6.12	Changelog	92
6.13	License	94

A simple interface to everyday GPIO components used with Raspberry Pi.

Created by [Ben Nuttall](#) of the [Raspberry Pi Foundation](#), [Dave Jones](#), and other contributors.

CHAPTER 1

About

Component interfaces are provided to allow a frictionless way to get started with physical computing:

```
from gpiozero import LED
from time import sleep

led = LED(17)

while True:
    led.on()
    sleep(1)
    led.off()
    sleep(1)
```

With very little code, you can quickly get going connecting your components together:

```
from gpiozero import LED, Button
from signal import pause

led = LED(17)
button = Button(3)

button.when_pressed = led.on
button.when_released = led.off

pause()
```

The library includes interfaces to many simple everyday components, as well as some more complex things like sensors, analogue-to-digital converters, full colour LEDs, robotics kits and more.

CHAPTER 2

Install

First, update your repositories list:

```
sudo apt-get update
```

Then install the package of your choice. Both Python 3 and Python 2 are supported. Python 3 is recommended:

```
sudo apt-get install python3-gpiozero
```

or:

```
sudo apt-get install python-gpiozero
```

CHAPTER 3

Documentation

Comprehensive documentation is available at <https://gpiozero.readthedocs.org/>.

CHAPTER 4

Development

This project is being developed on [GitHub](#). Join in:

- Provide suggestions, report bugs and ask questions as [issues](#)
- Provide examples we can use as [recipes](#)
- Contribute to the code

Alternatively, email suggestions and feedback to <mailto:ben@raspberrypi.org>

CHAPTER 5

Contributors

- Ben Nuttall (project maintainer)
- Dave Jones
- Martin O’Hanlon
- Andrew Scheller
- Schelto vanDoorn

Table of Contents

Recipes

The following recipes demonstrate some of the capabilities of the `gpiozero` library. Please note that all recipes are written assuming Python 3. Recipes *may* work under Python 2, but no guarantees!

Pin Numbering

This library uses Broadcom (BCM) pin numbering for the GPIO pins, as opposed to physical (BOARD) numbering. Unlike in the [RPi.GPIO](#) library, this is not configurable.

Any pin marked `GPIO` in the diagram below can be used for generic components:

LED

Turn an *LED* on and off repeatedly:

```
from gpiozero import LED
from time import sleep

red = LED(17)

while True:
    red.on()
    sleep(1)
    red.off()
    sleep(1)
```

Alternatively:

```
from gpiozero import LED
from signal import pause

red = LED(17)

red.blink()

pause()
```

Note: Reaching the end of a Python script will terminate the process and GPIOs may be reset. Keep your script alive with `signal.pause()`. See *Keep your script running* for more information.

Button

Check if a `Button` is pressed:

```
from gpiozero import Button

button = Button(2)

while True:
    if button.is_pressed:
        print("Button is pressed")
    else:
        print("Button is not pressed")
```

Wait for a button to be pressed before continuing:

```
from gpiozero import Button

button = Button(2)

button.wait_for_press()
print("Button was pressed")
```

Run a function every time the button is pressed:

```
from gpiozero import Button
from signal import pause

def say_hello():
    print("Hello!")

button = Button(2)

button.when_pressed = say_hello

pause()
```

Button controlled LED

Turn on an *LED* when a *Button* is pressed:

```
from gpiozero import LED, Button
from signal import pause

led = LED(17)
button = Button(2)

button.when_pressed = led.on
button.when_released = led.off

pause()
```

Alternatively:

```
from gpiozero import LED, Button
from signal import pause

led = LED(17)
button = Button(2)

led.source = button.values

pause()
```

Traffic Lights

A full traffic lights system.

Using a *TrafficLights* kit like Pi-Stop:

```
from gpiozero import TrafficLights
from time import sleep

lights = TrafficLights(2, 3, 4)

lights.green.on()

while True:
    sleep(10)
    lights.green.off()
    lights.amber.on()
    sleep(1)
    lights.amber.off()
    lights.red.on()
    sleep(10)
    lights.amber.on()
    sleep(1)
    lights.green.on()
    lights.amber.off()
    lights.red.off()
```

Alternatively:

```
from gpiozero import TrafficLights
from time import sleep
from signal import pause

lights = TrafficLights(2, 3, 4)

def traffic_light_sequence():
```

```

while True:
    yield (0, 0, 1) # green
    sleep(10)
    yield (0, 1, 0) # amber
    sleep(1)
    yield (1, 0, 0) # red
    sleep(10)
    yield (1, 1, 0) # red+amber
    sleep(1)

lights.source = traffic_light_sequence()

pause()

```

Using [LED](#) components:

```

from gpiozero import LED
from time import sleep

red = LED(2)
amber = LED(3)
green = LED(4)

green.on()
amber.off()
red.off()

while True:
    sleep(10)
    green.off()
    amber.on()
    sleep(1)
    amber.off()
    red.on()
    sleep(10)
    amber.on()
    sleep(1)
    green.on()
    amber.off()
    red.off()

```

Push button stop motion

Capture a picture with the camera module every time a button is pressed:

```

from gpiozero import Button
from picamera import PiCamera

button = Button(2)

with PiCamera() as camera:
    camera.start_preview()
    frame = 1
    while True:
        button.wait_for_press()
        camera.capture('/home/pi/frame%03d.jpg' % frame)
        frame += 1

```

See [Push Button Stop Motion](#) for a full resource.

Reaction Game

When you see the light come on, the first person to press their button wins!

```
from gpiozero import Button, LED
from time import sleep
import random

led = LED(17)

player_1 = Button(2)
player_2 = Button(3)

time = random.uniform(5, 10)
sleep(time)
led.on()

while True:
    if player_1.is_pressed:
        print("Player 1 wins!")
        break
    if player_2.is_pressed:
        print("Player 2 wins!")
        break

led.off()
```

See [Quick Reaction Game](#) for a full resource.

GPIO Music Box

Each button plays a different sound!

```
from gpiozero import Button
import pygame.mixer
from pygame.mixer import Sound
from signal import pause
```

```

pygame.mixer.init()

sound_pins = {
    2: Sound("samples/drum_tom_mid_hard.wav"),
    3: Sound("samples/drum_cymbal_open.wav"),
}

buttons = [Button(pin) for pin in sound_pins]
for button in buttons:
    sound = sound_pins[button.pin.number]
    button.when_pressed = sound.play

pause()

```

See [GPIO Music Box](#) for a full resource.

All on when pressed

While the button is pressed down, the buzzer and all the lights come on.

FishDish:

```

from gpiozero import FishDish
from signal import pause

fish = FishDish()

fish.button.when_pressed = fish.on
fish.button.when_released = fish.off

pause()

```

Ryanteck *TrafficHat*:

```

from gpiozero import TrafficHat
from signal import pause

th = TrafficHat()

th.button.when_pressed = th.on
th.button.when_released = th.off

pause()

```

Using *LED*, *Buzzer*, and *Button* components:

```

from gpiozero import LED, Buzzer, Button
from signal import pause

button = Button(2)
buzzer = Buzzer(3)
red = LED(4)
amber = LED(5)
green = LED(6)

things = [red, amber, green, buzzer]

def things_on():
    for thing in things:
        thing.on()

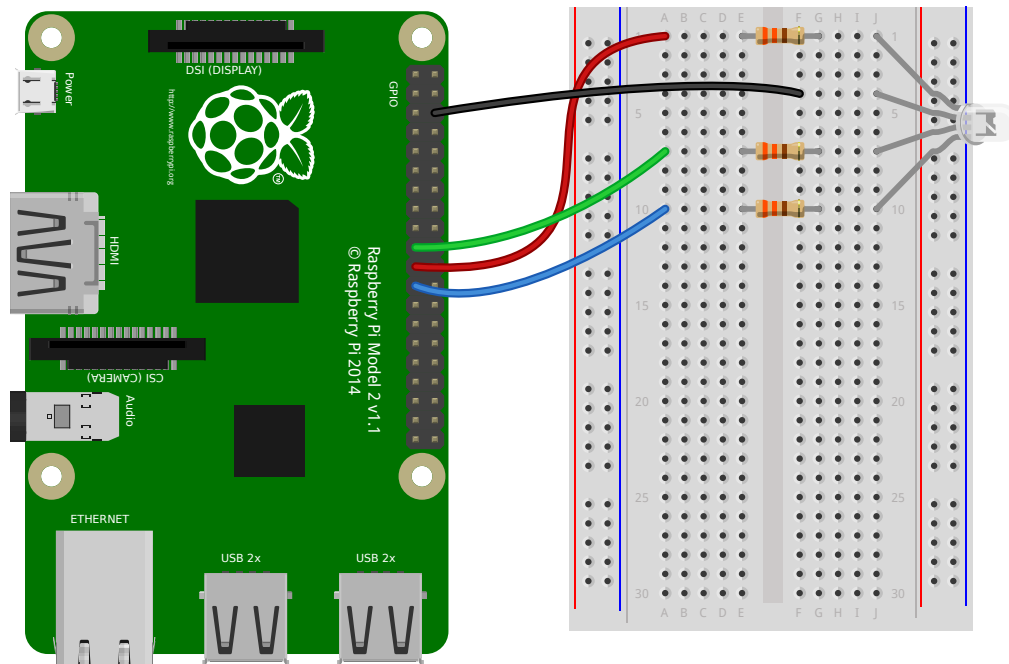

```

```
def things_off():
    for thing in things:
        thing.off()

button.when_pressed = things_on
button.when_released = things_off

pause()
```

RGB LED

Making colours with an *RGBLED*:

```
from gpiozero import RGBLED
from time import sleep

led = RGBLED(red=9, green=10, blue=11)

led.red = 1 # full red
sleep(1)
led.red = 0.5 # half red
sleep(1)

led.color = (0, 1, 0) # full green
sleep(1)
led.color = (1, 0, 1) # magenta
sleep(1)
led.color = (1, 1, 0) # yellow
sleep(1)
led.color = (0, 1, 1) # cyan
sleep(1)
led.color = (1, 1, 1) # white
sleep(1)

led.color = (0, 0, 0) # off
sleep(1)
```

```
# slowly increase intensity of blue
for n in range(100):
    led.blue = n/100
    sleep(0.1)
```

Motion sensor

Light an *LED* when a *MotionSensor* detects motion:

```
from gpiozero import MotionSensor, LED
from signal import pause

pir = MotionSensor(4)
led = LED(16)

pir.when_motion = led.on
pir.when_no_motion = led.off

pause()
```

Light sensor

Have a *LightSensor* detect light and dark:

```
from gpiozero import LightSensor

sensor = LightSensor(18)

while True:
    sensor.wait_for_light()
    print("It's light! :)")
    sensor.wait_for_dark()
    print("It's dark :(")
```

Run a function when the light changes:

```
from gpiozero import LightSensor, LED
from signal import pause

sensor = LightSensor(18)
led = LED(16)

sensor.when_dark = led.on
sensor.when_light = led.off

pause()
```

Or make a *PWMLED* change brightness according to the detected light level:

```
from gpiozero import LightSensor, LED
from signal import pause

sensor = LightSensor(18)
led = PWMLED(16)

led.source = sensor.values

pause()
```

Distance sensor

Have a *DistanceSensor* detect the distance to the nearest object:

```
from gpiozero import DistanceSensor
from time import sleep

sensor = DistanceSensor(23, 24)

while True:
    print('Distance to nearest object is', sensor.distance, 'm')
    sleep(1)
```

Run a function when something gets near the sensor:

```
from gpiozero import DistanceSensor, LED
from signal import pause

sensor = DistanceSensor(23, 24, max_distance=1, threshold_distance=0.2)
led = LED(16)

sensor.when_in_range = led.on
sensor.when_out_of_range = led.off

pause()
```

Motors

Spin a *Motor* around forwards and backwards:

```
from gpiozero import Motor
from time import sleep

motor = Motor(forward=4, back=14)

while True:
    motor.forward()
    sleep(5)
    motor.backward()
    sleep(5)
```

Robot

Make a *Robot* drive around in (roughly) a square:

```
from gpiozero import Robot
from time import sleep

robot = Robot(left=(4, 14), right=(17, 18))

for i in range(4):
    robot.forward()
    sleep(10)
    robot.right()
    sleep(1)
```

Make a robot with a distance sensor that runs away when things get within 20cm of it:

```
from gpiozero import Robot, DistanceSensor
from signal import pause

sensor = DistanceSensor(23, 24, max_distance=1, threshold_distance=0.2)
robot = Robot(left=(4, 14), right=(17, 18))

sensor.when_in_range = robot.backward
sensor.when_out_of_range = robot.stop
pause()
```

Button controlled robot

Use four GPIO buttons as forward/back/left/right controls for a robot:

```
from gpiozero import RyanteckRobot, Button
from signal import pause

robot = RyanteckRobot()

left = Button(26)
right = Button(16)
fw = Button(21)
bw = Button(20)

fw.when_pressed = robot.forward
fw.when_released = robot.stop

left.when_pressed = robot.left
left.when_released = robot.stop

right.when_pressed = robot.right
right.when_released = robot.stop

bw.when_pressed = robot.backward
bw.when_released = robot.stop

pause()
```

Keyboard controlled robot

Use up/down/left/right keys to control a robot:

```

import curses
from gpiozero import RyanteckRobot

robot = RyanteckRobot()

actions = {
    curses.KEY_UP:    robot.forward,
    curses.KEY_DOWN:  robot.backward,
    curses.KEY_LEFT:  robot.left,
    curses.KEY_RIGHT: robot.right,
}

def main(window):
    next_key = None
    while True:
        curses.halfdelay(1)
        if next_key is None:
            key = window.getch()
        else:
            key = next_key
            next_key = None
        if key != -1:
            # KEY DOWN
            curses.halfdelay(3)
            action = actions.get(key)
            if action is not None:
                action()
            next_key = key
            while next_key == key:
                next_key = window.getch()
            # KEY UP
            robot.stop()

curses.wrapper(main)

```

Note: This recipe uses the `curses` module. This module requires that Python is running in a terminal in order to work correctly, hence this recipe will *not* work in environments like IDLE.

If you prefer a version that works under IDLE, the following recipe should suffice, but will require that you install the `evdev` library with `sudo pip install evdev` first:

```

from gpiozero import RyanteckRobot
from evdev import InputDevice, list_devices, ecodes

robot = RyanteckRobot()

devices = [InputDevice(device) for device in list_devices()]
keyboard = devices[0] # this may vary

keypress_actions = {
    ecodes.KEY_UP: robot.forward,
    ecodes.KEY_DOWN: robot.backward,
    ecodes.KEY_LEFT: robot.left,
    ecodes.KEY_RIGHT: robot.right,
}

for event in keyboard.read_loop():
    if event.type == ecodes.EV_KEY:
        if event.value == 1: # key down
            keypress_actions[event.code]()
        if event.value == 0: # key up

```

```
robot.stop()
```

Motion sensor robot

Make a robot drive forward when it detects motion:

```
from gpiozero import Robot, MotionSensor
from signal import pause

robot = Robot(left=(4, 14), right=(17, 18))
pir = MotionSensor(5)

pir.when_motion = robot.forward
pir.when_no_motion = robot.stop

pause()
```

Alternatively:

```
from gpiozero import Robot, MotionSensor
from signal import pause

robot = Robot(left=(4, 14), right=(17, 18))
pir = MotionSensor(5)

robot.source = zip(pir.values, pir.values)

pause()
```

Potentiometer

Continually print the value of a potentiometer (values between 0 and 1) connected to a *MCP3008* analog to digital converter:

```
from gpiozero import MCP3008

while True:
    with MCP3008(channel=0) as pot:
        print(pot.value)
```

Present the value of a potentiometer on an LED bar graph using PWM to represent states that won't "fill" an LED:

```
from gpiozero import LEDBarGraph, MCP3008
from signal import pause

graph = LEDBarGraph(5, 6, 13, 19, 26, pwm=True)
pot = MCP3008(channel=0)
graph.source = pot.values
pause()
```

Measure temperature with an ADC

Wire a TMP36 temperature sensor to the first channel of an *MCP3008* analog to digital converter:

```
from gpiozero import MCP3008
from time import sleep

def convert_temp(gen):
    for value in gen:
```

```
        yield (value * 3.3 - 0.5) * 100

adc = MCP3008(channel=0)

for temp in convert_temp(adc.values):
    print('The temperature is', temp, 'C')
    sleep(1)
```

Full color LED controlled by 3 potentiometers

Wire up three potentiometers (for red, green and blue) and use each of their values to make up the colour of the LED:

```
from gpiozero import RGBLED, MCP3008

led = RGBLED(red=2, green=3, blue=4)
red_pot = MCP3008(channel=0)
green_pot = MCP3008(channel=1)
blue_pot = MCP3008(channel=2)

while True:
    led.red = red_pot.value
    led.green = green_pot.value
    led.blue = blue_pot.value
```

Alternatively, the following example is identical, but uses the `source` property rather than a `while` loop:

```
from gpiozero import RGBLED, MCP3008
from signal import pause

led = RGBLED(2, 3, 4)
red_pot = MCP3008(0)
green_pot = MCP3008(1)
blue_pot = MCP3008(2)

led.source = zip(red_pot.values, green_pot.values, blue_pot.values)

pause()
```

Please note the example above requires Python 3. In Python 2, `zip()` doesn't support lazy evaluation so the script will simply hang.

Controlling the Pi's own LEDs

On certain models of Pi (specifically the model A+, B+, and 2B) it's possible to control the power and activity LEDs. This can be useful for testing GPIO functionality without the need to wire up your own LEDs (also useful because the power and activity LEDs are “known good”).

Firstly you need to disable the usual triggers for the built-in LEDs. This can be done from the terminal with the following commands:

```
$ echo none | sudo tee /sys/class/leds/led0/trigger
$ echo gpio | sudo tee /sys/class/leds/led1/trigger
```

Now you can control the LEDs with `gpiozero` like so:

```
from gpiozero import LED
from signal import pause
```

```
power = LED(35)
activity = LED(47)

activity.blink()
power.blink()
pause()
```

To revert the LEDs to their usual purpose you can either reboot your Pi or run the following commands:

```
$ echo mmc0 | sudo tee /sys/class/leds/led0/trigger
$ echo input | sudo tee /sys/class/leds/led1/trigger
```

Note: On the Pi Zero you can control the activity LED with this recipe, but there's no separate power LED to control (it's also worth noting the activity LED is active low, so set `active_high=False` when constructing your LED component).

On the original Pi 1 (model A or B), the activity LED can be controlled with GPIO16 (after disabling its trigger as above) but the power LED is hard-wired on.

On the Pi 3B the LEDs are controlled by a GPIO expander which is not accessible from gpiozero (yet).

Notes

Keep your script running

The following script looks like it should turn an LED on:

```
from gpiozero import LED

led = LED(17)
led.on()
```

And it does, if you're using the Python (or IPython or IDLE) shell. However, if you saved this script as a Python file and ran it, it would flash on briefly, then the script would end and it would turn off.

The following file includes an intentional `pause()` to keep the script alive:

```
from gpiozero import LED
from signal import pause

led = LED(17)
led.on()
pause()
```

Now the script will stay running, leaving the LED on, until it is terminated manually (e.g. by pressing Ctrl+C). Similarly, when setting up callbacks on button presses or other input devices, the script needs to be running for the events to be detected:

```
from gpiozero import Button
from signal import pause

def hello():
    print("Hello")

button = Button(2)
button.when_pressed = hello
pause()
```

Importing from GPIO Zero

In Python, libraries and functions used in a script must be imported by name at the top of the file, with the exception of the functions built into Python by default.

For example, to use the `Button` interface from GPIO Zero, it should be explicitly imported:

```
from gpiozero import Button
```

Now `Button` is available directly in your script:

```
button = Button(2)
```

Alternatively, the whole GPIO Zero library can be imported:

```
import gpiozero
```

In this case, all references to items within GPIO Zero must be prefixed:

```
button = gpiozero.Button(2)
```

Input Devices

These input device component interfaces have been provided for simple use of everyday components. Components must be wired up correctly before use in code.

Note: All GPIO pin numbers use Broadcom (BCM) numbering. See the [Recipes](#) page for more information.

Button

class `gpiozero.Button` (*pin*, *pull_up=True*, *bounce_time=None*)

Extends `DigitalInputDevice` and represents a simple push button or switch.

Connect one side of the button to a ground pin, and the other to any GPIO pin. Alternatively, connect one side of the button to the 3V3 pin, and the other to any GPIO pin, then set *pull_up* to `False` in the `Button` constructor.

The following example will print a line of text when the button is pushed:

```
from gpiozero import Button

button = Button(4)
button.wait_for_press()
print("The button was pressed!")
```

Parameters

- **pin** (*int*) – The GPIO pin which the button is attached to. See [Notes](#) for valid pin numbers.
- **pull_up** (*bool*) – If `True` (the default), the GPIO pin will be pulled high by default. In this case, connect the other side of the button to ground. If `False`, the GPIO pin will be pulled low by default. In this case, connect the other side of the button to 3V3.
- **bounce_time** (*float*) – If `None` (the default), no software bounce compensation will be performed. Otherwise, this is the length in time (in seconds) that the component will ignore changes in state after an initial change.

- **hold_time** (*float*) – The length of time (in seconds) to wait after the button is pushed, until executing the `when_held` handler.
- **hold_repeat** (*bool*) – If `True`, the `when_held` handler will be repeatedly executed as long as the device remains active, every *hold_time* seconds.

wait_for_press (*timeout=None*)

Pause the script until the device is activated, or the timeout is reached.

Parameters **timeout** (*float*) – Number of seconds to wait before proceeding. If this is `None` (the default), then wait indefinitely until the device is active.

wait_for_release (*timeout=None*)

Pause the script until the device is deactivated, or the timeout is reached.

Parameters **timeout** (*float*) – Number of seconds to wait before proceeding. If this is `None` (the default), then wait indefinitely until the device is inactive.

is_pressed

Returns `True` if the device is currently active and `False` otherwise. This property is usually derived from `value`. Unlike `value`, this is *always* a boolean.

pin

The *Pin* that the device is connected to. This will be `None` if the device has been closed (see the `close()` method). When dealing with GPIO pins, query `pin.number` to discover the GPIO pin (in BCM numbering) that the device is connected to.

pull_up

If `True`, the device uses a pull-up resistor to set the GPIO pin “high” by default. Defaults to `False`.

when_pressed

The function to run when the device changes state from inactive to active.

This can be set to a function which accepts no (mandatory) parameters, or a Python function which accepts a single mandatory parameter (with as many optional parameters as you like). If the function accepts a single mandatory parameter, the device that activated will be passed as that parameter.

Set this property to `None` (the default) to disable the event.

when_released

The function to run when the device changes state from active to inactive.

This can be set to a function which accepts no (mandatory) parameters, or a Python function which accepts a single mandatory parameter (with as many optional parameters as you like). If the function accepts a single mandatory parameter, the device that deactivated will be passed as that parameter.

Set this property to `None` (the default) to disable the event.

Line Sensor (TRCT5000)

class `gpiozero.LineSensor` (*pin*)

Extends `DigitalInputDevice` and represents a single pin line sensor like the TCRT5000 infra-red proximity sensor found in the [CamJam #3 EduKit](#).

A typical line sensor has a small circuit board with three pins: VCC, GND, and OUT. VCC should be connected to a 3V3 pin, GND to one of the ground pins, and finally OUT to the GPIO specified as the value of the *pin* parameter in the constructor.

The following code will print a line of text indicating when the sensor detects a line, or stops detecting a line:

```
from gpiozero import LineSensor
from signal import pause

sensor = LineSensor(4)
```

```
sensor.when_line = lambda: print('Line detected')
sensor.when_no_line = lambda: print('No line detected')
pause()
```

Parameters

- **pin** (*int*) – The GPIO pin which the button is attached to. See *Notes* for valid pin numbers.
- **queue_len** (*int*) – The length of the queue used to store values read from the sensor. This defaults to 5.
- **sample_rate** (*float*) – The number of values to read from the device (and append to the internal queue) per second. Defaults to 100.
- **threshold** (*float*) – Defaults to 0.5. When the mean of all values in the internal queue rises above this value, the sensor will be considered “active” by the *is_active* property, and all appropriate events will be fired.
- **partial** (*bool*) – When False (the default), the object will not return a value for *is_active* until the internal queue has filled with values. Only set this to True if you require values immediately after object construction.

wait_for_line (*timeout=None*)

Pause the script until the device is deactivated, or the timeout is reached.

Parameters **timeout** (*float*) – Number of seconds to wait before proceeding. If this is None (the default), then wait indefinitely until the device is inactive.

wait_for_no_line (*timeout=None*)

Pause the script until the device is activated, or the timeout is reached.

Parameters **timeout** (*float*) – Number of seconds to wait before proceeding. If this is None (the default), then wait indefinitely until the device is active.

pin

The *Pin* that the device is connected to. This will be None if the device has been closed (see the `close()` method). When dealing with GPIO pins, query `pin.number` to discover the GPIO pin (in BCM numbering) that the device is connected to.

when_line

The function to run when the device changes state from active to inactive.

This can be set to a function which accepts no (mandatory) parameters, or a Python function which accepts a single mandatory parameter (with as many optional parameters as you like). If the function accepts a single mandatory parameter, the device that deactivated will be passed as that parameter.

Set this property to None (the default) to disable the event.

when_no_line

The function to run when the device changes state from inactive to active.

This can be set to a function which accepts no (mandatory) parameters, or a Python function which accepts a single mandatory parameter (with as many optional parameters as you like). If the function accepts a single mandatory parameter, the device that activated will be passed as that parameter.

Set this property to None (the default) to disable the event.

Motion Sensor (D-SUN PIR)

class gpiozero.**MotionSensor** (*pin, queue_len=1, sample_rate=10, threshold=0.5, partial=False*)

Extends *SmoothedInputDevice* and represents a passive infra-red (PIR) motion sensor like the sort found in the *CamJam #2 EduKit*.

A typical PIR device has a small circuit board with three pins: VCC, OUT, and GND. VCC should be connected to a 5V pin, GND to one of the ground pins, and finally OUT to the GPIO specified as the value of the *pin* parameter in the constructor.

The following code will print a line of text when motion is detected:

```
from gpiozero import MotionSensor

pir = MotionSensor(4)
pir.wait_for_motion()
print("Motion detected!")
```

Parameters

- **pin** (*int*) – The GPIO pin which the button is attached to. See *Notes* for valid pin numbers.
- **queue_len** (*int*) – The length of the queue used to store values read from the sensor. This defaults to 1 which effectively disables the queue. If your motion sensor is particularly “twitchy” you may wish to increase this value.
- **sample_rate** (*float*) – The number of values to read from the device (and append to the internal queue) per second. Defaults to 100.
- **threshold** (*float*) – Defaults to 0.5. When the mean of all values in the internal queue rises above this value, the sensor will be considered “active” by the *is_active* property, and all appropriate events will be fired.
- **partial** (*bool*) – When *False* (the default), the object will not return a value for *is_active* until the internal queue has filled with values. Only set this to *True* if you require values immediately after object construction.

wait_for_motion (*timeout=None*)

Pause the script until the device is activated, or the timeout is reached.

Parameters *timeout* (*float*) – Number of seconds to wait before proceeding. If this is *None* (the default), then wait indefinitely until the device is active.

wait_for_no_motion (*timeout=None*)

Pause the script until the device is deactivated, or the timeout is reached.

Parameters *timeout* (*float*) – Number of seconds to wait before proceeding. If this is *None* (the default), then wait indefinitely until the device is inactive.

motion_detected

Returns *True* if the device is currently active and *False* otherwise.

pin

The *Pin* that the device is connected to. This will be *None* if the device has been closed (see the *close()* method). When dealing with GPIO pins, query *pin.number* to discover the GPIO pin (in BCM numbering) that the device is connected to.

when_motion

The function to run when the device changes state from inactive to active.

This can be set to a function which accepts no (mandatory) parameters, or a Python function which accepts a single mandatory parameter (with as many optional parameters as you like). If the function accepts a single mandatory parameter, the device that activated will be passed as that parameter.

Set this property to *None* (the default) to disable the event.

when_no_motion

The function to run when the device changes state from active to inactive.

This can be set to a function which accepts no (mandatory) parameters, or a Python function which accepts a single mandatory parameter (with as many optional parameters as you like). If the function accepts a single mandatory parameter, the device that deactivated will be passed as that parameter.

Set this property to `None` (the default) to disable the event.

Light Sensor (LDR)

class gpiozero.**LightSensor** (*pin*, *queue_len*=5, *charge_time_limit*=0.01, *threshold*=0.1, *partial*=False)

Extends *SmoothedInputDevice* and represents a light dependent resistor (LDR).

Connect one leg of the LDR to the 3V3 pin; connect one leg of a 1µf capacitor to a ground pin; connect the other leg of the LDR and the other leg of the capacitor to the same GPIO pin. This class repeatedly discharges the capacitor, then times the duration it takes to charge (which will vary according to the light falling on the LDR).

The following code will print a line of text when light is detected:

```
from gpiozero import LightSensor

ldr = LightSensor(18)
ldr.wait_for_light()
print("Light detected!")
```

Parameters

- **pin** (*int*) – The GPIO pin which the button is attached to. See *Notes* for valid pin numbers.
- **queue_len** (*int*) – The length of the queue used to store values read from the circuit. This defaults to 5.
- **charge_time_limit** (*float*) – If the capacitor in the circuit takes longer than this length of time to charge, it is assumed to be dark. The default (0.01 seconds) is appropriate for a 0.01µf capacitor coupled with the LDR from the [CamJam #2 EduKit](#). You may need to adjust this value for different valued capacitors or LDRs.
- **threshold** (*float*) – Defaults to 0.1. When the mean of all values in the internal queue rises above this value, the area will be considered “light”, and all appropriate events will be fired.
- **partial** (*bool*) – When `False` (the default), the object will not return a value for *is_active* until the internal queue has filled with values. Only set this to `True` if you require values immediately after object construction.

wait_for_dark (*timeout*=None)

Pause the script until the device is deactivated, or the timeout is reached.

Parameters **timeout** (*float*) – Number of seconds to wait before proceeding. If this is `None` (the default), then wait indefinitely until the device is inactive.

wait_for_light (*timeout*=None)

Pause the script until the device is activated, or the timeout is reached.

Parameters **timeout** (*float*) – Number of seconds to wait before proceeding. If this is `None` (the default), then wait indefinitely until the device is active.

light_detected

Returns `True` if the device is currently active and `False` otherwise.

pin

The *Pin* that the device is connected to. This will be `None` if the device has been closed (see the

`close()` method). When dealing with GPIO pins, query `pin.number` to discover the GPIO pin (in BCM numbering) that the device is connected to.

when_dark

The function to run when the device changes state from active to inactive.

This can be set to a function which accepts no (mandatory) parameters, or a Python function which accepts a single mandatory parameter (with as many optional parameters as you like). If the function accepts a single mandatory parameter, the device that deactivated will be passed as that parameter.

Set this property to `None` (the default) to disable the event.

when_light

The function to run when the device changes state from inactive to active.

This can be set to a function which accepts no (mandatory) parameters, or a Python function which accepts a single mandatory parameter (with as many optional parameters as you like). If the function accepts a single mandatory parameter, the device that activated will be passed as that parameter.

Set this property to `None` (the default) to disable the event.

Distance Sensor (HC-SR04)

class `gpiozero.DistanceSensor` (*echo*, *trigger*, *queue_len=30*, *max_distance=1*, *threshold_distance=0.3*, *partial=False*)

Extends `SmoothedInputDevice` and represents an HC-SR04 ultrasonic distance sensor, as found in the CamJam #3 EduKit.

The distance sensor requires two GPIO pins: one for the *trigger* (marked TRIG on the sensor) and another for the *echo* (marked ECHO on the sensor). However, a voltage divider is required to ensure the 5V from the ECHO pin doesn't damage the Pi. Wire your sensor according to the following instructions:

1. Connect the GND pin of the sensor to a ground pin on the Pi.
2. Connect the TRIG pin of the sensor a GPIO pin.
3. Connect a 330 Ω resistor from the ECHO pin of the sensor to a different GPIO pin.
4. Connect a 470 Ω resistor from ground to the ECHO GPIO pin. This forms the required voltage divider.
5. Finally, connect the VCC pin of the sensor to a 5V pin on the Pi.

The following code will periodically report the distance measured by the sensor in cm assuming the TRIG pin is connected to GPIO17, and the ECHO pin to GPIO18:

```
from gpiozero import DistanceSensor
from time import sleep

sensor = DistanceSensor(18, 17)
while True:
    print('Distance: ', sensor.distance * 100)
    sleep(1)
```

Parameters

- **echo** (*int*) – The GPIO pin which the ECHO pin is attached to. See [Notes](#) for valid pin numbers.
- **trigger** (*int*) – The GPIO pin which the TRIG pin is attached to. See [Notes](#) for valid pin numbers.
- **queue_len** (*int*) – The length of the queue used to store values read from the sensor. This defaults to 30.

- **max_distance** (*float*) – The `value` attribute reports a normalized value between 0 (too close to measure) and 1 (maximum distance). This parameter specifies the maximum distance expected in meters. This defaults to 1.
- **threshold_distance** (*float*) – Defaults to 0.3. This is the distance (in meters) that will trigger the `in_range` and `out_of_range` events when crossed.
- **partial** (*bool*) – When `False` (the default), the object will not return a value for `is_active` until the internal queue has filled with values. Only set this to `True` if you require values immediately after object construction.

wait_for_in_range (*timeout=None*)

Pause the script until the device is deactivated, or the timeout is reached.

Parameters **timeout** (*float*) – Number of seconds to wait before proceeding. If this is `None` (the default), then wait indefinitely until the device is inactive.

wait_for_out_of_range (*timeout=None*)

Pause the script until the device is activated, or the timeout is reached.

Parameters **timeout** (*float*) – Number of seconds to wait before proceeding. If this is `None` (the default), then wait indefinitely until the device is active.

distance

Returns the current distance measured by the sensor in meters. Note that this property will have a value between 0 and `max_distance`.

echo

Returns the `Pin` that the sensor's echo is connected to. This is simply an alias for the usual `pin` attribute.

max_distance

The maximum distance that the sensor will measure in meters. This value is specified in the constructor and is used to provide the scaling for the `value` attribute. When `distance` is equal to `max_distance`, value will be 1.

threshold_distance

The distance, measured in meters, that will trigger the `when_in_range` and `when_out_of_range` events when crossed. This is simply a meter-scaled variant of the usual `threshold` attribute.

trigger

Returns the `Pin` that the sensor's trigger is connected to.

when_in_range

The function to run when the device changes state from active to inactive.

This can be set to a function which accepts no (mandatory) parameters, or a Python function which accepts a single mandatory parameter (with as many optional parameters as you like). If the function accepts a single mandatory parameter, the device that deactivated will be passed as that parameter.

Set this property to `None` (the default) to disable the event.

when_out_of_range

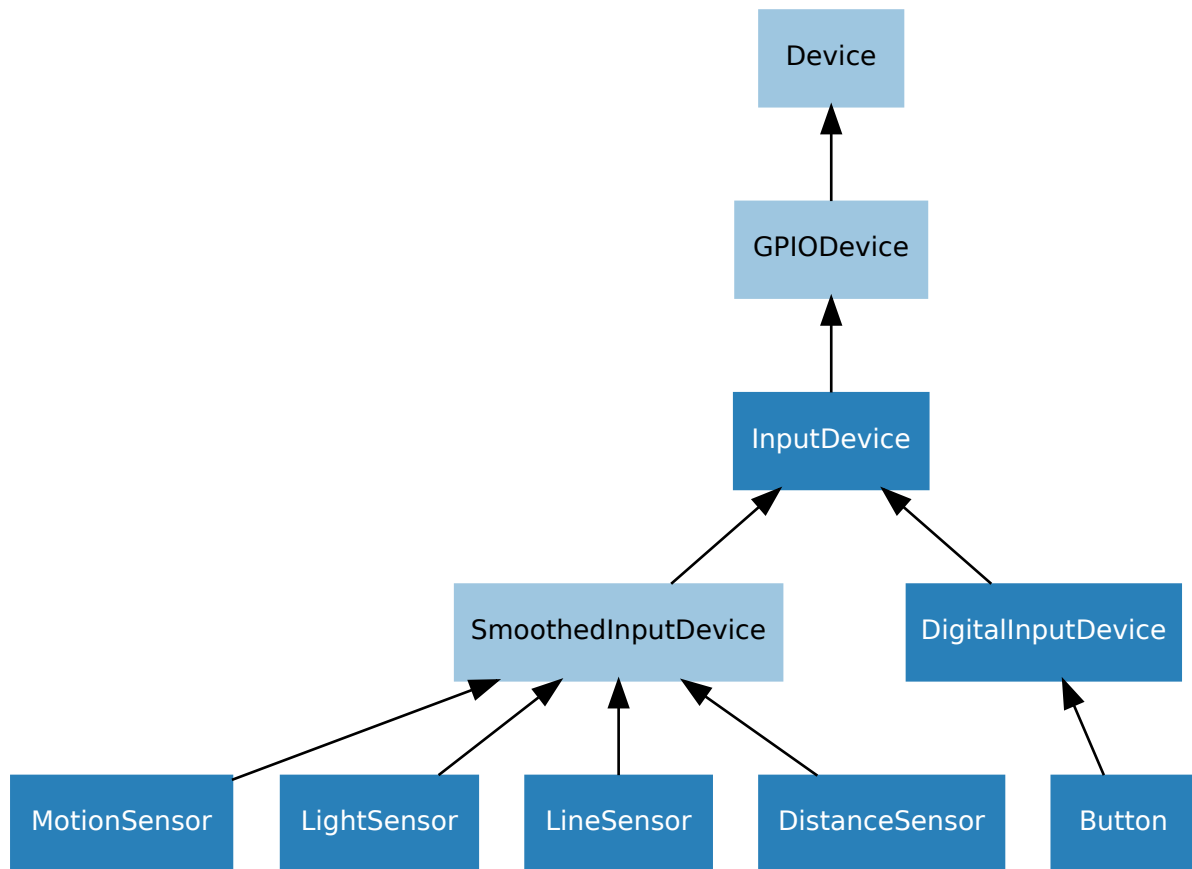

The function to run when the device changes state from inactive to active.

This can be set to a function which accepts no (mandatory) parameters, or a Python function which accepts a single mandatory parameter (with as many optional parameters as you like). If the function accepts a single mandatory parameter, the device that activated will be passed as that parameter.

Set this property to `None` (the default) to disable the event.

Base Classes

The classes in the sections above are derived from a series of base classes, some of which are effectively abstract. The classes form the (partial) hierarchy displayed in the graph below:

The following sections document these base classes for advanced users that wish to construct classes for their own devices.

DigitalInputDevice

class `gpiozero.DigitalInputDevice` (*pin*, *pull_up=False*, *bounce_time=None*)

Represents a generic input device with typical on/off behaviour.

This class extends `InputDevice` with machinery to fire the active and inactive events for devices that operate in a typical digital manner: straight forward on / off states with (reasonably) clean transitions between the two.

Parameters `bouncetime` (*float*) – Specifies the length of time (in seconds) that the component will ignore changes in state after an initial change. This defaults to `None` which indicates that no bounce compensation will be performed.

SmoothedInputDevice

class `gpiozero.SmoothedInputDevice` (*pin=None*, *pull_up=False*, *threshold=0.5*, *queue_len=5*, *sample_wait=0.0*, *partial=False*)

Represents a generic input device which takes its value from the mean of a queue of historical values.

This class extends `InputDevice` with a queue which is filled by a background thread which continually polls the state of the underlying device. The mean of the values in the queue is compared to a threshold which is used to determine the state of the `is_active` property.

Note: The background queue is not automatically started upon construction. This is to allow descendants to set up additional components before the queue starts reading values. Effectively this is an abstract base class.

This class is intended for use with devices which either exhibit analog behaviour (such as the charging time of a capacitor with an LDR), or those which exhibit “twitchy” behaviour (such as certain motion sensors).

Parameters

- **threshold** (*float*) – The value above which the device will be considered “on”.
- **queue_len** (*int*) – The length of the internal queue which is filled by the background thread.
- **sample_wait** (*float*) – The length of time to wait between retrieving the state of the underlying device. Defaults to 0.0 indicating that values are retrieved as fast as possible.
- **partial** (*bool*) – If False (the default), attempts to read the state of the device (from the *is_active* property) will block until the queue has filled. If True, a value will be returned immediately, but be aware that this value is likely to fluctuate excessively.

```
close()
```

Shut down the device and release all associated resources. This method can be called on an already closed device without raising an exception.

This method is primarily intended for interactive use at the command line. It disables the device and releases its pin(s) for use by another device.

You can attempt to do this simply by deleting an object, but unless you've cleaned up all references to the object this may not work (even if you've cleaned up all references, there's still no guarantee the garbage collector will actually delete the object at that point). By contrast, the `close` method provides a means of ensuring that the object is shut down.

For example, if you have a breadboard with a buzzer connected to pin 16, but then wish to attach an LED instead:

```
>>> from gpiozero import *
>>> bz = Buzzer(16)
>>> bz.on()
>>> bz.off()
>>> bz.close()
>>> led = LED(16)
>>> led.blink()
```

`Device` descendents can also be used as context managers using the `with` statement. For example:

```
>>> from gpiozero import *
>>> with Buzzer(16) as bz:
...     bz.on()
...
>>> with LED(16) as led:
...     led.on()
... 
```

is active

Returns `True` if the device is currently active and `False` otherwise.

partial

If `False` (the default), attempts to read the `value` or `is_active` properties will block until the queue has filled.

queue_len

The length of the internal queue of values which is averaged to determine the overall state of the device. This defaults to 5.

threshold

If *value* exceeds this amount, then *is_active* will return True.

value

Returns the mean of the values in the internal queue. This is compared to *threshold* to determine whether *is_active* is True.

InputDevice

class gpiozero.**InputDevice** (*pin*, *pull_up=False*)

Represents a generic GPIO input device.

This class extends *GPIODevice* to add facilities common to GPIO input devices. The constructor adds the optional *pull_up* parameter to specify how the pin should be pulled by the internal resistors. The *is_active* property is adjusted accordingly so that True still means active regardless of the *pull_up* setting.

Parameters

- **pin** (*int*) – The GPIO pin (in Broadcom numbering) that the device is connected to. If this is None a *GPIODeviceError* will be raised.
- **pull_up** (*bool*) – If True, the pin will be pulled high with an internal resistor. If False (the default), the pin will be pulled low.

pull_up

If True, the device uses a pull-up resistor to set the GPIO pin “high” by default. Defaults to False.

GPIODevice

class gpiozero.**GPIODevice** (*pin*)

Extends *Device*. Represents a generic GPIO device and provides the services common to all single-pin GPIO devices (like ensuring two GPIO devices do not share a *pin*).

Parameters **pin** (*int*) – The GPIO pin (in BCM numbering) that the device is connected to. If this is None, *GPIOPinMissing* will be raised. If the pin is already in use by another device, *GPIOPinInUse* will be raised.

close()

Shut down the device and release all associated resources. This method can be called on an already closed device without raising an exception.

This method is primarily intended for interactive use at the command line. It disables the device and releases its pin(s) for use by another device.

You can attempt to do this simply by deleting an object, but unless you’ve cleaned up all references to the object this may not work (even if you’ve cleaned up all references, there’s still no guarantee the garbage collector will actually delete the object at that point). By contrast, the close method provides a means of ensuring that the object is shut down.

For example, if you have a breadboard with a buzzer connected to pin 16, but then wish to attach an LED instead:

```
>>> from gpiozero import *
>>> bz = Buzzer(16)
>>> bz.on()
>>> bz.off()
>>> bz.close()
```

```
>>> led = LED(16)
>>> led.blink()
```

Device descendents can also be used as context managers using the `with` statement. For example:

```
>>> from gpiozero import *
>>> with Buzzer(16) as bz:
...     bz.on()
...
>>> with LED(16) as led:
...     led.on()
... 
```

pin

The *Pin* that the device is connected to. This will be `None` if the device has been closed (see the `close()` method). When dealing with GPIO pins, query `pin.number` to discover the GPIO pin (in BCM numbering) that the device is connected to.

Output Devices

These output device component interfaces have been provided for simple use of everyday components. Components must be wired up correctly before use in code.

Note: All GPIO pin numbers use Broadcom (BCM) numbering. See the [Recipes](#) page for more information.

LED

class `gpiozero.LED` (*pin*, *active_high=True*, *initial_value=False*)

Extends *DigitalOutputDevice* and represents a light emitting diode (LED).

Connect the cathode (short leg, flat side) of the LED to a ground pin; connect the anode (longer leg) to a limiting resistor; connect the other side of the limiting resistor to a GPIO pin (the limiting resistor can be placed either side of the LED).

The following example will light the LED:

```
from gpiozero import LED

led = LED(17)
led.on()
```

Parameters

- **pin** (*int*) – The GPIO pin which the LED is attached to. See [Notes](#) for valid pin numbers.
- **active_high** (*bool*) – If `True` (the default), the LED will operate normally with the circuit described above. If `False` you should wire the cathode to the GPIO pin, and the anode to a 3V3 pin (via a limiting resistor).
- **initial_value** (*bool*) – If `False` (the default), the LED will be off initially. If `None`, the LED will be left in whatever state the pin is found in when configured for output (warning: this can be on). If `True`, the LED will be switched on initially.

blink (*on_time=1*, *off_time=1*, *n=None*, *background=True*)

Make the device turn on and off repeatedly.

Parameters

- **on_time** (*float*) – Number of seconds on. Defaults to 1 second.
- **off_time** (*float*) – Number of seconds off. Defaults to 1 second.
- **n** (*int*) – Number of times to blink; `None` (the default) means forever.
- **background** (*bool*) – If `True` (the default), start a background thread to continue blinking and return immediately. If `False`, only return when the blink is finished (warning: the default value of *n* will result in this method never returning).

off()

Turns the device off.

on()

Turns the device on.

toggle()

Reverse the state of the device. If it's on, turn it off; if it's off, turn it on.

is_litReturns `True` if the device is currently active and `False` otherwise. This property is usually derived from `value`. Unlike `value`, this is *always* a boolean.**pin**The `Pin` that the device is connected to. This will be `None` if the device has been closed (see the `close()` method). When dealing with GPIO pins, query `pin.number` to discover the GPIO pin (in BCM numbering) that the device is connected to.**PWMLED****class** gpiozero.**PWMLED** (*pin*, *active_high=True*, *initial_value=0*, *frequency=100*)Extends `PWMOutputDevice` and represents a light emitting diode (LED) with variable brightness.

A typical configuration of such a device is to connect a GPIO pin to the anode (long leg) of the LED, and the cathode (short leg) to ground, with an optional resistor to prevent the LED from burning out.

Parameters

- **pin** (*int*) – The GPIO pin which the LED is attached to. See [Notes](#) for valid pin numbers.
- **active_high** (*bool*) – If `True` (the default), the `on()` method will set the GPIO to HIGH. If `False`, the `on()` method will set the GPIO to LOW (the `off()` method always does the opposite).
- **initial_value** (*bool*) – If 0 (the default), the LED will be off initially. Other values between 0 and 1 can be specified as an initial brightness for the LED. Note that `None` cannot be specified (unlike the parent class) as there is no way to tell PWM not to alter the state of the pin.
- **frequency** (*int*) – The frequency (in Hz) of pulses emitted to drive the LED. Defaults to 100Hz.

blink (*on_time=1*, *off_time=1*, *fade_in_time=0*, *fade_out_time=0*, *n=None*, *background=True*)

Make the device turn on and off repeatedly.

Parameters

- **on_time** (*float*) – Number of seconds on. Defaults to 1 second.
- **off_time** (*float*) – Number of seconds off. Defaults to 1 second.
- **fade_in_time** (*float*) – Number of seconds to spend fading in. Defaults to 0.
- **fade_out_time** (*float*) – Number of seconds to spend fading out. Defaults to 0.

- **n** (*int*) – Number of times to blink; `None` (the default) means forever.
- **background** (*bool*) – If `True` (the default), start a background thread to continue blinking and return immediately. If `False`, only return when the blink is finished (warning: the default value of *n* will result in this method never returning).

off()

Turns the device off.

on()

Turns the device on.

toggle()

Toggle the state of the device. If the device is currently off (*value* is 0.0), this changes it to “fully” on (*value* is 1.0). If the device has a duty cycle (*value*) of 0.1, this will toggle it to 0.9, and so on.

is_lit

Returns `True` if the device is currently active (*value* is non-zero) and `False` otherwise.

pin

The *Pin* that the device is connected to. This will be `None` if the device has been closed (see the `close()` method). When dealing with GPIO pins, query `pin.number` to discover the GPIO pin (in BCM numbering) that the device is connected to.

value

The duty cycle of the PWM device. 0.0 is off, 1.0 is fully on. Values in between may be specified for varying levels of power in the device.

RGBLED

class `gpiozero.RGBLED` (*red, green, blue, active_high=True, initial_value=(0, 0, 0)*)

Extends *Device* and represents a full color LED component (composed of red, green, and blue LEDs).

Connect the common cathode (longest leg) to a ground pin; connect each of the other legs (representing the red, green, and blue anodes) to any GPIO pins. You can either use three limiting resistors (one per anode) or a single limiting resistor on the cathode.

The following code will make the LED purple:

```
from gpiozero import RGBLED

led = RGBLED(2, 3, 4)
led.color = (1, 0, 1)
```

Parameters

- **red** (*int*) – The GPIO pin that controls the red component of the RGB LED.
- **green** (*int*) – The GPIO pin that controls the green component of the RGB LED.
- **blue** (*int*) – The GPIO pin that controls the blue component of the RGB LED.
- **active_high** (*bool*) – Set to `True` (the default) for common cathode RGB LEDs. If you are using a common anode RGB LED, set this to `False`.
- **initial_value** (*bool*) – The initial color for the LED. Defaults to black (0, 0, 0).

blink (*on_time=1, off_time=1, fade_in_time=0, fade_out_time=0, on_color=(1, 1, 1), off_color=(0, 0, 0), n=None, background=True*)

Make the device turn on and off repeatedly.

Parameters

- **on_time** (*float*) – Number of seconds on. Defaults to 1 second.

- **off_time** (*float*) – Number of seconds off. Defaults to 1 second.
- **fade_in_time** (*float*) – Number of seconds to spend fading in. Defaults to 0.
- **fade_out_time** (*float*) – Number of seconds to spend fading out. Defaults to 0.
- **on_color** (*tuple*) – The color to use when the LED is “on”. Defaults to white.
- **off_color** (*tuple*) – The color to use when the LED is “off”. Defaults to black.
- **n** (*int*) – Number of times to blink; `None` (the default) means forever.
- **background** (*bool*) – If `True` (the default), start a background thread to continue blinking and return immediately. If `False`, only return when the blink is finished (warning: the default value of *n* will result in this method never returning).

off()

Turn the LED off. This is equivalent to setting the LED color to black (0, 0, 0).

on()

Turn the LED on. This equivalent to setting the LED color to white (1, 1, 1).

toggle()

Toggle the state of the device. If the device is currently off (value is (0, 0, 0)), this changes it to “fully” on (value is (1, 1, 1)). If the device has a specific color, this method inverts the color.

color

Represents the color of the LED as an RGB 3-tuple of (red, green, blue) where each value is between 0 and 1.

For example, purple would be (1, 0, 1) and yellow would be (1, 1, 0), while orange would be (1, 0.5, 0).

is_lit

Returns `True` if the LED is currently active (not black) and `False` otherwise.

Buzzer

class gpiozero.**Buzzer** (*pin*, *active_high=True*, *initial_value=False*)

Extends *DigitalOutputDevice* and represents a digital buzzer component.

Connect the cathode (negative pin) of the buzzer to a ground pin; connect the other side to any GPIO pin.

The following example will sound the buzzer:

```
from gpiozero import Buzzer

bz = Buzzer(3)
bz.on()
```

Parameters

- **pin** (*int*) – The GPIO pin which the buzzer is attached to. See *Notes* for valid pin numbers.
- **active_high** (*bool*) – If `True` (the default), the buzzer will operate normally with the circuit described above. If `False` you should wire the cathode to the GPIO pin, and the anode to a 3V3 pin.
- **initial_value** (*bool*) – If `False` (the default), the buzzer will be silent initially. If `None`, the buzzer will be left in whatever state the pin is found in when configured for output (warning: this can be on). If `True`, the buzzer will be switched on initially.

beep (*on_time=1*, *off_time=1*, *n=None*, *background=True*)

Make the device turn on and off repeatedly.

Parameters

- **on_time** (*float*) – Number of seconds on. Defaults to 1 second.
- **off_time** (*float*) – Number of seconds off. Defaults to 1 second.
- **n** (*int*) – Number of times to blink; `None` (the default) means forever.
- **background** (*bool*) – If `True` (the default), start a background thread to continue blinking and return immediately. If `False`, only return when the blink is finished (warning: the default value of *n* will result in this method never returning).

off ()

Turns the device off.

on ()

Turns the device on.

toggle ()

Reverse the state of the device. If it's on, turn it off; if it's off, turn it on.

is_active

Returns `True` if the device is currently active and `False` otherwise. This property is usually derived from `value`. Unlike `value`, this is *always* a boolean.

pin

The *Pin* that the device is connected to. This will be `None` if the device has been closed (see the `close()` method). When dealing with GPIO pins, query `pin.number` to discover the GPIO pin (in BCM numbering) that the device is connected to.

Motor

class `gpiozero.Motor` (*forward*, *backward*)

Extends *CompositeDevice* and represents a generic motor connected to a bi-directional motor driver circuit (i.e. an *H-bridge*).

Attach an *H-bridge* motor controller to your Pi; connect a power source (e.g. a battery pack or the 5V pin) to the controller; connect the outputs of the controller board to the two terminals of the motor; connect the inputs of the controller board to two GPIO pins.

The following code will make the motor turn “forwards”:

```
from gpiozero import Motor

motor = Motor(17, 18)
motor.forward()
```

Parameters

- **forward** (*int*) – The GPIO pin that the forward input of the motor driver chip is connected to.
- **backward** (*int*) – The GPIO pin that the backward input of the motor driver chip is connected to.

backward (*speed=1*)

Drive the motor backwards.

Parameters **speed** (*float*) – The speed at which the motor should turn. Can be any value between 0 (stopped) and the default 1 (maximum speed).

forward (*speed=1*)

Drive the motor forwards.

Parameters `speed` (*float*) – The speed at which the motor should turn. Can be any value between 0 (stopped) and the default 1 (maximum speed).

stop()

Stop the motor.

Base Classes

The classes in the sections above are derived from a series of base classes, some of which are effectively abstract. The classes form the (partial) hierarchy displayed in the graph below:

The following sections document these base classes for advanced users that wish to construct classes for their own devices.

DigitalOutputDevice

class `gpiozero.DigitalOutputDevice` (*pin, active_high=True, initial_value=False*)

Represents a generic output device with typical on/off behaviour.

This class extends `OutputDevice` with a `blink()` method which uses an optional background thread to handle toggling the device state without further interaction.

blink (*on_time=1, off_time=1, n=None, background=True*)

Make the device turn on and off repeatedly.

Parameters

- **on_time** (*float*) – Number of seconds on. Defaults to 1 second.
- **off_time** (*float*) – Number of seconds off. Defaults to 1 second.
- **n** (*int*) – Number of times to blink; `None` (the default) means forever.

- **background** (*bool*) – If `True` (the default), start a background thread to continue blinking and return immediately. If `False`, only return when the blink is finished (warning: the default value of *n* will result in this method never returning).

close()

Shut down the device and release all associated resources. This method can be called on an already closed device without raising an exception.

This method is primarily intended for interactive use at the command line. It disables the device and releases its pin(s) for use by another device.

You can attempt to do this simply by deleting an object, but unless you’ve cleaned up all references to the object this may not work (even if you’ve cleaned up all references, there’s still no guarantee the garbage collector will actually delete the object at that point). By contrast, the `close` method provides a means of ensuring that the object is shut down.

For example, if you have a breadboard with a buzzer connected to pin 16, but then wish to attach an LED instead:

```
>>> from gpiozero import *
>>> bz = Buzzer(16)
>>> bz.on()
>>> bz.off()
>>> bz.close()
>>> led = LED(16)
>>> led.blink()
```

Device descendents can also be used as context managers using the `with` statement. For example:

```
>>> from gpiozero import *
>>> with Buzzer(16) as bz:
...     bz.on()
...
>>> with LED(16) as led:
...     led.on()
... 
```

off()

Turns the device off.

on()

Turns the device on.

PWMOutputDevice

class `gpiozero.PWMOutputDevice` (*pin*, *active_high=True*, *initial_value=0*, *frequency=100*)

Generic output device configured for pulse-width modulation (PWM).

Parameters

- **pin** (*int*) – The GPIO pin which the device is attached to. See *Notes* for valid pin numbers.
- **active_high** (*bool*) – If `True` (the default), the `on()` method will set the GPIO to HIGH. If `False`, the `on()` method will set the GPIO to LOW (the `off()` method always does the opposite).
- **initial_value** (*bool*) – If 0 (the default), the device’s duty cycle will be 0 initially. Other values between 0 and 1 can be specified as an initial duty cycle. Note that `None` cannot be specified (unlike the parent class) as there is no way to tell PWM not to alter the state of the pin.
- **frequency** (*int*) – The frequency (in Hz) of pulses emitted to drive the device. Defaults to 100Hz.

blink (*on_time=1, off_time=1, fade_in_time=0, fade_out_time=0, n=None, background=True*)
 Make the device turn on and off repeatedly.

Parameters

- **on_time** (*float*) – Number of seconds on. Defaults to 1 second.
- **off_time** (*float*) – Number of seconds off. Defaults to 1 second.
- **fade_in_time** (*float*) – Number of seconds to spend fading in. Defaults to 0.
- **fade_out_time** (*float*) – Number of seconds to spend fading out. Defaults to 0.
- **n** (*int*) – Number of times to blink; *None* (the default) means forever.
- **background** (*bool*) – If *True* (the default), start a background thread to continue blinking and return immediately. If *False*, only return when the blink is finished (warning: the default value of *n* will result in this method never returning).

close ()

Shut down the device and release all associated resources. This method can be called on an already closed device without raising an exception.

This method is primarily intended for interactive use at the command line. It disables the device and releases its pin(s) for use by another device.

You can attempt to do this simply by deleting an object, but unless you’ve cleaned up all references to the object this may not work (even if you’ve cleaned up all references, there’s still no guarantee the garbage collector will actually delete the object at that point). By contrast, the close method provides a means of ensuring that the object is shut down.

For example, if you have a breadboard with a buzzer connected to pin 16, but then wish to attach an LED instead:

```
>>> from gpiozero import *
>>> bz = Buzzer(16)
>>> bz.on()
>>> bz.off()
>>> bz.close()
>>> led = LED(16)
>>> led.blink()
```

Device descendents can also be used as context managers using the *with* statement. For example:

```
>>> from gpiozero import *
>>> with Buzzer(16) as bz:
...     bz.on()
...
>>> with LED(16) as led:
...     led.on()
...
...
>>>
```

off ()

Turns the device off.

on ()

Turns the device on.

pulse (*fade_in_time=1, fade_out_time=1, n=None, background=True*)

Make the device fade in and out repeatedly.

Parameters

- **fade_in_time** (*float*) – Number of seconds to spend fading in. Defaults to 1.
- **fade_out_time** (*float*) – Number of seconds to spend fading out. Defaults to 1.
- **n** (*int*) – Number of times to blink; *None* (the default) means forever.

- **background** (*bool*) – If `True` (the default), start a background thread to continue blinking and return immediately. If `False`, only return when the blink is finished (warning: the default value of *n* will result in this method never returning).

toggle()

Toggle the state of the device. If the device is currently off (*value* is 0.0), this changes it to “fully” on (*value* is 1.0). If the device has a duty cycle (*value*) of 0.1, this will toggle it to 0.9, and so on.

frequency

The frequency of the pulses used with the PWM device, in Hz. The default is 100Hz.

is_active

Returns `True` if the device is currently active (*value* is non-zero) and `False` otherwise.

value

The duty cycle of the PWM device. 0.0 is off, 1.0 is fully on. Values in between may be specified for varying levels of power in the device.

OutputDevice

class `gpiozero.OutputDevice` (*pin*, *active_high=True*, *initial_value=False*)

Represents a generic GPIO output device.

This class extends `GPIODevice` to add facilities common to GPIO output devices: an `on()` method to switch the device on, a corresponding `off()` method, and a `toggle()` method.

Parameters

- **pin** (*int*) – The GPIO pin (in BCM numbering) that the device is connected to. If this is `None` a `GPIOPinMissing` will be raised.
- **active_high** (*bool*) – If `True` (the default), the `on()` method will set the GPIO to HIGH. If `False`, the `on()` method will set the GPIO to LOW (the `off()` method always does the opposite).
- **initial_value** (*bool*) – If `False` (the default), the device will be off initially. If `None`, the device will be left in whatever state the pin is found in when configured for output (warning: this can be on). If `True`, the device will be switched on initially.

off()

Turns the device off.

on()

Turns the device on.

toggle()

Reverse the state of the device. If it’s on, turn it off; if it’s off, turn it on.

active_high

When `True`, the *value* property is `True` when the device’s pin is high. When `False` the *value* property is `True` when the device’s pin is low (i.e. the value is inverted).

This property can be set after construction; be warned that changing it will invert *value* (i.e. changing this property doesn’t change the device’s pin state - it just changes how that state is interpreted).

value

Returns `True` if the device is currently active and `False` otherwise. Setting this property changes the state of the device.

GPIODevice

class `gpiozero.GPIODevice` (*pin*)

Extends `Device`. Represents a generic GPIO device and provides the services common to all single-pin GPIO devices (like ensuring two GPIO devices do no share a *pin*).

Parameters `pin` (*int*) – The GPIO pin (in BCM numbering) that the device is connected to. If this is `None`, *GPIOPinMissing* will be raised. If the pin is already in use by another device, *GPIOPinInUse* will be raised.

```
close ()
```

Shut down the device and release all associated resources. This method can be called on an already closed device without raising an exception.

This method is primarily intended for interactive use at the command line. It disables the device and releases its pin(s) for use by another device.

You can attempt to do this simply by deleting an object, but unless you've cleaned up all references to the object this may not work (even if you've cleaned up all references, there's still no guarantee the garbage collector will actually delete the object at that point). By contrast, the `close` method provides a means of ensuring that the object is shut down.

For example, if you have a breadboard with a buzzer connected to pin 16, but then wish to attach an LED instead:

```
>>> from gpiozero import *
>>> bz = Buzzer(16)
>>> bz.on()
>>> bz.off()
>>> bz.close()
>>> led = LED(16)
>>> led.blink()
```

Device descendents can also be used as context managers using the `with` statement. For example:

```
>>> from gpiozero import *
>>> with Buzzer(16) as bz:
...     bz.on()
...
>>> with LED(16) as led:
...     led.on()
... 
```

pin

The `Pin` that the device is connected to. This will be `None` if the device has been closed (see the `close()` method). When dealing with GPIO pins, query `pin.number` to discover the GPIO pin (in BCM numbering) that the device is connected to.

SPI Devices

SPI stands for **Serial Peripheral Interface** and is a mechanism allowing compatible devices to communicate with the Pi. SPI is a four-wire protocol meaning it usually requires four pins to operate:

- A “clock” pin which provides timing information.
- A “MOSI” pin (Master Out, Slave In) which the Pi uses to send information to the device.
- A “MISO” pin (Master In, Slave Out) which the Pi uses to receive information from the device.
- A “select” pin which the Pi uses to indicate which device it’s talking to. This last pin is necessary because multiple devices can share the clock, MOSI, and MISO pins, but only one device can be connected to each select pin.

The `gpiozero` library provides two SPI implementations:

- A software based implementation. This is always available, can use any four GPIO pins for SPI communication, but is rather slow and won't work with all devices.

- A hardware based implementation. This is only available when the SPI kernel module is loaded, and the Python spidev library is available. It can only use specific pins for SPI communication (GPIO11=clock, GPIO10=MOSI, GPIO9=MISO, while GPIO8 is select for device 0 and GPIO7 is select for device 1). However, it is extremely fast and works with all devices.

SPI keyword args

When constructing an SPI device there are two schemes for specifying which pins it is connected to:

- You can specify *port* and *device* keyword arguments. The *port* parameter must be 0 (there is only one user-accessible hardware SPI interface on the Pi using GPIO11 as the clock pin, GPIO10 as the MOSI pin, and GPIO9 as the MISO pin), while the *device* parameter must be 0 or 1. If *device* is 0, the select pin will be GPIO8. If *device* is 1, the select pin will be GPIO7.
- Alternatively you can specify *clock_pin*, *mosi_pin*, *miso_pin*, and *select_pin* keyword arguments. In this case the pins can be any 4 GPIO pins (remember that SPI devices can share clock, MOSI, and MISO pins, but not select pins - the gpiozero library will enforce this restriction).

You cannot mix these two schemes, i.e. attempting to specify *port* and *clock_pin* will result in *SPIBadArgs* being raised. However, you can omit any arguments from either scheme. The defaults are:

- *port* and *device* both default to 0.
- *clock_pin* defaults to 11, *mosi_pin* defaults to 10, *miso_pin* defaults to 9, and *select_pin* defaults to 8.

Hence the following constructors are all equivalent:

```
from gpiozero import MCP3008

MCP3008(channel=0)
MCP3008(channel=0, device=0)
MCP3008(channel=0, port=0, device=0)
MCP3008(channel=0, select_pin=8)
MCP3008(channel=0, clock_pin=11, mosi_pin=10, miso_pin=9, select_pin=8)
```

Note that the defaults describe equivalent sets of pins and that these pins are compatible with the hardware implementation. Regardless of which scheme you use, gpiozero will attempt to use the hardware implementation if it is available and if the selected pins are compatible, falling back to the software implementation if not.

Analog to Digital Converters (ADC)

class gpiozero.**MCP3001** (***spi_args*)

The **MCP3001** is a 10-bit analog to digital converter with 1 channel

value

The current value read from the device, scaled to a value between 0 and 1 (or -1 to +1 for devices operating in differential mode).

class gpiozero.**MCP3002** (*channel=0*, *differential=False*, ***spi_args*)

The **MCP3002** is a 10-bit analog to digital converter with 2 channels (0-1).

channel

The channel to read data from. The MCP3008/3208/3304 have 8 channels (0-7), while the MCP3004/3204/3302 have 4 channels (0-3), and the MCP3301 only has 1 channel.

differential

If **True**, the device is operated in pseudo-differential mode. In this mode one channel (specified by the channel attribute) is read relative to the value of a second channel (implied by the chip's design).

Please refer to the device data-sheet to determine which channel is used as the relative base value (for example, when using an *MCP3008* in differential mode, channel 0 is read relative to channel 1).

value

The current value read from the device, scaled to a value between 0 and 1 (or -1 to +1 for devices operating in differential mode).

class `gpiozero.MCP3004` (*channel=0, differential=False, **spi_args*)

The [MCP3004](#) is a 10-bit analog to digital converter with 4 channels (0-3).

channel

The channel to read data from. The MCP3008/3208/3304 have 8 channels (0-7), while the MCP3004/3204/3302 have 4 channels (0-3), and the MCP3301 only has 1 channel.

differential

If `True`, the device is operated in pseudo-differential mode. In this mode one channel (specified by the channel attribute) is read relative to the value of a second channel (implied by the chip's design).

Please refer to the device data-sheet to determine which channel is used as the relative base value (for example, when using an [MCP3008](#) in differential mode, channel 0 is read relative to channel 1).

value

The current value read from the device, scaled to a value between 0 and 1 (or -1 to +1 for devices operating in differential mode).

class `gpiozero.MCP3008` (*channel=0, differential=False, **spi_args*)

The [MCP3008](#) is a 10-bit analog to digital converter with 8 channels (0-7).

channel

The channel to read data from. The MCP3008/3208/3304 have 8 channels (0-7), while the MCP3004/3204/3302 have 4 channels (0-3), and the MCP3301 only has 1 channel.

differential

If `True`, the device is operated in pseudo-differential mode. In this mode one channel (specified by the channel attribute) is read relative to the value of a second channel (implied by the chip's design).

Please refer to the device data-sheet to determine which channel is used as the relative base value (for example, when using an [MCP3008](#) in differential mode, channel 0 is read relative to channel 1).

value

The current value read from the device, scaled to a value between 0 and 1 (or -1 to +1 for devices operating in differential mode).

class `gpiozero.MCP3201` (***spi_args*)

The [MCP3201](#) is a 12-bit analog to digital converter with 1 channel

value

The current value read from the device, scaled to a value between 0 and 1 (or -1 to +1 for devices operating in differential mode).

class `gpiozero.MCP3202` (*channel=0, differential=False, **spi_args*)

The [MCP3202](#) is a 12-bit analog to digital converter with 2 channels (0-1).

channel

The channel to read data from. The MCP3008/3208/3304 have 8 channels (0-7), while the MCP3004/3204/3302 have 4 channels (0-3), and the MCP3301 only has 1 channel.

differential

If `True`, the device is operated in pseudo-differential mode. In this mode one channel (specified by the channel attribute) is read relative to the value of a second channel (implied by the chip's design).

Please refer to the device data-sheet to determine which channel is used as the relative base value (for example, when using an [MCP3008](#) in differential mode, channel 0 is read relative to channel 1).

value

The current value read from the device, scaled to a value between 0 and 1 (or -1 to +1 for devices operating in differential mode).

class `gpiozero.MCP3204` (*channel=0, differential=False, **spi_args*)

The [MCP3204](#) is a 12-bit analog to digital converter with 4 channels (0-3).

channel

The channel to read data from. The MCP3008/3208/3304 have 8 channels (0-7), while the MCP3004/3204/3302 have 4 channels (0-3), and the MCP3301 only has 1 channel.

differential

If `True`, the device is operated in pseudo-differential mode. In this mode one channel (specified by the channel attribute) is read relative to the value of a second channel (implied by the chip's design).

Please refer to the device data-sheet to determine which channel is used as the relative base value (for example, when using an [MCP3008](#) in differential mode, channel 0 is read relative to channel 1).

value

The current value read from the device, scaled to a value between 0 and 1 (or -1 to +1 for devices operating in differential mode).

class `gpiozero.MCP3208` (*channel=0, differential=False, **spi_args*)

The [MCP3208](#) is a 12-bit analog to digital converter with 8 channels (0-7).

channel

The channel to read data from. The MCP3008/3208/3304 have 8 channels (0-7), while the MCP3004/3204/3302 have 4 channels (0-3), and the MCP3301 only has 1 channel.

differential

If `True`, the device is operated in pseudo-differential mode. In this mode one channel (specified by the channel attribute) is read relative to the value of a second channel (implied by the chip's design).

Please refer to the device data-sheet to determine which channel is used as the relative base value (for example, when using an [MCP3008](#) in differential mode, channel 0 is read relative to channel 1).

value

The current value read from the device, scaled to a value between 0 and 1 (or -1 to +1 for devices operating in differential mode).

class `gpiozero.MCP3301` (***spi_args*)

The [MCP3301](#) is a signed 13-bit analog to digital converter. Please note that the MCP3301 always operates in differential mode between its two channels and the output value is scaled from -1 to +1.

value

The current value read from the device, scaled to a value between 0 and 1 (or -1 to +1 for devices operating in differential mode).

class `gpiozero.MCP3302` (*channel=0, differential=False, **spi_args*)

The [MCP3302](#) is a 12/13-bit analog to digital converter with 4 channels (0-3). When operated in differential mode, the device outputs a signed 13-bit value which is scaled from -1 to +1. When operated in single-ended mode (the default), the device outputs an unsigned 12-bit value scaled from 0 to 1.

channel

The channel to read data from. The MCP3008/3208/3304 have 8 channels (0-7), while the MCP3004/3204/3302 have 4 channels (0-3), and the MCP3301 only has 1 channel.

differential

If `True`, the device is operated in pseudo-differential mode. In this mode one channel (specified by the channel attribute) is read relative to the value of a second channel (implied by the chip's design).

Please refer to the device data-sheet to determine which channel is used as the relative base value (for example, when using an [MCP3008](#) in differential mode, channel 0 is read relative to channel 1).

value

The current value read from the device, scaled to a value between 0 and 1 (or -1 to +1 for devices operating in differential mode).

class `gpiozero.MCP3304` (*channel=0, differential=False, **spi_args*)

The [MCP3304](#) is a 12/13-bit analog to digital converter with 8 channels (0-7). When operated in differential mode, the device outputs a signed 13-bit value which is scaled from -1 to +1. When operated in single-ended mode (the default), the device outputs an unsigned 12-bit value scaled from 0 to 1.

channel

The channel to read data from. The MCP3008/3208/3304 have 8 channels (0-7), while the MCP3004/3204/3302 have 4 channels (0-3), and the MCP3301 only has 1 channel.

differential

If `True`, the device is operated in pseudo-differential mode. In this mode one channel (specified by the channel attribute) is read relative to the value of a second channel (implied by the chip's design).

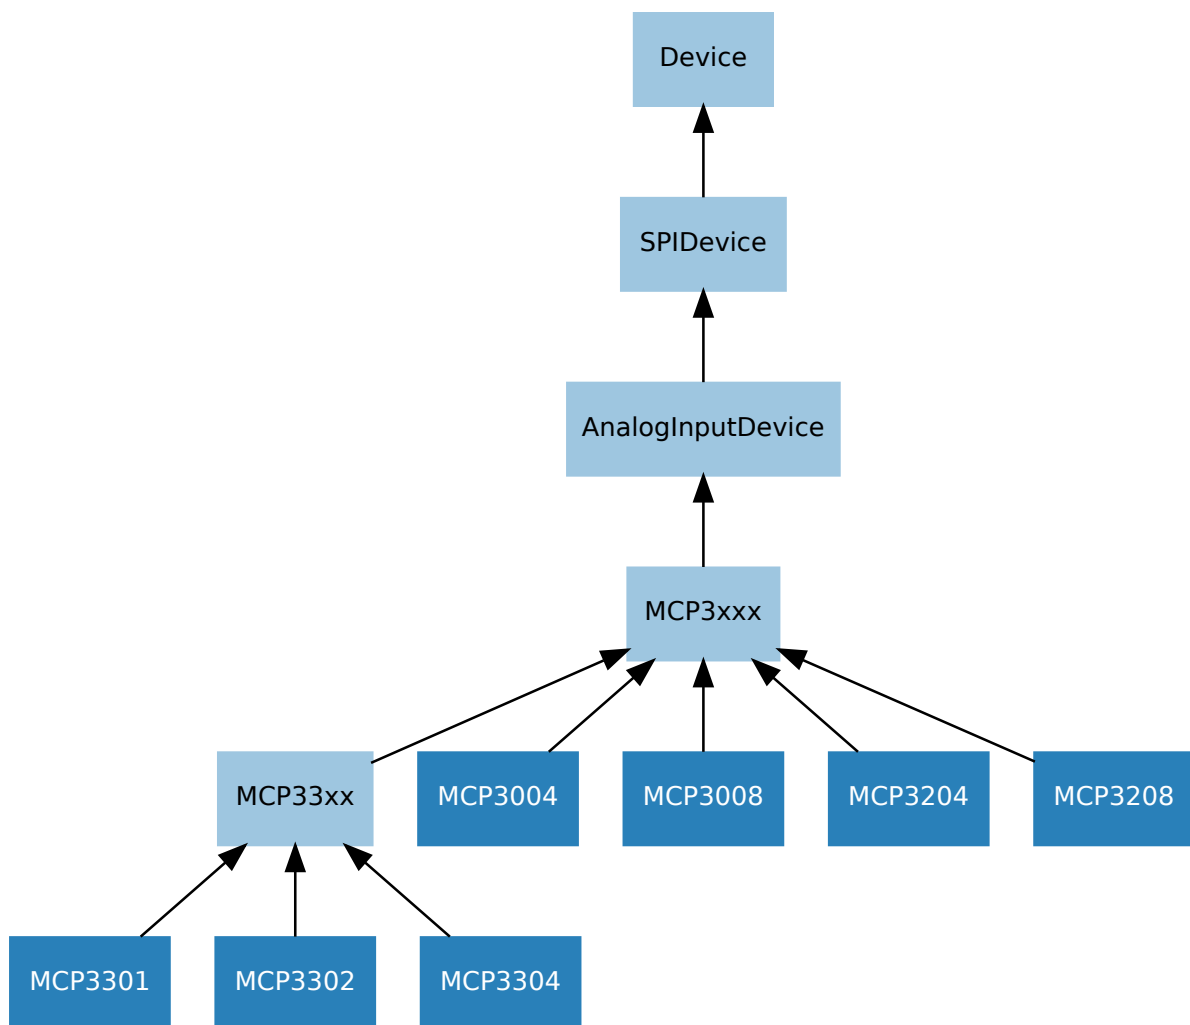

Please refer to the device data-sheet to determine which channel is used as the relative base value (for example, when using an [MCP3008](#) in differential mode, channel 0 is read relative to channel 1).

value

The current value read from the device, scaled to a value between 0 and 1 (or -1 to +1 for devices operating in differential mode).

Base Classes

The classes in the sections above are derived from a series of base classes, some of which are effectively abstract. The classes form the (partial) hierarchy displayed in the graph below:

The following sections document these base classes for advanced users that wish to construct classes for their own devices.

AnalogInputDevice

class gpiozero.**AnalogInputDevice** (*bits=None, **spi_args*)

Represents an analog input device connected to SPI (serial interface).

Typical analog input devices are [analog to digital converters](#) (ADCs). Several classes are provided for specific ADC chips, including [MCP3004](#), [MCP3008](#), [MCP3204](#), and [MCP3208](#).

The following code demonstrates reading the first channel of an MCP3008 chip attached to the Pi's SPI pins:

```
from gpiozero import MCP3008

pot = MCP3008(0)
print(pot.value)
```

The *value* attribute is normalized such that its value is always between 0.0 and 1.0 (or in special cases, such as differential sampling, -1 to +1). Hence, you can use an analog input to control the brightness of a [PWMLED](#) like so:

```
from gpiozero import MCP3008, PWMLED

pot = MCP3008(0)
led = PWMLED(17)
led.source = pot.values
```

bits

The bit-resolution of the device/channel.

raw_value

The raw value as read from the device.

value

The current value read from the device, scaled to a value between 0 and 1 (or -1 to +1 for devices operating in differential mode).

SPIDevice

class gpiozero.**SPIDevice** (***spi_args*)

Extends [Device](#). Represents a device that communicates via the SPI protocol.

See [SPI keyword args](#) for information on the keyword arguments that can be specified with the constructor.

close()

Shut down the device and release all associated resources. This method can be called on an already closed device without raising an exception.

This method is primarily intended for interactive use at the command line. It disables the device and releases its pin(s) for use by another device.

You can attempt to do this simply by deleting an object, but unless you've cleaned up all references to the object this may not work (even if you've cleaned up all references, there's still no guarantee the garbage collector will actually delete the object at that point). By contrast, the close method provides a means of ensuring that the object is shut down.

For example, if you have a breadboard with a buzzer connected to pin 16, but then wish to attach an LED instead:

```
>>> from gpiozero import *
>>> bz = Buzzer(16)
>>> bz.on()
>>> bz.off()
>>> bz.close()
```

```
>>> from gpiozero import *
>>> with Buzzer(16) as bz:
...     bz.on()
...
>>> with LED(16) as led:
...     led.on()
... 
```

These additional interfaces are provided to group collections of components together for ease of use, and as examples. They are composites made up of components from the various *Input Devices* and *Output Devices* provided by GPIO Zero. See those pages for more information on using components individually.

Extends *LEDCollection* and represents a generic LED board or collection of LEDs.

```
from gpiozero import LEDBoard

leds = LEDBoard(2, 3, 4, 5, 6)
leds.on()
```

- ***pins** (*int*) – Specify the GPIO pins that the LEDs of the board are attached to. You can designate as many pins as necessary. You can also specify *LEDBoard* instances to create trees of LEDs.
- **pwm** (*bool*) – If *True*, construct *PWMLED* instances for each pin. If *False* (the default), construct regular *LED* instances. This parameter can only be specified as a keyword parameter.
- **active_high** (*bool*) – If *True* (the default), the *on()* method will set all the associates pins to HIGH. If *False*, the *on()* method will set all pins to LOW (the *off()* method always does the opposite).
- **initial_value** (*bool*) – If *False* (the default), all LEDs will be off initially. If *None*, each device will be left in whatever state the pin is found in when configured for output (warning: this can be on). If *True*, the device will be switched on initially.
- ****named_pins** – Specify GPIO pins that LEDs of the board are attached to, associated each LED with a property name. You can designate as many pins as necessary and any name provided it's not already in use by something else. You can also specify *LEDBoard* instances to create trees of LEDs.

blink (*on_time=1, off_time=1, fade_in_time=0, fade_out_time=0, n=None, background=True*)
Make all the LEDs turn on and off repeatedly.

Parameters

- **on_time** (*float*) – Number of seconds on. Defaults to 1 second.
- **off_time** (*float*) – Number of seconds off. Defaults to 1 second.
- **fade_in_time** (*float*) – Number of seconds to spend fading in. Defaults to 0. Must be 0 if `pwm` was `False` when the class was constructed (`ValueError` will be raised if not).
- **fade_out_time** (*float*) – Number of seconds to spend fading out. Defaults to 0. Must be 0 if `pwm` was `False` when the class was constructed (`ValueError` will be raised if not).
- **n** (*int*) – Number of times to blink; `None` (the default) means forever.
- **background** (*bool*) – If `True`, start a background thread to continue blinking and return immediately. If `False`, only return when the blink is finished (warning: the default value of *n* will result in this method never returning).

close ()

Shut down the device and release all associated resources. This method can be called on an already closed device without raising an exception.

This method is primarily intended for interactive use at the command line. It disables the device and releases its pin(s) for use by another device.

You can attempt to do this simply by deleting an object, but unless you’ve cleaned up all references to the object this may not work (even if you’ve cleaned up all references, there’s still no guarantee the garbage collector will actually delete the object at that point). By contrast, the `close` method provides a means of ensuring that the object is shut down.

For example, if you have a breadboard with a buzzer connected to pin 16, but then wish to attach an LED instead:

```
>>> from gpiozero import *
>>> bz = Buzzer(16)
>>> bz.on()
>>> bz.off()
>>> bz.close()
>>> led = LED(16)
>>> led.blink()
```

Device descendents can also be used as context managers using the `with` statement. For example:

```
>>> from gpiozero import *
>>> with Buzzer(16) as bz:
...     bz.on()
...
>>> with LED(16) as led:
...     led.on()
... 
```

off (*args)

Turn all the output devices off.

on (*args)

Turn all the output devices on.

pulse (*fade_in_time=1, fade_out_time=1, n=None, background=True*)

Make the device fade in and out repeatedly.

Parameters

- **fade_in_time** (*float*) – Number of seconds to spend fading in. Defaults to 1.
- **fade_out_time** (*float*) – Number of seconds to spend fading out. Defaults to 1.
- **n** (*int*) – Number of times to blink; `None` (the default) means forever.
- **background** (*bool*) – If `True` (the default), start a background thread to continue blinking and return immediately. If `False`, only return when the blink is finished (warning: the default value of *n* will result in this method never returning).

toggle (**args*)

Toggle all the output devices. For each device, if it's on, turn it off; if it's off, turn it on.

leds

A flat iterator over all LEDs contained in this collection (and all sub-collections).

source

The iterable to use as a source of values for *value*.

source_delay

The delay (measured in seconds) in the loop used to read values from *source*. Defaults to 0.01 seconds which is generally sufficient to keep CPU usage to a minimum while providing adequate responsiveness.

value

A tuple containing a value for each subordinate device. This property can also be set to update the state of all subordinate output devices.

values

An infinite iterator of values read from *value*.

LEDBarGraph

class gpiozero.LEDBarGraph (**pins*, *initial_value=0*)

Extends *LEDCollection* to control a line of LEDs representing a bar graph. Positive values (0 to 1) light the LEDs from first to last. Negative values (-1 to 0) light the LEDs from last to first.

The following example demonstrates turning on the first two and last two LEDs in a board containing five LEDs attached to GPIOs 2 through 6:

```
from gpiozero import LEDBarGraph
from time import sleep

graph = LEDBarGraph(2, 3, 4, 5, 6)
graph.value = 2/5 # Light the first two LEDs only
sleep(1)
graph.value = -2/5 # Light the last two LEDs only
sleep(1)
graph.off()
```

As with other output devices, *source* and *values* are supported:

```
from gpiozero import LEDBarGraph, MCP3008
from signal import pause

graph = LEDBarGraph(2, 3, 4, 5, 6, pwm=True)
pot = MCP3008(channel=0)
graph.source = pot.values
pause()
```

Parameters

- ***pins** (*int*) – Specify the GPIO pins that the LEDs of the bar graph are attached to. You can designate as many pins as necessary.

- **initial_value** (*float*) – The initial *value* of the graph given as a float between -1 and +1. Defaults to 0.0. This parameter can only be specified as a keyword parameter.
- **pwm** (*bool*) – If `True`, construct *PWMLED* instances for each pin. If `False` (the default), construct regular *LED* instances. This parameter can only be specified as a keyword parameter.

off ()

Turn all the output devices off.

on ()

Turn all the output devices on.

toggle ()

Toggle all the output devices. For each device, if it's on, turn it off; if it's off, turn it on.

leds

A flat iterator over all LEDs contained in this collection (and all sub-collections).

source

The iterable to use as a source of values for *value*.

source_delay

The delay (measured in seconds) in the loop used to read values from *source*. Defaults to 0.01 seconds which is generally sufficient to keep CPU usage to a minimum while providing adequate responsiveness.

value

The value of the LED bar graph. When no LEDs are lit, the value is 0. When all LEDs are lit, the value is 1. Values between 0 and 1 light LEDs linearly from first to last. Values between 0 and -1 light LEDs linearly from last to first.

To light a particular number of LEDs, simply divide that number by the number of LEDs. For example, if your graph contains 3 LEDs, the following will light the first:

```
from gpiozero import LEDBarGraph

graph = LEDBarGraph(12, 16, 19)
graph.value = 1/3
```

Note: Setting value to -1 will light all LEDs. However, querying it subsequently will return 1 as both representations are the same in hardware. The readable range of *value* is effectively $-1 < \text{value} \leq 1$.

values

An infinite iterator of values read from *value*.

TrafficLights

class `gpiozero.TrafficLights` (*red=None, amber=None, green=None, pwm=False*)

Extends *LEDBoard* for devices containing red, amber, and green LEDs.

The following example initializes a device connected to GPIO pins 2, 3, and 4, then lights the amber LED attached to GPIO 3:

```
from gpiozero import TrafficLights

traffic = TrafficLights(2, 3, 4)
traffic.amber.on()
```

Parameters

- **red** (*int*) – The GPIO pin that the red LED is attached to.
- **amber** (*int*) – The GPIO pin that the amber LED is attached to.
- **green** (*int*) – The GPIO pin that the green LED is attached to.
- **pwm** (*bool*) – If `True`, construct `PWMLED` instances to represent each LED. If `False` (the default), construct regular `LED` instances.

blink (*on_time=1, off_time=1, fade_in_time=0, fade_out_time=0, n=None, background=True*)
Make all the LEDs turn on and off repeatedly.

Parameters

- **on_time** (*float*) – Number of seconds on. Defaults to 1 second.
- **off_time** (*float*) – Number of seconds off. Defaults to 1 second.
- **fade_in_time** (*float*) – Number of seconds to spend fading in. Defaults to 0. Must be 0 if `pwm` was `False` when the class was constructed (`ValueError` will be raised if not).
- **fade_out_time** (*float*) – Number of seconds to spend fading out. Defaults to 0. Must be 0 if `pwm` was `False` when the class was constructed (`ValueError` will be raised if not).
- **n** (*int*) – Number of times to blink; `None` (the default) means forever.
- **background** (*bool*) – If `True`, start a background thread to continue blinking and return immediately. If `False`, only return when the blink is finished (warning: the default value of *n* will result in this method never returning).

close ()

Shut down the device and release all associated resources. This method can be called on an already closed device without raising an exception.

This method is primarily intended for interactive use at the command line. It disables the device and releases its pin(s) for use by another device.

You can attempt to do this simply by deleting an object, but unless you’ve cleaned up all references to the object this may not work (even if you’ve cleaned up all references, there’s still no guarantee the garbage collector will actually delete the object at that point). By contrast, the `close` method provides a means of ensuring that the object is shut down.

For example, if you have a breadboard with a buzzer connected to pin 16, but then wish to attach an LED instead:

```
>>> from gpiozero import *
>>> bz = Buzzer(16)
>>> bz.on()
>>> bz.off()
>>> bz.close()
>>> led = LED(16)
>>> led.blink()
```

`Device` descendents can also be used as context managers using the `with` statement. For example:

```
>>> from gpiozero import *
>>> with Buzzer(16) as bz:
...     bz.on()
...
>>> with LED(16) as led:
...     led.on()
... 
```

off (*args)

Turn all the output devices off.

on (*args)

Turn all the output devices on.

pulse (fade_in_time=1, fade_out_time=1, n=None, background=True)

Make the device fade in and out repeatedly.

Parameters

- **fade_in_time** (*float*) – Number of seconds to spend fading in. Defaults to 1.
- **fade_out_time** (*float*) – Number of seconds to spend fading out. Defaults to 1.
- **n** (*int*) – Number of times to blink; `None` (the default) means forever.
- **background** (*bool*) – If `True` (the default), start a background thread to continue blinking and return immediately. If `False`, only return when the blink is finished (warning: the default value of *n* will result in this method never returning).

toggle (*args)

Toggle all the output devices. For each device, if it's on, turn it off; if it's off, turn it on.

leds

A flat iterator over all LEDs contained in this collection (and all sub-collections).

source

The iterable to use as a source of values for *value*.

source_delay

The delay (measured in seconds) in the loop used to read values from *source*. Defaults to 0.01 seconds which is generally sufficient to keep CPU usage to a minimum while providing adequate responsiveness.

value

A tuple containing a value for each subordinate device. This property can also be set to update the state of all subordinate output devices.

values

An infinite iterator of values read from *value*.

PiLITEr

class gpiozero.**PiLITEr** (pwm=False)

Extends [LEDBoard](#) for the [Ciseco Pi-LITEr](#): a strip of 8 very bright LEDs.

The Pi-LITEr pins are fixed and therefore there's no need to specify them when constructing this class. The following example turns on all the LEDs of the Pi-LITEr:

```
from gpiozero import PiLITEr

lite = PiLITEr()
lite.on()
```

Parameters **pwm** (*bool*) – If `True`, construct [PWMLED](#) instances for each pin. If `False` (the default), construct regular [LED](#) instances. This parameter can only be specified as a keyword parameter.

blink (on_time=1, off_time=1, fade_in_time=0, fade_out_time=0, n=None, background=True)

Make all the LEDs turn on and off repeatedly.

Parameters

- **on_time** (*float*) – Number of seconds on. Defaults to 1 second.
- **off_time** (*float*) – Number of seconds off. Defaults to 1 second.

- **fade_in_time** (*float*) – Number of seconds to spend fading in. Defaults to 0. Must be 0 if `pwm` was `False` when the class was constructed (`ValueError` will be raised if not).
- **fade_out_time** (*float*) – Number of seconds to spend fading out. Defaults to 0. Must be 0 if `pwm` was `False` when the class was constructed (`ValueError` will be raised if not).
- **n** (*int*) – Number of times to blink; `None` (the default) means forever.
- **background** (*bool*) – If `True`, start a background thread to continue blinking and return immediately. If `False`, only return when the blink is finished (warning: the default value of *n* will result in this method never returning).

close()

Shut down the device and release all associated resources. This method can be called on an already closed device without raising an exception.

This method is primarily intended for interactive use at the command line. It disables the device and releases its pin(s) for use by another device.

You can attempt to do this simply by deleting an object, but unless you’ve cleaned up all references to the object this may not work (even if you’ve cleaned up all references, there’s still no guarantee the garbage collector will actually delete the object at that point). By contrast, the `close` method provides a means of ensuring that the object is shut down.

For example, if you have a breadboard with a buzzer connected to pin 16, but then wish to attach an LED instead:

```
>>> from gpiozero import *
>>> bz = Buzzer(16)
>>> bz.on()
>>> bz.off()
>>> bz.close()
>>> led = LED(16)
>>> led.blink()
```

Device descendents can also be used as context managers using the `with` statement. For example:

```
>>> from gpiozero import *
>>> with Buzzer(16) as bz:
...     bz.on()
...
>>> with LED(16) as led:
...     led.on()
...
...
>>>
```

off(*args)

Turn all the output devices off.

on(*args)

Turn all the output devices on.

pulse(fade_in_time=1, fade_out_time=1, n=None, background=True)

Make the device fade in and out repeatedly.

Parameters

- **fade_in_time** (*float*) – Number of seconds to spend fading in. Defaults to 1.
- **fade_out_time** (*float*) – Number of seconds to spend fading out. Defaults to 1.
- **n** (*int*) – Number of times to blink; `None` (the default) means forever.
- **background** (*bool*) – If `True` (the default), start a background thread to continue blinking and return immediately. If `False`, only return when the blink is finished (warning: the default value of *n* will result in this method never returning).

toggle (*args)

Toggle all the output devices. For each device, if it's on, turn it off; if it's off, turn it on.

leds

A flat iterator over all LEDs contained in this collection (and all sub-collections).

source

The iterable to use as a source of values for *value*.

source_delay

The delay (measured in seconds) in the loop used to read values from *source*. Defaults to 0.01 seconds which is generally sufficient to keep CPU usage to a minimum while providing adequate responsiveness.

value

A tuple containing a value for each subordinate device. This property can also be set to update the state of all subordinate output devices.

values

An infinite iterator of values read from *value*.

PiLITEr Bar Graph

class gpiozero.**PiLiterBarGraph** (initial_value=0)

Extends *LEDBarGraph* to treat the *Ciseco Pi-LITEr* as an 8-segment bar graph.

The Pi-LITEr pins are fixed and therefore there's no need to specify them when constructing this class. The following example sets the graph value to 0.5:

```
from gpiozero import PiLiterBarGraph

graph = PiLiterBarGraph()
graph.value = 0.5
```

Parameters *initial_value* (*bool*) – The initial value of the graph given as a float between -1 and +1. Defaults to 0.0.

off ()

Turn all the output devices off.

on ()

Turn all the output devices on.

toggle ()

Toggle all the output devices. For each device, if it's on, turn it off; if it's off, turn it on.

leds

A flat iterator over all LEDs contained in this collection (and all sub-collections).

source

The iterable to use as a source of values for *value*.

source_delay

The delay (measured in seconds) in the loop used to read values from *source*. Defaults to 0.01 seconds which is generally sufficient to keep CPU usage to a minimum while providing adequate responsiveness.

value

The value of the LED bar graph. When no LEDs are lit, the value is 0. When all LEDs are lit, the value is 1. Values between 0 and 1 light LEDs linearly from first to last. Values between 0 and -1 light LEDs linearly from last to first.

To light a particular number of LEDs, simply divide that number by the number of LEDs. For example, if your graph contains 3 LEDs, the following will light the first:

```
from gpiozero import LEDBarGraph

graph = LEDBarGraph(12, 16, 19)
graph.value = 1/3
```

Note: Setting value to -1 will light all LEDs. However, querying it subsequently will return 1 as both representations are the same in hardware. The readable range of *value* is effectively $-1 < \text{value} \leq 1$.

values

An infinite iterator of values read from *value*.

PI-TRAFFIC

class gpiozero.PiTraffic

Extends *TrafficLights* for the [Low Voltage Labs PI-TRAFFIC](#): vertical traffic lights board when attached to GPIO pins 9, 10, and 11.

There's no need to specify the pins if the PI-TRAFFIC is connected to the default pins (9, 10, 11). The following example turns on the amber LED on the PI-TRAFFIC:

```
from gpiozero import PiTraffic

traffic = PiTraffic()
traffic.amber.on()
```

To use the PI-TRAFFIC board when attached to a non-standard set of pins, simply use the parent class, *TrafficLights*.

blink (*on_time=1, off_time=1, fade_in_time=0, fade_out_time=0, n=None, background=True*)

Make all the LEDs turn on and off repeatedly.

Parameters

- **on_time** (*float*) – Number of seconds on. Defaults to 1 second.
- **off_time** (*float*) – Number of seconds off. Defaults to 1 second.
- **fade_in_time** (*float*) – Number of seconds to spend fading in. Defaults to 0. Must be 0 if *pwm* was *False* when the class was constructed (*ValueError* will be raised if not).
- **fade_out_time** (*float*) – Number of seconds to spend fading out. Defaults to 0. Must be 0 if *pwm* was *False* when the class was constructed (*ValueError* will be raised if not).
- **n** (*int*) – Number of times to blink; *None* (the default) means forever.
- **background** (*bool*) – If *True*, start a background thread to continue blinking and return immediately. If *False*, only return when the blink is finished (warning: the default value of *n* will result in this method never returning).

close()

Shut down the device and release all associated resources. This method can be called on an already closed device without raising an exception.

This method is primarily intended for interactive use at the command line. It disables the device and releases its pin(s) for use by another device.

You can attempt to do this simply by deleting an object, but unless you've cleaned up all references to the object this may not work (even if you've cleaned up all references, there's still no guarantee the garbage collector will actually delete the object at that point). By contrast, the *close* method provides a means of ensuring that the object is shut down.

For example, if you have a breadboard with a buzzer connected to pin 16, but then wish to attach an LED instead:

```
>>> from gpiozero import *
>>> bz = Buzzer(16)
>>> bz.on()
>>> bz.off()
>>> bz.close()
>>> led = LED(16)
>>> led.blink()
```

Device descendents can also be used as context managers using the `with` statement. For example:

```
>>> from gpiozero import *
>>> with Buzzer(16) as bz:
...     bz.on()
...
>>> with LED(16) as led:
...     led.on()
...
...
```

off (*args)

Turn all the output devices off.

on (*args)

Turn all the output devices on.

pulse (fade_in_time=1, fade_out_time=1, n=None, background=True)

Make the device fade in and out repeatedly.

Parameters

- **fade_in_time** (*float*) – Number of seconds to spend fading in. Defaults to 1.
- **fade_out_time** (*float*) – Number of seconds to spend fading out. Defaults to 1.
- **n** (*int*) – Number of times to blink; None (the default) means forever.
- **background** (*bool*) – If True (the default), start a background thread to continue blinking and return immediately. If False, only return when the blink is finished (warning: the default value of *n* will result in this method never returning).

toggle (*args)

Toggle all the output devices. For each device, if it's on, turn it off; if it's off, turn it on.

leds

A flat iterator over all LEDs contained in this collection (and all sub-collections).

source

The iterable to use as a source of values for *value*.

source_delay

The delay (measured in seconds) in the loop used to read values from *source*. Defaults to 0.01 seconds which is generally sufficient to keep CPU usage to a minimum while providing adequate responsiveness.

value

A tuple containing a value for each subordinate device. This property can also be set to update the state of all subordinate output devices.

values

An infinite iterator of values read from *value*.

TrafficLightsBuzzer

class gpiozero.**TrafficLightsBuzzer** (*lights*, *buzzer*, *button*)

Extends *CompositeDevice* and is a generic class for HATs with traffic lights, a button and a buzzer.

Parameters

- **lights** (*TrafficLights*) – An instance of *TrafficLights* representing the traffic lights of the HAT.
- **buzzer** (*Buzzer*) – An instance of *Buzzer* representing the buzzer on the HAT.
- **button** (*Button*) – An instance of *Button* representing the button on the HAT.

off ()

Turn all the output devices off.

on ()

Turn all the output devices on.

toggle ()

Toggle all the output devices. For each device, if it's on, turn it off; if it's off, turn it on.

source

The iterable to use as a source of values for *value*.

source_delay

The delay (measured in seconds) in the loop used to read values from *source*. Defaults to 0.01 seconds which is generally sufficient to keep CPU usage to a minimum while providing adequate responsiveness.

value

A tuple containing a value for each subordinate device. This property can also be set to update the state of all subordinate output devices.

values

An infinite iterator of values read from *value*.

Fish Dish

class gpiozero.**FishDish** (*pwm=False*)

Extends *TrafficLightsBuzzer* for the Pi Supply FishDish: traffic light LEDs, a button and a buzzer.

The FishDish pins are fixed and therefore there's no need to specify them when constructing this class. The following example waits for the button to be pressed on the FishDish, then turns on all the LEDs:

```
from gpiozero import FishDish

fish = FishDish()
fish.button.wait_for_press()
fish.lights.on()
```

Parameters **pwm** (*bool*) – If *True*, construct *PWMLED* instances to represent each LED. If *False* (the default), construct regular *LED* instances.

off ()

Turn all the output devices off.

on ()

Turn all the output devices on.

toggle ()

Toggle all the output devices. For each device, if it's on, turn it off; if it's off, turn it on.

source

The iterable to use as a source of values for *value*.

source_delay

The delay (measured in seconds) in the loop used to read values from *source*. Defaults to 0.01 seconds which is generally sufficient to keep CPU usage to a minimum while providing adequate responsiveness.

value

A tuple containing a value for each subordinate device. This property can also be set to update the state of all subordinate output devices.

values

An infinite iterator of values read from *value*.

Traffic HAT

class gpiozero.**TrafficHat** (*pwm=False*)

Extends *TrafficLightsBuzzer* for the Ryantek Traffic HAT: traffic light LEDs, a button and a buzzer.

The Traffic HAT pins are fixed and therefore there's no need to specify them when constructing this class. The following example waits for the button to be pressed on the Traffic HAT, then turns on all the LEDs:

```
from gpiozero import TrafficHat

hat = TrafficHat()
hat.button.wait_for_press()
hat.lights.on()
```

Parameters *pwm* (*bool*) – If *True*, construct *PWMLED* instances to represent each LED. If *False* (the default), construct regular *LED* instances.

off()

Turn all the output devices off.

on()

Turn all the output devices on.

toggle()

Toggle all the output devices. For each device, if it's on, turn it off; if it's off, turn it on.

source

The iterable to use as a source of values for *value*.

source_delay

The delay (measured in seconds) in the loop used to read values from *source*. Defaults to 0.01 seconds which is generally sufficient to keep CPU usage to a minimum while providing adequate responsiveness.

value

A tuple containing a value for each subordinate device. This property can also be set to update the state of all subordinate output devices.

values

An infinite iterator of values read from *value*.

Robot

class gpiozero.**Robot** (*left=None, right=None*)

Extends *CompositeDevice* to represent a generic dual-motor robot.

This class is constructed with two tuples representing the forward and backward pins of the left and right controllers respectively. For example, if the left motor's controller is connected to GPIOs 4 and 14, while the right motor's controller is connected to GPIOs 17 and 18 then the following example will turn the robot left:

```
from gpiozero import Robot

robot = Robot(left=(4, 14), right=(17, 18))
robot.left()
```

Parameters

- **left** (*tuple*) – A tuple of two GPIO pins representing the forward and backward inputs of the left motor's controller.
- **right** (*tuple*) – A tuple of two GPIO pins representing the forward and backward inputs of the right motor's controller.

backward (*speed=1*)

Drive the robot backward by running both motors backward.

Parameters **speed** (*float*) – Speed at which to drive the motors, as a value between 0 (stopped) and 1 (full speed). The default is 1.

forward (*speed=1*)

Drive the robot forward by running both motors forward.

Parameters **speed** (*float*) – Speed at which to drive the motors, as a value between 0 (stopped) and 1 (full speed). The default is 1.

left (*speed=1*)

Make the robot turn left by running the right motor forward and left motor backward.

Parameters **speed** (*float*) – Speed at which to drive the motors, as a value between 0 (stopped) and 1 (full speed). The default is 1.

reverse ()

Reverse the robot's current motor directions. If the robot is currently running full speed forward, it will run full speed backward. If the robot is turning left at half-speed, it will turn right at half-speed. If the robot is currently stopped it will remain stopped.

right (*speed=1*)

Make the robot turn right by running the left motor forward and right motor backward.

Parameters **speed** (*float*) – Speed at which to drive the motors, as a value between 0 (stopped) and 1 (full speed). The default is 1.

stop ()

Stop the robot.

source

The iterable to use as a source of values for *value*.

source_delay

The delay (measured in seconds) in the loop used to read values from *source*. Defaults to 0.01 seconds which is generally sufficient to keep CPU usage to a minimum while providing adequate responsiveness.

values

An infinite iterator of values read from *value*.

Ryanteck MCB Robot

class `gpiozero.RyanteckRobot`

Extends `Robot` for the Ryanteck MCB robot.

The Ryanteck MCB pins are fixed and therefore there's no need to specify them when constructing this class. The following example turns the robot left:

```
from gpiozero import RyanteckRobot

robot = RyanteckRobot()
robot.left()
```

backward (*speed=1*)

Drive the robot backward by running both motors backward.

Parameters **speed** (*float*) – Speed at which to drive the motors, as a value between 0 (stopped) and 1 (full speed). The default is 1.

forward (*speed=1*)

Drive the robot forward by running both motors forward.

Parameters **speed** (*float*) – Speed at which to drive the motors, as a value between 0 (stopped) and 1 (full speed). The default is 1.

left (*speed=1*)

Make the robot turn left by running the right motor forward and left motor backward.

Parameters **speed** (*float*) – Speed at which to drive the motors, as a value between 0 (stopped) and 1 (full speed). The default is 1.

reverse ()

Reverse the robot's current motor directions. If the robot is currently running full speed forward, it will run full speed backward. If the robot is turning left at half-speed, it will turn right at half-speed. If the robot is currently stopped it will remain stopped.

right (*speed=1*)

Make the robot turn right by running the left motor forward and right motor backward.

Parameters **speed** (*float*) – Speed at which to drive the motors, as a value between 0 (stopped) and 1 (full speed). The default is 1.

stop ()

Stop the robot.

source

The iterable to use as a source of values for *value*.

source_delay

The delay (measured in seconds) in the loop used to read values from *source*. Defaults to 0.01 seconds which is generally sufficient to keep CPU usage to a minimum while providing adequate responsiveness.

values

An infinite iterator of values read from *value*.

CamJam #3 Kit Robot

class `gpiozero.CamJamKitRobot`

Extends `Robot` for the CamJam #3 EduKit robot controller.

The CamJam robot controller pins are fixed and therefore there's no need to specify them when constructing this class. The following example turns the robot left:

```
from gpiozero import CamJamKitRobot

robot = CamJamKitRobot()
robot.left()
```

backward (*speed=1*)

Drive the robot backward by running both motors backward.

Parameters **speed** (*float*) – Speed at which to drive the motors, as a value between 0 (stopped) and 1 (full speed). The default is 1.

forward (*speed=1*)

Drive the robot forward by running both motors forward.

Parameters **speed** (*float*) – Speed at which to drive the motors, as a value between 0 (stopped) and 1 (full speed). The default is 1.

left (*speed=1*)

Make the robot turn left by running the right motor forward and left motor backward.

Parameters **speed** (*float*) – Speed at which to drive the motors, as a value between 0 (stopped) and 1 (full speed). The default is 1.

reverse ()

Reverse the robot’s current motor directions. If the robot is currently running full speed forward, it will run full speed backward. If the robot is turning left at half-speed, it will turn right at half-speed. If the robot is currently stopped it will remain stopped.

right (*speed=1*)

Make the robot turn right by running the left motor forward and right motor backward.

Parameters **speed** (*float*) – Speed at which to drive the motors, as a value between 0 (stopped) and 1 (full speed). The default is 1.

stop ()

Stop the robot.

source

The iterable to use as a source of values for *value*.

source_delay

The delay (measured in seconds) in the loop used to read values from *source*. Defaults to 0.01 seconds which is generally sufficient to keep CPU usage to a minimum while providing adequate responsiveness.

values

An infinite iterator of values read from *value*.

Energenie

class gpiozero.**Energenie** (*socket=None, initial_value=False*)

Extends *Device* to represent an *Energenie socket* controller.

This class is constructed with a socket number and an optional initial state (defaults to *False*, meaning off). Instances of this class can be used to switch peripherals on and off. For example:

```
from gpiozero import Energenie

lamp = Energenie(1)
lamp.on()
```

Parameters

- **socket** (*int*) – Which socket this instance should control. This is an integer number between 1 and 4.
- **initial_value** (*bool*) – The initial state of the socket. As Energenie sockets provide no means of reading their state, you must provide an initial state for the socket, which will be set upon construction. This defaults to `False` which will switch the socket off.

close()

Shut down the device and release all associated resources. This method can be called on an already closed device without raising an exception.

This method is primarily intended for interactive use at the command line. It disables the device and releases its pin(s) for use by another device.

You can attempt to do this simply by deleting an object, but unless you’ve cleaned up all references to the object this may not work (even if you’ve cleaned up all references, there’s still no guarantee the garbage collector will actually delete the object at that point). By contrast, the `close` method provides a means of ensuring that the object is shut down.

For example, if you have a breadboard with a buzzer connected to pin 16, but then wish to attach an LED instead:

```
>>> from gpiozero import *
>>> bz = Buzzer(16)
>>> bz.on()
>>> bz.off()
>>> bz.close()
>>> led = LED(16)
>>> led.blink()
```

Device descendents can also be used as context managers using the `with` statement. For example:

```
>>> from gpiozero import *
>>> with Buzzer(16) as bz:
...     bz.on()
...
>>> with LED(16) as led:
...     led.on()
... 
```

is_active

Returns `True` if the device is currently active and `False` otherwise. This property is usually derived from `value`. Unlike `value`, this is *always* a boolean.

source

The iterable to use as a source of values for `value`.

source_delay

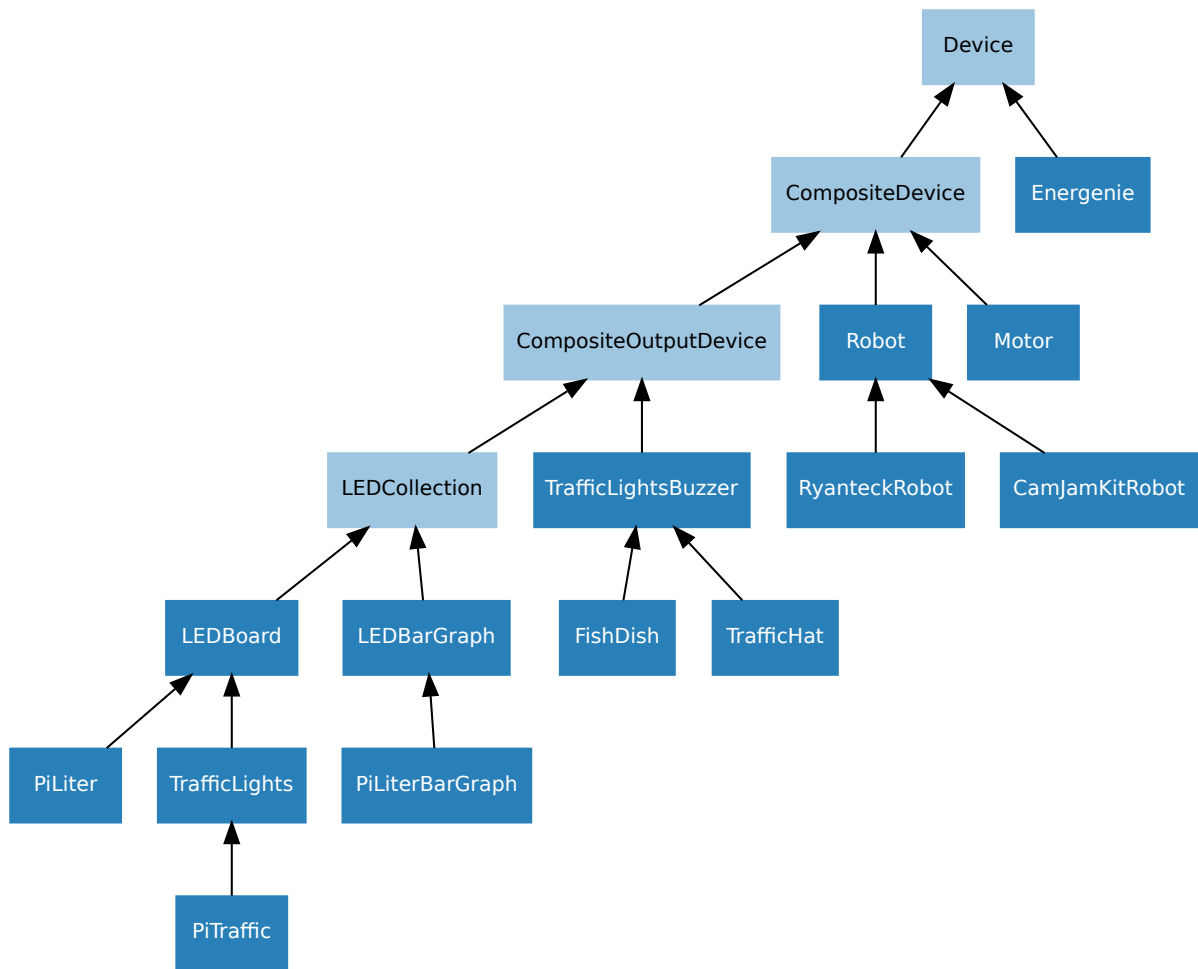

The delay (measured in seconds) in the loop used to read values from `source`. Defaults to 0.01 seconds which is generally sufficient to keep CPU usage to a minimum while providing adequate responsiveness.

values

An infinite iterator of values read from `value`.

Base Classes

The classes in the sections above are derived from a series of base classes, some of which are effectively abstract. The classes form the (partial) hierarchy displayed in the graph below:

For composite devices, the following chart shows which devices are composed of which other devices:

The following sections document these base classes for advanced users that wish to construct classes for their own devices.

LEDCollection

class gpiozero.**LEDCollection** (*args, **kwargs)

Extends *CompositeOutputDevice*. Abstract base class for *LEDBoard* and *LEDBarGraph*.

leds

A flat iterator over all LEDs contained in this collection (and all sub-collections).

CompositeOutputDevice

class gpiozero.**CompositeOutputDevice** (*args, _order=None, **kwargs)

Extends *CompositeDevice* with *on()*, *off()*, and *toggle()* methods for controlling subordinate

output devices. Also extends *value* to be writeable.

Parameters `_order` (*list*) – If specified, this is the order of named items specified by keyword arguments (to ensure that the *value* tuple is constructed with a specific order). All keyword arguments *must* be included in the collection. If omitted, an alphabetically sorted order will be selected for keyword arguments.

off()

Turn all the output devices off.

on()

Turn all the output devices on.

toggle()

Toggle all the output devices. For each device, if it's on, turn it off; if it's off, turn it on.

value

A tuple containing a value for each subordinate device. This property can also be set to update the state of all subordinate output devices.

CompositeDevice

class `gpiozero.CompositeDevice` (*args, _order=None, **kwargs)

Extends *Device*. Represents a device composed of multiple devices like simple HATs, H-bridge motor controllers, robots composed of multiple motors, etc.

The constructor accepts subordinate devices as positional or keyword arguments. Positional arguments form unnamed devices accessed via the `all` attribute, while keyword arguments are added to the device as named (read-only) attributes.

Parameters `_order` (*list*) – If specified, this is the order of named items specified by keyword arguments (to ensure that the *value* tuple is constructed with a specific order). All keyword arguments *must* be included in the collection. If omitted, an alphabetically sorted order will be selected for keyword arguments.

close()

Shut down the device and release all associated resources. This method can be called on an already closed device without raising an exception.

This method is primarily intended for interactive use at the command line. It disables the device and releases its pin(s) for use by another device.

You can attempt to do this simply by deleting an object, but unless you've cleaned up all references to the object this may not work (even if you've cleaned up all references, there's still no guarantee the garbage collector will actually delete the object at that point). By contrast, the `close` method provides a means of ensuring that the object is shut down.

For example, if you have a breadboard with a buzzer connected to pin 16, but then wish to attach an LED instead:

```
>>> from gpiozero import *
>>> bz = Buzzer(16)
>>> bz.on()
>>> bz.off()
>>> bz.close()
>>> led = LED(16)
>>> led.blink()
```

Device descendents can also be used as context managers using the `with` statement. For example:

```
>>> from gpiozero import *
>>> with Buzzer(16) as bz:
...     bz.on()
... 
```

```
>>> with LED(16) as led:
...     led.on()
... 
```

Internal Devices

GPIO Zero also provides several “internal” devices which represent facilities provided by the operating system itself. These can be used to react to things like the time of day, or whether a server is available on the network.

Warning: These devices are experimental and their API is not yet considered stable. We welcome any comments from testers, especially regarding new “internal devices” that you’d find useful!

TimeOfDay

class gpiozero.**TimeOfDay** (*start_time*, *end_time*, *utc=True*)

Extends *InternalDevice* to provide a device which is active when the computer’s clock indicates that the current time is between *start_time* and *end_time* (inclusive) which are *time* instances.

The following example turns on a lamp attached to an *Energenie* plug between 7 and 8 AM:

```
from datetime import time
from gpiozero import TimeOfDay, Energenie
from signal import pause

lamp = Energenie(0)
morning = TimeOfDay(time(7), time(8))
morning.when_activated = lamp.on
morning.when_deactivated = lamp.off
pause()
```

Parameters

- **start_time** (*time*) – The time from which the device will be considered active.
- **end_time** (*time*) – The time after which the device will be considered inactive.
- **utc** (*bool*) – If *True* (the default), a naive UTC time will be used for the comparison rather than a local time-zone reading.

PingServer

class gpiozero.**PingServer** (*host*)

Extends *InternalDevice* to provide a device which is active when a *host* on the network can be pinged.

The following example lights an LED while a server is reachable (note the use of *source_delay* to ensure the server is not flooded with pings):

```
from gpiozero import PingServer, LED
from signal import pause

server = PingServer('my-server')
led = LED(4)
led.source_delay = 1
led.source = server.values
pause()
```

Parameters `host` (*str*) – The hostname or IP address to attempt to ping.

Base Classes

The classes in the sections above are derived from a series of base classes, some of which are effectively abstract. The classes form the (partial) hierarchy displayed in the graph below:

The following sections document these base classes for advanced users that wish to construct classes for their own devices.

InternalDevice

class `gpiozero.InternalDevice`

Extends *Device* to provide a basis for devices which have no specific hardware representation. These are effectively pseudo-devices and usually represent operating system services like the internal clock, file systems or network facilities.

Generic Classes

The GPIO Zero class hierarchy is quite extensive. It contains several base classes (most of which are documented in their corresponding chapters):

- *Device* is the root of the hierarchy, implementing base functionality like `close()` and context manager handlers.
- *GPIODevice* represents individual devices that attach to a single GPIO pin
- *SPIDevice* represents devices that communicate over an SPI interface (implemented as four GPIO pins)
- *InternalDevice* represents devices that are entirely internal to the Pi (usually operating system related services)
- *CompositeDevice* represents devices composed of multiple other devices like HATs

There are also several *mixin classes* for adding important functionality at numerous points in the hierarchy, which is illustrated below:

```
class gpiozero.Device
```

close()

Shut down the device and release all associated resources. This method can be called on an already closed device without raising an exception.

This method is primarily intended for interactive use at the command line. It disables the device and releases its pin(s) for use by another device.

You can attempt to do this simply by deleting an object, but unless you've cleaned up all references to the object this may not work (even if you've cleaned up all references, there's still no guarantee the garbage collector will actually delete the object at that point). By contrast, the close method provides a means of ensuring that the object is shut down.

For example, if you have a breadboard with a buzzer connected to pin 16, but then wish to attach an LED instead:

Shut down the device and release all associated resources. This method can be called on an already closed device without raising an exception.

This method is primarily intended for interactive use at the command line. It disables the device and releases its pin(s) for use by another device.

You can attempt to do this simply by deleting an object, but unless you've cleaned up all references to the object this may not work (even if you've cleaned up all references, there's still no guarantee the garbage collector will actually delete the object at that point). By contrast, the `close` method provides a means of ensuring that the object is shut down.

For example, if you have a breadboard with a buzzer connected to pin 16, but then wish to attach an LED instead:

Device descendents can also be used as context managers using the `with` statement. For example:

closed

Returns `True` if the device is closed (see the `close()` method). Once a device is closed you can no longer use any other methods or properties to control or query the device.

Returns `True` if the device is currently active and `False` otherwise. This property is usually derived from `value`. Unlike `value`, this is *always* a boolean.

value

Returns a value representing the device's state. Frequently, this is a boolean value, or a number between 0 and 1 but some devices use larger ranges (e.g. -1 to +1) and composite devices usually use tuples to return the states of all their subordinate components.

ValuesMixin

class gpiozero.**ValuesMixin**(...)

Adds a *values* property to the class which returns an infinite generator of readings from the *value* property. There is rarely a need to use this mixin directly as all base classes in GPIO Zero include it.

Note: Use this mixin *first* in the parent class list.

values

An infinite iterator of values read from *value*.

SourceMixin

class gpiozero.**SourceMixin**(...)

Adds a *source* property to the class which, given an iterable, sets *value* to each member of that iterable until it is exhausted. This mixin is generally included in novel output devices to allow their state to be driven from another device.

Note: Use this mixin *first* in the parent class list.

source

The iterable to use as a source of values for *value*.

source_delay

The delay (measured in seconds) in the loop used to read values from *source*. Defaults to 0.01 seconds which is generally sufficient to keep CPU usage to a minimum while providing adequate responsiveness.

SharedMixin

class gpiozero.**SharedMixin**(...)

This mixin marks a class as “shared”. In this case, the meta-class (GPIONMeta) will use *__shared_key()* to convert the constructor arguments to an immutable key, and will check whether any existing instances match that key. If they do, they will be returned by the constructor instead of a new instance. An internal reference counter is used to determine how many times an instance has been “constructed” in this way.

When *close()* is called, an internal reference counter will be decremented and the instance will only close when it reaches zero.

classmethod *__shared_key*(*args, **kwargs)

Given the constructor arguments, returns an immutable key representing the instance. The default simply assumes all positional arguments are immutable.

EventsMixin

class gpiozero.**EventsMixin**(...)

Adds edge-detected *when_activated()* and *when_deactivated()* events to a device based on changes to the *is_active* property common to all devices. Also adds *wait_for_active()* and *wait_for_inactive()* methods for level-waiting.

Note: Note that this mixin provides no means of actually firing its events; call `_fire_events()` in sub-classes when device state changes to trigger the events. This should also be called once at the end of initialization to set initial states.

wait_for_active (*timeout=None*)

Pause the script until the device is activated, or the timeout is reached.

Parameters **timeout** (*float*) – Number of seconds to wait before proceeding. If this is `None` (the default), then wait indefinitely until the device is active.

wait_for_inactive (*timeout=None*)

Pause the script until the device is deactivated, or the timeout is reached.

Parameters **timeout** (*float*) – Number of seconds to wait before proceeding. If this is `None` (the default), then wait indefinitely until the device is inactive.

active_time

The length of time (in seconds) that the device has been active for. When the device is inactive, this is `None`.

inactive_time

The length of time (in seconds) that the device has been inactive for. When the device is active, this is `None`.

when_activated

The function to run when the device changes state from inactive to active.

This can be set to a function which accepts no (mandatory) parameters, or a Python function which accepts a single mandatory parameter (with as many optional parameters as you like). If the function accepts a single mandatory parameter, the device that activated will be passed as that parameter.

Set this property to `None` (the default) to disable the event.

when_deactivated

The function to run when the device changes state from active to inactive.

This can be set to a function which accepts no (mandatory) parameters, or a Python function which accepts a single mandatory parameter (with as many optional parameters as you like). If the function accepts a single mandatory parameter, the device that deactivated will be passed as that parameter.

Set this property to `None` (the default) to disable the event.

HoldMixin

class `gpiozero.HoldMixin(...)`

Extends `EventsMixin` to add the `when_held` event and the machinery to fire that event repeatedly (when `hold_repeat` is `True`) at intervals defined by `hold_time`.

held_time

The length of time (in seconds) that the device has been held for. This is counted from the first execution of the `when_held` event rather than when the device activated, in contrast to `active_time`. If the device is not currently held, this is `None`.

hold_repeat

If `True`, `when_held` will be executed repeatedly with `hold_time` seconds between each invocation.

hold_time

The length of time (in seconds) to wait after the device is activated, until executing the `when_held` handler. If `hold_repeat` is `True`, this is also the length of time between invocations of `when_held`.

`is_held`

When True, the device has been active for at least `hold_time` seconds.

`when_held`

The function to run when the device has remained active for `hold_time` seconds.

This can be set to a function which accepts no (mandatory) parameters, or a Python function which accepts a single mandatory parameter (with as many optional parameters as you like). If the function accepts a single mandatory parameter, the device that activated will be passed as that parameter.

Set this property to None (the default) to disable the event.

Source Tools

GPIO Zero includes several utility routines which are intended to be used with the `source` and `values` attributes common to most devices in the library. These utility routines are in the `tools` module of GPIO Zero and are typically imported as follows:

```
from gpiozero.tools import scaled, negated, conjunction
```

Given that `source` and `values` deal with infinite iterators, another excellent source of utilities is the `itertools` module in the standard library.

Warning: While the devices API is now considered stable and won't change in backwards incompatible ways, the tools API is *not* yet considered stable. It is potentially subject to change in future versions. We welcome any comments from testers!

Single source conversions

`gpiozero.tools.absoluted(values)`

Returns `values` with all negative elements negated (so that they're positive). For example:

```
from gpiozero import PWMLED, Motor, MCP3008
from gpiozero.tools import absoluted, scaled
from signal import pause

led = PWMLED(4)
motor = Motor(22, 27)
pot = MCP3008(channel=0)
motor.source = scaled(pot.values, -1, 1)
led.source = absoluted(motor.values)
pause()
```

`gpiozero.tools.clamped(values, output_min=0, output_max=1)`

Returns `values` clamped from `output_min` to `output_max`, i.e. any items less than `output_min` will be returned as `output_min` and any items larger than `output_max` will be returned as `output_max` (these default to 0 and 1 respectively). For example:

```
from gpiozero import PWMLED, MCP3008
from gpiozero.tools import clamped
from signal import pause

led = PWMLED(4)
pot = MCP3008(channel=0)
led.source = clamped(pot.values, 0.5, 1.0)
pause()
```

`gpiozero.tools.inverted(values)`

Returns the inversion of the supplied values (1 becomes 0, 0 becomes 1, 0.1 becomes 0.9, etc.). For example:

```
from gpiozero import MCP3008, PWMLED
from gpiozero.tools import inverted
from signal import pause

led = PWMLED(4)
pot = MCP3008(channel=0)
led.source = inverted(pot.values)
pause()
```

`gpiozero.tools.negated(values)`

Returns the negation of the supplied values (True becomes False, and False becomes True). For example:

```
from gpiozero import Button, LED
from gpiozero.tools import negated
from signal import pause

led = LED(4)
btn = Button(17)
led.source = negated(btn.values)
pause()
```

`gpiozero.tools.post_delayed(values, delay)`

Waits for *delay* seconds after returning each item from *values*.

`gpiozero.tools.pre_delayed(values, delay)`

Waits for *delay* seconds before returning each item from *values*.

`gpiozero.tools.quantized(values, steps, output_min=0, output_max=1)`

Returns *values* quantized to *steps* increments. All items in *values* are assumed to be between *output_min* and *output_max* (use *scaled()* to ensure this if necessary).

For example, to quantize values between 0 and 1 to 5 “steps” (0.0, 0.25, 0.5, 0.75, 1.0):

```
from gpiozero import PWMLED, MCP3008
from gpiozero.tools import quantized
from signal import pause

led = PWMLED(4)
pot = MCP3008(channel=0)
led.source = quantized(pot.values, 4)
pause()
```

`gpiozero.tools.queued(values, qsize)`

Queues up readings from *values* (the number of readings queued is determined by *qsize*) and begins yielding values only when the queue is full. For example, to “cascade” values along a sequence of LEDs:

```
from gpiozero import LEDBoard, Button
from gpiozero.tools import queued
from signal import pause

leds = LEDBoard(5, 6, 13, 19, 26)
btn = Button(17)
for i in range(4):
    leds[i].source = queued(leds[i + 1].values, 5)
    leds[i].source_delay = 0.01
leds[4].source = btn.values
pause()
```

`gpiozero.tools.scaled(values, output_min, output_max, input_min=0, input_max=1)`

Returns *values* scaled from *output_min* to *output_max*, assuming that all items in *values* lie between *input_min* and *input_max* (which default to 0 and 1 respectively). For example, to control the direction of a motor (which is represented as a value between -1 and 1) using a potentiometer (which typically provides values between 0 and 1):

```
from gpiozero import Motor, MCP3008
from gpiozero.tools import scaled
from signal import pause

motor = Motor(20, 21)
pot = MCP3008(channel=0)
motor.source = scaled(pot.values, -1, 1)
pause()
```

Warning: If *values* contains elements that lie outside *input_min* to *input_max* (inclusive) then the function will not produce values that lie within *output_min* to *output_max* (inclusive).

Combining sources

`gpiozero.tools.all_values(*values)`

Returns the **logical conjunction** of all supplied values (the result is only `True` if and only if all input values are simultaneously `True`). One or more *values* can be specified. For example, to light an LED only when *both* buttons are pressed:

```
from gpiozero import LED, Button
from gpiozero.tools import all_values
from signal import pause

led = LED(4)
btn1 = Button(20)
btn2 = Button(21)
led.source = all_values(btn1.values, btn2.values)
pause()
```

`gpiozero.tools.any_values(*values)`

Returns the **logical disjunction** of all supplied values (the result is `True` if any of the input values are currently `True`). One or more *values* can be specified. For example, to light an LED when *any* button is pressed:

```
from gpiozero import LED, Button
from gpiozero.tools import any_values
from signal import pause

led = LED(4)
btn1 = Button(20)
btn2 = Button(21)
led.source = any_values(btn1.values, btn2.values)
pause()
```

`gpiozero.tools.averaged(*values)`

Returns the mean of all supplied values. One or more *values* can be specified. For example, to light a PWMLED as the average of several potentiometers connected to an MCP3008 ADC:

```
from gpiozero import MCP3008, PWMLED
from gpiozero.tools import averaged
from signal import pause

pot1 = MCP3008(channel=0)
pot2 = MCP3008(channel=1)
```

```
pot3 = MCP3008(channel=2)
led = PWMLED(4)
led.source = averaged(pot1.values, pot2.values, pot3.values)
pause()
```

Artificial sources

`gpiozero.tools.cos_values` (*period=360*)

Provides an infinite source of values representing a cosine wave (from -1 to +1) which repeats every *period* values. For example, to produce a “siren” effect with a couple of LEDs that repeats once a second:

```
from gpiozero import PWMLED
from gpiozero.tools import cos_values, scaled, inverted
from signal import pause

red = PWMLED(2)
blue = PWMLED(3)
red.source_delay = 0.01
blue.source_delay = 0.01
red.source = scaled(cos_values(100), 0, 1, -1, 1)
blue.source = inverted(red.values)
pause()
```

If you require a different range than -1 to +1, see `scaled()`.

`gpiozero.tools.random_values` ()

Provides an infinite source of random values between 0 and 1. For example, to produce a “flickering candle” effect with an LED:

```
from gpiozero import PWMLED
from gpiozero.tools import random_values
from signal import pause

led = PWMLED(4)
led.source = random_values()
pause()
```

If you require a wider range than 0 to 1, see `scaled()`.

`gpiozero.tools.sin_values` (*period=360*)

Provides an infinite source of values representing a sine wave (from -1 to +1) which repeats every *period* values. For example, to produce a “siren” effect with a couple of LEDs that repeats once a second:

```
from gpiozero import PWMLED
from gpiozero.tools import sin_values, scaled, inverted
from signal import pause

red = PWMLED(2)
blue = PWMLED(3)
red.source_delay = 0.01
blue.source_delay = 0.01
red.source = scaled(sin_values(100), 0, 1, -1, 1)
blue.source = inverted(red.values)
pause()
```

If you require a different range than -1 to +1, see `scaled()`.

Pins

As of release 1.1, the GPIO Zero library can be roughly divided into two things: pins and the devices that are connected to them. The majority of the documentation focuses on devices as pins are below the level that most users are concerned with. However, some users may wish to take advantage of the capabilities of alternative GPIO implementations or (in future) use GPIO extender chips. This is the purpose of the pins portion of the library.

When you construct a device, you pass in a GPIO pin number. However, what the library actually expects is a *Pin* implementation. If it finds a simple integer number instead, it uses one of the following classes to provide the *Pin* implementation (classes are listed in favoured order):

1. `gpiozero.pins.rpigpio.RPiGPIOPin`
2. `gpiozero.pins.rpio.RPIOPin`
3. `gpiozero.pins.pigpiod.PiGPIOPin`
4. `gpiozero.pins.native.NativePin`

You can change the default pin implementation by over-writing the `DefaultPin` global in the `devices` module like so:

```
from gpiozero.pins.native import NativePin
import gpiozero.devices
# Force the default pin implementation to be NativePin
gpiozero.devices.DefaultPin = NativePin

from gpiozero import LED

# This will now use NativePin instead of RPiGPIOPin
led = LED(16)
```

Alternatively, instead of passing an integer to the device constructor, you can pass a *Pin* object itself:

```
from gpiozero.pins.native import NativePin
from gpiozero import LED

led = LED(NativePin(16))
```

This is particularly useful with implementations that can take extra parameters such as *PiGPIOPin* which can address pins on remote machines:

```
from gpiozero.pins.pigpiod import PiGPIOPin
from gpiozero import LED

led = LED(PiGPIOPin(16, host='my_other_pi'))
```

In future, this separation of pins and devices should also permit the library to utilize pins that are part of IO extender chips. For example:

```
from gpiozero import IOExtender, LED

ext = IOExtender()
led = LED(ext.pins[0])
led.on()
```

Warning: While the devices API is now considered stable and won't change in backwards incompatible ways, the pins API is *not* yet considered stable. It is potentially subject to change in future versions. We welcome any comments from testers!

Warning: The astute and mischievous reader may note that it is possible to mix pin implementations, e.g. using `RPiGPIOPin` for one pin, and `NativePin` for another. This is unsupported, and if it results in your script crashing, your components failing, or your Raspberry Pi turning into an actual raspberry pie, you have only yourself to blame.

RPiGPIOPin

class `gpiozero.pins.rpigpio.RPiGPIOPin`

Uses the `RPi.GPIO` library to interface to the Pi's GPIO pins. This is the default pin implementation if the `RPi.GPIO` library is installed. Supports all features including PWM (via software).

Because this is the default pin implementation you can use it simply by specifying an integer number for the pin in most operations, e.g.:

```
from gpiozero import LED

led = LED(12)
```

However, you can also construct `RPi.GPIO` pins manually if you wish:

```
from gpiozero.pins.rpigpio import RPiGPIOPin
from gpiozero import LED

led = LED(RPiGPIOPin(12))
```

RPIOPin

class `gpiozero.pins.rpio.RPIOPin`

Uses the `RPIO` library to interface to the Pi's GPIO pins. This is the default pin implementation if the `RPi.GPIO` library is not installed, but `RPIO` is. Supports all features including PWM (hardware via DMA).

Note: Please note that at the time of writing, `RPIO` is only compatible with Pi 1's; the Raspberry Pi 2 Model B is *not* supported. Also note that root access is required so scripts must typically be run with `sudo`.

You can construct `RPIO` pins manually like so:

```
from gpiozero.pins.rpio import RPIOPin
from gpiozero import LED

led = LED(RPIOPin(12))
```

PiGPIOPin

class `gpiozero.pins.pigpiod.PiGPIOPin`

Uses the `pigpio` library to interface to the Pi's GPIO pins. The `pigpio` library relies on a daemon (`pigpiod`) to be running as root to provide access to the GPIO pins, and communicates with this daemon over a network socket.

While this does mean only the daemon itself should control the pins, the architecture does have several advantages:

- Pins can be remote controlled from another machine (the other machine doesn't even have to be a Raspberry Pi; it simply needs the `pigpio` client library installed on it)
- The daemon supports hardware PWM via the DMA controller

- Your script itself doesn't require root privileges; it just needs to be able to communicate with the daemon

You can construct pigpiod pins manually like so:

```
from gpiozero.pins.pigpiod import PiGPIOPin
from gpiozero import LED

led = LED(PiGPIOPin(12))
```

This is particularly useful for controlling pins on a remote machine. To accomplish this simply specify the host (and optionally port) when constructing the pin:

```
from gpiozero.pins.pigpiod import PiGPIOPin
from gpiozero import LED
from signal import pause

led = LED(PiGPIOPin(12, host='192.168.0.2'))
```

Note: In some circumstances, especially when playing with PWM, it does appear to be possible to get the daemon into “unusual” states. We would be most interested to hear any bug reports relating to this (it may be a bug in our pin implementation). A workaround for now is simply to restart the pigpiod daemon.

NativePin

class `gpiozero.pins.native.NativePin`

Uses a built-in pure Python implementation to interface to the Pi's GPIO pins. This is the default pin implementation if no third-party libraries are discovered.

Warning: This implementation does *not* currently support PWM. Attempting to use any class which requests PWM will raise an exception. This implementation is also experimental; we make no guarantees it will not eat your Pi for breakfast!

You can construct native pin instances manually like so:

```
from gpiozero.pins.native import NativePin
from gpiozero import LED

led = LED(NativePin(12))
```

Abstract Pin

class `gpiozero.Pin`

Abstract base class representing a GPIO pin or a pin from an IO extender.

Descendents should override property getters and setters to accurately represent the capabilities of pins. The following functions *must* be overridden:

- `_get_function()`
- `_set_function()`
- `_get_state()`

The following functions *may* be overridden if applicable:

- `close()`

- `_set_state()`
- `_get_frequency()`
- `_set_frequency()`
- `_get_pull()`
- `_set_pull()`

- `_set_when_changed()`
- `output_with_state()`
- `input_with_pull()`

Warning: Descendents must ensure that pin instances representing the same physical hardware are identical, right down to object identity. The framework relies on this to correctly clean up resources at interpreter shutdown.

close()

Cleans up the resources allocated to the pin. After this method is called, this *Pin* instance may no longer be used to query or control the pin's state.

input_with_pull(*pull*)

Sets the pin's function to "input" and specifies an initial pull-up for the pin. By default this is equivalent to performing:

```
pin.function = 'input'
pin.pull = pull
```

However, descendents may override this order to provide the smallest possible delay between configuring the pin for input and pulling the pin up/down (which can be important for avoiding "blips" in some configurations).

output_with_state(*state*)

Sets the pin's function to "output" and specifies an initial state for the pin. By default this is equivalent to performing:

```
pin.function = 'output'
pin.state = state
```

However, descendents may override this in order to provide the smallest possible delay between configuring the pin for output and specifying an initial value (which can be important for avoiding "blips" in active-low configurations).

bounce

The amount of bounce detection (elimination) currently in use by edge detection, measured in seconds. If bounce detection is not currently in use, this is `None`.

If the pin does not support edge detection, attempts to set this property will raise *PinEdgeDetectUnsupported*. If the pin supports edge detection, the class must implement bounce detection, even if only in software.

edges

The edge that will trigger execution of the function or bound method assigned to `when_changed`. This can be one of the strings “both” (the default), “rising”, “falling”, or “none”.

If the pin does not support edge detection, attempts to set this property will raise `PinEdgeDetectUnsupported`.

frequency

The frequency (in Hz) for the pin’s PWM implementation, or `None` if PWM is not currently in use. This value always defaults to `None` and may be changed with certain pin types to activate or deactivate PWM.

If the pin does not support PWM, `PinPWMUnsupported` will be raised when attempting to set this to a value other than `None`.

function

The function of the pin. This property is a string indicating the current function or purpose of the pin. Typically this is the string “input” or “output”. However, in some circumstances it can be other strings indicating non-GPIO related functionality.

With certain pin types (e.g. GPIO pins), this attribute can be changed to configure the function of a pin. If an invalid function is specified, for this attribute, `PinInvalidFunction` will be raised.

pull

The pull-up state of the pin represented as a string. This is typically one of the strings “up”, “down”, or “floating” but additional values may be supported by the underlying hardware.

If the pin does not support changing pull-up state (for example because of a fixed pull-up resistor), attempts to set this property will raise `PinFixedPull`. If the specified value is not supported by the underlying hardware, `PinInvalidPull` is raised.

state

The state of the pin. This is 0 for low, and 1 for high. As a low level view of the pin, no swapping is performed in the case of pull ups (see `pull` for more information).

If PWM is currently active (when `frequency` is not `None`), this represents the PWM duty cycle as a value between 0.0 and 1.0.

If a pin is currently configured for input, and an attempt is made to set this attribute, `PinSetInput` will be raised. If an invalid value is specified for this attribute, `PinInvalidState` will be raised.

when_changed

A function or bound method to be called when the pin’s state changes (more specifically when the edge specified by `edges` is detected on the pin). The function or bound method must take no parameters.

If the pin does not support edge detection, attempts to set this property will raise `PinEdgeDetectUnsupported`.

Utilities

The pins module also contains a database of information about the various revisions of Raspberry Pi. This is used internally to raise warnings when non-physical pins are used, or to raise exceptions when pull-downs are requested on pins with physical pull-up resistors attached. The following functions and classes can be used to query this database:

`gpiozero.pi_info (revision=None)`

Returns a `PiBoardInfo` instance containing information about a *revision* of the Raspberry Pi.

Parameters `revision (str)` – The revision of the Pi to return information about. If this is omitted or `None` (the default), then the library will attempt to determine the model of Pi it is running on and return information about that.

class gpiozero.**PiBoardInfo**

This class is a `namedtuple()` derivative used to represent information about a particular model of Raspberry Pi. While it is a tuple, it is strongly recommended that you use the following named attributes to access the data contained within.

revision

A string indicating the revision of the Pi. This is unique to each revision and can be considered the “key” from which all other attributes are derived. However, in itself the string is fairly meaningless.

model

A string containing the model of the Pi (for example, “B”, “B+”, “A+”, “2B”, “CM” (for the Compute Module), or “Zero”).

pcb_revision

A string containing the PCB revision number which is silk-screened onto the Pi (on some models).

Note: This is primarily useful to distinguish between the model B revision 1.0 and 2.0 (not to be confused with the model 2B) which had slightly different pinouts on their 26-pin GPIO headers.

released

A string containing an approximate release date for this revision of the Pi (formatted as yyyyQq, e.g. 2012Q1 means the first quarter of 2012).

soc

A string indicating the SoC ([system on a chip](#)) that this revision of the Pi is based upon.

manufacturer

A string indicating the name of the manufacturer (usually “Sony” but a few others exist).

memory

An integer indicating the amount of memory (in Mb) connected to the SoC.

Note: This can differ substantially from the amount of RAM available to the operating system as the GPU’s memory is shared with the CPU. When the camera module is activated, at least 128Mb of RAM is typically reserved for the GPU.

storage

A string indicating the type of bootable storage used with this revision of Pi, e.g. “SD”, “MicroSD”, or “eMMC” (for the Compute Module).

usb

An integer indicating how many USB ports are physically present on this revision of the Pi.

Note: This does *not* include the micro-USB port used to power the Pi. On the Compute Module this is listed as 0 as the compute module itself doesn’t have any physical USB headers, despite providing one on the I/O development board and having the pins for one on the module itself.

ethernet

An integer indicating how many Ethernet ports are physically present on this revision of the Pi.

wifi

A bool indicating whether this revision of the Pi has wifi built-in.

bluetooth

A bool indicating whether this revision of the Pi has bluetooth built-in.

csi

An integer indicating the number of CSI (camera) ports available on this revision of the Pi.

dsi

An integer indicating the number of DSI (display) ports available on this revision of the Pi.

headers

A dictionary which maps header labels to dictionaries which map physical pin numbers to `PinInfo` tuples. For example, to obtain information about pin 12 on header P1 you would query `headers['P1'][12]`.

class `gpiozero.PinInfo`

This class is a `namedtuple()` derivative used to represent information about a pin present on a GPIO header. The following attributes are defined:

number

An integer containing the physical pin number on the header (starting from 1 in accordance with convention).

function

A string describing the function of the pin. Some common examples include “GND” (for pins connecting to ground), “3V3” (for pins which output 3.3 volts), “GPIO9” (for GPIO9 in the Broadcom numbering scheme), etc.

pull_up

A bool indicating whether the pin has a physical pull-up resistor permanently attached (this is usually `False` but GPIO2 and GPIO3 are *usually* `True`). This is used internally by gpiozero to raise errors when pull-down is requested on a pin with a physical pull-up resistor.

Exceptions

The following exceptions are defined by GPIO Zero. Please note that multiple inheritance is heavily used in the exception hierarchy to make testing for exceptions easier. For example, to capture any exception generated by GPIO Zero’s code:

```
from gpiozero import *

led = PWMLED(17)
try:
    led.value = 2
except GPIOZeroError:
    print('A GPIO Zero error occurred')
```

Since all GPIO Zero’s exceptions descend from `GPIOZeroError`, this will work. However, certain specific errors have multiple parents. For example, in the case that an out of range value is passed to `OutputDevice.value` you would expect a `ValueError` to be raised. In fact, a `OutputDeviceBadValue` error will be raised. However, note that this descends from both `GPIOZeroError` (indirectly) and from `ValueError` so you can still do:

```
from gpiozero import *

led = PWMLED(17)
try:
    led.value = 2
except ValueError:
    print('Bad value specified')
```

Errors

exception `gpiozero.GPIOZeroError`

Base class for all exceptions in GPIO Zero

exception `gpiozero.DeviceClosed`

Error raised when an operation is attempted on a closed device

exception `gpiozero.BadEventHandler`

Error raised when an event handler with an incompatible prototype is specified

exception `gpiozero.BadQueueLen`

Error raised when non-positive queue length is specified

exception `gpiozero.BadWaitTime`

Error raised when an invalid wait time is specified

exception `gpiozero.CompositeDeviceError`

Base class for errors specific to the CompositeDevice hierarchy

exception `gpiozero.CompositeDeviceBadName`

Error raised when a composite device is constructed with a reserved name

exception `gpiozero.EnergenieSocketMissing`

Error raised when socket number is not specified

exception `gpiozero.EnergenieBadSocket`

Error raised when an invalid socket number is passed to *Energenie*

exception `gpiozero.SPIError`

Base class for errors related to the SPI implementation

exception `gpiozero.SPIBadArgs`

Error raised when invalid arguments are given while constructing *SPIDevice*

exception `gpiozero.GPIODeviceError`

Base class for errors specific to the GPIODevice hierarchy

exception `gpiozero.GPIODeviceClosed`

Deprecated descendent of *DeviceClosed*

exception `gpiozero.GPIOPinInUse`

Error raised when attempting to use a pin already in use by another device

exception `gpiozero.GPIOPinMissing`

Error raised when a pin number is not specified

exception `gpiozero.InputDeviceError`

Base class for errors specific to the InputDevice hierarchy

exception `gpiozero.OutputDeviceError`

Base class for errors specified to the OutputDevice hierarchy

exception `gpiozero.OutputDeviceBadValue`

Error raised when value is set to an invalid value

exception `gpiozero.PinError`

Base class for errors related to pin implementations

exception `gpiozero.PinInvalidFunction`

Error raised when attempting to change the function of a pin to an invalid value

exception `gpiozero.PinInvalidState`

Error raised when attempting to assign an invalid state to a pin

exception `gpiozero.PinInvalidPull`

Error raised when attempting to assign an invalid pull-up to a pin

exception `gpiozero.PinInvalidEdges`

Error raised when attempting to assign an invalid edge detection to a pin

exception `gpiozero.PinSetInput`

Error raised when attempting to set a read-only pin

exception `gpiozero.PinFixedPull`

Error raised when attempting to set the pull of a pin with fixed pull-up

exception `gpiozero.PinEdgeDetectUnsupported`

Error raised when attempting to use edge detection on unsupported pins

exception `gpiozero.PinPWMError`

Base class for errors related to PWM implementations

exception `gpiozero.PinPWMUnsupported`

Error raised when attempting to activate PWM on unsupported pins

exception `gpiozero.PinPWMFxedValue`

Error raised when attempting to initialize PWM on an input pin

exception `gpiozero.PinMultiplePins`

Error raised when multiple pins support the requested function

exception `gpiozero.PinNoPins`

Error raised when no pins support the requested function

exception `gpiozero.PinUnknownPi`

Error raised when gpiozero doesn't recognize a revision of the Pi

Warnings

exception `gpiozero.GPIOZeroWarning`

Base class for all warnings in GPIO Zero

exception `gpiozero.SPIWarning`

Base class for warnings related to the SPI implementation

exception `gpiozero.SPISoftwareFallback`

Warning raised when falling back to the software implementation

Changelog

Release 1.2.0 (2016-04-10)

- Added *Energenie* class for controlling Energenie plugs (#69)
- Added *LineSensor* class for single line-sensors (#109)
- Added *DistanceSensor* class for HC-SR04 ultra-sonic sensors (#114)
- Added *SnowPi* class for the Ryantek Snow-pi board (#130)
- Added `when_held` (and related properties) to *Button* (#115)
- Fixed issues with installing GPIO Zero for python 3 on Raspbian Wheezy releases (#140)
- Added support for lots of ADC chips (MCP3xxx family) (#162) - many thanks to pcopa and lurch!
- Added support for pigpiod as a pin implementation with *PiGPIOPin* (#180)
- Many refinements to the base classes mean more consistency in composite devices and several bugs squashed (#164, #175, #182, #189, #193, #229)
- GPIO Zero is now aware of what sort of Pi it's running on via `pi_info()` and has a fairly extensive database of Pi information which it uses to determine when users request impossible things (like pull-down on a pin with a physical pull-up resistor) (#222)
- The source/values system was enhanced to ensure normal usage doesn't stress the CPU and lots of utilities were added (#181, #251)

And I'll just add a note of thanks to the many people in the community who contributed to this release: we've had some great PRs, suggestions, and bug reports in this version. Of particular note:

- Schelto van Doorn was instrumental in adding support for numerous ADC chips
- Alex Eames generously donated a RasPiO Analog board which was extremely useful in developing the software SPI interface (and testing the ADC support)
- Andrew Scheller squashed several dozen bugs (usually a day or so after Dave had introduced them ;)

As always, many thanks to the whole community - we look forward to hearing from you more in 1.3!

Release 1.1.0 (2016-02-08)

- Documentation converted to reST and expanded to include generic classes and several more recipes (#80, #82, #101, #119, #135, #168)
- New *CamJamKitRobot* class with the pre-defined motor pins for the new CamJam EduKit
- New *LEDBarGraph* class (many thanks to Martin O'Hanlon!) (#126, #176)
- New *Pin* implementation abstracts out the concept of a GPIO pin paving the way for alternate library support and IO extenders in future (#141)
- New *LEDBoard.blink()* method which works properly even when background is set to `False` (#94, #161)
- New *RGBLED.blink()* method which implements (rudimentary) color fading too! (#135, #174)
- New `initial_value` attribute on *OutputDevice* ensures consistent behaviour on construction (#118)
- New `active_high` attribute on *PWMOutputDevice* and *RGBLED* allows use of common anode devices (#143, #154)
- Loads of new ADC chips supported (many thanks to GitHub user pcopa!) (#150)

Release 1.0.0 (2015-11-16)

- Debian packaging added (#44)
- *PWMLED* class added (#58)
- *TemperatureSensor* removed pending further work (#93)
- *Buzzer.beep()* alias method added (#75)
- *Motor* PWM devices exposed, and *Robot* motor devices exposed (#107)

Release 0.9.0 (2015-10-25)

Fourth public beta

- Added source and values properties to all relevant classes (#76)
- Fix names of parameters in *Motor* constructor (#79)
- Added wrappers for LED groups on add-on boards (#81)

Release 0.8.0 (2015-10-16)

Third public beta

- Added generic *AnalogInputDevice* class along with specific classes for the *MCP3008* and *MCP3004* (#41)
- Fixed *DigitalOutputDevice.blink()* (#57)

Release 0.7.0 (2015-10-09)

Second public beta

Release 0.6.0 (2015-09-28)

First public beta

Release 0.5.0 (2015-09-24)

Release 0.4.0 (2015-09-23)

Release 0.3.0 (2015-09-22)

Release 0.2.0 (2015-09-21)

Initial release
