoneType`

Returns the row count (None until set from the server).

patch(*client=None*, *friendly_name=<object object>*, *description=<object object>*, *location=<object object>*, *expires=<object object>*, *view_query=<object object>*, *schema=<object object>*)
API call: update individual table properties via a PATCH request

See https://cloud.google.com/bigquery/docs/reference/v2/tables/patch

Parameters

- **client** (*gcloud.bigquery.client.Client* or `NoneType`) – the client to use. If not passed, falls back to the `client` stored on the current dataset.
- **friendly_name** (string or `NoneType`) – point in time at which the table expires.
- **description** (string or `NoneType`) – point in time at which the table expires.
- **location** (string or `NoneType`) – point in time at which the table expires.
- **expires** (`datetime.datetime` or `NoneType`) – point in time at which the table expires.
- **view_query** (*string*) – SQL query defining the table as a view
- **schema** (list of *SchemaField*) – fields describing the schema

Raises ValueError for invalid value types.

path
URL path for the table's APIs.

Return type string

Returns the path based on project and dataste name.

project
Project bound to the table.

Return type string

Returns the project (derived from the dataset).

reload(*client=None*)
API call: refresh table properties via a GET request

See https://cloud.google.com/bigquery/docs/reference/v2/tables/get

Parameters **client** (*gcloud.bigquery.client.Client* or `NoneType`) – the client to use. If not passed, falls back to the `client` stored on the current dataset.

schema
Table's schema.

Return type list of *SchemaField*

Returns fields describing the schema

self_link
URL for the table resource.

Return type string, or NoneType

Returns the URL (None until set from the server).

table_id
ID for the table resource.

Return type string, or NoneType

Returns the ID (None until set from the server).

table_type
The type of the table.

Possible values are "TABLE" or "VIEW".

Return type string, or NoneType

Returns the URL (None until set from the server).

update(*client=None*)
API call: update table properties via a PUT request

See https://cloud.google.com/bigquery/docs/reference/v2/tables/update

Parameters **client** (*gcloud.bigquery.client.Client* or NoneType) – the client to use. If not passed, falls back to the client stored on the current dataset.

view_query
SQL query defining the table as a view.

Return type string, or NoneType

Returns The query as set by the user, or None (the default).

CHAPTER 25

Resource Manager Overview

The Cloud Resource Manager API provides methods that you can use to programmatically manage your projects in the Google Cloud Platform. With this API, you can do the following:

- Get a list of all projects associated with an account
- Create new projects
- Update existing projects
- Delete projects
- Undelete, or recover, projects that you don't want to delete

Note: Don't forget to look at the *Authentication* section below. It's slightly different from the rest of this library.

Here's a quick example of the full life-cycle:

```
>>> from gcloud import resource_manager
>>> client = resource_manager.Client()

>>> # List all projects you have access to
>>> for project in client.list_projects():
...     print(project)

>>> # Create a new project
>>> new_project = client.new_project('your-project-id-here',
...                                  name='My new project)
>>> new_project.create()

>>> # Update an existing project
>>> project = client.fetch_project('my-existing-project')
>>> print(project)
<Project: Existing Project (my-existing-project)>
>>> project.name = 'Modified name'
>>> project.update()
>>> print(project)
<Project: Modified name (my-existing-project)>

>>> # Delete a project
>>> project = client.new_project('my-existing-project')
>>> project.delete()

>>> # Undelete a project
```

```
>>> project = client.new_project('my-existing-project')
>>> project.undelete()
```

25.1 Authentication

Unlike the other APIs, the Resource Manager API is focused on managing your various projects inside Google Cloud Platform. What this means (currently, as of August 2015) is that you can't use a Service Account to work with some parts of this API (for example, creating projects).

The reason is actually pretty simple: if your API call is trying to do something like create a project, what project's Service Account can you use? Currently none.

This means that for this API you should always use the credentials provided by the Google Cloud SDK, which you can get by running `gcloud auth login`.

Once you run that command, `gcloud-python` will automatically pick up the credentials, and you can use the "automatic discovery" feature of the library.

Start by authenticating:

```
$ gcloud auth login
```

And then simply create a client:

```
>>> from gcloud import resource_manager
>>> client = resource_manager.Client()
```

CHAPTER 26

Client

A Client for interacting with the Resource Manager API.

class gcloud.resource_manager.client.**Client**(*credentials=None*, *http=None*)
Bases: *gcloud.client.Client*

Client to bundle configuration needed for API requests.

See https://cloud.google.com/resource-manager/reference/rest/ for more information on this API.

Automatically get credentials:

```
>>> from gcloud import resource_manager
>>> client = resource_manager.Client()
```

Parameters

- **credentials** (oauth2client.client.OAuth2Credentials or NoneType) – The OAuth2 Credentials to use for the connection owned by this client. If not passed (and if no http object is passed), falls back to the default inferred from the environment.
- **http** (httplib2.Http or class that defines request().) – An optional HTTP object to make requests. If not passed, an http object is created that is bound to the credentials for the current object.

fetch_project(*project_id*)
Fetch an existing project and it's relevant metadata by ID.

Note: If the project does not exist, this will raise a *NotFound* error.

Parameters **project_id** (*str*) – The ID for this project.

Return type *Project*

Returns A *Project* with metadata fetched from the API.

classmethod from_service_account_json(**args*, ***kwargs*)
Factory to retrieve JSON credentials while creating client.

The behavior from the parent class is disabled here since the Resource Manager API can only use credentials from a user account, not a service account.

Raises NotImplementedError always.

classmethod **from_service_account_p12**(**args*, ***kwargs*)
Factory to retrieve P12 credentials while creating client.

The behavior from the parent class is disabled here since the Resource Manager API can only use credentials from a user account, not a service account.

Raises NotImplementedError always.

list_projects(*filter_params=None*, *page_size=None*)
List the projects visible to this client.

Example:

```
>>> from gcloud import resource_manager
>>> client = resource_manager.Client()
>>> for project in client.list_projects():
...     print project.project_id
```

List all projects with label 'environment' set to 'prod' (filtering by labels):

```
>>> from gcloud import resource_manager
>>> client = resource_manager.Client()
>>> env_filter = {'labels.environment': 'prod'}
>>> for project in client.list_projects(env_filter):
...     print project.project_id
```

See: https://cloud.google.com/resource-manager/reference/rest/v1beta1/projects/list

Complete filtering example:

```
>>> project_filter = {  # Return projects with...
...     'name': 'My Project',  # name set to 'My Project'.
...     'id': 'my-project-id',  # id set to 'my-project-id'.
...     'labels.stage': 'prod',  # the label 'stage' set to 'prod'
...     'labels.color': '*'  # a label 'color' set to anything.
... }
>>> client.list_projects(project_filter)
```

Parameters

- **filter_params** (*dict*) – (Optional) A dictionary of filter options where each key is a property to filter on, and each value is the (case-insensitive) value to check (or the glob * to check for existence of the property). See the example above for more details.
- **page_size** (*int*) – (Optional) Maximum number of projects to return in a single page. If not passed, defaults to a value set by the API.

Return type _ProjectIterator

Returns A project iterator. The iterator will make multiple API requests if you continue iterating and there are more pages of results. Each item returned will be a. *Project*.

new_project(*project_id*, *name=None*, *labels=None*)
Creates a *Project* bound to the current client.

Use *Project.reload()* to retrieve project metadata after creating a *Project* instance.

Parameters

- **project_id** (*str*) – The ID for this project.
- **name** (*string*) – The display name of the project.

- **labels** (*dict*) – A list of labels associated with the project.

Return type *Project*

Returns A new instance of a *Project* **without** any metadata loaded.

26.1 Connection

Create / interact with gcloud.resource_manager connections.

class gcloud.resource_manager.connection.**Connection**(*credentials=None*, *http=None*)
Bases: *gcloud.connection.JSONConnection*

A connection to Google Cloud Resource Manager via the JSON REST API.

Parameters

- **credentials** (oauth2client.client.OAuth2Credentials) – (Optional) The OAuth2 Credentials to use for this connection.
- **http** (httplib2.Http or class that defines request().) – (Optional) HTTP object to make requests.

API_BASE_URL = 'https://cloudresourcemanager.googleapis.com'
The base of the API call URL.

API_URL_TEMPLATE = '{api_base_url}/{api_version}{path}'
A template for the URL of a particular API call.

API_VERSION = 'v1beta1'
The version of the API, used in building the API call's URL.

SCOPE = ('https://www.googleapis.com/auth/cloud-platform',)
The scopes required for authenticating as a Resouce Manager consumer.

CHAPTER 27

Projects

Utility for managing projects via the Cloud Resource Manager API.

class gcloud.resource_manager.project.**Project**(*project_id*, *client*, *name=None*, *labels=None*)

Bases: object

Projects are containers for your work on Google Cloud Platform.

Note: A *Project* can also be created via *Client.new_project()*

To manage labels on a *Project*:

```
>>> from gcloud import resource_manager
>>> client = resource_manager.Client()
>>> project = client.new_project('purple-spaceship-123')
>>> project.labels = {'color': 'purple'}
>>> project.labels['environment'] = 'production'
>>> project.update()
```

See: https://cloud.google.com/resource-manager/reference/rest/v1beta1/projects

Parameters

- **project_id** (*string*) – The globally unique ID of the project.
- **client** (*gcloud.resource_manager.client.Client*) – The Client used with this project.
- **name** (*string*) – The display name of the project.
- **labels** (*dict*) – A list of labels associated with the project.

create(*client=None*)

API call: create the project via a POST request.

See https://cloud.google.com/resource-manager/reference/rest/v1beta1/projects/create

Parameters **client** (*gcloud.resource_manager.client.Client* or NoneType) – the client to use. If not passed, falls back to the client stored on the current project.

delete(*client=None*, *reload_data=False*)

API call: delete the project via a DELETE request.

See: https://cloud.google.com/resource-manager/reference/rest/v1beta1/projects/delete

This actually changes the status (`lifecycleState`) from `ACTIVE` to `DELETE_REQUESTED`. Later (it's not specified when), the project will move into the `DELETE_IN_PROGRESS` state, which means the deleting has actually begun.

Parameters

- **client** (*gcloud.resource_manager.client.Client* or `NoneType`) – the client to use. If not passed, falls back to the client stored on the current project.
- **reload_data** (*bool*) – Whether to reload the project with the latest state. If you want to get the updated status, you'll want this set to `True` as the DELETE method doesn't send back the updated project. Default: `False`.

exists(*client=None*)

API call: test the existence of a project via a `GET` request.

See https://cloud.google.com/pubsub/reference/rest/v1beta2/projects/projects/get

Parameters **client** (*gcloud.resource_manager.client.Client* or `NoneType`) – the client to use. If not passed, falls back to the client stored on the current project.

classmethod from_api_repr(*resource*, *client*)

Factory: construct a project given its API representation.

Parameters

- **resource** (*dict*) – project resource representation returned from the API
- **client** (*gcloud.resource_manager.client.Client*) – The Client used with this project.

Return type *gcloud.resource_manager.project.Project*

full_name

Fully-qualified name (ie, `'projects/purple-spaceship-123'`).

path

URL for the project (ie, `'/projects/purple-spaceship-123'`).

reload(*client=None*)

API call: reload the project via a `GET` request.

This method will reload the newest metadata for the project. If you've created a new *Project* instance via *Client.new_project()*, this method will retrieve project metadata.

> **Warning:** This will overwrite any local changes you've made and not saved via *update()*.

See https://cloud.google.com/resource-manager/reference/rest/v1beta1/projects/get

Parameters **client** (*gcloud.resource_manager.client.Client* or `NoneType`) – the client to use. If not passed, falls back to the client stored on the current project.

set_properties_from_api_repr(*resource*)

Update specific properties from its API representation.

undelete(*client=None*, *reload_data=False*)

API call: undelete the project via a `POST` request.

See https://cloud.google.com/resource-manager/reference/rest/v1beta1/projects/undelete

This actually changes the project status (`lifecycleState`) from `DELETE_REQUESTED` to `ACTIVE`. If the project has already reached a status of `DELETE_IN_PROGRESS`, this request will fail and the project cannot be restored.

Parameters

- **client** (*gcloud.resource_manager.client.Client* or NoneType) – the client to use. If not passed, falls back to the client stored on the current project.
- **reload_data** (*bool*) – Whether to reload the project with the latest state. If you want to get the updated status, you'll want this set to True as the DELETE method doesn't send back the updated project. Default: False.

update(*client=None*)

API call: update the project via a PUT request.

See https://cloud.google.com/resource-manager/reference/rest/v1beta1/projects/update

Parameters **client** (*gcloud.resource_manager.client.Client* or NoneType) – the client to use. If not passed, falls back to the client stored on the current project.

CHAPTER 28

Using the API

28.1 Client

Client objects provide a means to configure your DNS applications. Eash instance holds both a `project` and an authenticated connection to the DNS service.

For an overview of authentication in `gcloud-python`, see Authentication.

Assuming your environment is set up as described in that document, create an instance of *Client*.

```
>>> from gcloud import dns
>>> client = dns.Client()
```

28.2 Projects

A project is the top-level container in the `DNS` API: it is tied closely to billing, and can provide default access control across all its datasets. If no `project` is passed to the client container, the library attempts to infer a project using the environment (including explicit environment variables, GAE, or GCE).

To override the project inferred from the environment, pass an explicit `project` to the constructor, or to either of the alternative `classmethod` factories:

```
>>> from gcloud import dns
>>> client = dns.Client(project='PROJECT_ID')
```

28.3 Project Quotas

Query the quotas for a given project:

```
>>> from gcloud import dns
>>> client = dns.Client(project='PROJECT_ID')
>>> quotas = client.quotas()  # API request
>>> for key, value in sorted(quotas.items()):
...     print('%s: %s' % (key, value))
managedZones: 10000
resourceRecordsPerRrset: 100
rrsetsPerManagedZone: 10000
rrsetAdditionsPerChange: 100
```

```
    rrsetDeletionsPerChange: 100
    totalRrdataSizePerChange: 10000
```

28.3.1 Project ACLs

Each project has an access control list granting reader / writer / owner permission to one or more entities. This list cannot be queried or set via the API: it must be managed using the Google Developer Console.

28.4 Managed Zones

A "managed zone" is the container for DNS records for the same DNS name suffix and has a set of name servers that accept and responds to queries:

```
    >>> from gcloud import dns
    >>> client = dns.Client(project='PROJECT_ID')
    >>> zone = client.zone('acme-co', description='Acme Company zone',
    ...                    dns_name='example.com')

    >>> zone.exists()  # API request
    False
    >>> zone.create()  # API request
    >>> zone.exists()  # API request
    True
```

List the zones for a given project:

```
    >>> from gcloud import dns
    >>> client = dns.Client(project='PROJECT_ID')
    >>> zones = client.list_zones()  # API request
    >>> [zone.name for zone in zones]
    ['acme-co']
```

28.5 Resource Record Sets

Each managed zone exposes a read-only set of resource records:

```
    >>> from gcloud import dns
    >>> client = dns.Client(project='PROJECT_ID')
    >>> zone = client.zone('acme-co')
    >>> records, page_token = zone.list_resource_record_sets()  # API request
    >>> [(record.name, record.type, record.ttl, record.rrdatas) for record in records]
    [('example.com.', 'SOA', 21600, ['ns-cloud1.googlecomains.com dns-admin.google.com 1 21600 3600
```

Note: The `page_token` returned from `zone.list_resource_record_sets()` will be an opaque string if there are more resources than can be returned in a single request. To enumerate them all, repeat calling `zone.list_resource_record_sets()`, passing the `page_token`, until the token is `None`. E.g.

```
>>> records, page_token = zone.list_resource_record_sets()  # API request
>>> while page_token is not None:
...     next_batch, page_token = zone.list_resource_record_sets(
...         page_token=page_token)  # API request
...     records.extend(next_batch)
```

28.6 Change requests

Update the resource record set for a zone by creating a change request bundling additions to or deletions from the set.

```
>>> import time
>>> from gcloud import dns
>>> client = dns.Client(project='PROJECT_ID')
>>> zone = client.zone('acme-co')
>>> record = dns.ResourceRecord(name='www.example.com', type='CNAME')
>>> change = zone.change_request(additions=[record])
>>> change.begin()  # API request
>>> while change.status != 'done':
...     print('Waiting for change to complete')
...     time.sleep(60)  # or whatever interval is appropriate
...     change.reload()  # API request
```

List changes made to the resource record set for a given zone:

```
>>> from gcloud import dns
>>> client = dns.Client(project='PROJECT_ID')
>>> zone = client.zone('acme-co')
>>> changes = []
>>> changes, page_token = zone.list_changes()  # API request
```

Note: The `page_token` returned from `zone.list_changes()` will be an opaque string if there are more changes than can be returned in a single request. To enumerate them all, repeat calling `zone.list_changes()`, passing the `page_token`, until the token is `None`. E.g.:

```
>>> changes, page_token = zone.list_changes()  # API request
>>> while page_token is not None:
...     next_batch, page_token = zone.list_changes(
...         page_token=page_token)  # API request
...     changes.extend(next_batch)
```

CHAPTER 29

DNS Client

Client for interacting with the Google Cloud DNS API.

class gcloud.dns.client.**Client**(*project=None*, *credentials=None*, *http=None*)
Bases: *gcloud.client.JSONClient*

Client to bundle configuration needed for API requests.

Parameters

- **project** (*string*) – the project which the client acts on behalf of. Will be passed when creating a zone. If not passed, falls back to the default inferred from the environment.
- **credentials** (oauth2client.client.OAuth2Credentials or NoneType) – The OAuth2 Credentials to use for the connection owned by this client. If not passed (and if no http object is passed), falls back to the default inferred from the environment.
- **http** (httplib2.Http or class that defines request().) – An optional HTTP object to make requests. If not passed, an http object is created that is bound to the credentials for the current object.

list_zones(*max_results=None*, *page_token=None*)
List zones for the project associated with this client.

See: https://cloud.google.com/dns/api/v1/managedZones/list

Parameters

- **max_results** (*int*) – maximum number of zones to return, If not passed, defaults to a value set by the API.
- **page_token** (*string*) – opaque marker for the next "page" of zones. If not passed, the API will return the first page of zones.

Return type tuple, (list, str)

Returns list of *gcloud.dns.zone.ManagedZone*, plus a "next page token" string: if the token is not None, indicates that more zones can be retrieved with another call (pass that value as page_token).

quotas()
Return DNS quots for the project associated with this client.

See: https://cloud.google.com/dns/api/v1/projects/get

Return type mapping

Returns keys for the mapping correspond to those of the quota sub-mapping of the project resource.

zone(*name*, *dns_name*)
Construct a zone bound to this client.

Parameters

- **name** (*string*) – Name of the zone.
- **dns_name** (*string*) – DNS name of the zone.

Return type *gcloud.dns.zone.ManagedZone*

Returns a new `ManagedZone` instance

29.1 Connection

Create / interact with gcloud dns connections.

class `gcloud.dns.connection.`**Connection**(*credentials=None*, *http=None*)
Bases: *gcloud.connection.JSONConnection*

A connection to Google Cloud DNS via the JSON REST API.

API_BASE_URL = 'https://www.googleapis.com'
The base of the API call URL.

API_URL_TEMPLATE = '{api_base_url}/dns/{api_version}{path}'
A template for the URL of a particular API call.

API_VERSION = 'v1'
The version of the API, used in building the API call's URL.

SCOPE = ('https://www.googleapis.com/auth/ndev.clouddns.readwrite',)
The scopes required for authenticating as a Cloud DNS consumer.

CHAPTER 30

Managed Zones

Define API ManagedZones.

class gcloud.dns.zone.**ManagedZone**(*name*, *dns_name*, *client*)
Bases: object

ManagedZones are containers for DNS resource records.

See: https://cloud.google.com/dns/api/v1/managedZones

Parameters

- **name** (*string*) – the name of the zone
- **dns_name** (*string*) – the DNS name of the zone
- **client** (*gcloud.dns.client.Client*) – A client which holds credentials and project configuration for the zone (which requires a project).

changes()
Construct a change set bound to this zone.

Return type *gcloud.dns.changes.Changes*

Returns a new Changes instance

create(*client=None*)
API call: create the zone via a PUT request

See: https://cloud.google.com/dns/api/v1/managedZones/create

Parameters **client** (*gcloud.dns.client.Client* or NoneType) – the client to use. If not passed, falls back to the client stored on the current zone.

created
Datetime at which the zone was created.

Return type datetime.datetime, or NoneType

Returns the creation time (None until set from the server).

delete(*client=None*)
API call: delete the zone via a DELETE request

See: https://cloud.google.com/dns/api/v1/managedZones/delete

Parameters **client** (*gcloud.dns.client.Client* or NoneType) – the client to use. If not passed, falls back to the client stored on the current zone.

description
Description of the zone.

Return type string, or NoneType

Returns The description as set by the user, or None (the default).

exists(*client=None*)
API call: test for the existence of the zone via a GET request

See https://cloud.google.com/dns/api/v1/managedZones/get

Parameters **client** (*gcloud.dns.client.Client* or NoneType) – the client to use. If not passed, falls back to the client stored on the current zone.

classmethod from_api_repr(*resource*, *client*)
Factory: construct a zone given its API representation

Parameters

- **resource** (*dict*) – zone resource representation returned from the API
- **client** (*gcloud.dns.client.Client*) – Client which holds credentials and project configuration for the zone.

Return type *gcloud.dns.zone.ManagedZone*

Returns Zone parsed from resource.

list_changes(*max_results=None*, *page_token=None*, *client=None*)
List change sets for this zone.

See: https://cloud.google.com/dns/api/v1/resourceRecordSets/list

Parameters

- **max_results** (*int*) – maximum number of zones to return, If not passed, defaults to a value set by the API.
- **page_token** (*string*) – opaque marker for the next "page" of zones. If not passed, the API will return the first page of zones.
- **client** (*gcloud.dns.client.Client* or NoneType) – the client to use. If not passed, falls back to the client stored on the current zone.

Return type tuple, (list, str)

Returns list of *gcloud.dns.resource_record_set.ResourceRecordSet*, plus a "next page token" string: if the token is not None, indicates that more zones can be retrieved with another call (pass that value as page_token).

list_resource_record_sets(*max_results=None*, *page_token=None*, *client=None*)
List resource record sets for this zone.

See: https://cloud.google.com/dns/api/v1/resourceRecordSets/list

Parameters

- **max_results** (*int*) – maximum number of zones to return, If not passed, defaults to a value set by the API.
- **page_token** (*string*) – opaque marker for the next "page" of zones. If not passed, the API will return the first page of zones.
- **client** (*gcloud.dns.client.Client* or NoneType) – the client to use. If not passed, falls back to the client stored on the current zone.

Return type tuple, (list, str)

Returns list of *gcloud.dns.resource_record_set.ResourceRecordSet*, plus a "next page token" string: if the token is not None, indicates that more zones can be retrieved with another call (pass that value as `page_token`).

name_server_set
Named set of DNS name servers that all host the same ManagedZones.

Most users will leave this blank.

See: https://cloud.google.com/dns/api/v1/managedZones#nameServerSet

Return type string, or `NoneType`

Returns The name as set by the user, or None (the default).

name_servers
Datetime at which the zone was created.

Return type list of strings, or `NoneType`.

Returns the assigned name servers (None until set from the server).

path
URL path for the zone's APIs.

Return type string

Returns the path based on project and dataste name.

project
Project bound to the zone.

Return type string

Returns the project (derived from the client).

reload(*client=None*)
API call: refresh zone properties via a GET request

See https://cloud.google.com/dns/api/v1/managedZones/get

Parameters **client** (*gcloud.dns.client.Client* or `NoneType`) – the client to use. If not passed, falls back to the `client` stored on the current zone.

resource_record_set(*name*, *record_type*, *ttl*, *rrdatas*)
Construct a resource record set bound to this zone.

Parameters

- **name** (*string*) – Name of the record set.
- **record_type** (*string*) – RR type
- **ttl** (*integer*) – TTL for the RR, in seconds
- **rrdatas** (*list of string*) – resource data for the RR

Return type *gcloud.dns.resource_record_set.ResourceRecordSet*

Returns a new `ResourceRecordSet` instance

zone_id
ID for the zone resource.

Return type string, or `NoneType`

Returns the ID (None until set from the server).

CHAPTER 31

Resource Record Sets

Define API ResourceRecordSets.

class gcloud.dns.resource_record_set.**ResourceRecordSet**(*name*, *record_type*, *ttl*, *rrdatas*, *zone*)

Bases: object

ResourceRecordSets are DNS resource records.

RRS are owned by a *gcloud.dns.zone.ManagedZone* instance.

See: https://cloud.google.com/dns/api/v1/resourceRecordSets

Parameters

- **name** (*string*) – the name of the record set
- **record_type** (*string*) – the RR type of the zone
- **ttl** (*integer*) – TTL (in seconds) for caching the record sets
- **rrdatas** (*list of string*) – one or more lines containing the resource data
- **zone** (*gcloud.dns.zone.ManagedZone*) – A zone which holds one or more record sets.

classmethod from_api_repr(*resource*, *zone*)

Factory: construct a record set given its API representation

Parameters

- **resource** (*dict*) – record sets representation returned from the API
- **zone** (*gcloud.dns.zone.ManagedZone*) – A zone which holds one or more record sets.

Return type gcloud.dns.zone.ResourceRecordSet

Returns RRS parsed from resource.

CHAPTER 32

Change Sets

Define API ResourceRecordSets.

class gcloud.dns.changes.**Changes**(*zone*)
Bases: object

Changes are bundled additions / deletions of DNS resource records.

Changes are owned by a *gcloud.dns.zone.ManagedZone* instance.

See: https://cloud.google.com/dns/api/v1/changes

Parameters **zone** (*gcloud.dns.zone.ManagedZone*) – A zone which holds one or more record sets.

add_record_set(*record_set*)
Append a record set to the 'additions' for the change set.

Parameters **record_set** (*gcloud.dns.resource_record_set.ResourceRecordSet*) – the record set to append

Raises ValueError if record_set is not of the required type.

additions
Resource record sets to be added to the zone.

Return type sequence of *gcloud.dns.resource_record_set.ResourceRecordSet*.

Returns record sets appended via *add_record_set()*

create(*client=None*)
API call: create the change set via a POST request

See: https://cloud.google.com/dns/api/v1/changes/create

Parameters **client** (*gcloud.dns.client.Client* or NoneType) – the client to use. If not passed, falls back to the client stored on the current zone.

delete_record_set(*record_set*)
Append a record set to the 'deletions' for the change set.

Parameters **record_set** (*gcloud.dns.resource_record_set.ResourceRecordSet*) – the record set to append

Raises ValueError if record_set is not of the required type.

deletions
Resource record sets to be deleted from the zone.

Return type sequence of *gcloud.dns.resource_record_set.ResourceRecordSet*.

Returns record sets appended via *delete_record_set()*

exists(*client=None*)
API call: test for the existence of the change set via a GET request

See https://cloud.google.com/dns/api/v1/changes/get

Parameters **client** (*gcloud.dns.client.Client* or NoneType) – the client to use. If not passed, falls back to the client stored on the current zone.

classmethod from_api_repr(*resource*, *zone*)
Factory: construct a change set given its API representation

Parameters

- **resource** (*dict*) – change set representation returned from the API
- **zone** (*gcloud.dns.zone.ManagedZone*) – A zone which holds zero or more change sets.

Return type *gcloud.dns.changes.Changes*

Returns RRS parsed from resource.

name
Name of the change set.

Return type string or NoneType

Returns Name, as set by the back-end, or None.

path
URL path for change set APIs.

Return type string

Returns the path based on project, zone, and change set names.

reload(*client=None*)
API call: refresh zone properties via a GET request

See https://cloud.google.com/dns/api/v1/changes/get

Parameters **client** (*gcloud.dns.client.Client* or NoneType) – the client to use. If not passed, falls back to the client stored on the current zone.

started
Time when the change set was started.

Return type datetime.datetime or NoneType

Returns Time, as set by the back-end, or None.

status
Status of the change set.

Return type string or NoneType

Returns Status, as set by the back-end, or None.

CHAPTER 33

Using the API

33.1 Overview

Cloud Search allows an application to quickly perform full-text and geospatial searches without having to spin up instances and without the hassle of managing and maintaining a search service.

Cloud Search provides a model for indexing documents containing structured data, with documents and indexes saved to a separate persistent store optimized for search operations.

The API supports full text matching on string fields and allows indexing any number of documents in any number of indexes.

33.1.1 Client

`Client` objects provide a means to configure your Cloud Search applications. Eash instance holds both a `project` and an authenticated connection to the Cloud Search service.

For an overview of authentication in `gcloud-python`, see Authentication.

Assuming your environment is set up as described in that document, create an instance of `Client`.

```
>>> from gcloud import search
>>> client = search.Client()
```

33.2 Indexes

Indexes are searchable collections of documents.

List all indexes in the client's project:

```
>>> indexes = client.list_indexes()  # API call
>>> for index in indexes:
...     print(index.name)
...     field_names = ', '.join([field.name for field in index.fields])
...     print('- %s' % field_names)
index-name
- field-1, field-2
another-index-name
- field-3
```

Create a new index:

```
>>> new_index = client.index('new-index-name')
```

Note: Indexes cannot be created, updated, or deleted directly on the server: they are derived from the documents which are created "within" them.

33.3 Documents

Create a document instance, which is not yet added to its index on the server:

```
>>> index = client.index('index-id')
>>> document = index.document('document-1')
>>> document.exists()  # API call
False
>>> document.rank
None
```

Add one or more fields to the document:

```
>>> field = document.Field('fieldname')
>>> field.add_value('string')
```

Save the document into the index:

```
>>> document.create()  # API call
>>> document.exists()  # API call
True
>>> document.rank      # set by the server
1443648166
```

List all documents in an index:

```
>>> documents = index.list_documents()  # API call
>>> [document.id for document in documents]
['document-1']
```

Delete a document from its index:

```
>>> document = index.document('to-be-deleted')
>>> document.exists()  # API call
True
>>> document.delete()  # API call
>>> document.exists()  # API clal
False
```

Note: To update a document in place after manipulating its fields or rank, just recreate it: E.g.:

```
>>> document = index.document('document-id')
>>> document.exists()  # API call
True
>>> document.rank = 12345
>>> field = document.field('field-name')
>>> field.add_value('christina aguilera')
>>> document.create()  # API call
```

33.4 Fields

Fields belong to documents and are the data that actually gets searched.

Each field can have multiple values, which can be of the following types:

- String (Python2 `unicode`, Python3 `str`)
- Number (Python `int` or `float`)
- Timestamp (Python `datetime.datetime`)
- Geovalue (Python tuple, (`float`, `float`))

String values can be tokenized using one of three different types of tokenization, which can be passed when the value is added:

- **Atom** (`atom`) means "don't tokenize this string", treat it as one thing to compare against.
- **Text** (`text`) means "treat this string as normal text" and split words apart to be compared against.
- **HTML** (`html`) means "treat this string as HTML", understanding the tags, and treating the rest of the content like Text.

```
>>> from gcloud import search
>>> client = search.Client()
>>> index = client.index('index-id')
>>> document = index.document('document-id')
>>> field = document.field('field-name')
>>> field.add_value('britney spears', tokenization='atom')
>>> field.add_value('''<h1>Britney Spears</h1>', tokenization='html')
```

33.5 Searching

After populating an index with documents, search through them by issuing a search query:

```
>>> from gcloud import search
>>> client = search.Client()
>>> index = client.index('index-id')
>>> query = client.query('britney spears')
>>> matching_documents = index.search(query)  # API call
>>> for document in matching_documents:
...     print(document.id)
['document-id']
```

By default, all queries are sorted by the `rank` value set when the document was created. See: https://cloud.google.com/search/reference/rest/v1/projects/indexes/documents#resource_representation.google.cloudsearch.v1.Documer

To sort differently, use the `order_by` parameter:

```
>>> ordered = client.query('britney spears', order_by=['field1', '-field2'])
```

Note that the `-` character before `field2` means that this query will be sorted ascending by `field1` and then descending by `field2`.

To limit the fields to be returned in the match, use the `fields` paramater:

```
>>> projected = client.query('britney spears', fields=['field1', 'field2'])
```

CHAPTER 34

Getting started

The `gcloud` library is `pip` install-able:

```
$ pip install gcloud
```

If you have trouble installing `pycrypto` or `pyopenssl` (and you're on Ubuntu), you can try install the precompiled packages:

```
$ sudo apt-get install python-crypto python-openssl
```

If you want to install everything with `pip`, try installing the `dev` packages beforehand:

```
$ sudo apt-get install python-dev libssl-dev
```

If you want to install *gcloud-python* from source, you can clone the repository from GitHub:

```
$ git clone git://github.com/GoogleCloudPlatform/gcloud-python.git
$ cd gcloud-python
$ python setup.py install
```

34.1 Cloud Datastore

Google Cloud Datastore is a fully managed, schemaless database for storing non-relational data.

```
from gcloud import datastore

client = datastore.Client()
key = client.key('Person')

entity = datastore.Entity(key=key)
entity['name'] = 'Your name'
entity['age'] = 25
client.put(entity)
```

34.2 Cloud Storage

Google Cloud Storage allows you to store data on Google infrastructure.

```
from gcloud import storage

client = storage.Client()
bucket = client.get_bucket('<your-bucket-name>')
blob = bucket.blob('my-test-file.txt')
blob.upload_from_string('this is test content!')
```
