# 6 Troubleshooting

6.1 Sharing config and log output

6.2 Show effective configuration
Mopidy is an extensible music server written in Python.

Mopidy plays music from local disk, Spotify, SoundCloud, Google Play Music, and more. You edit the playlist from any phone, tablet, or computer using a range of MPD and web clients.

**Stream music from the cloud**

Vanilla Mopidy only plays music from your local disk and radio streams. Through extensions, Mopidy can play music from cloud services like Spotify, SoundCloud, and Google Play Music. With Mopidy’s extension support, backends for new music sources can be easily added.

**Mopidy is just a server**

Mopidy is a Python application that runs in a terminal or in the background on Linux computers or Macs that have network connectivity and audio output. Out of the box, Mopidy is an MPD and HTTP server. Additional frontends for controlling Mopidy can be installed from extensions.

**Everybody use their favorite client**

You and the people around you can all connect their favorite MPD or web client to the Mopidy server to search for music and manage the playlist together. With a browser or MPD client, which is available for all popular operating systems, you can control the music from any phone, tablet, or computer.

**Mopidy on Raspberry Pi**

The Raspberry Pi is a popular device to run Mopidy on, either using Raspbian or Arch Linux. It is quite slow, but it is very affordable. In fact, the Kickstarter funded Gramofon: Modern Cloud Jukebox project used Mopidy on a Raspberry Pi to prototype the Gramofon device. Mopidy is also a major building block in the Pi Musicbox integrated audio jukebox system for Raspberry Pi.

**Mopidy is hackable**

Mopidy’s extension support and Python, JSON-RPC, and JavaScript APIs makes Mopidy perfect for building your own hacks. In one project, a Raspberry Pi was embedded in an old cassette player. The buttons and volume control are wired up with GPIO on the Raspberry Pi, and is used to control playback through a custom Mopidy extension. The cassettes have NFC tags used to select playlists from Spotify.

**Getting started**

To get started with Mopidy, start by reading Installation.

**Getting help**

If you get stuck, you can get help at the Mopidy discussion forum. We also hang around at IRC on the #mopidy channel at irc.freenode.net.

If you stumble into a bug or have a feature request, please create an issue in the issue tracker. If you’re unsure if it’s a bug or not, ask for help in the forum or at IRC first. The source code may also be of help.

If you want to stay up to date on Mopidy developments, you can follow @mopidy on Twitter. There’s also a mailing list used for announcements related to Mopidy and Mopidy extensions.
There are several ways to install Mopidy. What way is best depends upon your OS and/or distribution. If you want to contribute to the development of Mopidy, you should first follow the instructions here to install a regular install of Mopidy, then continue with reading Contributing and Development environment.

1.1 Debian/Ubuntu: Install from apt.mopidy.com

If you run a Debian based Linux distribution, like Ubuntu, the easiest way to install Mopidy is from the Mopidy APT archive. When installing from the APT archive, you will automatically get updates to Mopidy in the same way as you get updates to the rest of your system.

If you’re on a Raspberry Pi running Debian or Raspbian, the following instructions should work for you as well. If you’re setting up a Raspberry Pi from scratch, we have a guide for installing Debian/Raspbian and Mopidy. See Raspberry Pi.

The packages are built for:

- Debian stretch (stable), which also works for Raspbian stretch and Ubuntu 16.04 LTS and newer.

The packages are available for multiple CPU architectures: i386, amd64, armel, and armhf (compatible with all Raspberry Pi models).

**Note:** This is just what we currently support, not a promise to continue to support the same in the future. We will drop support for older distributions and architectures when supporting those stops us from moving forward with the project.

1. Add the archive’s GPG key:

   `wget -q -O - https://apt.mopidy.com/mopidy.gpg | sudo apt-key add -`

2. Add the APT repo to your package sources:
3. Install Mopidy and all dependencies:

```
sudo apt-get update
dsudo apt-get install mopidy
```

4. Finally, you need to set a couple of config values, and then you’re ready to run Mopidy. Alternatively you may want to have Mopidy run as a system service, automatically starting at boot.

When a new release of Mopidy is out, and you can’t wait for you system to figure it out for itself, run the following to upgrade right away:

```
sudo apt-get update
sudo apt-get dist-upgrade
```

### 1.1.1 Installing extensions

If you want to use any Mopidy extensions, like Spotify support or Last.fm scrobbling, you need to install additional packages.

To list all the extensions available from apt.mopidy.com, you can run:

```
apt-cache search mopidy
```

To install one of the listed packages, e.g. `mopidy-spotify`, simply run:

```
sudo apt-get install mopidy-spotify
```

You can also install any Mopidy extension directly from PyPI with pip. To list all the extensions available from PyPI, run:

```
pip search mopidy
```

Note that extensions installed from PyPI will only automatically install Python dependencies. Please refer to the extension’s documentation for information about any other requirements needed for the extension to work properly.

For a full list of available Mopidy extensions, including those not installable from apt.mopidy.com, see Extensions.

### 1.2 Arch Linux: Install from community

If you are running Arch Linux, you can install Mopidy using the mopidy package found in community.

1. To install Mopidy with all dependencies, you can use:

```
pacman -S mopidy
```

To upgrade Mopidy to future releases, just upgrade your system using:

```
pacman -Syu
```

2. Finally, you need to set a couple of config values, and then you’re ready to run Mopidy or run Mopidy as a service.
1.2.1 Installing extensions

If you want to use any Mopidy extensions, like Spotify support or Last.fm scrobbling, AUR has packages for lots of Mopidy extensions.

You can also install any Mopidy extension directly from PyPI with pip. To list all the extensions available from PyPI, run:

```bash
pip search mopidy
```

Note that extensions installed from PyPI will only automatically install Python dependencies. Please refer to the extension’s documentation for information about any other requirements needed for the extension to work properly.

For a full list of available Mopidy extensions, including those not installable from AUR, see Extensions.

1.3 OS X: Install from Homebrew

If you are running OS X, you can install everything needed with Homebrew.

1. Install Xcode command line developer tools. Do this even if you already have Xcode installed:

```bash
xcode-select --install
```

2. Install Homebrew.

3. If you are already using Homebrew, make sure your installation is up to date before you continue:

```bash
brew upgrade
```

Note that this will upgrade all software on your system that have been installed with Homebrew.

4. Mopidy works out of box if you have installed Python from Homebrew:

```bash
brew install python
```

Note: If you want to use the Python version bundled with OS X, you’ll need to include Python packages installed by Homebrew in your PYTHONPATH. If you don’t do this, the mopidy executable will not find its dependencies and will crash.

You can either amend your PYTHONPATH permanently, by adding the following statement to your shell’s init file, e.g. `~/.bashrc`:

```bash
export PYTHONPATH=$(brew --prefix)/lib/python2.7/site-packages:$PYTHONPATH
```

And then reload the shell’s init file or restart your terminal:

```bash
source ~/.bashrc
```

Or, you can prefix the Mopidy command every time you run it:

```bash
PYTHONPATH=$(brew --prefix)/lib/python2.7/site-packages mopidy
```

5. Mopidy has its own Homebrew formula repo, called a “tap”. To enable our Homebrew tap, run:
brew tap mopidy/mopidy

**Note:** Mopidy currently requires that a few of its dependencies be built with Python 2 support via the `--with-python@2` build option. To ensure that this is done for your installation, it is recommended to uninstall the dependencies first with:

```bash
deprecated
brew uninstall --ignore-dependencies gst-python pygobject3
```

These dependencies will be re-installed automatically when Mopidy is installed.

6. To install Mopidy, run:

```bash
deprecated
brew install mopidy
```

7. Finally, you need to set a couple of `config values`, and then you're ready to run Mopidy.

### 1.3.1 Installing extensions

If you want to use any Mopidy extensions, like Spotify support or Last.fm scrobbling, the Homebrew tap has formulas for several Mopidy extensions as well. Extensions installed from Homebrew will come complete with all dependencies, both Python and non-Python ones.

To list all the extensions available from our tap, you can run:

```bash
deprecated
brew search mopidy
```

You can also install any Mopidy extension directly from PyPI with `pip`, just like on Linux. To list all the extensions available from PyPI, run:

```bash
pip search mopidy
```

Note that extensions installed from PyPI will only automatically install Python dependencies. Please refer to the extension’s documentation for information about any other requirements needed for the extension to work properly.

For a full list of available Mopidy extensions, including those not installable from Homebrew, see [Extensions](#).

### 1.3.2 Running Mopidy automatically on login

On OS X, you can use `launchctl` to start Mopidy automatically at login.

If you installed Mopidy from Homebrew, simply run `brew info mopidy` and follow the instructions in the “Caveats” section:

```bash
$ brew info mopidy
...
== Caveats

To have launchd start mopidy at login:
  ln -sfv /usr/local/opt/mopidy/*.plist ~/Library/LaunchAgents
Then to load mopidy now:
  launchctl load ~/Library/LaunchAgents/homebrew.mopidy.mopidy.plist
Or, if you don't want/need launchctl, you can just run:
  mopidy
```
If you happen to be on OS X, but didn’t install Mopidy with Homebrew, you can get the same effect by adding the file 
~/Library/LaunchAgents/mopidy.plist with the following contents:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE plist PUBLIC "-//Apple//DTD PLIST 1.0//EN" "http://www.apple.com/DTDs/PropertyList-1.0.dtd">  
<plist version="1.0">
  <dict>
    <key>Label</key>
    <string>mopidy</string>
    <key>ProgramArguments</key>
    <array>
      <string>/usr/local/bin/mopidy</string>
    </array>
    <key>RunAtLoad</key>
    <true/>
    <key>KeepAlive</key>
    <true/>
  </dict>
</plist>
```

You might need to adjust the path to the mopidy executable, /usr/local/bin/mopidy, to match your system.

Then, to start Mopidy with launchd right away:

```
launchctl load ~/Library/LaunchAgents/mopidy.plist
```

## 1.4 Install from source

If you are on Linux, but can’t install from the APT archive or from the Arch Linux repository, you can install Mopidy from PyPI using the pip installer.

If you are looking to contribute or wish to install from source using git please follow the directions [here](#).

1. First of all, you need Python 2.7. Check if you have Python and what version by running:

   ```bash
   python --version
   ```

2. You need to make sure you have pip, the Python package installer. You’ll also need a C compiler and the Python development headers to build pyspotify later.

   This is how you install it on Debian/Ubuntu:

   ```bash
   sudo apt-get install build-essential python-dev python-pip
   ```

   And on Arch Linux from the official repository:

   ```bash
   sudo pacman -S base-devel python2-pip
   ```

   And on Fedora Linux from the official repositories:

   ```bash
   sudo yum install -y gcc python-devel python-pip
   ```

   **Note:** On Fedora Linux, you must replace pip with pip-python in the following steps.
3. Then you’ll need to install GStreamer >= 1.2.3, with Python bindings. GStreamer is packaged for most popular Linux distributions. Search for GStreamer in your package manager, and make sure to install the Python bindings, and the “good” and “ugly” plugin sets.

If you use Debian/Ubuntu you can install GStreamer like this:

```
sudo apt-get install python-gst-1.0 \
gir1.2-gstreamer-1.0 gir1.2-gst-plugins-base-1.0 \
gstreamer1.0-plugins-good gstreamer1.0-plugins-ugly \
gstreamer1.0-tools
```

If you use Arch Linux, install the following packages from the official repository:

```
sudo pacman -S gst-python2 gst-plugins-good gst-plugins-ugly
```

If you use Fedora you can install GStreamer like this:

```
sudo yum install -y python-gstreamer1 gstreamer1-plugins-good \
gstreamer1-plugins-ugly
```

If you use Gentoo you can install GStreamer like this:

```
emerge -av gst-python gst-plugins-meta
```

`gst-plugins-meta` is the one that actually pulls in the plugins you want, so pay attention to the USE flags, e.g. alsa, mp3, etc.

4. Install the latest release of Mopidy:

```
sudo pip install -U mopidy
```

This will use pip to install the latest release of Mopidy from PyPI. To upgrade Mopidy to future releases, just rerun this command.

5. Finally, you need to set a couple of `config values`, and then you’re ready to run Mopidy.

### 1.4.1 Installing extensions

If you want to use any Mopidy extensions, like Spotify support or Last.fm scrobbling, you need to install additional Mopidy extensions.

You can install any Mopidy extension directly from PyPI with pip. To list all the extensions available from PyPI, run:

```
pip search mopidy
```

Note that extensions installed from PyPI will only automatically install Python dependencies. Please refer to the extension’s documentation for information about any other requirements needed for the extension to work properly.

For a full list of available Mopidy extensions see `Extensions`.

### 1.5 Raspberry Pi

Mopidy runs on all versions of Raspberry Pi. However, note that the Raspberry Pi 2 and 3 are significantly more powerful than the Raspberry Pi 1 and Raspberry Pi Zero; Mopidy will run noticeably faster on the later models.
1.5.1 How to for Raspbian

   Unless you need a full graphical desktop the Lite image is preferable since it’s much smaller.

2. Flash the Raspbian image you downloaded to your SD card.

   See the Raspberry Pi installation docs for instructions.

   You’ll need to enable SSH if you are not connecting a monitor and a keyboard. As of the November 2016 release, Raspbian has the SSH server disabled by default. SSH can be enabled by placing a file named ‘ssh’, without any extension, onto the boot partition of the SD card. See here for more details.

3. If you boot with only a network cable connected, you’ll have to find the IP address of the Pi yourself, e.g. by looking in the client list on your router/DHCP server. When you have found the Pi’s IP address, you can SSH to the IP address and login with the user pi and password raspberry. Once logged in, run sudo raspi-config to start the config tool as the root user.

4. Use the raspi-config tool to setup the basics of your Pi. You might want to do one or more of the following:
   • Change the password of the pi user.
   • Change the language, time zone, etc.

Under “Advanced Options”:
   • Set a hostname.
   • Enable SSH if not already enabled.
   • Force a specific audio output. By default, when using a HDMI display the audio will also be output over HDMI, otherwise the 3.5mm jack will be used.
• Adjust the memory split. If you’re not using a display (i.e. Raspbian Lite), you should set the minimum value here in order to make best use of the available RAM.

Once done, select “Finish”. Depending on what you changed you may be asked if you want to restart your Pi, select “Yes” and then log back in again afterwards.

If you want to change any settings later, you can simply rerun `sudo raspi-config`.

5. Install Mopidy and any Mopidy extensions you want, as described in *Debian/Ubuntu: Install from apt.mopidy.com*.

---

**Note:** If you used the Raspbian *Desktop* image you may also need to add the *mopidy* user to the *video* group. Run `sudo adduser mopidy video` to do this.

---

### 1.5.2 Testing sound output

You can test sound output independent of Mopidy by running:

```
`aplay /usr/share/sounds/alsa/Front_Center.wav`
```

If you hear a voice saying “Front Center”, then your sound is working.

If you want to change your audio output setting, simply rerun `sudo raspi-config`. 

Mopidy has a lot of config values you can tweak, but you only need to change a few to get up and running. A complete
~/.config/mopidy/mopidy.conf may be as simple as this:

```
[mopidy]
hostname = ::

[spotify]
username = alice
password = mysecret
```

Mopidy primarily reads config from the file ~/.config/mopidy/mopidy.conf, where ~ means your home directory. If your username is alice and you are running Linux, the config file should probably be at /home/alice/.config/mopidy/mopidy.conf. You can either create the configuration file yourself, or run the mopidy command, and it will create an empty config file for you and print what config values must be set to successfully start Mopidy.

If running Mopidy as a service, the location of the config file and other details documented here differs a bit. See Running as a service for details about this.

When you have created the configuration file, open it in a text editor, and add the config values you want to change. If you want to keep the default for a config value, you should not add it to the config file, but leave it out so that when we change the default value in a future version, you won’t have to change your configuration accordingly.

To see what’s the effective configuration for your Mopidy installation, you can run:

```
mopidy config
```

This will print your full effective config with passwords masked out so that you safely can share the output with others for debugging.

You can find a description of all config values belonging to Mopidy’s core below, together with their default values. In addition, all extensions got additional config values. The extension’s config values and config defaults are documented on the extension pages.
2.1 Default configuration

This is the default configuration for Mopidy itself. All extensions bring additional configuration values with their own defaults.

```ini
[core]
cache_dir = $XDG_CACHE_DIR/mopidy
config_dir = $XDG_CONFIG_DIR/mopidy
data_dir = $XDG_DATA_DIR/mopidy
max_tracklist_length = 10000
restore_state = false

[logging]
color = true
console_format = %(levelname)-8s %(message)s
debug_format = %(levelname)-8s %(asctime)s [%(process)d:%(threadName)s] %(name)s
  %(message)s
debug_file = mopidy.log
config_file =

[audio]
mixer = software
mixer_volume =
output = autoaudiosink
buffer_time =

[proxy]
scheme =
hostname =
port =
username =
password =
```

2.2 Core config section

**core/cache_dir**
Path to base directory for storing cached data.

Mopidy and extensions will use this path to cache data that can safely be thrown away.

If your system is running from an SD card, it can help avoid wear and corruption of your SD card by pointing this config to another location. If you have enough RAM, a tmpfs might be a good choice.

When running Mopidy as a regular user, this should usually be `$XDG_CACHE_DIR/mopidy`, i.e. `~/.cache/mopidy`.

When running Mopidy as a system service, this should usually be `/var/cache/mopidy`.

**core/config_dir**
Path to base directory for config files.

When running Mopidy as a regular user, this should usually be `$XDG_CONFIG_DIR/mopidy`, i.e. `~/.config/mopidy`.

When running Mopidy as a system service, this should usually be `/etc/mopidy`.

**core/data_dir**
Path to base directory for persistent data files.
Mopidy and extensions will use this path to store data that cannot be be thrown away and reproduced without some effort. Examples include Mopidy-Local’s index of your media library and Mopidy-M3U’s stored playlists.

When running Mopidy as a regular user, this should usually be $XDG_DATA_DIR/mopidy, i.e. ~/.local/share/mopidy.

When running Mopidy as a system service, this should usually be /var/lib/mopidy.

**core/max_tracklist_length**

Max length of the tracklist. Defaults to 10000.

The original MPD server only supports 10000 tracks in the tracklist. Some MPD clients will crash if this limit is exceeded.

**core/restore_state**

When set to true, Mopidy restores its last state when started. The restored state includes the tracklist, playback history, the playback state, the volume, and mute state.

Default is false.

### 2.3 Audio configuration

These are the available audio configurations. For specific use cases, see [Advanced audio setups](#).

**audio/mixer**

Audio mixer to use.

The default is software, which does volume control inside Mopidy before the audio is sent to the audio output. This mixer does not affect the volume of any other audio playback on the system. It is the only mixer that will affect the audio volume if you’re streaming the audio from Mopidy through Shoutcast.

If you want to disable audio mixing set the value to none.

If you want to use a hardware mixer, you need to install a Mopidy extension which integrates with your sound subsystem. E.g. for ALSA, install Mopidy-ALSA-Mixer.

**audio/mixer_volume**

Initial volume for the audio mixer.

Expects an integer between 0 and 100.

Setting the config value to blank leaves the audio mixer volume unchanged. For the software mixer blank means 100.

**audio/output**

Audio output to use.

Expects a GStreamer sink. Typical values are autoaudiosink, alsasink, osssink, oss4sink, pulsesink, and shout2send, and additional arguments specific to each sink. You can use the command `gst-inspect-1.0` to see what output properties can be set on the sink. For example: `gst-inspect-1.0 shout2send`

**audio/buffer_time**

Buffer size in milliseconds.

Expects an integer above 0.

Sets the buffer size of the GStreamer queue. If you experience buffering before track changes, it may help to increase this, possibly by at least a few seconds. The default is letting GStreamer decide the size, which at the time of this writing is 1000.
2.4 Logging configuration

logging/color
Whether or not to colorize the console log based on log level. Defaults to true.

logging/console_format
The log format used for informational logging.
See the Python logging docs for details on the format.

logging/debug_format
The log format used for debug logging.
See the Python logging docs for details on the format.

logging/debug_file
The file to dump debug log data to when Mopidy is run with the mopidy --save-debug-log option.

logging/config_file
Config file that overrides all logging config values, see the Python logging docs for details.

loglevels/*
The loglevels config section can be used to change the log level for specific parts of Mopidy during development or debugging. Each key in the config section should match the name of a logger. The value is the log level to use for that logger, one of debug, info, warning, error, or critical.

logcolors/*
The logcolors config section can be used to change the log color for specific parts of Mopidy during development or debugging. Each key in the config section should match the name of a logger. The value is the color to use for that logger, one of black, red, green, yellow, blue, magenta, cyan or white.

2.5 Proxy configuration

Not all parts of Mopidy or all Mopidy extensions respect the proxy server configuration when connecting to the Internet. Currently, this is at least used when Mopidy’s audio subsystem reads media directly from the network, like when listening to Internet radio streams, and by the Mopidy-Spotify extension. With time, we hope that more of the Mopidy ecosystem will respect these configurations to help users on locked down networks.

proxy/scheme
URI scheme for the proxy server. Typically http, https, socks4, or socks5.

proxy/hostname
Hostname of the proxy server.

proxy/port
Port number of the proxy server.

proxy/username
Username for the proxy server, if needed.

proxy/password
Password for the proxy server, if needed.

2.6 Extension configuration

Each installed Mopidy extension adds its own configuration section with one or more config values that you may want to tweak. For the available config values, please refer to the docs for each extension. Most, if not all, can be found at
Extensions

Mopidy extensions are enabled by default when they are installed. If you want to disable an extension without uninstalling it, all extensions support the enabled config value even if it isn’t explicitly documented by all extensions. If the enabled config value is set to false the extension will not be started. For example, to disable the Spotify extension, add the following to your mopidy.conf:

```
[spotify]
enabled = false
```

2.7 Adding new configuration values

Mopidy’s config validator will validate all of its own config sections and the config sections belonging to any installed extension. It will raise an error if you add any config values in your config file that Mopidy doesn’t know about. This may sound obnoxious, but it helps us detect typos in your config, and to warn about deprecated config values that should be removed or updated.

If you’re extending Mopidy, and want to use Mopidy’s configuration system, you can add new sections to the config without triggering the config validator. We recommend that you choose a good and unique name for the config section so that multiple extensions to Mopidy can be used at the same time without any danger of naming collisions.
To start Mopidy, simply open a terminal and run:

```
mopidy
```

For a complete reference to the Mopidy commands and their command line options, see `mopidy command`.

When Mopidy says MPD server running at [127.0.0.1]:6600 it's ready to accept connections by any MPD client. Check out our non-exhaustive MPD clients list to find recommended clients.

### 3.1 Updating the library

To update the library, e.g. after audio files have changed, run:

```
mopidy local scan
```

Afterwards, to refresh the library (which is for now only available through the API) it is necessary to run:

```
curl -d '{"jsonrpc": "2.0", "id": 1, "method": "core.library.refresh"}' http://localhost:6680/mopidy/rpc
```

This makes the changes in the library visible to the clients.

### 3.2 Stopping Mopidy

To stop Mopidy, press `CTRL+C` in the terminal where you started Mopidy.

Mopidy will also shut down properly if you send it the TERM signal, e.g. by using `pkill`:

```
pkill mopidy
```
3.3 Running as a service

Once you’re done exploring Mopidy and want to run it as a proper service, check out Running as a service.
Running as a service

If you want to run Mopidy as a service using either an init script or a systemd service, there’s a few differences from running Mopidy as your own user you’ll want to know about. The following applies to Debian, Ubuntu, Raspbian, and Arch. Hopefully, other distributions packaging Mopidy will make sure this works the same way on their distribution.

### 4.1 Configuration

All configuration is in `/etc/mopidy/mopidy.conf`, not in your user’s home directory.

### 4.2 mopidy user

The Mopidy service runs as the `mopidy` user, which is automatically created when you install the Mopidy package. The `mopidy` user will need read access to any local music you want Mopidy to play.

### 4.3 Subcommands

To run Mopidy subcommands with the same user and config files as the service uses, you can use `sudo mopidyctl <subcommand>`. In other words, where you’ll usually run:

```
mopidy config
```

You should instead run the following to inspect the service’s configuration:

```
sudo mopidyctl config
```

The same applies to scanning your local music collection. Where you’ll normally run:

```
mopidy local scan
```
You should instead run:

```
sudo mopidyctl local scan
```

### 4.4 Service management with systemd

On modern systems using systemd you can enable the Mopidy service by running:

```
sudo systemctl enable mopidy
```

This will make Mopidy start when the system boots.

Mopidy is started, stopped, and restarted just like any other systemd service:

```
sudo systemctl start mopidy  
sudo systemctl stop mopidy  
sudo systemctl restart mopidy
```

You can check if Mopidy is currently running as a service by running:

```
sudo systemctl status mopidy
```

### 4.5 Service management on Debian

On Debian systems (both those using systemd and not) you can enable the Mopidy service by running:

```
sudo dpkg-reconfigure mopidy
```

Mopidy can be started, stopped, and restarted using the `service` command:

```
sudo service mopidy start  
sudo service mopidy stop  
sudo service mopidy restart
```

You can check if Mopidy is currently running as a service by running:

```
sudo service mopidy status
```

### 4.6 Service on OS X

If you’re installing Mopidy on OS X, see *Running Mopidy automatically on login*.

### 4.7 Configure PulseAudio

When using PulseAudio, you will typically have a PulseAudio server run by your main user. Since Mopidy is running as its own user, it can’t access this server directly. Running PulseAudio as a system-wide daemon is discouraged by upstream (see *here* for details). Rather you can configure PulseAudio and Mopidy so Mopidy sends the sound to the PulseAudio server already running as your main user.
First, configure PulseAudio to accept sound over TCP from localhost by uncommenting or adding the TCP module to /etc/pulse/default.pa or $XDG_CONFIG_HOME/pulse/default.pa (typically ~/.config/pulse/default.pa):

```ini
[Network access (may be configured with paprefs, so leave this commented here if you plan to use paprefs)]
#load-module module-esound-protocol-tcp
load-module module-native-protocol-tcp auth-ip-acl=127.0.0.1
#load-module module-zeroconf-publish
```

Next, configure Mopidy to use this PulseAudio server:

```ini
[audio]
output = pulsesink server=127.0.0.1
```

After this, restart both PulseAudio and Mopidy:

```bash
pulseaudio --kill
start-pulseaudio-x11
sudo systemctl restart mopidy
```

If you are not running any X server, run `pulseaudio --start` instead of `start-pulseaudio-x11`.

If you don’t want to hard code the output in your Mopidy config, you can instead of adding any config to Mopidy add this to `~/.pulse/client.conf`:

```ini
default-server=127.0.0.1
```
Mopidy has very few audio configs, but the ones we have are very powerful because they let you modify the GStreamer audio pipeline directly. Here we describe some use cases that can be solved with the audio configs and GStreamer.

## 5.1 Custom audio sink

If you have successfully installed GStreamer, and then run the `gst-inspect-1.0` command, you should see a long listing of installed plugins, ending in a summary line:

```bash
$ gst-inspect-1.0
... long list of installed plugins ...
Total count: 233 plugins, 1339 features
```

Next, you should be able to produce a audible tone by running:

```
gst-launch-1.0 audiotestsrc ! audioresample ! autoaudiosink
```

If you cannot hear any sound when running this command, you won’t hear any sound from Mopidy either, as Mopidy by default uses GStreamer’s `autoaudiosink` to play audio. Thus, make this work before you file a bug against Mopidy.

If you for some reason want to use some other GStreamer audio sink than `autoaudiosink`, you can set the `audio/output` config value to a partial GStreamer pipeline description describing the GStreamer sink you want to use.

Example `mopidy.conf` for using OSS4:

```
[audio]
output = oss4sink
```

Again, this is the equivalent of the following `gst-launch-1.0` command, so make this work first:

```
gst-launch-1.0 audiotestsrc ! audioresample ! oss4sink
```
5.2 Streaming through Icecast

If you want to play the audio on another computer than the one running Mopidy, you can stream the audio from Mopidy through an Icecast audio streaming server. Multiple media players can then be connected to the streaming server simultaneously. To use the Icecast output, do the following:

1. Install, configure and start the Icecast server. It can be found in the icecast2 package in Debian/Ubuntu.

2. Set the `audio/output` config value to encode the output audio to MP3 (lamemp3enc) or Ogg Vorbis (audioresample ! audioconvert ! vorbisenc ! oggmux) and send it to Icecast (shout2send).

You might also need to change the `shout2send` default settings, run `gst-inspect-1.0 shout2send` to see the available settings. Most likely you want to change `ip`, `username`, `password`, and `mount`.

Example for MP3 streaming:

```plaintext
[audio]
output = lamemp3enc ! shout2send async=false mount=mopidy ip=127.0.0.1 port=8000 →password=hackme
```

Example for Ogg Vorbis streaming:

```plaintext
[audio]
output = audioresample ! audioconvert ! vorbisenc ! oggmux ! shout2send async=false mount=mopidy ip=127.0.0.1 port=8000 password=hackme
```

Example for MP3 streaming and local audio (multiple outputs):

```plaintext
[audio]
output = tee name=t ! queue ! audioresample ! autoaudiosink t. ! queue ! lamemp3enc ! shout2send async=false mount=mopidy ip=127.0.0.1 port=8000 →password=hackme
```

Other advanced setups are also possible for outputs. Basically, anything you can use with the `gst-launch-1.0` command can be plugged into `audio/output`.

5.2.1 Known issues

- **Changing track**: As of Mopidy 1.2 we support gapless playback, and the stream does no longer end when changing from one track to another.

- **Previous/next**: The stream ends on previous and next. See #1306 for details. This can be worked around using a fallback stream, as described below.

- **Pause**: Pausing playback stops the stream. This is probably not something we’re going to fix. This can be worked around using a fallback stream, as described below.

- **Metadata**: Track metadata is mostly missing from the stream. For Spotify, fixing #1357 should help. The general issue for other extensions is #866.

5.2.2 Fallback stream

By using a fallback stream playing silence, you can somewhat mitigate the known issues above.

Example Icecast configuration:
You can easily find MP3 files with just silence by searching the web. The silence.mp3 file needs to be placed in the directory defined by `<webroot>...</webroot>` in the Icecast configuration.
If you run into problems with Mopidy, we usually hang around at #mopidy on irc.freenode.net and also have a discussion forum. If you stumble into a bug or have a feature request, please create an issue in the issue tracker.

When you’re debugging yourself or asking for help, there are some tools built into Mopidy that you should know about.

### 6.1 Sharing config and log output

If you’re getting help at IRC, we recommend that you use a pastebin, like pastebin.com or GitHub Gist, to share your configuration and log output. Pasting more than a couple of lines on IRC is generally frowned upon. On the mailing list or when reporting an issue, somewhat longer text dumps are accepted, but large logs should still be shared through a pastebin.

### 6.2 Show effective configuration

The command `mopidy config` will print your full effective configuration the way Mopidy sees it after all defaults and all config files have been merged into a single config document. Any secret values like passwords are masked out, so the output of the command should be safe to share with others for debugging.

### 6.3 Show installed dependencies

The command `mopidy deps` will list the paths to and versions of any dependency Mopidy or the extensions might need to work. This is very useful data for checking that you’re using the right versions, and that you’re using the right installation if you have multiple installations of a dependency on your system.
6.4 Debug logging

If you run `mopidy -v` or `mopidy -vv` or `mopidy -vvv` Mopidy will print more and more debug log to stdout. All three options will give you debug level output from Mopidy and extensions, while `-vv` and `-vvv` will give you more log output from their dependencies as well.

If you run `mopidy --save-debug-log`, it will save the log equivalent with `-vvv` to the file `mopidy.log` in the directory you ran the command from.

If you want to reduce the logging for some component, see the docs for the `loglevels/*` config section.

6.5 Debugging deadlocks

If Mopidy hangs without an obvious explanation, you can send the `SIGUSR1` signal to the Mopidy process. If Mopidy’s main thread is still responsive, it will log a traceback for each running thread, showing what the threads are currently doing. This is a very useful tool for understanding exactly how the system is deadlocking. If you have the `pkill` command installed, you can use this by simply running:

```
pkill -SIGUSR1 mopidy
```

6.6 Debugging GStreamer

If you really want to dig in and debug GStreamer behaviour, then check out the Debugging section of GStreamer’s documentation for your options. Note that Mopidy does not support the GStreamer command line options, like `--gst-debug-level=3`, but setting GStreamer environment variables, like `GST_DEBUG`, works with Mopidy. For example, to run Mopidy with debug logging and GStreamer logging at level 3, you can run:

```
GST_DEBUG=3 mopidy -v
```

This will produce a lot of output, but given some GStreamer knowledge this is very useful for debugging GStreamer pipeline issues. Additionally `GST_DEBUG_FILE=gstreamer.log` can be used to redirect the debug logging to a file instead of standard out.

Lastly `GST_DEBUG_DUMP_DOT_DIR` can be used to get descriptions of the current pipeline in dot format. Currently we trigger a dump of the pipeline on every completed state change:

```
GST_DEBUG_DUMP_DOT_DIR=. mopidy
```
Mopidy-Local is an extension for playing music from your local music archive. It is bundled with Mopidy and enabled by default. Though, you’ll have to scan your music collection to build a cache of metadata before the Mopidy-Local will be able to play your music.

This backend handles URIs starting with `local:`.

### 7.1 Generating a local library

The command `mopidy local scan` will scan the path set in the `local/media_dir` config value for any audio files and build a library of metadata.

To make a local library for your music available for Mopidy:

1. Ensure that the `local/media_dir` config value points to where your music is located. Check the current setting by running:
   ```
mopyid config
   ```

2. Scan your media library:
   ```
mopyid local scan
   ```

3. Start Mopidy, find the music library in a client, and play some local music!

### 7.2 Updating the local library

When you’ve added or removed music in your collection and want to update Mopidy’s index of your local library, you need to rescan:

```
mopyid local scan
```
Note that if you are using the default local library storage, `json`, you need to restart Mopidy after the scan completes for the updated index to be used.

If you want index updates to come into effect immediately, you can try out Mopidy-Local-SQLite, which will probably become the default backend in the near future.

### 7.3 Pluggable library support

Local libraries are fully pluggable. What this means is that users may opt to disable the current default library `json`, replacing it with a third party one. When running `mopidy local scan` Mopidy will populate whatever the current active library is with data. Only one library may be active at a time.

To create a new library provider you must create class that implements the `mopidy.local.Library` interface and install it in the extension registry under `local:library`. Any data that the library needs to store on disc should be stored in the extension’s data dir, as returned by `get_data_dir()`.

### 7.4 Configuration

See `Configuration` for general help on configuring Mopidy.

```conf
[local]
enabled = true
library = json
media_dir = $XDG_MUSIC_DIR
scan_timeout = 1000
scan_flush_threshold = 100
scan_follow_symlinks = false
excluded_file_extensions =
    .directory
    .html
    .jpeg
    .jpg
    .log
    .nfo
    .pdf
    .png
    .txt
    .zip
```

**local/enabled**

If the local extension should be enabled or not.

**local/library**

Local library provider to use, change this if you want to use a third party library for local files.

**local/media_dir**

Path to directory with local media files.

**local/scan_timeout**

Number of milliseconds before giving up scanning a file and moving on to the next file.

**local/scan_follow_symlinks**

If we should follow symlinks found in `local/media_dir`.

---

**Chapter 7. Mopidy-Local**
local/scan_flush_threshold
Number of tracks to wait before telling library it should try and store its progress so far. Some libraries might
not respect this setting. Set this to zero to disable flushing.

local/excluded_file_extensions
File extensions to exclude when scanning the media directory. Values should be separated by either comma or
newline.
Mopidy-File is an extension for playing music from your local music archive. It is bundled with Mopidy and enabled by default. It allows you to browse through your local file system. Only files that are considered playable will be shown.

This backend handles URIs starting with \texttt{file:}.

\section{8.1 Configuration}

See \textit{Configuration} for general help on configuring Mopidy.

\begin{verbatim}
[file]
enabled = true
media_dirs =
   $XDG_MUSIC_DIR|Music
   ~/|Home
show_dotfiles = false
excluded_file_extensions =
   .directory
   .html
   .jpeg
   .jpg
   .log
   .nfo
   .pdf
   .png
   .txt
   .zip
follow_symlinks = false
metadata_timeout = 1000
\end{verbatim}

\texttt{file/} enabled

If the file extension should be enabled or not.
file/media_dirs
   A list of directories to be browsable. Optionally the path can be followed by | and a name that will be shown for that path.

file/show_dotfiles
   Whether to show hidden files and directories that start with a dot. Default is false.

file/excluded_file_extensions
   File extensions to exclude when scanning the media directory. Values should be separated by either comma or newline.

file/follow_symlinks
   Whether to follow symbolic links found in file/media_dirs. Directories and files that are outside the configured directories will not be shown. Default is false.

file/metadata_timeout
   Number of milliseconds before giving up scanning a file and moving on to the next file. Reducing the value might speed up the directory listing, but can lead to some tracks not being shown.
Mopidy-M3U

Mopidy-M3U is an extension for reading and writing M3U playlists stored on disk. It is bundled with Mopidy and enabled by default.

This backend handles URIs starting with m3u:

9.1 Migrating from Mopidy-Local playlists

Mopidy-M3U was split out of the Mopidy-Local extension in Mopidy 1.0. To migrate your playlists from Mopidy-Local, simply move them from the local/playlists_dir directory to the m3u/playlists_dir directory. Assuming you have not changed the default config, run the following commands to migrate:

```
mkdir -p ~/.local/share/mopidy/m3u/
mv ~/.local/share/mopidy/local/playlists/* ~/.local/share/mopidy/m3u/
```

9.2 Editing playlists

There is a core playlist API in place for editing playlists. This is supported by a few Mopidy clients, but not through Mopidy’s MPD server yet.

It is possible to edit playlists by editing the M3U files located in the m3u/playlists_dir directory, usually ~/.local/share/mopidy/m3u/, by hand with a text editor. See Wikipedia for a short description of the quite simple M3U playlist format.

9.3 Configuration

See Configuration for general help on configuring Mopidy.
[m3u]
  enabled = true
  playlists_dir =
  base_dir = $XDG_MUSIC_DIR
  default_encoding = latin-1
  default_extension = .m3u8

**m3u/enabled**
If the M3U extension should be enabled or not.

**m3u/playlists_dir**
Path to directory with M3U files. Unset by default, in which case the extension’s data dir is used to store playlists.

**m3u/base_dir**
Path to base directory for resolving relative paths in M3U files. If not set, relative paths are resolved based on the M3U file’s location.

**m3u/default_encoding**
Text encoding used for files with extension .m3u. Default is latin-1. Note that files with extension .m3u8 are always expected to be UTF-8 encoded.

**m3u/default_extension**
The file extension for M3U playlists created using the core playlist API. Default is .m3u8.
Mopidy-Stream is an extension for playing streaming music. It is bundled with Mopidy and enabled by default.

This backend does not provide a library or playlist storage. It simply accepts any URI added to Mopidy’s tracklist that matches any of the protocols in the `stream/protocols` config value. It then tries to retrieve metadata and play back the URI using GStreamer. For example, if you’re using an MPD client, you’ll just have to find your clients “add URI” interface, and provide it with the URI of a stream.

In addition to playing streams, the extension also understands how to extract streams from a lot of playlist formats. This is convenient as most Internet radio stations links to playlists instead of directly to the radio streams.

If you’re having trouble playing back a stream, run the `mopidy deps` command to check if you have all relevant GStreamer plugins installed.

### 10.1 Configuration

See *Configuration* for general help on configuring Mopidy.

```ini
[stream]
enabled = true
protocols =
    http
    https
    mms
    rtmp
    rtmps
    rtsp
timeout = 5000
metadata_blacklist =
```

**stream/enabled**

If the stream extension should be enabled or not.

**stream/protocols**

Whitelist of URI schemas to allow streaming from. Values should be separated by either comma or newline.
stream/timeout

Number of milliseconds before giving up looking up stream metadata.

stream/metadata_blacklist

List of URI globs to not fetch metadata from before playing. This feature is typically needed for play once URIs provided by certain streaming providers. Regular POSIX glob semantics apply, so `http://*.example.com/*` would match all example.com sub-domains.
Mopidy-HTTP is an extension that lets you control Mopidy through HTTP and WebSockets, for example from a web client. It is bundled with Mopidy and enabled by default.

When it is enabled it starts a web server at the port specified by the `http/port` config value.

**Warning:** As a simple security measure, the web server is by default only available from localhost. To make it available from other computers, change the `http/hostname` config value. Before you do so, note that the HTTP extension does not feature any form of user authentication or authorization. Anyone able to access the web server can use the full core API of Mopidy. Thus, you probably only want to make the web server available from your local network or place it behind a web proxy which takes care of user authentication. You have been warned.

### 11.1 Hosting web clients

Mopidy-HTTP’s web server can also host Tornado apps or any static files, for example the HTML, CSS, JavaScript, and images needed for a web based Mopidy client. See [HTTP server side API](#) for how to make static files or server-side functionality from a Mopidy extension available through Mopidy’s web server.

If you’re making a web based client and want to do server side development using some other technology than Tornado, you are of course free to run your own web server and just use Mopidy’s web server to host the API endpoints. But, for clients implemented purely in JavaScript, letting Mopidy host the files is a simpler solution.

See [HTTP JSON-RPC API](#) for details on how to integrate with Mopidy over HTTP. If you’re looking for a web based client for Mopidy, go check out [HTTP clients](#).

### 11.2 Configuration

See [Configuration](#) for general help on configuring Mopidy.
http/enabled
If the HTTP extension should be enabled or not.

http/hostname
Which address the HTTP server should bind to.
- **127.0.0.1** Listens only on the IPv4 loopback interface
- **::1** Listens only on the IPv6 loopback interface
- **0.0.0.0** Listens on all IPv4 interfaces
- **::** Listens on all interfaces, both IPv4 and IPv6

http/port
Which TCP port the HTTP server should listen to.

http/static_dir
Deprecated: This config is deprecated and will be removed in a future version of Mopidy.
Which directory the HTTP server should serve at “/”
Change this to have Mopidy serve e.g. files for your JavaScript client. “/mopidy” will continue to work as usual even if you change this setting, but any other Mopidy webclient installed with pip to be served at “/ext_name” will stop working if you set this config.
You’re strongly encouraged to make Mopidy extensions which use the the HTTP server side API to host static files on Mopidy’s web server instead of using http/static_dir. That way, installation of your web client will be a lot easier for your end users, and multiple web clients can easily share the same web server.

http/zeroconf
Name of the HTTP service when published through Zeroconf. The variables $hostname and $port can be used in the name.
If set, the Zeroconf services _http._tcp and _mopidy-http._tcp will be published.
Set to an empty string to disable Zeroconf for HTTP.

http/allowed_origins
A list of domains allowed to perform Cross-Origin Resource Sharing (CORS) requests. This applies to both JSON-RPC and WebSocket requests. Values should be in the format hostname:port, should not specify any scheme and be separated by either a comma or newline. Additionally, the port should not be specified if it is the default (80 for http, 443 for https).
Same-origin requests (i.e. requests from Mopidy’s web server) are always allowed and so you don’t need an entry for those. However, if your requests originate from a different web server, you will need to add an entry for that server in this list. For example, to allow requests from a web server at ‘http://my-web-client.example.com’ you would specify the entry ‘my-web-client.example.com’.

http/csrf_protection
Enable the HTTP server’s protection against Cross-Site Request Forgery (CSRF) from both JSON-RPC and WebSocket requests.
Disabling this will remove the requirement to set a `Content-Type: application/json` header for JSON-RPC POST requests. It will also disable all same-origin checks, effectively ignoring the `http/allowed_origins` config since requests from any origin will be allowed. Lastly, all `Access-Control-Allow-*` response headers will be suppressed.

This config should only be disabled if you understand the security implications and require the HTTP server’s old behaviour.
Mopidy-MPD is an extension that provides a full MPD server implementation to make Mopidy available to MPD clients. It is bundled with Mopidy and enabled by default.

**Warning:** As a simple security measure, the MPD server is by default only available from localhost. To make it available from other computers, change the `mpd/hostname` config value. Before you do so, note that the MPD server does not support any form of encryption and only a single clear text password (see `mpd/password`) for weak authentication. Anyone able to access the MPD server can control music playback on your computer. Thus, you probably only want to make the MPD server available from your local network. You have been warned.

MPD stands for Music Player Daemon, which is also the name of the original MPD server project. Mopidy does not depend on the original MPD server, but implements the MPD protocol itself, and is thus compatible with clients for the original MPD server.

For more details on our MPD server implementation, see `mopidy.mpd`.

### 12.1 Limitations

This is a non exhaustive list of MPD features that Mopidy doesn’t support. Items on this list will probably not be supported in the near future.

- Only a single password is supported. It gives all-or-nothing access.
- Toggling of audio outputs is not supported
- Channels for client-to-client communication are not supported
- Stickers are not supported
- Crossfade is not supported
- Replay gain is not supported
- `stats` does not provide any statistics
decoders does not provide information about available decoders

The following items are currently not supported, but should be added in the near future:

- **tagtypes** is not supported
- Live update of the music database is not supported

# 12.2 Configuration

See *Configuration* for general help on configuring Mopidy.

```ini
[mpd]
enabled = true
hostname = 127.0.0.1
port = 6600
password =
max_connections = 20
connection_timeout = 60
zeroconf = Mopidy MPD server on $hostname
command_blacklist = listall,listallinfo
default_playlist_scheme = m3u
```

**mpd/enabled**
- If the MPD extension should be enabled or not.

**mpd/hostname**
- Which address the MPD server should bind to. This can be a network address or the path to a Unix socket.
  - *127.0.0.1* Listens only on the IPv4 loopback interface
  - *::1* Listens only on the IPv6 loopback interface
  - *0.0.0.0* Listens on all IPv4 interfaces
  - *::* Listens on all interfaces, both IPv4 and IPv6
  - *unix:/path/to/unix/socket.sock* Listen on the Unix socket at the specified path. Must be prefixed with *unix:*

**mpd/port**
- Which TCP port the MPD server should listen to.

**mpd/password**
- The password required for connecting to the MPD server. If blank, no password is required.

**mpd/max_connections**
- The maximum number of concurrent connections the MPD server will accept.

**mpd/connection_timeout**
- Number of seconds an MPD client can stay inactive before the connection is closed by the server.

**mpd/zeroconf**
- Name of the MPD service when published through Zeroconf. The variables $hostname and $port can be used in the name.
  - Set to an empty string to disable Zeroconf for MPD.

**mpd/command_blacklist**
- List of MPD commands which are disabled by the server. By default this setting blacklists *listall* and
listallinfo. These commands don’t fit well with many of Mopidy’s backends and are better left disabled unless you know what you are doing.
Mopidy-SoftwareMixer is an extension for controlling audio volume in software through GStreamer. It is the only mixer bundled with Mopidy and is enabled by default.

If you use PulseAudio, the software mixer will control the per-application volume for Mopidy in PulseAudio, and any changes to the per-application volume done from outside Mopidy will be reflected by the software mixer.

If you don’t use PulseAudio, the mixer will adjust the volume internally in Mopidy’s GStreamer pipeline.

### 13.1 Configuration

Multiple mixers can be installed and enabled at the same time, but only the mixer pointed to by the `audio/mixer` config value will actually be used.

See [Configuration](#) for general help on configuring Mopidy.

```ini
[softwaremixer]
enabled = true
```

**softwaremixer/enabled**

If the software mixer should be enabled or not. Usually you don’t want to change this, but instead change the `audio/mixer` config value to decide which mixer is actually used.
Here you can find a list of external packages that extend Mopidy with additional audio mixers by implementing the `mopidy.mixer — Audio mixer API` which was added in Mopidy 0.19.

This list is moderated and updated on a regular basis. If you want your package to show up here, follow the guide on creating extensions.

### 14.1 Mopidy-ALSAMixer

https://github.com/mopidy/mopidy-alsamixer

Extension for controlling volume on a Linux system using ALSA.

### 14.2 Mopidy-Arcam

https://github.com/TooDizzy/mopidy-arcam

Extension for controlling volume using an external Arcam amplifier. Developed and tested with an Arcam AVR-300.

### 14.3 Mopidy-dam1021

https://github.com/fortaa/mopidy-dam1021

Extension for controlling volume using a dam1021 DAC device.

### 14.4 Mopidy-NAD

https://github.com/mopidy/mopidy-nad
Extension for controlling volume using an external NAD amplifier. Developed and tested with a NAD C355BEE.

### 14.5 Mopidy-SoftwareMixer

Bundled with Mopidy. See *Mopidy-SoftwareMixer*.

### 14.6 Mopidy-Yamaha

[https://github.com/knutz3n/mopidy-yamaha](https://github.com/knutz3n/mopidy-yamaha)

Extension for controlling volume using an external Yamaha network connected amplifier.
Here you can find a list of external packages that extend Mopidy with additional music sources by implementing the `mopidy.backend — Backend API`.

This list is moderated and updated on a regular basis. If you want your package to show up here, follow the guide on creating extensions.

### 15.1 Mopidy-AudioAddict

https://github.com/nilicule/mopidy-audioaddict

Provides a backend for playing music from the AudioAddict network of sites, including Digitally Imported, RadioTunes, RockRadio, JazzRadio, and FrescaRadio.

### 15.2 Mopidy-Banshee

https://github.com/tamland/mopidy-banshee

Provides a backend for playing music from the Banshee music player’s music library.

### 15.3 Mopidy-Bassdrive

https://github.com/felixb/mopidy-Bassdrive

Provides a backend for playing radio streams from BassDrive.

### 15.4 Mopidy-Beets

https://github.com/mopidy/mopidy-beets
Provides a backend for playing music from your Beets music library through Beets’ web extension.

15.5 Mopidy-Dirble

https://github.com/mopidy/mopidy-dirble
Provides a backend for browsing the Internet radio channels from the Dirble directory.

15.6 Mopidy-dLeyna

https://github.com/tkem/mopidy-dleyna
Provides a backend for playing music from Digital Media Servers using the dLeyna D-Bus interface.

15.7 Mopidy-Emby

https://github.com/xsteadfastx/mopidy-emby
Provides a backend for playing music from Emby Media Servers.

15.8 Mopidy-File

Bundled with Mopidy. See Mopidy-File.

15.9 Mopidy-GMusic

https://github.com/mopidy/mopidy-gmusic
Provides a backend for playing music from Google Play Music.

15.10 Mopidy-InternetArchive

https://github.com/tkem/mopidy-internetarchive
Extension for playing music and audio from the Internet Archive.

15.11 Mopidy-Local

Bundled with Mopidy. See Mopidy-Local.
15.12 Mopidy-Local-Images

https://github.com/mopidy/mopidy-local-images

Extension which plugs into Mopidy-Local to allow Web clients access to album art embedded in local media files. Not to be used on its own, but acting as a proxy between mopidy local scan and the actual local library provider being used.

15.13 Mopidy-Local-SQLite

https://github.com/mopidy/mopidy-local-sqlite

Extension which plugs into Mopidy-Local to use an SQLite database to keep track of your local media. This extension lets you browse your music collection by album, artist, composer and performer, and provides full-text search capabilities based on SQLite’s FTS modules. It also notices updates via mopidy local scan while Mopidy is running, so you can scan your media library periodically from a cron job, for example.

15.14 Mopidy-OE1

https://github.com/tischlda/mopidy-oe1

Extension for playing the live stream and browsing the 7-day archive of the Austrian radio station OE1.

15.15 Mopidy-Podcast

https://github.com/tkem/mopidy-podcast

Extension for browsing RSS feeds of podcasts and stream the episodes.

15.16 Mopidy-Podcast-gpodder

https://github.com/tkem/mopidy-podcast-gpodder

Extension for Mopidy-Podcast that lets you search and browse podcasts from the gpodder web site.

15.17 Mopidy-Podcast-iTunes

https://github.com/tkem/mopidy-podcast-itunes

Extension for Mopidy-Podcast that lets you search and browse podcasts from the Apple iTunes Store.

15.18 Mopidy-radio-de

https://github.com/hechtus/mopidy-radio-de

Extension for listening to Internet radio stations and podcasts listed at radio.de, radio.net, radio.fr, and radio.at.
15.19 Mopidy-RNZ

https://github.com/danbrough/mopidy-rnz
Extension for playing Radio New Zealand’s podcasts, live streams and latest news bulletin.

15.20 Mopidy-SomaFM

https://github.com/AlexandrePTJ/mopidy-somafm
Provides a backend for playing music from the SomaFM service.

15.21 Mopidy-SoundCloud

https://github.com/mopidy/mopidy-soundcloud
Provides a backend for playing music from the SoundCloud service.

15.22 Mopidy-Spotify

https://github.com/mopidy/mopidy-spotify
Extension for playing music from the Spotify music streaming service.

15.23 Mopidy-Spotify-Tunigo

https://github.com/trygveaa/mopidy-spotify-tunigo
Extension for providing the browse feature of Spotify. This lets you browse playlists, genres and new releases.

15.24 Mopidy-Stream

Bundled with Mopidy. See Mopidy-Stream.

15.25 Mopidy-Subsonic

https://github.com/rattboi/mopidy-subsonic
Provides a backend for playing music from a Subsonic Music Streamer library.

15.26 Mopidy-TuneIn

https://github.com/kingosticks/mopidy-tunein
Provides a backend for playing music from the TuneIn online radio service.
15.27 Mopidy-VKontakte

https://github.com/sibuser/mopidy-vkontakte
Provides a backend for playing music from the VKontakte social network.

15.28 Mopidy-YDisk

https://github.com/vonZeppelin/mopidy-ydisk
Provides a backend for playing music from Yandex.Disk cloud storage.

15.29 Mopidy-YouTube

https://github.com/mopidy/mopidy-youtube
Provides a backend for playing music from the YouTube service.
Frontend extensions

Here you can find a list of external packages that extend Mopidy with additional frontends, which includes just about anything that use the `mopidy.core — Core API`.

This list is moderated and updated on a regular basis. If you want your package to show up here, follow the `guide on creating extensions`.

### 16.1 Mopidy-EvtDev

https://github.com/liamw9534/mopidy-evtdev

Extension for controlling Mopidy from virtual input devices.

### 16.2 Mopidy-HTTP

Bundled with Mopidy. See `Mopidy-HTTP`.

### 16.3 Mopidy-MPD

Bundled with Mopidy. See `Mopidy-MPD`.

### 16.4 Mopidy-MPRIS

https://github.com/mopidy/mopidy-mpris

Extension for controlling Mopidy through the `MPRIS D-Bus` interface, for example using the Ubuntu Sound Menu.
16.5 Mopidy-Scrobbler

https://github.com/mopidy/mopidy-scrobbler
Extension for scrobbling played tracks to Last.fm.

16.6 Mopidy-Touchscreen

https://github.com/9and3r/mopidy-touchscreen
Extension for displaying track info and controlling Mopidy from a touch screen using PyGame/SDL.

16.7 Mopidy-TtsGpio

https://github.com/9and3r/mopidy-ttsgpio
Extension for controlling Mopidy without a display by using e.g. buttons connected to GPIO and text-to-speech for track information.

16.8 Mopidy-Webhooks

https://github.com/paddycarey/mopidy-webhooks
Extension for sending HTTP POST requests with JSON payloads to a remote server when Mopidy core triggers an event and on regular intervals.
Here you can find a list of external packages that extend Mopidy with additional web interfaces by implementing the HTTP server side API, which was added in Mopidy 0.19, and optionally using the HTTP JSON-RPC API.

This list is moderated and updated on a regular basis. If you want your package to show up here, follow the guide on creating extensions.

17.1 Mopidy-API-Explorer

https://github.com/dz0ny/mopidy-api-explorer

Web extension for browsing the Mopidy HTTP API.
To install, run:

```
pip install Mopidy-API-Explorer
```

## 17.2 Mopidy-Auto

https://github.com/gotling/mopidy-auto

Mopidy extension to automate music playback based on time of day.

**Warning:** This extension reacts to the events `tracklist_changed`, `track_playback_ended`, and `track_playback_resumed` to accomplish its goals. Other web extensions will not work as expected when this extension is installed.
To install, run:

```
pip install Mopidy-Auto
```

17.3 Mopidy-Iris

https://github.com/jaedb/iris

To install, run:

```
pip install Mopidy-Iris
```

## 17.4 Mopidy-Local-Images

https://github.com/tkem/mopidy-local-images

Not a full-featured web client, but rather a local library and web extension which allows other web clients access to album art embedded in local media files.
Mopidy-Local-Images

This Web client is used to serve album art extracted from local media files by the Mopidy-Local-Images extension.

To install, run:

```
pip install Mopidy-Local-Images
```

17.5 Mopidy-Material-Webclient

https://github.com/matgallacher/mopidy-material-webclient

A Mopidy web client with an Android Material design feel.
To install, run:

```
pip install Mopidy-Material-Webclient
```

### 17.6 Mopidy-Mobile

https://github.com/tkem/mopidy-mobile

A Mopidy web client extension and hybrid mobile app, made with Ionic, AngularJS and Apache Cordova by Thomas Kemmer.
To install, run:

```
pip install Mopidy-Mobile
```

## 17.7 Mopidy-Moped

https://github.com/martijnboland/moped

A Mopidy web client made with AngularJS by Martijn Boland.
To install, run:

```
pip install Mopidy-Moped
```

## 17.8 Mopidy-Mopify

[https://github.com/dirkgroenen/mopidy-mopify](https://github.com/dirkgroenen/mopidy-mopify)

A web client that uses external web services to provide additional features and a more “complete” Spotify music experience. It’s currently targeted at people using Spotify through Mopidy. Made by Dirk Groenen.
To install, run:

```
pip install Mopidy-Mopify
```

17.9 Mopidy-MusicBox-Webclient

https://github.com/pimusicbox/mopidy-musicbox-webclient

The first web client for Mopidy, made with jQuery Mobile by Wouter van Wijk. Also the web client used for Wouter’s popular Pi Musicbox image for Raspberry Pi.
To install, run:

```
pip install Mopidy-MusicBox-Webclient
```

## 17.10 Mopidy-Party

https://github.com/Lesterpig/mopidy-party

Minimal web client designed for collaborative music management during parties.
To install, run:

```
pip install Mopidy-Party
```

## 17.11 Mopidy-Simple-Webclient

https://github.com/xolox/mopidy-simple-webclient

A minimalistic web client targeted for mobile devices. Made with jQuery and Bootstrap by Peter Odding.
To install, run:

```
pip install Mopidy-Simple-Webclient
```

### 17.12 Mopidy-WebSettings

https://github.com/pimusicbox/mopidy-websettings

A web extension for changing settings. Used by the Pi MusicBox distribution for Raspberry Pi, but also usable for other projects.

### 17.13 Mopster

https://github.com/cowbell/mopster

Simple web client hosted online written in Ember.js and styled using basic Bootstrap by Wojciech Wnętrzak.
To use, just visit http://mopster.urizen.pl/.

17.14 Mopidy-Jukepi

https://github.com/meantimeit/jukepi

A Mopidy web client built with Backbone by connrs.
To install, run:

```
pip install Mopidy-Jukepi
```

## 17.15 Other web clients

There are also some other web clients for Mopidy that use the *HTTP JSON-RPC API* but are not installable using `pip`:

- Apollo Player

In addition, there are several web based MPD clients, which doesn’t use the *Mopidy-HTTP* frontend at all, but connect to Mopidy through our *Mopidy-MPD* frontend. For a list of those, see *MPD web clients*. 
CHAPTER 18

HTTP clients

See Web extensions.
This is a list of MPD clients we either know works well with Mopidy, or that we know won’t work well. For a more exhaustive list of MPD clients, see https://mpd.fandom.com/wiki/Clients.

Contents

- MPD console clients
  - ncmcpp
  - ncmpc
  - mpc
- MPD graphical clients
  - Cantata
  - GMPC
  - MPDel
  - Sonata
  - Theremin
- MPD Android clients
  - MPDroid
- MPD iOS clients
  - MPoD
  - MPaD
- MPD web clients
  - Rompr
19.1 MPD console clients

19.1.1 ncmpcpp

A console client that works well with Mopidy, and is regularly used by Mopidy developers.

Search does not work in the “Match if tag contains search phrase (regexes supported)” mode because the client tries to fetch all known metadata and do the search on the client side. The two other search modes works nicely, so this is not a problem.

With ncmpcpp <= 0.5, the library view is very slow when used together with Mopidy-Spotify. A workaround is to edit the ncmpcpp configuration file (~/.ncmpcpp/config) and set:

```bash
media_library_display_date = "no"
```

With this change ncmpcpp’s library view will still be a bit slow, but usable.

Note that this option was removed in ncmpcpp 0.6, but with this version, the library view works well without it.
19.1.2 ncmpc

A console client. Works with Mopidy 0.6 and upwards. Uses the idle MPD command, but in a resource inefficient way.

19.1.3 mpc

A command line client. Version 0.16 and upwards seems to work nicely with Mopidy.

19.2 MPD graphical clients

19.2.1 Cantata

Cantata is a graphical MPD client with support for Linux, mac OS, and Windows.

![Cantata](image)

19.2.2 GMPC

GMPC is a graphical MPD client (GTK+) which works well with Mopidy.
GMPC may sometimes requests a lot of meta data of related albums, artists, etc. This takes more time with Mopidy, which needs to query Spotify for the data, than with a normal MPD server, which has a local cache of meta data. Thus, GMPC may sometimes feel frozen, but usually you just need to give it a bit of slack before it will catch up.

19.2.3 MPDel

MPDel is an MPD client working within Emacs.
19.2.4 Sonata

Sonata is a graphical MPD client (GTK+). It generally works well with Mopidy, except for search.
When you search in Sonata, it only sends the first two letters of the search query to Mopidy, and then does the rest of the filtering itself on the client side. Since Spotify has a collection of millions of tracks and they only return the first 100 hits for any search query, searching for two-letter combinations seldom returns any useful results. See #1 for details.

19.2.5 Theremin

Theremin is a graphical MPD client for OS X. It is unmaintained, but generally works well with Mopidy.
19.3 MPD Android clients

19.3.1 MPDroid

You can get MPDroid from Google Play.

MPDroid is a good MPD client, and really the only one we can recommend.
19.4 MPD iOS clients

19.4.1 MPoD

The MPoD iPhone/iPod Touch app can be installed from MPoD at iTunes Store.
19.4.2 MPaD

![MPaD iPad app](image)

The MPaD iPad app can be purchased from MPaD at iTunes Store

19.5 MPD web clients

The following web clients use the MPD protocol to communicate with Mopidy. For other web clients, see *HTTP clients*. 
19.5.1 Rompr

Rompr is a web based MPD client. mrvanes, a Mopidy and Rompr user, said: “These projects are a real match made in heaven.”

19.5.2 Partify

Partify is a web based MPD client focussing on making music playing collaborative and social.
MPRIS is short for Media Player Remote Interfacing Specification. It is a spec that describes a standard D-Bus interface for making media players available to other applications on the same system.

See the Mopidy-MPRIS documentation for a survey of some MPRIS clients.
UPnP is a set of specifications for media sharing, playing, remote control, etc, across a home network. The specs are supported by a lot of consumer devices (like smartphones, TVs, Xbox, and PlayStation) that are often labeled as being DLNA compatible or certified.

The DLNA guidelines and UPnP specifications defines several device roles, of which Mopidy may play two:

DLNA Digital Media Server (DMS) / UPnP AV MediaServer:
A MediaServer provides a library of media and is capable of streaming that media to a MediaRenderer. If Mopidy was a MediaServer, you could browse and play Mopidy’s music on a TV, smartphone, or tablet supporting UPnP. Mopidy does not currently support this, but we may in the future. #52 is the relevant wishlist issue.

DLNA Digital Media Renderer (DMR) / UPnP AV MediaRenderer:
A MediaRenderer is asked by some remote controller to play some given media, typically served by a MediaServer. If Mopidy was a MediaRenderer, you could use e.g. your smartphone or tablet to make Mopidy play media. Mopidy does already have experimental support for being a MediaRenderer, as you can read more about below.

### 21.1 Mopidy as an UPnP MediaRenderer

There are two ways Mopidy can be made available as an UPnP MediaRenderer: Using Mopidy-MPRIS and Rygel, or using Mopidy-MPD and upmpdcli.

#### 21.1.1 Mopidy-MPD and upmpdcli

upmpdcli is recommended, since it is easier to setup, and offers OpenHome compatibility. upmpdcli exposes a UPnP MediaRenderer to the network, while using the MPD protocol to control Mopidy.

1. Install upmpdcli. On Debian/Ubuntu:
apt-get install upmpdcli

Alternatively, follow the instructions from the upmpdcli website.

2. The default settings of upmpdcli will work with the default settings of Mopidy-MPD. Edit /etc/upmpdcli.conf if you want to use different ports, hosts, or other settings.

3. Start upmpdcli using the command:

upmpdcli

Or, run it in the background as a service:

sudo service upmpdcli start

4. A UPnP renderer should be available now.

21.1.2 Mopidy-MPRIS and Rygel

See the Mopidy-MPRIS documentation for how to setup Rygel to make Mopidy an UPnP MediaRenderer.

21.2 Clients

For a long list of UPnP clients for all possible platforms, see Wikipedia’s List of UPnP AV media servers and clients.
Mopidy is copyright 2009-2018 Stein Magnus Jodal and contributors. Mopidy is licensed under the Apache License, Version 2.0.

If you want to help us making Mopidy better, the best way to do so is to contribute back to the community, either through code, documentation, tests, bug reports, or by helping other users, spreading the word, etc. See Contributing for a head start.
The Mopidy project would like to thank the following sponsors for supporting the project.

### 23.1 Rackspace

Rackspace lets Mopidy use their hosting services for free. We use their services for the following sites:

### 23.2 Fastly

Fastly lets Mopidy use their CDN for free. We accelerate requests to most Mopidy services, including:

- https://apt.mopidy.com/dists/, which is used to distribute Debian packages.

### 23.3 Discourse

Discourse sponsors Mopidy with free hosting of our discussion forum at https://discourse.mopidy.com.
Mopidy follows Semantic Versioning. In summary this means that our version numbers have three parts, MAJOR.MINOR.PATCH, which change according to the following rules:

- When we make incompatible API changes, we increase the MAJOR number.
- When we add features in a backwards-compatible manner, we increase the MINOR number.
- When we fix bugs in a backwards-compatible manner, we increase the PATCH number.

The promise is that if you make a Mopidy extension for Mopidy 1.0, it should work unchanged with any Mopidy 1.x release, but probably not with 2.0. When a new major version is released, you must review the incompatible changes and update your extension accordingly.

### 24.1 Release schedule

We intend to have about one feature release every month in periods of active development. The features added is a mix of what we feel is most important/requested of the missing features, and features we develop just because we find them fun to make, even though they may be useful for very few users or for a limited use case.

Bugfix releases will be released whenever we discover bugs that are too serious to wait for the next feature release. We will only release bugfix releases for the last feature release. E.g. when 1.2.0 is released, we will no longer provide bugfix releases for the 1.1.x series. In other words, there will be just a single supported release at any point in time. This is to not spread our limited resources too thin.
This changelog is used to track all major changes to Mopidy.
For older releases, see History.

25.1 v2.2.3 (2019-06-20)

Bug fix release.

- Audio: Fix switching between tracks with different sample rates. (Fixes: #1528, PR: #1735)
- Audio: Prevent buffering handling interfering with track changes. (Fixes: #1722, PR: #1740)
- Local: Add .pdf and .zip to the default local/excluded_file_extensions config value. (PR: #1737)
- File: Synchronised the default file/excluded_file_extensions config values with local/excluded_file_extensions. (PR: #1743)
- Stream: Fix error when playing stream from .pls playlist with quoted URLs. (Fixes: #1770, PR: #1771)
- Docs: Resize and compress images, reducing the release tarball size from 3.5 to 1.1 MB.
- Docs: Fix broken links.

25.2 v2.2.2 (2018-12-29)

Bug fix release.

- HTTP: Fix hang on exit due to change in Tornado v5.0 IOLoop. (Fixes: #1715, PR: #1716)
- Files: Fix crash due to mix of text and bytes in paths that come from $XDG_CONFIG_HOME/user-dirs. (Fixes: #1676, #1725)
25.3 v2.2.1 (2018-10-15)

Bug fix release.

- HTTP: Stop blocking connections where the network location part of the Origin header is empty, such as WebSocket connections originating from local files. (Fixes: #1711, PR: #1712)

- HTTP: Add new config value `http/csrf_protection` which enables all CSRF protections introduced in Mopidy 2.2.0. It is enabled by default and should only be disabled by those users who are unable to set a Content-Type: application/json request header or cannot utilise the `http/allowed_origins` config value. (Fixes: #1713, PR: #1714)

25.4 v2.2.0 (2018-09-30)

Mopidy 2.2.0, a feature release, is out. It is a quite small release, featuring mostly minor fixes and improvements.

Most notably, this release introduces CSRF protection for both the HTTP and WebSocket RPC interfaces, and improves the file path checking in the M3U backend. The CSRF protection should stop attacks against local Mopidy servers from malicious websites, like what was demonstrated by Josef Gajdusek in #1659.

Since the release of 2.1.0, we’ve closed approximately 21 issues and pull requests through 133 commits by 22 authors.

- Dependencies: Drop support for Tornado < 4.4. Though strictly a breaking change, this shouldn’t affect any supported systems as even Debian stable includes Tornado >= 4.4.

- Core: Remove upper limit of 10000 tracks in tracklist. 10000 tracks is still the default limit as some MPD clients crash if the tracklist is longer, but it is now possible to set the `core/max_tracklist_length` config value as high as you want to. (Fixes: #1600, PR: #1666)

- Core: Fix crash on `library.lookup(uris=[])`. (Fixes: #1619, PR: #1620)

- Core: Define return value of `playlists.delete()` to be a bool, True on success, False otherwise. (PR: #1702)

- M3U: Ignore all attempts at accessing files outside the `m3u/playlist_dir`. (Partly fixes: #1659, PR: #1702)

- File: Change default ordering to show directories first, then files. (PR: #1595)

- File: Fix extraneous encoding of path. (PR: #1611)

- HTTP: Protect RPC and WebSocket interfaces against CSRF by blocking requests that originate from servers other than those specified in the new config value `http/allowed_origins`. An artifact of this is that all JSON-RPC requests must now always set the header Content-Type: application/json. (Partly fixes: #1659, PR: #1668)

- MPD: Added `idle` to the list of available commands. (Fixes: #1593, PR: #1597)

- MPD: Added Unix domain sockets for binding MPD to. (Fixes: #1531, PR: #1629)

- MPD: Lookup track metadata for MPD `load` and `listplaylistinfo`. (Fixes: #1511, PR: #1621)

- Ensure that decoding of OS errors with unknown encoding never crashes, but instead replaces unknown bytes with a replacement marker. (Fixes: #1599)

- Set GLib program and application name, so that we show up as “Mopidy” in PulseAudio instead of “python …”. (PR: #1626)
Mopidy 2.1.0, a feature release, is finally out!

Since the release of 2.0.0, it has been quiet times in Mopidy circles. This is mainly caused by core developers moving from the enterprise to startups or into positions with more responsibility, and getting more kids. Of course, this has greatly decreased the amount of spare time available for open source work. But fear not, Mopidy is not dead. We’ve returned from year long periods with close to no activity before, and will hopefully do so again.

Despite all, we’ve closed or merged approximately 18 issues and pull requests through about 170 commits since the release of v2.0.1 back in August.

The major new feature in Mopidy 2.1 is support for restoring playback state and the current playlist after a restart. This feature was contributed by Jens Lütjen.

- Dependencies: Drop support for Tornado < 3.2. Though strictly a breaking change, this shouldn’t have any effect on what systems we support, as Tornado 3.2 or newer is available from the distros that include GStreamer >= 1.2.3, which we already require.
- Core: Mopidy restores its last state when started. Can be enabled by setting the config value `core/restore_state` to `true`.
- Audio: Update scanner to handle sources such as RTSP. (Fixes: #1479)
- Audio: The scanner set the date to `mopidy.models.Track.date` and `mopidy.models.Album.date` (Fixes: #1741)
- File: Add new config value `file/excluded_file_extensions`.
- Local: Skip hidden directories directly in `media_dir` (Fixes: #1559, PR: #1555)
- MPD: Fix MPD protocol for `replay_gain_status` command. The actual command remains unimplemented. (PR: #1520)
- MPD: Add `nextsong` and `nextsongid` to the response of MPD `status` command. (Fixes: #1133, #1516, PR: #1523)
- MPD: Fix inconsistent playlist state after playlist is emptied with repeat and consume mode turned on. (Fixes: #1512, PR: #1549)
- Audio: Improve handling of duration in scanning. VBR tracks should fail less frequently and MMS works again. (Fixes: #1553, PR #1575, #1576, #1577)

25.6 v2.0.1 (2016-08-16)

Bug fix release.

- Audio: Set `soft-volume` flag on GStreamer’s playbin element. This is the playbin’s default, but we managed to override it when configuring the playbin to only process audio. This should fix the “Volume/mute is not available” warning.
- Audio: Fix buffer conversion. This fixes image extraction. (Fixes: #1469, PR: #1472)
- Audio: Update scan logic to workaround GStreamer issue where tags and duration might only be available after we start playing. (Fixes: #935, #1453, #1474, #1480, PR: #1487)
- Audio: Better handling of seek when position does not match the expected pending position. (Fixes: #1462, #1505, PR: #1496)
- Audio: Handle bad date tags from audio, thanks to Mario Lang and Tom Parker who fixed this in parallel. (Fixes: #1506, PR: #1525, #1517)
• Audio: Make sure scanner handles streams without a duration. (Fixes: #1526)
• Audio: Ensure audio tags are never None. (Fixes: #1449)
• Audio: Update mopidy.audio.Audio.set_metadata() to postpone sending tags if there is a pending track change. (Fixes: #1357, PR: #1538)
• Core: Avoid endless loop if all tracks in the tracklist are unplayable and consume mode is off. (Fixes: #1221, #1454, PR: #1455)
• Core: Correctly record the last position of a track when switching to another one. Particularly relevant for Mopidy-Scrobbler users, as before it was essentially unusable. (Fixes: #1456, PR: #1534)
• Models: Fix encoding error if Identifier fields, like the musicbrainz_id model fields, contained non-ASCII Unicode data. (Fixes: #1508, PR: #1546)
• File: Ensure path comparison is done between bytestrings only. Fixes crash where a file/media_dirs path contained non-ASCII characters. (Fixes: #1345, PR: #1493)
• Stream: Fix milliseconds vs seconds mistake in timeout handling. (Fixes: #1521, PR: #1522)
• Docs: Fix the rendering of mopidy.core.Core and mopidy.audio.Audio docs. This should also contribute towards making the Mopidy Debian package build bit-by-bit reproducible. (Fixes: #1500)

25.7 v2.0.0 (2016-02-15)

Mopidy 2.0 is here!

Since the release of 1.1, we’ve closed or merged approximately 80 issues and pull requests through about 350 commits by 14 extraordinary people, including 10 newcomers. That’s about the same amount of issues and commits as between 1.0 and 1.1. The number of contributors is a bit lower but we didn’t have a real life sprint during this development cycle. Thanks to everyone who has contributed!

With the release of Mopidy 1.0 we promised that any extension working with Mopidy 1.0 should continue working with all Mopidy 1.x releases. Mopidy 2.0 is quite a friendly major release and will only break a single extension that we know of: Mopidy-Spotify. To ensure that everything continues working, please upgrade to Mopidy 2.0 and Mopidy-Spotify 3.0 at the same time.

No deprecated functionality has been removed in Mopidy 2.0.

The major features of Mopidy 2.0 are:

• Gapless playback has been mostly implemented. It works as long as you don’t change tracks in the middle of a track or use previous and next. In a future release, previous and next will also become gapless. It is now quite easy to have Mopidy streaming audio over the network using Icecast. See the updated Streaming through Icecast docs for details of how to set it up and workarounds for the remaining issues.
• Mopidy has upgraded from GStreamer 0.10 to 1.x. This has been in our backlog for more than three years. With this upgrade we’re ridding ourselves of years of GStreamer bugs that have been fixed in newer releases, we can get into Debian testing again, and we’ve removed the last major roadblock for running Mopidy on Python 3.

25.7.1 Dependencies

• Mopidy now requires GStreamer >= 1.2.3, as we’ve finally ported from GStreamer 0.10. Since we’re requiring a new major version of our major dependency, we’re upping the major version of Mopidy too. (Fixes: #225)
25.7.2 Core API

• Start \texttt{tlid} counting at 1 instead of 0 to keep in sync with MPD's \texttt{songid}.

• \texttt{get_time_position()} now returns the seek target while a seek is in progress. This gives better results than just failing the position query. (Fixes: \#312 PR: \#1346)

• Add \texttt{mopidy.core.PlaylistsController.get_uri_schemes()}. (PR: \#1362)

• The \texttt{track_playback_ended} event now includes the correct \texttt{tl_track} reference when changing to the next track in consume mode. (Fixes: \#1402 PR: \#1403 PR: \#1406)

25.7.3 Models

• Deprecated: \texttt{mopidy.models.Album.images} is deprecated. Use \texttt{mopidy.core.LibraryController.get_images()} instead. (Fixes: \#1325)

25.7.4 Extension support

• Log exception and continue if an extension crashes during setup. Previously, we let Mopidy crash if an extension's setup crashed. (PR: \#1337)

25.7.5 Local backend

• Made \texttt{local/data\_dir} really deprecated. This change breaks older versions of Mopidy-Local-SQLite and Mopidy-Local-Images.

25.7.6 M3U backend

• Add \texttt{m3u/base\_dir} for resolving relative paths in M3U files. (Fixes: \#1428, PR: \#1442)

• Derive track name from file name for non-extended M3U playlists. (Fixes: \#1364, PR: \#1369)

• Major refactoring of the M3U playlist extension. (Fixes: \#1370 PR: \#1386)
  – Add \texttt{m3u/default\_encoding} and \texttt{m3u/default\_extension} config values for improved text encoding support.
  – No longer scan playlist directory and parse playlists at startup or refresh. Similarly to the file extension, this now happens on request.
  – Use \texttt{mopidy.models.Ref} instances when reading and writing playlists. Therefore, \texttt{Track.length} is no longer stored in extended M3U playlists and \texttt{EXTINF} runtime is always set to -1.
  – Improve reliability of playlist updates using the core playlist API by applying the write-replace pattern for file updates.

25.7.7 Stream backend

• Make sure both lookup and playback correctly handle playlists and our blacklist support. (Fixes: \#1445, PR: \#1447)
25.7.8 MPD frontend

- Implemented commands for modifying stored playlists:
  - playlistadd
  - playlistclear
  - playlistdelete
  - playlistmove
  - rename
  - rm
  - save
  (Fixes: #1014, PR: #1187, #1308, #1322)
- Start songid counting at 1 instead of 0 to match the original MPD server.
- Idle events are now emitted on seeked events. This fix means that clients relying on idle events now get notified about seeks. (Fixes: #1331, PR: #1347)
- Idle events are now emitted on playlists_loaded events. This fix means that clients relying on idle events now get notified about playlist loads. (Fixes: #1331, PR: #1347)
- Event handler for playlist_deleted has been unbroken. This unreported bug would cause the MPD frontend to crash preventing any further communication via the MPD protocol. (PR: #1347)

25.7.9 Zeroconf

- Require stype argument to mopidy.zeroconf.Zeroconf.
- Use Avahi’s interface selection by default. (Fixes: #1283)
- Use Avahi server’s hostname instead of socket.getfqdn() in service display name.

25.7.10 Cleanups

- Removed warning if ~/.mopidy exists. We stopped using this location in 0.6, released in October 2011.
- Removed warning if ~/.config/mopidy/settings.py exists. We stopped using this settings file in 0.14, released in April 2013.
- The on_event handler in our listener helper now catches exceptions. This means that any errors in event handling won’t crash the actor in question.
- Catch errors when loading logging/config_file. (Fixes: #1320)
- Breaking: Removed unused internal mopidy.internal.process.BaseThread. This breaks Mopidy-Spotify 1.4.0. Versions < 1.4.0 was already broken by Mopidy 1.1, while versions >= 2.0 doesn’t use this class.

25.7.11 Audio

- Breaking: The audio scanner now returns ISO-8601 formatted strings instead of datetime objects for dates found in tags. Because of this change, we can now return years without months or days, which matches the semantics of the date fields in our data models.
• **Breaking**: `mopidy.audio.Audio.set_appsrc()`’s `caps` argument has changed format due to the upgrade from GStreamer 0.10 to GStreamer 1. As far as we know, this is only used by Mopidy-Spotify. As an example, with GStreamer 0.10 the Mopidy-Spotify caps was:

```
audio/x-raw-int, endianness=(int)1234, channels=(int)2, width=(int)16, depth=(int)16, signed=(boolean)true, rate=(int)44100
```

With GStreamer 1 this changes to:

```
audio/x-raw, format=S16LE, rate=44100, channels=2, layout=interleaved
```

If your Mopidy backend uses `set_appsrc()`, please refer to GStreamer documentation for details on the new caps string format.

• **Breaking**: `mopidy.audio.utils.create_buffer()`’s `capabilities` argument is no longer in use and has been removed. As far as we know, this was only used by Mopidy-Spotify.

• Duplicate seek events getting to `appsrc` based backends is now fixed. This should prevent seeking in Mopidy-Spotify from glitching. (Fixes: #1404)

• Workaround crash caused by a race that does not seem to affect functionality. This should be fixed properly together with #1222. (Fixes: #1430, PR: #1438)

• Add a new config option, `audio/buffer_time`, for setting the buffer time of the GStreamer queue. If you experience buffering before track changes, it may help to increase this. (Workaround for #1409)

• `tags_changed` events are only emitted for fields that have changed. Previous behavior was to emit this for all fields received from GStreamer. (PR: #1439)

### 25.7.12 Gapless

• Add partial support for gapless playback. Gapless now works as long as you don’t change tracks or use `next/previous`. (PR: #1288)

The *Streaming through Icecast* docs has been updated with the workarounds still needed to properly stream Mopidy audio through Icecast.

• Core playback has been refactored to better handle gapless, and async state changes.

• Tests have been updated to always use a core actor so async state changes don’t trip us up.

• Seek events are now triggered when the seek completes. Previously the event was emitted when the seek was requested, not when it completed. Further changes have been made to make seek work correctly for gapless related corner cases. (Fixes: #1305 PR: #1346)
These are the changelogs for historical releases of Mopidy.
For the latest releases, see Changelog.

26.1 Changelog 1.x series

This is the changelog of Mopidy v1.0.0 through v1.1.2.
For the latest releases, see Changelog.

26.1.1 v1.1.2 (2016-01-18)

Bug fix release.

- Main: Catch errors when loading the logging/config_file file. (Fixes: #1320)
- Core: If changing to another track while the player is paused, the new track would not be added to the history or marked as currently playing. (Fixes: #1352, PR: #1356)
- Core: Skips over unplayable tracks if the user attempts to change tracks while paused, like we already did if in playing state. (Fixes #1378, PR: #1379)
- Core: Make lookup() ignore tracks with empty URIs. (Partly fixes: #1340, PR: #1381)
- Core: Fix crash if backends emits events with wrong names or arguments. (Fixes: #1383)
- Stream: If an URI is considered playable, don’t consider it as a candidate for playlist parsing. Just looking at MIME type prefixes isn’t enough, as for example Ogg Vorbis has the MIME type application/ogg. (Fixes: #1299)
- Local: If the scan or clear commands are used on a library that does not exist, exit with an error. (Fixes: #1298)
- MPD: Notify idling clients when a seek is performed. (Fixes: #1331)
- MPD: Don’t return tracks with empty URIs. (Partly fixes: #1340, PR: #1343)
• MPD: Add `volume` command that was reintroduced, though still as a deprecated command, in MPD 0.18 and is in use by some clients like mpc. (Fixes: #1393, PR: #1397)
• Proxy: Handle case where `proxy/port` is either missing from config or set to an empty string. (PR: #1371)

26.1.2 v1.1.1 (2015-09-14)

Bug fix release.

• Dependencies: Specify that we need Requests >= 2.0, not just any version. This ensures that we fail earlier if Mopidy is used with a too old Requests.
• Core: Make `mopidy.core.LibraryController.refresh()` work for all backends with a library provider. Previously, it wrongly worked for all backends with a playlists provider. (Fixes: #1257)
• Core: Respect `core/cache_dir` and `core/data_dir` config values added in 1.1.0 when creating the dirs Mopidy need to store data. This should not change the behavior for desktop users running Mopidy. When running Mopidy as a system service installed from a package which sets the core dir configs properly (e.g. Debian and Arch packages), this fix avoids the creation of a couple of directories that should not be used, typically `/var/lib/mopidy/.local` and `/var/lib/mopidy/.cache`. (Fixes: #1259, PR: #1266)
• Core: Fix error in `get_eot_tlid()` docstring. (Fixes: #1269)
• Audio: Add `timeout` parameter to `scan()`. (Part of: #1250, PR: #1281)
• Extension support: Make `get_cache_dir()`, `get_config_dir()`, and `get_data_dir()` class methods, so they can be used without creating an instance of the `Extension` class. (Fixes: #1275)
• Local: Deprecate `local/data_dir` and respect `core/data_dir` instead. This does not change the defaults for desktop users, only system services installed from packages that properly set `core/data_dir`, like the Debian and Arch packages. (Fixes: #1259, PR: #1266)
• Local: Change default value of `local/scan_flush_threshold` from 1000 to 100 to shorten the time Mopidy-Local-SQLite blocks incoming requests while scanning the local library.
• M3U: Changed default for the `m3u/playlists_dir` from `$XDG_DATA_DIR/mopidy/m3u` to unset, which now means the extension’s data dir. This does not change the defaults for desktop users, only system services installed from packages that properly set `core/data_dir`, like the Debian and Arch packages. (Fixes: #1259, PR: #1266)
• Stream: Expand nested playlists to find the stream URI. This used to work, but regressed in 1.1.0 with the extraction of stream playlist parsing from GStreamer to being handled by the Mopidy-Stream backend. (Fixes: #1250, PR: #1281)
• Stream: If “file” is present in the `stream/protocols` config value and the `Mopidy-File` extension is enabled, we exited with an error because two extensions claimed the same URI scheme. We now log a warning recommending to remove “file” from the `stream/protocols` config, and then proceed startup. (Fixes: #1248, PR: #1254)
• Stream: Fix bug in new playlist parser. A non-ASCII char in an urlist comment would cause a crash while parsing due to comparison of a non-ASCII bytestring with a Unicode string. (Fixes: #1265)
• File: Adjust log levels when failing to expand `$XDG_MUSIC_DIR` into a real path. This usually happens when running Mopidy as a system service, and thus with a limited set of environment variables. (Fixes: #1249, PR: #1255)
• File: When browsing files, we no longer scan the files to check if they’re playable. This makes browsing of the file hierarchy instant for HTTP clients, which do no scanning of the files’ metadata, and a bit faster for MPD clients, which no longer scan the files twice. (Fixes: #1260, PR: #1261)
• File: Allow looking up metadata about any file:// URI, just like we did in Mopidy 1.0.x, where Mopidy-Stream handled file:// URIs. In Mopidy 1.1.0, Mopidy-File did not allow one to lookup files outside the directories listed in file/media_dir. This broke Mopidy-Local-SQLite when the local/media_dir directory was not within one of the file/media_dirs directories. For browsing of files, we still limit access to files inside the file/media_dir directories. For lookup, you can now read metadata for any file you know the path of. (Fixes: #1268, PR: #1273)

• Audio: Fix timeout handling in scanner. This regression caused timeouts to expire before it should, causing scans to fail.

• Audio: Update scanner to emit MIME type instead of an error when missing a plugin.

26.1.3 v1.1.0 (2015-08-09)

Mopidy 1.1 is here!

Since the release of 1.0, we’ve closed or merged approximately 65 issues and pull requests through about 400 commits by a record high 20 extraordinary people, including 14 newcomers. That’s less issues and commits than in the 1.0 release, but even more contributors, and a doubling of the number of newcomers. Thanks to everyone who has contributed, especially those that joined the sprint at EuroPython 2015 in Bilbao, Spain a couple of weeks ago!

As we promised with the release of Mopidy 1.0, any extension working with Mopidy 1.0 should continue working with all Mopidy 1.x releases. However, this release brings a lot stronger enforcement of our documented APIs. If an extension doesn’t use the APIs properly, it may no longer work. The advantage of this change is that Mopidy is now more robust against errors in extensions, and also provides vastly better error messages when extensions misbehave. This should make it easier to create quality extensions.

The major features of Mopidy 1.1 are:

• Validation of the arguments to all core API methods, as well as all responses from backends and all data model attributes.

• New bundled backend, Mopidy-File. It is similar to Mopidy-Local, but allows you to browse and play music from local disk without running a scan to index the music first. The drawback is that it doesn’t support searching.

• The Mopidy-MPD server should now be up to date with the 0.19 version of the MPD protocol.

Dependencies

• Mopidy now requires Requests.

• Heads up: Porting from GStreamer 0.10 to 1.x and support for running Mopidy with Python 3.4+ is not far off on our roadmap.

Core API

• Deprecated: Calling the following methods with kwargs is being deprecated. (PR: #1090)
  - mopidy.core.LibraryController.search()
  - mopidy.core.PlaylistsController.filter()
  - mopidy.core.TracklistController.filter()
  - mopidy.core.TracklistController.remove()

• Updated core controllers to handle backend exceptions in all calls that rely on multiple backends. (Issue: #667)

• Update core methods to do strict input checking. (Fixes: #700)
• Add `tlid` alternatives to methods that take `tl_track` and also add `get_{eot, next, previous}_tlid` methods as light weight alternatives to the `tl_track` versions of the calls. (Fixes: #1131, PR: #1136, #1140)

• Add `mopidy.core.PlaybackController.get_current_tlid()`. (Part of: #1137)

• Update core to handle backend crashes and bad data. (Fixes: #1161)

• Add `core/max_tracklist_length` config and limitation. (Fixes: #997 PR: #1225)

• Added `playlist_deleted` event. (Fixes: #996)

Models

• Added type checks and other sanity checks to model construction and serialization. (Fixes: #865)

• Memory usage for models has been greatly improved. We now have a lower overhead per instance by using slots, interned identifiers and automatically reuse instances. For the test data set this was developed against, a library of ~14,000 tracks, went from needing ~75MB to ~17MB. (Fixes: #348)

• Added `mopidy.models.Artist.sortname` field that is mapped to `musicbrainz-sortname` tag. (Fixes: #940)

Configuration

• Add new configurations to set base directories to be used by Mopidy and Mopidy extensions: `core/cache_dir`, `core/config_dir`, and `core/data_dir`. (Fixes: #843, PR: #1232)

Extension support

• Add new methods to `Extension` class for getting cache, config and data directories specific to your extension:
  
  – `mopidy.ext.Extension.get_cache_dir()`
  
  – `mopidy.ext.Extension.get_config_dir()`
  
  – `mopidy.ext.Extension.get_data_dir()`

  Extensions should use these methods so that the correct directories are used both when Mopidy is run by a regular user and when run as a system service. (Fixes: #843, PR: #1232)

• Add `mopidy.httpclient.format_proxy()` and `mopidy.httpclient.format_user_agent()`. (Part of: #1156)

• It is now possible to import `mopidy.backends` without having GObject or GStreamer installed. In other words, a lot of backend extensions should now be able to run tests in a virtualenv with global site-packages disabled. This removes a lot of potential error sources. (Fixes: #1068, PR: #1115)

Local backend

• Filter out `None` from `get_distinct()` results. All returned results should be strings. (Fixes: #1202)

Stream backend

• Move stream playlist parsing from GStreamer to the stream backend. (Fixes: #671)
File backend

The Mopidy-File backend is a new bundled backend. It is similar to Mopidy-Local since it works with local files, but it differs in a few key ways:

- Mopidy-File lets you browse your media files by their file hierarchy.
- It supports multiple media directories, all exposed under the “Files” directory when you browse your library with e.g. an MPD client.
- There is no index of the media files, like the JSON or SQLite files used by Mopidy-Local. Thus no need to scan the music collection before starting Mopidy. Everything is read from the file system when needed and changes to the file system is thus immediately visible in Mopidy clients.
- Because there is no index, there is no support for search.

Our long term plan is to keep this very simple file backend in Mopidy, as it has a well defined and limited scope, while splitting the more feature rich Mopidy-Local extension out to an independent project. (Fixes: #1004, PR: #1207)

M3U backend

- Support loading UTF-8 encoded M3U files with the .m3u8 file extension. (PR: #1193)

MPD frontend

- The MPD command `count` now ignores tracks with no length, which would previously cause a TypeError. (PR: #1192)
- Concatenate multiple artists, composers and performers using the “A;B” format instead of “A, B”. This is a part of updating our protocol implementation to match MPD 0.19. (PR: #1213)
- Add “not implemented” skeletons of new commands in the MPD protocol version 0.19:
  - Current playlist:
    * rangeid
    * addtagid
    * cleartagid
  - Mounts and neighbors:
    * mount
    * unmount
    * listmounts
    * listneighbors
  - Music DB:
    * listfiles
- Track data now include the Last-Modified field if set on the track model. (Fixes: #1218, PR: #1219)
- Implement tagtypes MPD command. (PR: #1235)
- Exclude empty tags fields from metadata output. (Fixes: #1045, PR: #1235)
- Implement protocol extensions to output Album URIs and Album Images when outputting track data to clients. (PR: #1230)
• The MPD commands `lsinfo` and `listplaylists` are now implemented using the `as_list()` method, which retrieves a lot less data and is thus much faster than the deprecated `get_playlists()`. The drawback is that the Last-Modified timestamp is not available through this method, and the timestamps in the MPD command responses are now always set to the current time.

Internal changes

• Tests have been cleaned up to stop using deprecated APIs where feasible. (Partial fix: #1083, PR: #1090)

26.1.4 v1.0.8 (2015-07-22)

Bug fix release.

• Fix reversal of Title and Name in MPD protocol (Fixes: #1212 PR: #1214)
• Fix crash if an M3U file in the `m3u/playlist_dir` directory has a file name not decodable with the current file system encoding. (Fixes: #1209)

26.1.5 v1.0.7 (2015-06-26)

Bug fix release.

• Fix error in the MPD command `list title ...`. The error was introduced in v1.0.6.

26.1.6 v1.0.6 (2015-06-25)

Bug fix release.

• Core/MPD/Local: Add support for title in `mopidy.core.LibraryController.get_distinct()` (Fixes: #1181, PR: #1183)
• Core: Make sure track changes make it to audio while paused. (Fixes: #1177, PR: #1185)

26.1.7 v1.0.5 (2015-05-19)

Bug fix release.

• Core: Add workaround for playlist providers that do not support creating playlists. (Fixes: #1162, PR: #1165)
• M3U: Fix encoding error when saving playlists with non-ASCII track titles. (Fixes: #1175, PR: #1176)

26.1.8 v1.0.4 (2015-04-30)

Bug fix release.

• Audio: Since all previous attempts at tweaking the queuing for #1097 seems to break things in subtle ways for different users. We are giving up on tweaking the defaults and just going to live with a bit more lag on software volume changes. (Fixes: #1147)
26.1.9 v1.0.3 (2015-04-28)

Bug fix release.

- HTTP: Another follow-up to the Tornado <3.0 fixing. Since the tests aren’t run for Tornado 2.3 we didn’t catch that our previous fix wasn’t sufficient. (Fixes: #1153, PR: #1154)
- Audio: Follow-up fix for #1097 still exhibits issues for certain setups. We are giving this get an other go by setting the buffer size to maximum 100ms instead of a fixed number of buffers. (Addresses: #1147, PR: #1154)

26.1.10 v1.0.2 (2015-04-27)

Bug fix release.

- HTTP: Make event broadcasts work with Tornado 2.3 again. The threading fix in v1.0.1 broke this.
- Audio: Fix for #1097 tuned down the buffer size in the queue. Turns out this can cause distortions in certain cases. Give this an other go with a more generous buffer size. (Addresses: #1147, PR: #1152)
- Audio: Make sure mute events get emitted by software mixer. (Fixes: #1146, PR: #1152)

26.1.11 v1.0.1 (2015-04-23)

Bug fix release.

- Core: Make the new history controller available for use. (Fixes: mopidy.js#6)
- Audio: Software volume control has been reworked to greatly reduce the delay between changing the volume and the change taking effect. (Fixes: #1097, PR: #1101)
- Audio: As a side effect of the previous bug fix, software volume is no longer tied to the PulseAudio application volume when using pulsesink. This behavior was confusing for many users and doesn’t work well with the plans for multiple outputs.
- Audio: Update scanner to decode all media it finds. This should fix cases where the scanner hangs on non-audio files like video. The scanner will now also let us know if we found any decodeable audio. (Fixes: #726, PR: issue:1124)
- HTTP: Fix threading bug that would cause duplicate delivery of WS messages. (PR: #1127)
- MPD: Fix case where a playlist that is present in both browse and as a listed playlist breaks the MPD frontend protocol output. (Fixes #1120, PR: #1142)

26.1.12 v1.0.0 (2015-03-25)

Three months after our fifth anniversary, Mopidy 1.0 is finally here!

Since the release of 0.19, we’ve closed or merged approximately 140 issues and pull requests through more than 600 commits by a record high 19 extraordinary people, including seven newcomers. Thanks to everyone who has contributed!

For the longest time, the focus of Mopidy 1.0 was to be another incremental improvement, to be numbered 0.20. The result is still very much an incremental improvement, with lots of small and larger improvements across Mopidy’s functionality.

The major features of Mopidy 1.0 are:

- **Semantic Versioning.** We promise to not break APIs before Mopidy 2.0. A Mopidy extension working with Mopidy 1.0 should continue to work with all Mopidy 1.x releases.
• Preparation work to ease migration to a cleaned up and leaner core API in Mopidy 2.0, and to give us some of
the benefits of the cleaned up core API right away.
• Preparation work to enable gapless playback in an upcoming 1.x release.

Dependencies

Since the previous release there are no changes to Mopidy’s dependencies. However, porting from GStreamer 0.10 to
1.x and support for running Mopidy with Python 3.4+ is not far off on our roadmap.

Core API

In the API used by all frontends and web extensions there is lots of methods and arguments that are now deprecated in
preparation for the next major release. With the exception of some internals that leaked out in the playback controller,
no core APIs have been removed in this release. In other words, most clients should continue to work unchanged when
upgrading to Mopidy 1.0. Though, it is strongly encouraged to review any use of the deprecated parts of the API as
those parts will be removed in Mopidy 2.0.

• **Deprecated:** Deprecate all Python properties in the core API. The previously undocumented getter and setter
methods are now the official API. This aligns the Python API with the WebSocket/JavaScript API. Python
frontends needs to be updated. WebSocket/JavaScript API users are not affected. (Fixes: #952)

• Add `mopidy.core.HistoryController` which keeps track of what tracks have been played. (Fixes:
#423, #1056, PR: #803, #1063)

• Add `mopidy.core.MixerController` which keeps track of volume and mute. (Fixes: #962)

Core library controller

• **Deprecated:** `mopidy.core.LibraryController.find_exact()`. Use `mopidy.core.
LibraryController.search()` with the `exact` keyword argument set to True.

• **Deprecated:** The `uri` argument to `mopidy.core.LibraryController.lookup()`. Use new `uris`
keyword argument instead.

• Add `exact` keyword argument to `mopidy.core.LibraryController.search()`.

• Add `uris` keyword argument to `mopidy.core.LibraryController.lookup()` which allows for
simpler lookup of multiple URIs. (Fixes: #1008, PR: #1047)

• Updated `mopidy.core.LibraryController.search()` and `mopidy.core.
LibraryController.find_exact()` to normalize and warn about malformed queries from clients.
(Fixes: #1067, PR: #1073)

• Add `mopidy.core.LibraryController.get_distinct()` for getting unique values for a given
field. (Fixes: #913, PR: #1022)

• Add `mopidy.core.LibraryController.get_images()` for looking up images for any URI that is
known to the backends. (Fixes #973, PR: #981, #992 and #1013)

Core playlist controller

• **Deprecated:** `mopidy.core.PlaylistsController.get_playlists()`. Use `as_list()` and
`get_items()` instead. (Fixes: #1057, PR: #1075)
• **Deprecated:** `mopidy.core.PlaylistsController.filter()`. Use `as_list()` and filter yourself.

• Add `mopidy.core.PlaylistsController.as_list()`. (Fixes: #1057, PR: #1075)

• Add `mopidy.core.PlaylistsController.get_items()`. (Fixes: #1057, PR: #1075)

**Core tracklist controller**

• **Removed:** The following methods were documented as internal. They are now fully private and unavailable outside the core actor. (Fixes: #1058, PR: #1062)
  - `mopidy.core.TracklistController.mark_played()`
  - `mopidy.core.TracklistController.mark_playing()`
  - `mopidy.core.TracklistController.mark_unplayable()`

• Add `uris` argument to `mopidy.core.TracklistController.add()` which allows for simpler addition of multiple URIs to the tracklist. (Fixes: #1060, PR: #1065)

**Core playback controller**

• **Removed:** Remove several internal parts that were leaking into the public API and was never intended to be used externally. (Fixes: #1070, PR: #1076)
  - `mopidy.core.PlaybackController.change_track()` is now internal.
  - Removed `on_error_step` keyword argument from `mopidy.core.PlaybackController.play()`.
  - Removed `clear_current_track` keyword argument to `mopidy.core.PlaybackController.stop()`.
  - Made the following event triggers internal:
    * `mopidy.core.PlaybackController.on_end_of_track()`
    * `mopidy.core.PlaybackController.on_stream_changed()`
    * `mopidy.core.PlaybackController.on_tracklist_changed()`
  - `mopidy.core.PlaybackController.set_current_tl_track()` is now internal.

• **Deprecated:** The old methods on `mopidy.core.PlaybackController` for volume and mute management have been deprecated. Use `mopidy.core.MixerController` instead. (Fixes: #962)

• When seeking while paused, we no longer change to playing. (Fixes: #939, PR: #1018)

• Changed `mopidy.core.PlaybackController.play()` to take the return value from `mopidy.backend.PlaybackProvider.change_track()` into account when determining the success of the `play()` call. (PR: #1071)

• Add `mopidy.core.Listener.stream_title_changed()` and `mopidy.core.PlaybackController.get_stream_title()` for letting clients know about the current title in streams. (PR: #938, #1030)
Backend API

In the API implemented by all backends there have been way fewer but somewhat more drastic changes with some methods removed and new ones being required for certain functionality to continue working. Most backends were already updated to be compatible with Mopidy 1.0 before the release. New versions of the backends will be released shortly after Mopidy itself.

Backend library providers

- **Removed**: Remove `mopidy.backend.LibraryProvider.find_exact()`.
- Add an `exact` keyword argument to `mopidy.backend.LibraryProvider.search()` to replace the old `find_exact()` method.

Backend playlist providers

- **Removed**: Remove default implementation of `mopidy.backend.PlaylistsProvider.playlists`. This is potentially backwards incompatible. (PR: #1046)
- Changed the API for `mopidy.backend.PlaylistsProvider`. Note that this change is not backwards compatible. These changes are important to reduce the Mopidy startup time. (Fixes: #1057, PR: #1075)
  - Add `mopidy.backend.PlaylistsProvider.as_list()`.
  - Add `mopidy.backend.PlaylistsProvider.get_items()`.
  - Remove `mopidy.backend.PlaylistsProvider.playlists` property.

Backend playback providers

- Changed the API for `mopidy.backend.PlaybackProvider`. Note that this change is not backwards compatible for certain backends. These changes are crucial to adding gapless in one of the upcoming releases. (Fixes: #1052, PR: #1064)
  - `mopidy.backend.PlaybackProvider.translate_uri()` has been added. It is strongly recommended that all backends migrate to using this API for translating “Mopidy URIs” to real ones for playback.
  - The semantics and signature of `mopidy.backend.PlaybackProvider.play()` has changed. The method is now only used to set the playback state to playing, and no longer takes a track.
    - Backends must migrate to `mopidy.backend.PlaybackProvider.translate_uri()` or `mopidy.backend.PlaybackProvider.change_track()` to continue working.
  - `mopidy.backend.PlaybackProvider.prepare_change()` has been added.

Models

- Add `mopidy.models.Image` model to be returned by `mopidy.core.LibraryController.get_images()`. (Part of #973)
- Change the semantics of `mopidy.models.Track.last_modified` to be milliseconds instead of seconds since Unix epoch, or a simple counter, depending on the source of the track. This makes it match the semantics of `mopidy.models.Playlist.last_modified`. (Fixes: #678, PR: #1036)
Commands

- Make the `mopidy` command print a friendly error message if the `gobject` Python module cannot be imported. (Fixes: #836)
- Add support for repeating the `-v` argument four times to set the log level for all loggers to the lowest possible value, including log records at levels lower than `DEBUG` too.
- Add path to the current `mopidy` executable to the output of `mopidy deps`. This make it easier to see that a user is using pip-installed Mopidy instead of APT-installed Mopidy without asking for which `mopidy` output.

Configuration

- Add support for the log level value `all` to the loglevels configurations. This can be used to show absolutely all log records, including those at custom levels below `DEBUG`.
- Add debug logging of unknown sections. (Fixes: #694, PR: #1002)

Logging

- Add custom log level `TRACE` (numerical level 5), which can be used by Mopidy and extensions to log at an even more detailed level than `DEBUG`.
- Add support for per logger color overrides. (Fixes: #808, PR: #1005)

Local backend

- Improve error logging for scanner. (Fixes: #856, PR: #874)
- Add symlink support with loop protection to file finder. (Fixes: #858, PR: #874)
- Add `--force` option for `mopidy local scan` for forcing a full rescan of the library. (Fixes: #910, PR: #1010)
- Stop ignoring `offset` and `limit` in searches when using the default JSON backed local library. (Fixes: #917, PR: #949)
- Removed double triggering of `playlists_loaded` event. (Fixes: #998, PR: #999)
- Cleanup and refactoring of local playlist code. Preserves playlist names better and fixes bug in deletion of playlists. (Fixes: #937, PR: #995 and rebased into #1000)
- Sort local playlists by name. (Fixes: #1026, PR: #1028)
- Moved playlist support out to a new extension, `Mopidy-M3U`.
- Deprecated: The config value `local/playlists_dir` is no longer in use and can be removed from your config.

Local library API

- Implementors of `mopidy.local.Library.lookup()` should now return a list of `Track` instead of a single track, just like the other `lookup()` methods in Mopidy. For now, returning a single track will continue to work. (PR: #840)
- Add support for giving local libraries direct access to tags and duration. (Fixes: #967)
• Add `mopidy.local.Library.get_images()` for looking up images for local URIs. (Fixes: #1031, PR: #1032 and #1037)

Stream backend

• Add support for HTTP proxies when doing initial metadata lookup for a stream. (Fixes #390, PR: #982)
• Add basic tests for the stream library provider.

M3U backend

• Mopidy-M3U is a new bundled backend. It provides the same M3U support as was previously part of the local backend. See Migrating from Mopidy-Local playlists for how to migrate your local playlists to work with the M3U backend. (Fixes: #1054, PR: #1066)
• In playlist names, replace “/”, which are illegal in M3U file names, with “|”. (PR: #1084)

MPD frontend

• Add support for blacklisting MPD commands. This is used to prevent clients from using `listall` and `listallinfo` which recursively lookup the entire “database”. If you insist on using a client that needs these commands change `mpd/command_blacklist`.
• Start setting the `Name` field with the stream title when listening to radio streams. (Fixes: #944, PR: #1030)
• Enable browsing of artist references, in addition to albums and playlists. (PR: #884)
• Switch the `list` command over to using the new method `mopidy.core.LibraryController.get_distinct()` for increased performance. (Fixes: #913)
• In stored playlist names, replace “/”, which are illegal, with “|” instead of a whitespace. Pipes are more similar to forward slash.
• Share a single mapping between names and URIs across all MPD sessions. (Fixes: #934, PR: #968)
• Add support for `toggleoutput` command. (PR: #1015)
• The `mixrampdb` and `mixrampdelay` commands are now known to Mopidy, but are not implemented. (PR: #1015)
• Fix crash on socket error when using a locale causing the exception’s error message to contain characters not in ASCII. (Fixes: issue:971, PR: #1044)

HTTP frontend

• Deprecated: Deprecated the `http/static_dir` config. Please make your web clients pip-installable Mopidy extensions to make it easier to install for end users.
• Prevent a race condition in WebSocket event broadcasting from crashing the web server. (PR: #1020)

Mixers

• Add support for disabling volume control in Mopidy entirely by setting the configuration `audio/mixer` to `none`. (Fixes: #936, PR: #1015, #1035)
Audio

• **Removed**: Support for visualizers and the `audio/visualizer` config value. The feature was originally added as a workaround for all the people asking for ncmpcpp visualizer support, and since we could get it almost for free thanks to GStreamer. But, this feature did never make sense for a server such as Mopidy.

• **Deprecated**: Deprecated `mopidy.audio.Audio.emit_end_of_stream()`. Pass a `None` buffer to `mopidy.audio.Audio.emit_data()` to end the stream. This should only affect Mopidy-Spotify.

• **Add** `mopidy.audio.AudioListener.tags_changed()`. Notifies core when new tags are found.

• **Add** `mopidy.audio.Audio.get_current_tags()` for looking up the current tags of the playing media.

• **Internal code cleanup within audio subsystem:**
  – Started splitting audio code into smaller better defined pieces.
  – Improved GStreamer related debug logging.
  – Provide better error messages for missing plugins.
  – Add foundation for trying to re-add multiple output support.
  – Add internal helper for converting GStreamer data types to Python.
  – Reduce scope of audio scanner to just find tags and duration. Modification time, URI and minimum length handling are now outside of this class.
  – Update scanner to operate with milliseconds for duration.
  – Update scanner to use a custom source, typefind and decodebin. This allows us to detect playlists before we try to decode them.
  – Refactored scanner to create a new pipeline per track, this is needed as resetting decodebin is much slower than tearing it down and making a fresh one.

• Move and rename helper for converting tags to tracks.

• Ignore albums without a name when converting tags to tracks.

• Support UTF-8 in M3U playlists. (Fixes: #853)

• Add workaround for volume not persisting across tracks on OS X. (Issue: #886, PR: #958)

• Improved missing plugin error reporting in scanner. (PR: #1033)

• Introduced a new return type for the scanner, a named tuple with `uri`, `tags`, `duration`, `seekable` and `mime`. (PR: #1033)

• Added support for checking if the media is seekable, and getting the initial MIME type guess. (PR: #1033)

Mopidy.js client library

This version has been released to npm as Mopidy.js v0.5.0.

• Reexport When.js library as `Mopidy.when`, to make it easily available to users of Mopidy.js. (Fixes: `mopidy.js#1`)

• Default to `wss://` as the WebSocket protocol if the page is hosted on `https://`. This has no effect if the `webSocketUrl` setting is specified. (Pull request: `mopidy.js#2`)

• Upgrade dependencies.
Development

- Add new contribution guidelines.
- Add new development guide.
- Speed up event emitting.
- Changed test runner from nose to py.test. (PR: #1024)

26.2 Changelog 0.x series

This is the changelog of Mopidy v0.1.0a0 through v0.19.5.
For the latest releases, see Changelog.

26.2.1 v0.19.5 (2014-12-23)

Today is Mopidy’s five year anniversary. We’re celebrating with a bugfix release and are looking forward to the next five years!

- Config: Support UTF-8 in extension’s default config. If an extension with non-ASCII characters in its default config was installed, and Mopidy didn’t already have a config file, Mopidy would crashed when trying to create the initial config file based on the default config of all available extensions. (Fixes: discourse.mopidy.com/t/428)
- Extensions: Fix crash when unpacking data from pkg_resources.VersionConflict created with a single argument. (Fixes: #911)
- Models: Hide empty collections from repr() representations.
- Models: Field values are no longer stored on the model instance when the value matches the default value for the field. This makes two models equal when they have a field which in one case is implicitly set to the default value and in the other case explicitly set to the default value, but with otherwise equal fields. (Fixes: #837)
- Models: Changed the default value of mopidy.models.Album.num_tracks, mopidy.models.Track.track_no, and mopidy.models.Track.last_modified from 0 to None.
- Core: When skipping to the next track in consume mode, remove the skipped track from the tracklist. This is consistent with the original MPD server’s behavior. (Fixes: #902)
- Local: Fix scanning of modified files. (PR: #904)
- MPD: Re-enable browsing of empty directories. (PR: #906)
- MPD: Remove track comments from responses. They are not included by the original MPD server, and this works around #881. (PR: #882)
- HTTP: Errors while starting HTTP apps are logged instead of crashing the HTTP server. (Fixes: #875)

26.2.2 v0.19.4 (2014-09-01)

Bug fix release.

- Configuration: mopidy --config now supports directories.
- Logging: Fix that some loggers would be disabled if logging/config_file was set. (Fixes: #740)
- Quit process with exit code 1 when stopping because of a backend, frontend, or mixer initialization error.
• Backend API: Update `mopidy.backend.LibraryProvider.browse()` signature and docs to match how the core use the backend’s browse method. (Fixes: #833)

• Local library API: Add `mopidy.local.Library.ROOT_DIRECTORY_URI` constant for use by implementors of `mopidy.local.Library.browse()` (Related to: #833)

• HTTP frontend: Guard against double close of WebSocket, which causes an AttributeError on Tornado < 3.2.

• MPD frontend: Make the `list` command return albums when sending 3 arguments. This was incorrectly returning artists after the MPD command changes in 0.19.0. (Fixes: #817)

• MPD frontend: Fix a race condition where two threads could try to free the same data simultaneously. (Fixes: #781)

## 26.2.3 v0.19.3 (2014-08-03)

Bug fix release.

• Audio: Fix negative track length for radio streams. (Fixes: #662, PR: #796)

• Audio: Tell GStreamer to not pick Jack sink. (Fixes: #604)

• Zeroconf: Fix discovery by adding `.local` to the announced hostname. (PR: #795)

• Zeroconf: Fix intermittent DBus/Avahi exception.

• Extensions: Fail early if trying to setup an extension which doesn’t implement the `mopidy.ext.Extension.setup()` method. (Fixes: #813)

## 26.2.4 v0.19.2 (2014-07-26)

Bug fix release, directly from the Mopidy development sprint at EuroPython 2014 in Berlin.

• Audio: Make `audio/mixer_volume` work on the software mixer again. This was broken with the mixer changes in 0.19.0. (Fixes: #791)

• HTTP frontend: When using Tornado 4.0, allow WebSocket requests from other hosts. (Fixes: #788)

• MPD frontend: Fix crash when MPD commands are called with the wrong number of arguments. This was broken with the MPD command changes in 0.19.0. (Fixes: #789)

## 26.2.5 v0.19.1 (2014-07-23)

Bug fix release.

• Dependencies: Mopidy now requires Tornado >= 2.3, instead of >= 3.1. This should make Mopidy continue to work on Debian/Raspbian stable, where Tornado 2.3 is the newest version available.

• HTTP frontend: Add missing string interpolation placeholder.

• Development: `mopidy --version` and `mopidy.core.Core.get_version()` now returns the correct version when Mopidy is run from a Git repo other than Mopidy’s own. (Related to #706)

26.2. Changelog 0.x series
The focus of 0.19 have been on improving the MPD implementation, replacing GStreamer mixers with our own mixer API, and on making web clients installable with `pip`, like any other Mopidy extension.

Since the release of 0.18, we’ve closed or merged 53 issues and pull requests through about 445 commits by 12 people, including five new guys. Thanks to everyone that has contributed!

**Dependencies**

- Mopidy now requires Tornado $\geq 3.1$.
- Mopidy no longer requires CherryPy or ws4py. Previously, these were optional dependencies required for the HTTP frontend to work.

**Backend API**

- **Breaking change:** Imports of the backend API from `mopidy.backends` no longer works. The new API introduced in v0.18 is now required. Most extensions already use the new API location.

**Commands**

- The `mopidy-convert-config` tool for migrating the settings.py configuration file used by Mopidy up until 0.14 to the new config file format has been removed after over a year of trusty service. If you still need to convert your old settings.py configuration file, do so using and older release, like Mopidy 0.18, or migrate the configuration to the new format by hand.

**Configuration**

- Add `optional=True` support to `mopidy.config.Boolean`.

**Logging**

- Fix proper decoding of exception messages that depends on the user’s locale.
- Colorize logs depending on log level. This can be turned off with the new `logging/color` configuration. (Fixes: #772)

**Extension support**

- **Breaking change:** Removed the Extension methods that were deprecated in 0.18: `get_backend_classes()`, `get_frontend_classes()`, and `register_gstreamer_elements()`. Use `mopidy.ext.Extension.setup()` instead, as most extensions already do.

**Audio**

- **Breaking change:** Removed support for GStreamer mixers. GStreamer 1.x does not support volume control, so we changed to use software mixing by default in v0.17.0. Now, we’re removing support for all other GStreamer mixers and are reintroducing mixers as something extensions can provide independently of GStreamer. (Fixes: #665, PR: #760)

- **Breaking change:** Changed the `audio/mixer` config value to refer to Mopidy mixer extensions instead of GStreamer mixers. The default value, `software`, still has the same behavior. All other values will either no longer work or will at the very least require you to install an additional extension.

- Changed the `audio/mixer_volume` config value behavior from affecting GStreamer mixers to affecting Mopidy mixer extensions instead. The end result should be the same without any changes to this config value.

- Deprecated the `audio/mixer_track` config value. This config value is no longer in use. Mixer extensions that need additional configuration handle this themselves.

- Use `Proxy configuration` when streaming media from the Internet. (Partly fixing #390)

- Fix proper decoding of exception messages that depends on the user’s locale.
• Fix recognition of ASX and XSPF playlists with tags in all caps or with carriage return line endings. (Fixes: #687)

• Support simpler ASX playlist variant with `<ENTRY>` elements without children.

• Added `target_state` attribute to the audio layer’s `state_changed()` event. Currently, it is `None` except when we’re paused because of buffering. Then the new field exposes our target state after buffering has completed.

Mixers

• Added new `mopidy.mixer.Mixer` API which can be implemented by extensions.

• Created a bundled extension, `Mopidy-SoftwareMixer`, for controlling volume in software in GStreamer’s pipeline. This is Mopidy’s default mixer. To use this mixer, set the `audio/mixer` config value to `software`.

• Created an external extension, `Mopidy-ALSAMixer`, for controlling volume with hardware through ALSA. To use this mixer, install the extension, and set the `audio/mixer` config value to `alsamixer`.

HTTP frontend

• CherryPy and ws4py have been replaced with Tornado. This will hopefully reduce CPU usage on OS X (#445) and improve error handling in corner cases, like when returning from suspend (#718).

• Added support for packaging web clients as Mopidy extensions and installing them using pip. See the `HTTP server side API` for details. (Fixes: #440)

• Added web page at `/mopidy/` which lists all web clients installed as Mopidy extensions. (Fixes: #440)

• Added support for extending the HTTP frontend with additional server side functionality. See `HTTP server side API` for details.

• Exposed the core API using HTTP POST requests with JSON-RPC payloads at `/mopidy/rpc`. This is the same JSON-RPC interface as is exposed over the WebSocket at `/mopidy/ws`, so you can run any core API command.

The HTTP POST interfaces does not give you access to events from Mopidy, like the WebSocket does. The WebSocket interface is still recommended for web clients. The HTTP POST interface may be easier to use for simpler programs, that just needs to query the currently playing track or similar. See `HTTP POST API` for details.

• If Zeroconf is enabled, we now announce the `_mopidy-http._tcp` service in addition to `_http._tcp`. This is to make it easier to automatically find Mopidy’s HTTP server among other Zeroconf-published HTTP servers on the local network.

Mopidy.js client library

This version has been released to npm as Mopidy.js v0.4.0.

• Update Mopidy.js to use when.js 3. If you maintain a Mopidy client, you should review the differences between when.js 2 and 3 and the when.js debugging guide.

• All of Mopidy.js’ promise rejection values are now of the Error type. This ensures that all JavaScript VMs will show a useful stack trace if a rejected promise’s value is used to throw an exception. To allow catch clauses to handle different errors differently, server side errors are of the type `Mopidy.ServerError`, and connection related errors are of the type `Mopidy.ConnectionError`.

• Add support for method calls with by-name arguments. The old calling convention, `by-position-only`, is still the default, but this will change in the future. A warning is logged to the console if you don’t explicitly select a calling convention. See the `Mopidy.js JavaScript library` docs for details.

MPD frontend
• Proper command tokenization for MPD requests. This replaces the old regex based system with an MPD protocol specific tokenizer responsible for breaking requests into pieces before the handlers have at them. (Fixes: #591 and #592)

• Updated command handler system. As part of the tokenizer cleanup we’ve updated how commands are registered and making it simpler to create new handlers.

• Simplified a bunch of handlers. All the “browse” type commands now use a common browse helper under the hood for less repetition. Likewise the query handling of “search” commands has been somewhat simplified.

• Adds placeholders for missing MPD commands, preparing the way for bumping the protocol version once they have been added.

• Respond to all pending requests before closing connection. (PR: #722)

• Stop incorrectly catching LookupError in command handling. (Fixes: #741)

• Browse support for playlists and albums has been added. (PR: #749, #754)

• The lsinfo command now returns browse results before local playlists. This is helpful as not all clients sort the returned items. (PR: #755)

• Browse now supports different entries with identical names. (PR: #762)

• Search terms that are empty or consists of only whitespace are no longer included in the search query sent to backends. (PR: #758)

Local backend

• The JSON local library backend now logs a friendly message telling you about mopidy local scan if you don’t have a local library cache. (Fixes: #711)

• The local scan command now use multiple threads to walk the file system and check files’ modification time. This speeds up scanning, especially when scanning remote file systems over e.g. NFS.

• the local scan command now creates necessary folders if they don’t already exist. Previously, this was only done by the Mopidy server, so doing a local scan before running the server the first time resulted in a crash. (Fixes: #703)

• Fix proper decoding of exception messages that depends on the user’s locale.

Stream backend

• Add config value stream/metadata_blacklist to blacklist certain URIs we should not open to read metadata from before they are opened for playback. This is typically needed for services that invalidate URIs after a single use. (Fixes: #660)

26.2.7 v0.18.3 (2014-02-16)

Bug fix release.

• Fix documentation build.

26.2.8 v0.18.2 (2014-02-16)

Bug fix release.

• We now log warnings for wrongly configured extensions, and clearly label them in mopidy config, but does no longer stop Mopidy from starting because of misconfigured extensions. (Fixes: #682)

• Fix a crash in the server side WebSocket handler caused by connection problems with clients. (Fixes: #428, #571)
• Fix the `time_position` field of the `track_playback_ended` event, which has been always 0 since v0.18.0. This made scrobbles by Mopidy-Scrobblizer not be persisted by Last.fm, because Mopidy reported that you listened to 0 seconds of each track. (Fixes: #674)

• Fix the log setup so that it is possible to increase the amount of logging from a specific logger using the `loglevels` config section. (Fixes: #684)

• Serialization of `Playlist` models with the `last_modified` field set to a `datetime.datetime` instance did not work. The type of `mopidy.models.Playlist.last_modified` has been redefined from a `datetime.datetime` instance to the number of milliseconds since Unix epoch as an integer. This makes serialization of the time stamp simpler.

• Minor refactor of the MPD server context so that Mopidy’s MPD protocol implementation can easier be reused. (Fixes: #646)

• Network and signal handling has been updated to play nice on Windows systems.

### 26.2.9 v0.18.1 (2014-01-23)

Bug fix release.

• Disable extension instead of crashing if a dependency has the wrong version. (Fixes: #657)

• Make logging work to both console, debug log file, and any custom logging setup from `logging/config_file` at the same time. (Fixes: #661)

### 26.2.10 v0.18.0 (2014-01-19)

The focus of 0.18 have been on two fronts: the local library and browsing.

First, the local library’s old tag cache file used for storing the track metadata scanned from your music collection has been replaced with a far simpler implementation using JSON as the storage format. At the same time, the local library have been made replaceable by extensions, so you can now create extensions that use your favorite database to store the metadata.

Second, we’ve finally implemented the long awaited “file system” browsing feature that you know from MPD. It is supported by both the MPD frontend and the local and Spotify backends. It is also used by the new Mopidy-Dirble extension to provide you with a directory of Internet radio stations from all over the world.

Since the release of 0.17, we’ve closed or merged 49 issues and pull requests through about 285 commits by 11 people, including six new guys. Thanks to everyone that has contributed!

#### Core API

• Add `mopidy.core.Core.version()` for HTTP clients to manage compatibility between API versions. (Fixes: #597)

• Add `mopidy.models.Ref` class for use as a lightweight reference to other model types, containing just an URI, a name, and an object type. It is barely used for now, but its use will be extended over time.

• Add `mopidy.core.LibraryController.browse()` method for browsing a virtual file system of tracks. Backends can implement support for this by implementing `mopidy.backend.LibraryProvider.browse()`.

• Events emitted on play/stop, pause/resume, next/previous and on end of track has been cleaned up to work consistently. See the message of commit 1d108752f6 for the full details. (Fixes: #629)

#### Backend API
• Move the backend API classes from `mopidy.backends.base` to `mopidy.backend` and remove the
  Base prefix from the class names:

  – From `mopidy.backends.base.Backend` to `mopidy.backend.Backend`
  – From `mopidy.backends.base.BaseLibraryProvider` to `mopidy.backend.LibraryProvider`
  – From `mopidy.backends.base.BasePlaybackProvider` to `mopidy.backend.PlaybackProvider`
  – From `mopidy.backends.base.BasePlaylistsProvider` to `mopidy.backend.PlaylistsProvider`
  – From `mopidy.backends.listener.BackendListener` to `mopidy.backend.BackendListener`

  Imports from the old locations still works, but are deprecated.

• Add `mopidy.backend.LibraryProvider.browse()`, which can be implemented by backends that
  wants to expose directories of tracks in Mopidy’s virtual file system.

Frontend API

• The dummy backend used for testing many frontends have moved from `mopidy.backends.dummy` to
  `mopidy.backend.dummy`. (PR: #984)

Commands

• Reduce amount of logging from dependencies when using `mopidy -v`. (Fixes: #593)

• Add support for additional logging verbosity levels with `mopidy -vv` and `mopidy -vvv` which increases
  the amount of logging from dependencies. (Fixes: #593)

Configuration

• The default for the `mopidy --config` option has been updated to include `$XDG_CONFIG_DIRS`
  in addition to `$XDG_CONFIG_DIR`. (Fixes #431)

• Added support for deprecating config values in order to allow for graceful removal of the no longer used config
  value `local/tag_cache_file`.

Extension support

• Switched to using a registry model for classes provided by extension. This allows extensions to be extended
  by other extensions, as needed by for example pluggable libraries for the local backend. See `mopidy.ext.
  Registry` for details. (Fixes #601)

• Added the new method `mopidy.ext.Extension.setup()`. This method replaces
  the now deprecated `get_backend_classes()`, `get_frontend_classes()`, and
  `register_gstreamer_elements()`.

Audio

• Added `audio/mixer_volume` to set the initial volume of mixers. This is especially useful for setting the
  software mixer volume to something else than the default 100%. (Fixes: #633)

Local backend

Note: After upgrading to Mopidy 0.18 you must run `mopidy local scan` to reindex your local music collection.
This is due to the change of storage format.

• Added support for browsing local directories in Mopidy’s virtual file system.
• Finished the work on creating pluggable libraries. Users can now reconfigure Mopidy to use alternate library providers of their choosing for local files. (Fixes issue #44, partially resolves #397, and causes a temporary regression of #527.)

• Switched default local library provider from a “tag cache” file that closely resembled the one used by the original MPD server to a compressed JSON file. This greatly simplifies our library code and reuses our existing model serialization code, as used by the HTTP API and web clients.

• Removed our outdated and bug-ridden “tag cache” local library implementation.

• Added the config value `local/library` to select which library to use. It defaults to `json`, which is the only local library bundled with Mopidy.

• Added the config value `local/data_dir` to have a common config for where to store local library data. This is intended to avoid every single local library provider having to have it’s own config value for this.

• Added the config value `local/scan_flush_threshold` to control how often to tell local libraries to store changes when scanning local music.

Streaming backend

• Add live lookup of URI metadata. (Fixes #540)

• Add support for extended M3U playlist, meaning that basic track metadata stored in playlists will be used by Mopidy.

HTTP frontend

• Upgrade Mopidy.js dependencies and add support for using Mopidy.js with Browserify. This version has been released to npm as Mopidy.js v0.2.0. (Fixes: #609)

MPD frontend

• Make the `lsinfo`, `listall`, and `listallinfo` commands support browsing of Mopidy’s virtual file system. (Fixes: #145)

• Empty commands now return a `ACK [5@0] {} No command given` error instead of `OK`. This is consistent with the original MPD server implementation.

Internal changes

• Events from the audio actor, backends, and core actor are now emitted asynchronously through the GObject event loop. This should resolve the issue that has blocked the merge of the EOT-vs-EOS fix for a long time.

26.2.11 v0.17.0 (2013-11-23)

The focus of 0.17 has been on introducing subcommands to the `mopidy` command, making it possible for extensions to add subcommands of their own, and to improve the default config file when starting Mopidy the first time. In addition, we’ve grown support for Zeroconf publishing of the MPD and HTTP servers, and gotten a much faster scanner. The scanner now also scans some additional tags like composers and performers.

Since the release of 0.16, we’ve closed or merged 22 issues and pull requests through about 200 commits by five people, including one new contributor.

Commands

• Switched to subcommands for the `mopidy` command, this implies the following changes: (Fixes: #437)

<table>
<thead>
<tr>
<th>Old command</th>
<th>New command</th>
</tr>
</thead>
<tbody>
<tr>
<td>mopidy --show-deps</td>
<td>mopidy deps</td>
</tr>
<tr>
<td>mopidy --show-config</td>
<td>mopidy config</td>
</tr>
<tr>
<td>mopidy-scan</td>
<td>mopidy local scan</td>
</tr>
</tbody>
</table>
• Added hooks for extensions to create their own custom subcommands and converted `mopidy-scan` as a first user of the new API. (Fixes: #436)

Configuration

• When `mopidy` is started for the first time we create an empty `$XDG_CONFIG_DIR/mopidy/mopidy.conf` file. We now populate this file with the default config for all installed extensions so it’ll be easier to set up Mopidy without looking through all the documentation for relevant config values. (Fixes: #467)

Core API

• The `Track` model has grown fields for composers, performers, genre, and comment.
• The search field `track` has been renamed to `track_name` to avoid confusion with `track_no`. (Fixes: #535)
• The signature of the tracklist’s `filter()` and `remove()` methods have changed. Previously, they expected e.g. `tracklist.filter(tlid=17)`. Now, the value must always be a list, e.g. `tracklist.filter(tlid=[17])`. This change allows you to get or remove multiple tracks with a single call, e.g. `tracklist.remove(tlid=[1, 2, 7])`. This is especially useful for web clients, as requests can be batched. This also brings the interface closer to the library’s `find_exact()` and `search()` methods.

Audio

• Change default volume mixer from `autoaudiomixer` to `software`. GStreamer 1.x does not support volume control, so we’re changing to use software mixing by default, as that may be the only thing we’ll support in the future when we upgrade to GStreamer 1.x.

Local backend

• Library scanning has been switched back from GStreamer’s discoverer to our custom implementation due to various issues with GStreamer 0.10’s built in scanner. This also fixes the scanner slowdown. (Fixes: #565)
• When scanning, we no longer default the album artist to be the same as the track artist. Album artist is now only populated if the scanned file got an explicit album artist set.
• The scanner will now extract multiple artists from files with multiple artist tags.
• The scanner will now extract composers and performers, as well as genre, bitrate, and comments. (Fixes: #577)
• Fix scanner so that time of last modification is respected when deciding which files can be skipped when scanning the music collection for changes.
• The scanner now ignores the capitalization of file extensions in `local/excluded_file_extensions`, so you no longer need to list both `.jpg` and `.JPG` to ignore JPEG files when scanning. (Fixes: #525)
• The scanner now by default ignores `*.nfo` and `*.html` files too.

MPD frontend

• The MPD service is now published as a Zeroconf service if avahi-daemon is running on the system. Some MPD clients will use this to present Mopidy as an available server on the local network without needing any configuration. See the `mpd/zeroconf` config value to change the service name or disable the service. (Fixes: #39)
• Add support for `composer`, `performer`, `comment`, `genre`, and `performer`. These tags can be used with `list` ..., `search` ..., and `find` ... and their variants, and are supported in the `any` tag also
• The `bitrate` field in the `status` response is now always an integer. This follows the behavior of the original MPD server. (Fixes: #577)

HTTP frontend

• The HTTP service is now published as a Zeroconf service if avahi-daemon is running on the system. Some browsers will present HTTP Zeroconf services on the local network as “local sites” bookmarks. See the `http/zeroconf` config value to change the service name or disable the service. (Fixes: #39)
DBUS/MPRIS

- The mopidy process now registers it’s GObject event loop as the default eventloop for dbus-python. (Fixes: mopidy-mpris#2)

26.2.12 v0.16.1 (2013-11-02)

This is very small release to get Mopidy’s Debian package ready for inclusion in Debian.

Commands

- Fix removal of last dir level in paths to dependencies in mopidy --show-deps output.
- Add manpages for all commands.

Local backend

- Fix search filtering by track number that was added in 0.16.0.

MPD frontend

- Add support for list "albumartist" ... which was missed when find and search learned to handle albumartist in 0.16.0. (Fixes: #553)

26.2.13 v0.16.0 (2013-10-27)

The goals for 0.16 were to add support for queuing playlists of e.g. radio streams directly to Mopidy, without manually extracting the stream URLs from the playlist first, and to move the Spotify, Last.fm, and MPRIS support out to independent Mopidy extensions, living outside the main Mopidy repo. In addition, we’ve seen some cleanup to the playback vs tracklist part of the core API, which will require some changes for users of the HTTP/JavaScript APIs, as well as the addition of audio muting to the core API. To speed up the development of new extensions, we’ve added a cookiecutter project to get the skeleton of a Mopidy extension up and running in a matter of minutes. Read below for all the details and for links to issues with even more details.

Since the release of 0.15, we’ve closed or merged 31 issues and pull requests through about 200 commits by five people, including three new contributors.

Dependencies

Parts of Mopidy have been moved to their own external extensions. If you want Mopidy to continue to work like it used to, you may have to install one or more of the following extensions as well:

- The Spotify backend has been moved to Mopidy-Spotify.
- The Last.fm scrobbler has been moved to Mopidy-Scrobbler.
- The MPRIS frontend has been moved to Mopidy-MPRIS.

Core

- Parts of the functionality in mopidy.core.PlaybackController have been moved to mopidy.core. TracklistController:
<table>
<thead>
<tr>
<th>Old location</th>
<th>New location</th>
</tr>
</thead>
<tbody>
<tr>
<td>playback.get_consume()</td>
<td>tracklist.get_consume()</td>
</tr>
<tr>
<td>playback.set_consume(v)</td>
<td>tracklist.set_consume(v)</td>
</tr>
<tr>
<td>playback.consume</td>
<td>tracklist.consume</td>
</tr>
<tr>
<td>playback.get_random()</td>
<td>tracklist.get_random()</td>
</tr>
<tr>
<td>playback.set_random(v)</td>
<td>tracklist.set_random(v)</td>
</tr>
<tr>
<td>playback.random</td>
<td>tracklist.random</td>
</tr>
<tr>
<td>playback.get_repeat()</td>
<td>tracklist.getRepeat()</td>
</tr>
<tr>
<td>playback.set_repeat(v)</td>
<td>tracklist.setRepeat(v)</td>
</tr>
<tr>
<td>playback.repeat</td>
<td>tracklist.repeat</td>
</tr>
<tr>
<td>playback.get_single()</td>
<td>tracklist.get_single()</td>
</tr>
<tr>
<td>playback.set_single(v)</td>
<td>tracklist.set_single(v)</td>
</tr>
<tr>
<td>playback.single</td>
<td>tracklist.single</td>
</tr>
<tr>
<td>playback.get_tracklist_position()</td>
<td>tracklist.index(tl_track)</td>
</tr>
<tr>
<td>playback.tracklist_position</td>
<td>tracklist.index(tl_track)</td>
</tr>
<tr>
<td>playback.get_tl_track_at_eot()</td>
<td>tracklist.eot_track(tl_track)</td>
</tr>
<tr>
<td>playback.tl_track_at_eot</td>
<td>tracklist.eot_track(tl_track)</td>
</tr>
<tr>
<td>playback.get_tl_track_at_next()</td>
<td>tracklist.next_track(tl_track)</td>
</tr>
<tr>
<td>playback.tl_track_at_next</td>
<td>tracklist.next_track(tl_track)</td>
</tr>
<tr>
<td>playback.get_tl_track_at_previous()</td>
<td>tracklist.previous_track(tl_track)</td>
</tr>
<tr>
<td>playback.tl_track_at_previous</td>
<td>tracklist.previous_track(tl_track)</td>
</tr>
</tbody>
</table>

The `tl_track` argument to the last four new functions are used as the reference `tl_track` in the tracklist to find e.g. the next track. Usually, this will be `current_tl_track`.

- Added `mopidy.core.PlaybackController.mute` for muting and unmuting audio. (Fixes: #186)
- Added `mopidy.core.CoreListener.mute_changed()` event that is triggered when the mute state changes.
- In “random” mode, after a full playthrough of the tracklist, playback continued from the last track played to the end of the playlist in non-random order. It now stops when all tracks have been played once, unless “repeat” mode is enabled. (Fixes: #453)
- In “single” mode, after a track ended, playback continued with the next track in the tracklist. It now stops after playing a single track, unless “repeat” mode is enabled. (Fixes: #496)

**Audio**

- Added support for parsing and playback of playlists in GStreamer. For end users this basically means that you can now add a radio playlist to Mopidy and we will automatically download it and play the stream inside it. Currently we support M3U, PLS, XSPF and ASX files. Also note that we can currently only play the first stream in the playlist.
- We now handle the rare case where an audio track has max volume equal to min. This was causing divide by zero errors when scaling volumes to a zero to hundred scale. (Fixes: #525)
- Added support for muting audio without setting the volume to 0. This works both for the software and hardware mixers. (Fixes: #186)

**Local backend**

- Replaced our custom media library scanner with GStreamer’s builtin scanner. This should make scanning less error prone and faster as timeouts should be infrequent. (Fixes: #198)
- Media files with less than 100ms duration are now excluded from the library.
• Media files with the file extensions .jpeg, .jpg, .png, .txt, and .log are now skipped by the media library scanner. You can change the list of excluded file extensions by setting the local/excluded_file_extensions config value. (Fixes: #516)

• Unknown URIs found in playlists are now made into track objects with the URI set instead of being ignored. This makes it possible to have playlists with e.g. HTTP radio streams and not just local:track:... URIs. This used to work, but was broken in Mopidy 0.15.0. (Fixes: #527)

• Fixed crash when playing local:track:... URIs which contained non-ASCII chars after uridecode.

• Removed media files are now also removed from the in-memory media library when the media library is reloaded from disk. (Fixes: #500)

MPD frontend

• Made the formerly unused commands outputs, enableoutput, and disableoutput mute/unmute audio. (Related to: #186)

• The MPD command list now works with "albumartist" as its second argument, e.g. list "album" "albumartist" "anartist". (Fixes: #468)

• The MPD commands find and search now accepts albumartist and track (this is the track number, not the track name) as field types to limit the search result with.

• The MPD command count is now implemented. It accepts the same type of arguments as find and search, but returns the number of tracks and their total playtime instead.

Extension support

• A cookiecutter project for quickly creating new Mopidy extensions have been created. You can find it at cookiecutter-mopidy-ext. (Fixes: #522)

26.2.14 v0.15.0 (2013-09-19)

A release with a number of small and medium fixes, with no specific focus.

Dependencies

• Mopidy no longer supports Python 2.6. Currently, the only Python version supported by Mopidy is Python 2.7. We’re continuously working towards running Mopidy on Python 3. (Fixes: #344)

Command line options

• Converted from the optparse to the argparse library for handling command line options.

• mopidy --show-config will now take into consideration any mopidy --option arguments appearing later on the command line. This helps you see the effective configuration for runs with the same mopidy --options arguments.

Audio

• Added support for audio visualization. audio/visualizer can now be set to GStreamer visualizers.

• Properly encode localized mixer names before logging.

Local backend

• An album’s number of discs and a track’s disc number are now extracted when scanning your music collection.

• The scanner now gives up scanning a file after a second, and continues with the next file. This fixes some hangs on non-media files, like logs. (Fixes: #476, #483)

• Added support for pluggable library updaters. This allows extension writers to start providing their own custom libraries instead of being stuck with just our tag cache as the only option.
• Converted local backend to use new `local:playlist:path` and `local:track:path` URI scheme. Also moves support of `file://` to streaming backend.

**Spotify backend**

• Prepend playlist folder names to the playlist name, so that the playlist hierarchy from your Spotify account is available in Mopidy. (Fixes: #62)

• Fix proxy config values that was broken with the config system change in 0.14. (Fixes: #472)

**MPD frontend**

• Replace newline, carriage return and forward slash in playlist names. (Fixes: #474, #480)

• Accept `listall` and `listallinfo` commands without the URI parameter. The methods are still not implemented, but now the commands are accepted as valid.

**HTTP frontend**

• Fix too broad truth test that caused `mopidy.models.TlTrack` objects with `tlid` set to 0 to be sent to the HTTP client without the `tlid` field. (Fixes: #501)

• Upgrade Mopidy.js dependencies. This version has been released to npm as Mopidy.js v0.1.1.

**Extension support**

• `mopidy.config.Secret` is now deserialized to unicode instead of bytes. This may require modifications to extensions.

### 26.2.15 v0.14.2 (2013-07-01)

This is a maintenance release to make Mopidy 0.14 work with pyspotify 1.11.

**Dependencies**

• pyspotify >= 1.9, < 2 is now required for Spotify support. In other words, you’re free to upgrade to pyspotify 1.11, but it isn’t a requirement.

### 26.2.16 v0.14.1 (2013-04-28)

This release addresses an issue in v0.14.0 where the new `mopidy-convert-config` tool and the new `mopidy --option` command line option was broken because some string operations inadvertently converted some byte strings to unicode.

### 26.2.17 v0.14.0 (2013-04-28)

The 0.14 release has a clear focus on two things: the new configuration system and extension support. Mopidy’s documentation has also been greatly extended and improved.

Since the last release a month ago, we’ve closed or merged 53 issues and pull requests. A total of seven authors have contributed, including one new.

**Dependencies**

• setuptools or distribute is now required. We’ve introduced this dependency to use setuptools’ entry points functionality to find installed Mopidy extensions.

**New configuration system**
• Mopidy has a new configuration system based on ini-style files instead of a Python file. This makes configuration easier for users, and also makes it possible for Mopidy extensions to have their own config sections.

As part of this change we have cleaned up the naming of our config values.

To ease migration we've made a tool named mopidy-convert-config for automatically converting the old settings.py to a new mopidy.conf file. This tool takes care of all the renamed config values as well. See mopidy-convert-config for details on how to use it.

• A long wanted feature: You can now enable or disable specific frontends or backends without having to redefine FRONTENDS or BACKENDS in your config. Those config values are gone completely.

Extension support

• Mopidy now supports extensions. This means that any developer now easily can create a Mopidy extension to add new control interfaces or music backends. This helps spread the maintenance burden across more developers, and also makes it possible to extend Mopidy with new backends the core developers are unable to create and/or maintain because of geo restrictions, etc. If you’re interested in creating an extension for Mopidy, read up on Extension development.

• All of Mopidy’s existing frontends and backends are now plugged into Mopidy as extensions, but they are still distributed together with Mopidy and are enabled by default.

• The NAD mixer have been moved out of Mopidy core to its own project, Mopidy-NAD. See Extensions for more information.

• Janez Troha has made the first two external extensions for Mopidy: a backend for playing music from Soundcloud, and a backend for playing music from a Beets music library. See Extensions for more information.

Command line options

• The command option mopidy --list-settings is now named mopidy --show-config.

• The command option mopidy --list-deps is now named mopidy --show-deps.

• What configuration files to use can now be specified through the command option mopidy --config, multiple files can be specified using colon as a separator.

• Configuration values can now be overridden through the command option mopidy --option. For example: mopidy --option spotify/enabled=false.

• The GStreamer command line options, mopidy --gst-* and mopidy --help-gst are no longer supported. To set GStreamer debug flags, you can use environment variables such as GST_DEBUG. Refer to GStreamer’s documentation for details.

Spotify backend

• Add support for starred playlists, both your own and those owned by other users. (Fixes: #326)

• Fix crash when a new playlist is added by another Spotify client. (Fixes: #387, #425)

MPD frontend

• Playlists with identical names are now handled properly by the MPD frontend by suffixing the duplicate names with e.g. [2]. This is needed because MPD identify playlists by name only, while Mopidy and Spotify supports multiple playlists with the same name, and identify them using an URI. (Fixes: #114)

MPRIS frontend

• The frontend is now disabled if the DISPLAY environment variable is unset. This avoids some harmless error messages, that have been known to confuse new users debugging other problems.

Development
• Developers running Mopidy from a Git clone now need to run `python setup.py develop` to register the bundled extensions. If you don’t do this, Mopidy will not find any frontends or backends. Note that we highly recommend you do this in a virtualenv, not system wide. As a bonus, the command also gives you a `mopidy` executable in your search path.

26.2.18 v0.13.0 (2013-03-31)

The 0.13 release brings small improvements and bugfixes throughout Mopidy. There are no major new features, just incremental improvement of what we already have.

Dependencies
• Pykka >= 1.1 is now required.

Core
• Removed the `mopidy.settings.DEBUG_THREAD` setting and the `mopidy --debug-thread` command line option. Sending SIGUSR1 to the Mopidy process will now always make it log tracebacks for all alive threads.
• Log a warning if a track isn’t playable to make it more obvious that backend X needs backend Y to be present for playback to work.
• `mopidy.core.TracklistController.add()` now accepts a `uri` which it will lookup in the library and then add to the tracklist. This is helpful for e.g. web clients that doesn’t want to transfer all track meta data back to the server just to add it to the tracklist when the server already got all the needed information easily available. (Fixes: #325)
• Change the following methods to accept an `uris` keyword argument:
  – `mopidy.core.LibraryController.find_exact()`  
  – `mopidy.core.LibraryController.search()`  
  Search queries will only be forwarded to backends handling the given URI roots, and the backends may use the URI roots to further limit what results are returned. For example, a search with `uris=['file:]` will only be processed by the local backend. A search with `uris=['file:///media/music']` will only be processed by the local backend, and, if such filtering is supported by the backend, will only return results with URIs within the given URI root.

Audio sub-system
• Make audio error logging handle log messages with non-ASCII chars. (Fixes: #347)

Local backend
• Make `mopidy-scan` work with Ogg Vorbis files. (Fixes: #275)
• Fix playback of files with non-ASCII chars in their file path. (Fixes: #353)

Spotify backend
• Let GStreamer handle time position tracking and seeks. (Fixes: #191)
• For all playlists owned by other Spotify users, we now append the owner’s username to the playlist name. (Partly fixes: #114)

HTTP frontend
• Mopidy.js now works both from browsers and from Node.js environments. This means that you now can make Mopidy clients in Node.js. Mopidy.js has been published to the npm registry for easy installation in Node.js projects.
• Upgrade Mopidy.js’ build system Grunt from 0.3 to 0.4.
• Upgrade Mopidy.js’ dependencies when.js from 1.6.1 to 2.0.0.
• Expose `mopidy.core.Core.get_uri_schemes()` to HTTP clients. It is available through Mopidy.js as `mopidy.getUriSchemes()`.

**MPRIS frontend**
• Publish album art URIs if available.
• Publish disc number of track if available.

### 26.2.19 v0.12.0 (2013-03-12)

The 0.12 release has been delayed for a while because of some issues related some ongoing GStreamer cleanup we didn’t invest enough time to finish. Finally, we’ve come to our senses and have now cherry-picked the good parts to bring you a new release, while postponing the GStreamer changes to 0.13. The release adds a new backend for playing audio streams, as well as various minor improvements throughout Mopidy.

• Make Mopidy work on early Python 2.6 versions. (Fixes: #302)
  – `optparse` fails if the first argument to `add_option` is a unicode string on Python < 2.6.2rc1.
  – `foo(**data)` fails if the keys in `data` is unicode strings on Python < 2.6.5rc1.

**Audio sub-system**
• Improve selection of mixer tracks for volume control. (Fixes: #307)

**Local backend**
• Make `mopidy-scan` support symlinks.

**Stream backend**

We’ve added a new backend for playing audio streams, the stream backend. It is activated by default. The stream backend supports the intersection of what your GStreamer installation supports and what protocols are included in the `mopidy.settings.STREAM_PROTOCOLS` setting.

Current limitations:

• No metadata about the current track in the stream is available.
• Playlists are not parsed, so you can’t play e.g. a M3U or PLS file which contains stream URIs. You need to extract the stream URL from the playlist yourself. See #303 for progress on this.

**Core API**

• `mopidy.core.PlaylistsController.get_playlists()` now accepts an argument `include_tracks`. This defaults to True, which has the same old behavior. If set to False, the tracks are stripped from the playlists before they are returned. This can be used to limit the amount of data returned if the response is to be passed out of the application, e.g. to a web client. (Fixes: #297)

**Models**

• Add `mopidy.models.Album.images` field for including album art URIs. (Partly fixes #263)
• Add `mopidy.models.Track.disc_no` field. (Partly fixes: #286)
• Add `mopidy.models.Album.num_discs` field. (Partly fixes: #286)
26.2.20 v0.11.1 (2012-12-24)

Spotify search was broken in 0.11.0 for users of Python 2.6. This release fixes it. If you’re using Python 2.7, v0.11.0 and v0.11.1 should be equivalent.

26.2.21 v0.11.0 (2012-12-24)

In celebration of Mopidy’s three year anniversary December 23, we’re releasing Mopidy 0.11. This release brings several improvements, most notably better search which now includes matching artists and albums from Spotify in the search results.

Settings

• The settings validator now complains if a setting which expects a tuple of values (e.g. `mopidy.settings.BACKENDS`, `mopidy.settings.FRONTENDS`) has a non-iterable value. This typically happens because the setting value contains a single value and one has forgotten to add a comma after the string, making the value a tuple. (Fixes: #278)

Spotify backend

• Add `mopidy.settings.SPOTIFY_TIMEOUT` setting which allows you to control how long we should wait before giving up on Spotify searches, etc.

• Add support for looking up albums, artists, and playlists by URI in addition to tracks. (Fixes: #67)

As an example of how this can be used, you can try the the following MPD commands which now all adds one or more tracks to your tracklist:

```plaintext
add "spotify:track:1mwt9hzaH7idmC5UCoOUkz"
add "spotify:album:3gpHG5MGwnipnap32lFYvI"
add "spotify:artist:5TgQ66WuWkoQ2xYxaSTnVP"
add "spotify:user:p3.no:playlist:0XX6tamRiqEgh3t6FPFEkw"
```

• Increase max number of tracks returned by searches from 100 to 200, which seems to be Spotify’s current max limit.

Local backend

• Load track dates from tag cache.

• Add support for searching by track date.

MPD frontend

• Add `mopidy.settings.MPD_SERVER_CONNECTION_TIMEOUT` setting which controls how long an MPD client can stay inactive before the connection is closed by the server.

• Add support for the `findadd` command.

• Updated to match the MPD 0.17 protocol (Fixes: #228):
  
  – Add support for `seekcur` command.
  
  – Add support for `config` command.
  
  – Add support for loading a range of tracks from a playlist to the `load` command.
  
  – Add support for `searchadd` command.
  
  – Add support for `searchaddpl` command.

• Add empty stubs for channel commands for client to client communication.

• Add support for search by date.
• Make \texttt{seek} and \texttt{seekid} not restart the current track before seeking in it.

• Include fake tracks representing albums and artists in the search results. When these are added to the tracklist, they expand to either all tracks in the album or all tracks by the artist. This makes it easy to play full albums in proper order, which is a feature that have been frequently requested. (Fixes: #67, #148)

\textbf{Internal changes}

\textit{Models:}

• Specified that \texttt{mopidy.models.Playlist.last_modified} should be in UTC.

• Added \texttt{mopidy.models.SearchResult} model to encapsulate search results consisting of more than just tracks.

\textit{Core API:}

• Change the following methods to return \texttt{mopidy.models.SearchResult} objects which can include both track results and other results:
  – \texttt{mopidy.core.LibraryController.find_exact()}
  – \texttt{mopidy.core.LibraryController.search()}

• Change the following methods to accept either a dict with filters or kwargs. Previously they only accepted kwargs, which made them impossible to use from the Mopidy.js through JSON-RPC, which doesn’t support kwargs.
  – \texttt{mopidy.core.LibraryController.find_exact()}
  – \texttt{mopidy.core.LibraryController.search()}
  – \texttt{mopidy.core.PlaylistsController.filter()}
  – \texttt{mopidy.core.TracklistController.filter()}
  – \texttt{mopidy.core.TracklistController.remove()}

• Actually trigger the \texttt{mopidy.core.CoreListener.volume_changed()} event.

• Include the new volume level in the \texttt{mopidy.core.CoreListener.volume_changed()} event.

• The \texttt{track_playback_{paused,resumed,started,ended}} events now include a \texttt{mopidy.models.TlTrack} instead of a \texttt{mopidy.models.Track}.

\textit{Audio:}

• Mixers with fewer than 100 volume levels could report another volume level than what you just set due to the conversion between Mopidy’s 0-100 range and the mixer’s range. Now Mopidy returns the recently set volume if the mixer reports a volume level that matches the recently set volume, otherwise the mixer’s volume level is rescaled to the 1-100 range and returned.

\textbf{26.2.22 \textit{v0.10.0 (2012-12-12)}}

We’ve added an HTTP frontend for those wanting to build web clients for Mopidy!

\textbf{Dependencies}

• \texttt{pyspotify} \(\geq 1.9, < 1.11\) is now required for Spotify support. In other words, you’re free to upgrade to pyspotify 1.10, but it isn’t a requirement.

\textbf{Documentation}

• Added installation instructions for Fedora.

\textbf{Spotify backend}
• Save a lot of memory by reusing artist, album, and track models.
• Make sure the playlist loading hack only runs once.

Local backend
• Change log level from error to warning on messages emitted when the tag cache isn’t found and a couple of similar cases.
• Make mopidy-scan ignore invalid dates, e.g. dates in years outside the range 1-9999.
• Make mopidy-scan accept -q/--quiet and -v/--verbose options to control the amount of logging output when scanning.
• The scanner can now handle files with other encodings than UTF-8. Rebuild your tag cache with mopidy-scan to include tracks that may have been ignored previously.

HTTP frontend
• Added new optional HTTP frontend which exposes Mopidy’s core API through JSON-RPC 2.0 messages over a WebSocket. See HTTP JSON-RPC API for further details.
• Added a JavaScript library, Mopidy.js, to make it easier to develop web based Mopidy clients using the new HTTP frontend.

Bug fixes
• #256: Fix crash caused by non-ASCII characters in paths returned from glib. The bug can be worked around by overriding the settings that includes offending $XDG_ variables.

26.2.23 v0.9.0 (2012-11-21)

Support for using the local and Spotify backends simultaneously have for a very long time been our most requested feature. Finally, it’s here!

Dependencies
• pyspotify >= 1.9, < 1.10 is now required for Spotify support.

Documentation
• New Installation guides, organized by OS and distribution so that you can follow one concise list of instructions instead of jumping around the docs to look for instructions for each dependency.
• Moved Raspberry Pi howto from the wiki to the docs.
• Updated MPD clients overview.
• Added MPRIS clients and UPnP clients overview.

Multiple backends support
• Both the local backend and the Spotify backend are now turned on by default. The local backend is listed first in the mopidy.settings.BACKENDS setting, and are thus given the highest priority in e.g. search results, meaning that we’re listing search hits from the local backend first. If you want to prioritize the backends in another way, simply set BACKENDS in your own settings file and reorder the backends.

There are no other setting changes related to the local and Spotify backends. As always, see mopidy.settings for the full list of available settings.

Spotify backend
• The Spotify backend now includes release year and artist on albums.
• #233: The Spotify backend now returns the track if you search for the Spotify track URI.
• Added support for connecting to the Spotify service through an HTTP or SOCKS proxy, which is supported by pyspotify >= 1.9.
• Subscriptions to other Spotify user’s “starred” playlists are ignored, as they currently isn’t fully supported by pyspotify.

Local backend
• #236: The mopidy-scan command failed to include tags from ALAC files (Apple lossless) because it didn’t support multiple tag messages from GStreamer per track it scanned.
• Added support for search by filename to local backend.

MPD frontend
• #218: The MPD commands listplaylist and listplaylistinfo now accepts unquoted playlist names if they don’t contain spaces.
• #246: The MPD command list album artist "" and similar search, find, and list commands with empty filter values caused a LookupError, but should have been ignored by the MPD server.
• The MPD frontend no longer lowercases search queries. This broke e.g. search by URI, where casing may be essential.
• The MPD command plchanges always returned the entire playlist. It now returns an empty response when the client has seen the latest version.
• The MPD commands search and find now allows the key file, which is used by ncmpepp instead of filename.
• The MPD commands search and find now allow search query values to be empty strings.
• The MPD command listplaylists will no longer return playlists without a name. This could crash ncmpepp.
• The MPD command list will no longer return artist names, album names, or dates that are blank.
• The MPD command decoders will now return an empty response instead of a “not implemented” error to make the ncmpepp browse view work the first time it is opened.

MPRIS frontend
• The MPRIS playlists interface is now supported by our MPRIS frontend. This means that you now can select playlists to queue and play from the Ubuntu Sound Menu.

Audio mixers
• Made the NAD mixer responsive to interrupts during amplifier calibration. It will now quit immediately, while previously it completed the calibration first, and then quit, which could take more than 15 seconds.

Developer support
• Added optional background thread for debugging deadlocks. When the feature is enabled via the mopidy --debug-thread option or mopidy.settings.DEBUG_THREAD setting a SIGUSR1 signal will dump the traceback for all running threads.
• The settings validator will now allow any setting prefixed with CUSTOM_ to exist in the settings file.

Internal changes
Internally, Mopidy have seen a lot of changes to pave the way for multiple backends and the future HTTP frontend.
• A new layer and actor, “core”, has been added to our stack, inbetween the frontends and the backends. The responsibility of the core layer and actor is to take requests from the frontends, pass them on to one or more backends, and combining the response from the backends into a single response to the requesting frontend.
Frontends no longer know anything about the backends. They just use the `mopidy.core — Core API`.

• The dependency graph between the core controllers and the backend providers have been straightened out, so that we don’t have any circular dependencies. The frontend, core, backend, and audio layers are now strictly separate. The frontend layer calls on the core layer, and the core layer calls on the backend layer. Both the core layer and the backends are allowed to call on the audio layer. Any data flow in the opposite direction is done by broadcasting of events to listeners, through e.g. `mopidy.core.CoreListener` and `mopidy.audio.AudioListener`.

See `Architecture` for more details and illustrations of all the relations.

• All dependencies are now explicitly passed to the constructors of the frontends, core, and the backends. This makes testing each layer with dummy/mocked lower layers easier than with the old variant, where dependencies where looked up in Pykka’s actor registry.

• All properties in the core API now got getters, and setters if setting them is allowed. They are not explictly listed in the docs as they have the same behavior as the documented properties, but they are available and may be used. This is useful for the future HTTP frontend.

**Models:**

• Added `mopidy.models.Album.date` attribute. It has the same format as the existing `mopidy.models.Track.date`.

• Added `mopidy.models.ModelJSONEncoder` and `mopidy.models.model_json_decoder()` for automatic JSON serialization and deserialization of data structures which contains Mopidy models. This is useful for the future HTTP frontend.

**Library:**

• `mopidy.core.LibraryController.find_exact()` and `mopidy.core.LibraryController.search()` now returns plain lists of tracks instead of playlist objects.

• `mopidy.core.LibraryController.lookup()` now returns a list of tracks instead of a single track. This makes it possible to support lookup of artist or album URIs which then can expand to a list of tracks.

**Playback:**

• The base playback provider has been updated with sane default behavior instead of empty functions. By default, the playback provider now lets GStreamer keep track of the current track’s time position. The local backend simply uses the base playback provider without any changes. Any future backend that just feeds URIs to GStreamer to play can also use the base playback provider without any changes.

• Removed `mopidy.core.PlaybackController.track_at_previous`. Use `mopidy.core.PlaybackController.tl_track_at_previous` instead.

• Removed `mopidy.core.PlaybackController.track_at_next`. Use `mopidy.core.PlaybackController.tl_track_at_next` instead.

• Removed `mopidy.core.PlaybackController.track_at_eot`. Use `mopidy.core.PlaybackController.tl_track_at_eot` instead.

• Removed `mopidy.core.PlaybackController.current_tlid`. Use `mopidy.core.PlaybackController.current_tl_track` instead.

**Playlists:**

The playlists part of the core API has been revised to be more focused around the playlist URI, and some redundant functionality has been removed:

• Renamed “stored playlists” to “playlists” everywhere, including the core API used by frontends.
• `mopidy.core.PlaylistsController.playlists` no longer supports assignment to it. The `playlists` property on the backend layer still does, and all functionality is maintained by assigning to the playlists collections at the backend level.

• `mopidy.core.PlaylistsController.delete()` now accepts an URI, and not a playlist object.

• `mopidy.core.PlaylistsController.save()` now returns the saved playlist. The returned playlist may differ from the saved playlist, and should thus be used instead of the playlist passed to `mopidy.core.PlaylistsController.save()`.

• `mopidy.core.PlaylistsController.rename()` has been removed, since renaming can be done with `mopidy.core.PlaylistsController.save()`.

• `mopidy.core.PlaylistsController.get()` has been replaced by `mopidy.core.PlaylistsController.filter()`.

• The event `mopidy.core.CoreListener.playlist_changed()` has been changed to include the playlist that was changed.

**Tracklist:**

• Renamed “current playlist” to “tracklist” everywhere, including the core API used by frontends.

• Removed `mopidy.core.TracklistController.append()`. Use `mopidy.core.TracklistController.add()` instead, which is now capable of adding multiple tracks.

• `mopidy.core.TracklistController.get()` has been replaced by `mopidy.core.TracklistController.filter()`.

• `mopidy.core.TracklistController.remove()` can now remove multiple tracks, and returns the tracks it removed.

• When the tracklist is changed, we now trigger the new `mopidy.core.CoreListener.tracklist_changed()` event. Previously we triggered `mopidy.core.CoreListener.playlist_changed()`, which is intended for stored playlists, not the tracklist.

**Towards Python 3 support:**

• Make the entire code base use unicode strings by default, and only fall back to bytestrings where it is required. Another step closer to Python 3.

---

**26.2.24 v0.8.1 (2012-10-30)**

A small maintenance release to fix a bug introduced in 0.8.0 and update Mopidy to work with Pykka 1.0.

**Dependencies**

• Pykka >= 1.0 is now required.

**Bug fixes**

• #213: Fix “streaming task paused, reason not-negotiated” errors observed by some users on some Spotify tracks due to a change introduced in 0.8.0. See the issue for a patch that applies to 0.8.0.

• #216: Volume returned by the MPD command `status` contained a floating point `.0` suffix. This bug was introduced with the large audio output and mixer changes in v0.8.0 and broke the MPDroid Android client. It now returns an integer again.
26.2.25 v0.8.0 (2012-09-20)

This release does not include any major new features. We’ve done a major cleanup of how audio outputs and audio mixers work, and on the way we’ve resolved a bunch of related issues.

Audio output and mixer changes

- Removed multiple outputs support. Having this feature currently seems to be more trouble than what it is worth. The `mopidy.settings.OUTPUTS` setting is no longer supported, and has been replaced with `mopidy.settings.OUTPUT` which is a GStreamer bin description string in the same format as `gst-launch` expects. Default value is `autoaudiosink`. (Fixes: #81, #115, #121, #159)

- Switch to pure GStreamer based mixing. This implies that users setup a GStreamer bin with a mixer in it in `mopidy.settings.MIXER`. The default value is `autoaudiomixer`, a custom mixer that attempts to find a mixer that will work on your system. If this picks the wrong mixer you can of course override it. Setting the mixer to `None` is also supported. MPD protocol support for volume has also been updated to return -1 when we have no mixer set. `software` can be used to force software mixing.

- Removed the Denon hardware mixer, as it is not maintained.

- Updated the NAD hardware mixer to work in the new GStreamer based mixing regime. Settings are now passed as GStreamer element properties. In practice that means that the following old-style config:

```
MIXER = u'mopidy.mixers.nad.NadMixer'
MIXER_EXT_PORT = u'/dev/ttyUSB0'
MIXER_EXT_SOURCE = u'Aux'
MIXER_EXT_SPEAKERS_A = u'On'
MIXER_EXT_SPEAKERS_B = u'Off'
```

Now is reduced to simply:

```
MIXER = u'nadmixer port=/dev/ttyUSB0 source=aux speakers-a=on speakers-b=off'
```

The `port` property defaults to `/dev/ttyUSB0`, and the rest of the properties may be left out if you don’t want the mixer to adjust the settings on your NAD amplifier when Mopidy is started.

Changes

- When unknown settings are encountered, we now check if it’s similar to a known setting, and suggests to the user what we think the setting should have been.

- Added `mopidy --list-deps` option that lists required and optional dependencies, their current versions, and some other information useful for debugging. (Fixes: #74)

- Added `tools/debug-proxy.py` to tee client requests to two backends and diff responses. Intended as a developer tool for checking for MPD protocol changes and various client support. Requires `gevent`, which currently is not a dependency of Mopidy.

- Support tracks with only release year, and not a full release date, like e.g. Spotify tracks.

- Default value of `LOCAL_MUSIC_PATH` has been updated to be `$XDG_MUSIC_DIR`, which on most systems this is set to `$HOME`. Users of local backend that relied on the old default `~/music` need to update their settings. Note that the code responsible for finding this music now also ignores UNIX hidden files and folders.

- File and path settings now support `$XDG_CACHE_DIR`, `$XDG_DATA_DIR` and `$XDG_MUSIC_DIR` substitution. Defaults for such settings have been updated to use this instead of hidden away defaults.

- Playback is now done using `playbin2` from GStreamer instead of rolling our own. This is the first step towards resolving #171.

Bug fixes
• #72: Created a Spotify track proxy that will switch to using loaded data as soon as it becomes available.

• #150: Fix bug which caused some clients to block Mopidy completely. The bug was caused by some clients sending `close` and then shutting down the connection right away. This trigged a situation in which the connection cleanup code would wait for an response that would never come inside the event loop, blocking everything else.

• #162: Fixed bug when the MPD command `playlistinfo` is used with a track position. Track position and CPID was intermixed, so it would cause a crash if a CPID matching the track position didn’t exist.

• Fixed crash on lookup of unknown path when using local backend.

• #189: `LOCAL_MUSIC_PATH` and path handling in rest of settings has been updated so all of the code now uses the correct value.

• Fixed incorrect track URIs generated by M3U playlist parsing code. Generated tracks are now relative to `LOCAL_MUSIC_PATH`.

• #203: Re-add support for software mixing.

26.2.26 v0.7.3 (2012-08-11)

A small maintenance release to fix a crash affecting a few users, and a couple of small adjustments to the Spotify backend.

Changes

• Fixed crash when logging `IOError` exceptions on systems using languages with non-ASCII characters, like French.

• Move the default location of the Spotify cache from `~/.cache/mopidy` to `~/.cache/mopidy/spotify`. You can change this by setting `mopidy.settings.SPOTIFY_CACHE_PATH`.

• Reduce time required to update the Spotify cache on startup. One one system/Spotify account, the time from clean cache to ready for use was reduced from 35s to 12s.

26.2.27 v0.7.2 (2012-05-07)

This is a maintenance release to make Mopidy 0.7 build on systems without all of Mopidy’s runtime dependencies, like Launchpad PPAs.

Changes

• Change from version tuple at `mopidy.VERSION` to PEP 386 compliant version string at `mopidy. __version__` to conform to PEP 396.

26.2.28 v0.7.1 (2012-04-22)

This is a maintenance release to make Mopidy 0.7 work with pyspotify >= 1.7.

Changes

• Don’t override pyspotify’s `notify_main_thread` callback. The default implementation is sensible, while our override did nothing.
26.2.29 v0.7.0 (2012-02-25)

Not a big release with regard to features, but this release got some performance improvements over v0.6, especially for slower Atom systems. It also fixes a couple of other bugs, including one which made Mopidy crash when using GStreamer from the prereleases of Ubuntu 12.04.

Changes

• The MPD command `playlistinfo` is now faster, thanks to John Bäckstrand.
• Added the method `mopidy.backends.base.CurrentPlaylistController.length()`, `mopidy.backends.base.CurrentPlaylistController.index()`, and `mopidy.backends.base.CurrentPlaylistController.slice()` to reduce the need for copying the entire current playlist from one thread to another. Thanks to John Bäckstrand for pinpointing the issue.
• Fix crash on creation of config and cache directories if intermediate directories does not exist. This was especially the case on OS X, where `~/.config` doesn’t exist for most users.
• Fix `gst.LinkError` which appeared when using newer versions of GStreamer, e.g. on Ubuntu 12.04 Alpha. (Fixes: #144)
• Fix crash on mismatching quotation in list MPD queries. (Fixes: #137)
• Volume is now reported to be the same as the volume was set to, also when internal rounding have been done due to `mopidy.settings.MIXER_MAX_VOLUME` has been set to cap the volume. This should make it possible to manage capped volume from clients that only increase volume with one step at a time, like ncmpcpp does.

26.2.30 v0.6.1 (2011-12-28)

This is a maintenance release to make Mopidy 0.6 work with pyspotify >= 1.5, which Mopidy’s develop branch have supported for a long time. This should also make the Debian packages work out of the box again.

Important changes

• pyspotify 1.5 or greater is required.

Changes

• Spotify playlist folder boundaries are now properly detected. In other words, if you use playlist folders, you will no longer get lots of log messages about bad playlists.

26.2.31 v0.6.0 (2011-10-09)

The development of Mopidy have been quite slow for the last couple of months, but we do have some goodies to release which have been idling in the develop branch since the warmer days of the summer. This release brings support for the MPD `idle` command, which makes it possible for a client wait for updates from the server instead of polling every second. Also, we’ve added support for the MPRIS standard, so that Mopidy can be controlled over D-Bus from e.g. the Ubuntu Sound Menu.

Please note that 0.6.0 requires some updated dependencies, as listed under Important changes below.

Important changes

• Pykka 0.12.3 or greater is required.
• pyspotify 1.4 or greater is required.
• All config, data, and cache locations are now based on the XDG spec.
  • This means that your settings file will need to be moved from `~/.mopidy/settings.py` to `~/.config/mopidy/settings.py`. 
– Your Spotify cache will now be stored in ~/.cache/mopidy instead of ~/.mopidy/spotify_cache.
– The local backend's tag_cache should now be in ~/.local/share/mopidy/tag_cache, likewise your playlists will be in ~/.local/share/mopidy/playlists.
– The local client now tries to lookup where your music is via XDG, it will fall-back to ~/music or use whatever setting you set manually.

• The MPD command idle is now supported by Mopidy for the following subsystems: player, playlist, options, and mixer. (Fixes: #32)
• A new frontend mopidy.frontends.mpris have been added. It exposes Mopidy through the MPRIS interface over D-Bus. In practice, this makes it possible to control Mopidy through the Ubuntu Sound Menu.

Changes
• Replace mopidy.backends.base.Backend.uri_handlers with mopidy.backends.base.Backend.uri_schemes, which just takes the part up to the colon of an URI, and not any prefix.
• Add Listener API, mopidy.listeners, to be implemented by actors wanting to receive events from the backend. This is a formalization of the ad hoc events the Last.fm scrobbler has already been using for some time.
• Replaced all of the MPD network code that was provided by asyncore with custom stack. This change was made to facilitate support for the idle command, and to reduce the number of event loops being used.
• Fix metadata update in Shoutcast streaming. (Fixes: #122)
• Unescape all incoming MPD requests. (Fixes: #113)
• Increase the maximum number of results returned by Spotify searches from 32 to 100.
• Send Spotify search queries to pyspotify as unicode objects, as required by pyspotify 1.4. (Fixes: #129)
• Add setting mopidy.settings.MPD_SERVER_MAX_CONNECTIONS. (Fixes: #134)
• Remove destroy() methods from backend controller and provider APIs, as it was not in use and actually not called by any code. Will reintroduce when needed.

26.2.32 v0.5.0 (2011-06-15)
Since last time we’ve added support for audio streaming to SHOUTcast servers and fixed the longstanding playlist loading issue in the Spotify backend. As always the release has a bunch of bug fixes and minor improvements.

Please note that 0.5.0 requires some updated dependencies, as listed under Important changes below.

Important changes
• If you use the Spotify backend, you must upgrade to libspotify 0.0.8 and pyspotify 1.3. If you install from APT, libspotify and pyspotify will automatically be upgraded. If you are not installing from APT, follow the instructions at Installation.
• If you have explicitly set the mopidy.settings.SPOTIFY_HIGH_BITRATE setting, you must update your settings file. The new setting is named mopidy.settings.SPOTIFY_BITRATE and accepts the integer values 96, 160, and 320.
• Mopidy now supports running with 1 to N outputs at the same time. This feature was mainly added to facilitate SHOUTcast support, which Mopidy has also gained. In its current state outputs can not be toggled during runtime.

Changes
• Local backend:
– Fix local backend time query errors that where coming from stopped pipeline. (Fixes: #87)

• Spotify backend:
  – Thanks to Antoine Pierlot-Garcin’s recent work on updating and improving pyspotify, stored playlists will again load when Mopidy starts. The workaround of searching and reconnecting to make the playlists appear are no longer necessary. (Fixes: #59)
  – Track’s that are no longer available in Spotify’s archives are now “autolinked” to corresponding tracks in other albums, just like the official Spotify clients do. (Fixes: #34)

• MPD frontend:
  – Refactoring and cleanup. Most notably, all request handlers now get an instance of mopidy.frontends.mpd.dispatcher.MpdContext as the first argument. The new class contains reference to any object in Mopidy the MPD protocol implementation should need access to.
  – Close the client connection when the command close is received.
  – Do not allow access to the command kill.
  – commands and notcommands now have correct output if password authentication is turned on, but the connected user has not been authenticated yet.

• Command line usage:
  – Support passing options to GStreamer. See mopidy --help-gst for a list of available options. (Fixes: #95)
  – Improve mopidy --list-settings output. (Fixes: #91)
  – Added mopidy --interactive for reading missing local settings from stdin. (Fixes: #96)
  – Improve shutdown procedure at CTRL+C. Add signal handler for SIGTERM, which initiates the same shutdown procedure as CTRL+C does.

• Tag cache generator:
  – Made it possible to abort mopidy-scan with CTRL+C.
  – Fixed bug regarding handling of bad dates.
  – Use logging instead of print statements.
  – Found and worked around strange WMA metadata behaviour.

• Backend API:
  – Calling on mopidy.backends.base.playback.PlaybackController.next() and mopidy.backends.base.playback.PlaybackController.previous() no longer implies that playback should be started. The playback state—whether playing, paused or stopped—will now be kept.
  – The method mopidy.backends.base.playback.PlaybackController.change_track() has been added. Like next(), and prev(), it changes the current track without changing the playback state.

26.2.33 v0.4.1 (2011-05-06)

This is a bug fix release fixing audio problems on older GStreamer and some minor bugs.

Bug fixes

• Fix broken audio on at least GStreamer 0.10.30, which affects Ubuntu 10.10. The GStreamer appsrc bin wasn’t being linked due to lack of default caps. (Fixes: #85)
• Fix crash in mopidy.mixers.nad that occurs at startup when the io module is available. We used an eol keyword argument which is supported by serial.FileLike.readline(), but not by io.RawBaseIO.readline(). When the io module is available, it is used by PySerial instead of the FileLike implementation.

• Fix UnicodeDecodeError in MPD frontend on non-english locale. Thanks to Antoine Pierlot-Garcin for the patch. (Fixes: #88)

• Do not create Pykka proxies that are not going to be used in mopidy.core. The underlying actor may already intentionally be dead, and thus the program may crash on creating a proxy it doesn’t need. Combined with the Pykka 0.12.2 release this fixes a crash in the Last.fm frontend which may occur when all dependencies are installed, but the frontend isn’t configured. (Fixes: #84)

## 26.2.34 v0.4.0 (2011-04-27)

Mopidy 0.4.0 is another release without major feature additions. In 0.4.0 we’ve fixed a bunch of issues and bugs, with the help of several new contributors who are credited in the changelog below. The major change of 0.4.0 is an internal refactoring which clears way for future features, and which also make Mopidy work on Python 2.7. In other words, Mopidy 0.4.0 works on Ubuntu 11.04 and Arch Linux.

Please note that 0.4.0 requires some updated dependencies, as listed under Important changes below. Also, the known bug in the Spotify playlist loading from Mopidy 0.3.0 is still present.

### Warning: Known bug in Spotify playlist loading

There is a known bug in the loading of Spotify playlists. To avoid the bug, follow the simple workaround described at #59.

### Important changes

• Mopidy now depends on Pykka >=0.12. If you install from APT, Pykka will automatically be installed. If you are not installing from APT, you may install Pykka from PyPI:

```
sudo pip install -U Pykka
```

• If you use the Spotify backend, you should upgrade to libspotify 0.0.7 and the latest pyspotify from the Mopidy developers. If you install from APT, libspotify and pyspotify will automatically be upgraded. If you are not installing from APT, follow the instructions at Installation.

### Changes

• Mopidy now use Pykka actors for thread management and inter-thread communication. The immediate advantage of this is that Mopidy now works on Python 2.7, which is the default on e.g. Ubuntu 11.04. (Fixes: #66)

• Spotify backend:
  – Fixed multiple segmentation faults due to bugs in Pyspotify. Thanks to Antoine Pierlot-Garcin and Jamie Kirkpatrick for patches to Pyspotify.
  – Better error messages on wrong login or network problems. Thanks to Antoine Pierlot-Garcin for patches to Mopidy and Pyspotify. (Fixes: #77)
  – Reduce log level for trivial log messages from warning to info. (Fixes: #71)
  – Pause playback on network connection errors. (Fixes: #65)

• Local backend:

---

### 26.2. Changelog 0.x series

145
– Fix crash in `mopidy-scan` if a track has no artist name. Thanks to Martins Grunskis for test and patch and “octe” for patch.

– Fix crash in `tag_cache` parsing if a track has no total number of tracks in the album. Thanks to Martins Grunskis for the patch.

• MPD frontend:

  – Add support for “date” queries to both the `find` and `search` commands. This makes media library browsing in ncmcppp work, though very slow due to all the meta data requests to Spotify.

  – Add support for `play "-1"` when in playing or paused state, which fixes resume and addition of tracks to the current playlist while playing for the MPoD client.

  – Fix bug where `status returned song: None`, which caused MPDroid to crash. (Fixes: #69)

  – Gracefully fallback to IPv4 sockets on systems that supports IPv6, but has turned it off. (Fixes: #75)

• GStreamer output:

  – Use `uridecodebin` for playing audio from both Spotify and the local backend. This contributes to support for multiple backends simultaneously.

• Settings:

  – Fix crash on `mopidy --list-settings` on clean installation. Thanks to Martins Grunskis for the bug report and patch. (Fixes: #63)

• Packaging:

  – Replace test data symlinks with real files to avoid symlink issues when installing with pip. (Fixes: #68)

• Debugging:

  – Include platform, architecture, Linux distribution, and Python version in the debug log, to ease debugging of issues with attached debug logs.

### 26.2.35 v0.3.1 (2011-01-22)

A couple of fixes to the 0.3.0 release is needed to get a smooth installation.

**Bug fixes**

• The Spotify application key was missing from the Python package.

• Installation of the Python package as a normal user failed because it did not have permissions to install `mopidy.desktop`. The file is now only installed if the installation is executed as the root user.

### 26.2.36 v0.3.0 (2011-01-22)

Mopidy 0.3.0 brings a bunch of small changes all over the place, but no large changes. The main features are support for high bitrate audio from Spotify, and MPD password authentication.

Regarding the docs, we’ve improved the installation instructions and done a bit of testing of the available Android and iOS clients for MPD.

Please note that 0.3.0 requires some updated dependencies, as listed under Important changes below. Also, there is a known bug in the Spotify playlist loading, as described below. As the bug will take some time to fix and has a known workaround, we did not want to delay the release while waiting for a fix to this problem.
**Warning:** Known bug in Spotify playlist loading

There is a known bug in the loading of Spotify playlists. This bug affects both Mopidy 0.2.1 and 0.3.0, given that you use libspotify 0.0.6. To avoid the bug, either use Mopidy 0.2.1 with libspotify 0.0.4, or use either Mopidy version with libspotify 0.0.6 and follow the simple workaround described at #59.

**Important changes**

- If you use the Spotify backend, you need to upgrade to libspotify 0.0.6 and the latest pyspotify from the Mopidy developers. Follow the instructions at [Installation](#).
- If you use the Last.fm frontend, you need to upgrade to pylast 0.5.7. Run `sudo pip install --upgrade pylast` or install Mopidy from APT.

**Changes**

- **Spotify backend:**
  - Support high bitrate (320k) audio. Set the new setting `mopidy.settings.SPOTIFY_HIGH_BITRATE` to `True` to switch to high bitrate audio.
  - Rename `mopidy.backends.libspotify` to `mopidy.backends.spotify`. If you have set `mopidy.settings.BACKENDS` explicitly, you may need to update the setting’s value.
  - Catch and log error caused by playlist folder boundaries being treated as normal playlists. More permanent fix requires support for checking playlist types in pyspotify (see #62).
  - Fix crash on failed lookup of track by URI. (Fixes: #60)

- **Local backend:**
  - Add `mopidy-scan` command to generate `tag_cache` files without any help from the original MPD server. See [Generating a local library](#) for instructions on how to use it.
  - Fix support for UTF-8 encoding in tag caches.

- **MPD frontend:**
  - Add support for password authentication. See `mopidy.settings.MPD_SERVER_PASSWORD` for details on how to use it. (Fixes: #41)
  - Support `setvol 50` without quotes around the argument. Fixes volume control in Droid MPD.
  - Support `seek 1 120` without quotes around the arguments. Fixes seek in Droid MPD.

- **Last.fm frontend:**
  - Update to use Last.fm’s new Scrobbling 2.0 API, as the old Submissions Protocol 1.2.1 is deprecated. (Fixes: #33)
  - Fix crash when track object does not contain all the expected meta data.
  - Fix crash when response from Last.fm cannot be decoded as UTF-8. (Fixes: #37)
  - Fix crash when response from Last.fm contains invalid XML.
  - Fix crash when response from Last.fm has an invalid HTTP status line.

- **Mixers:**
  - Support use of unicode strings for settings specific to `mopidy.mixers.nad`.

- **Settings:**
  - Automatically expand the “~” character to the user’s home directory and make the path absolute for settings with names ending in `_PATH` or `_FILE`.
– Rename the following settings. The settings validator will warn you if you need to change your local settings.
  * LOCAL_MUSIC_FOLDER to mopidy.settings.LOCAL_MUSIC_PATH
  * LOCAL_PLAYLIST_FOLDER to mopidy.settings.LOCAL_PLAYLIST_PATH
  * LOCAL_TAG_CACHE to mopidy.settings.LOCAL_TAG_CACHE_FILE
  * SPOTIFY_LIB_CACHE to mopidy.settings.SPOTIFY_CACHE_PATH
– Fix bug which made settings set to None or 0 cause a mopidy.SettingsError to be raised.

• Packaging and distribution:
  – Setup APT repository and create Debian packages of Mopidy. See Installation for instructions for how to install Mopidy, including all dependencies, from APT.
  – Install mopidy.desktop file that makes Mopidy available from e.g. Gnome application menus.

• API:
  – Rename and generalize Playlist._with(**kwargs) to mopidy.models.ImmutableObject.copy().
  – Add musicbrainz_id field to mopidy.models.Artist, mopidy.models.Album, and mopidy.models.Track.
  – Prepare for multi-backend support (see #40) by introducing the provider concept. Split the backend API into a backend controller API (for frontend use) and a backend provider API (for backend implementation use), which includes the following changes:
    * Rename BaseBackend to mopidy.backends.base.Backend.
    * Split BasePlaybackController to mopidy.backends.base.PlaybackController and mopidy.backends.base.BasePlaybackProvider.
  – Move BaseMixer to mopidy.mixers.base.BaseMixer.
  – Add docs for the current non-stable output API, mopidy.outputs.base.BaseOutput.

26.2.37 v0.2.1 (2011-01-07)

This is a maintenance release without any new features.

Bug fixes

  • Fix crash in mopidy.frontends.lastfm which occurred at playback if either pylast was not installed or the Last.fm scrobbling was not correctly configured. The scrobbling thread now shuts properly down at failure.
26.2.38 v0.2.0 (2010-10-24)

In Mopidy 0.2.0 we’ve added a Last.fm scrobbling support, which means that Mopidy now can submit meta data about the tracks you play to your Last.fm profile. See mopidy.frontends.lastfm for details on new dependencies and settings. If you use Mopidy’s Last.fm support, please join the Mopidy group at Last.fm.

With the exception of the work on the Last.fm scrobbler, there has been a couple of quiet months in the Mopidy camp. About the only thing going on, has been stabilization work and bug fixing. All bugs reported on GitHub, plus some, have been fixed in 0.2.0. Thus, we hope this will be a great release!

We’ve worked a bit on OS X support, but not all issues are completely solved yet. #25 is the one that is currently blocking OS X support. Any help solving it will be greatly appreciated!

Finally, please update your pyspotify installation when upgrading to Mopidy 0.2.0. The latest pyspotify got a fix for the segmentation fault that occurred when playing music and searching at the same time, thanks to Valentin David.

Important changes

• Added a Last.fm scrobbler. See mopidy.frontends.lastfm for details.

Changes

• Logging and command line options:
  – Simplify the default log format, mopidy.settings.CONSOLE_LOG_FORMAT. From a user’s point of view: Less noise, more information.
  – Rename the mopidy --dump command line option to mopidy --save-debug-log.
  – Rename setting mopidy.settings.DUMP_LOG_FORMAT to mopidy.settings.DEBUG_LOG_FORMAT and use it for mopidy --verbose too.
  – Rename setting mopidy.settings.DUMP_LOG_FILENAME to mopidy.settings.DEBUG_LOG_FILENAME.

• MPD frontend:
  – MPD command list now supports queries by artist, album name, and date, as used by e.g. the Ario client. (Fixes: #20)
  – MPD command add "" and addid "" now behaves as expected. (Fixes #16)
  – MPD command playid "-1" now correctly resumes playback if paused.

• Random mode:
  – Fix wrong behavior on end of track and next after random mode has been used. (Fixes: #18)
  – Fix infinite recursion loop crash on playback of non-playable tracks when in random mode. (Fixes #17)
  – Fix assertion error that happened if one removed tracks from the current playlist, while in random mode. (Fixes #22)

• Switched from using subprocesses to threads. (Fixes: #14)

• mopidy.outputs.gstreamer: Set caps on the appsrbc bin before use. This makes sound output work with GStreamer >= 0.10.29, which includes the versions used in Ubuntu 10.10 and on OS X if using Homebrew. (Fixes: #21, #24, contributes to #14)

• Improved handling of uncaught exceptions in threads. The entire process should now exit immediately.
After three weeks of long nights and sprints we’re finally pleased enough with the state of Mopidy to remove the alpha label, and do a regular release.

Mopidy 0.1.0 got important improvements in search functionality, working track position seeking, no known stability issues, and greatly improved MPD client support. There are lots of changes since 0.1.0a3, and we urge you to at least read the important changes below.

This release does not support OS X. We’re sorry about that, and are working on fixing the OS X issues for a future release. You can track the progress at #14.

Important changes

- License changed from GPLv2 to Apache License, version 2.0.
- GStreamer is now a required dependency. See our GStreamer installation docs.
- mopidy.backends.libspotify is now the default backend. mopidy.backends.despotify is no longer available. This means that you need to install the dependencies for libspotify.
- If you used mopidy.backends.libspotify previously, pyspotify must be updated when updating to this release, to get working seek functionality.
- mopidy.settings.SERVER_HOSTNAME and mopidy.settings.SERVER_PORT has been renamed to mopidy.settings.MPD_SERVER_HOSTNAME and mopidy.settings.MPD_SERVER_PORT to allow for multiple frontends in the future.

Changes

- Exit early if not Python >= 2.6, < 3.
- Validate settings at startup and print useful error messages if the settings has not been updated or anything is misspelled.
- Add command line option mopidy --list-settings to print the currently active settings.
- Include Sphinx scripts for building docs, pyntrc, tests and test data in the packages created by setup.py for i.e. PyPI.
- MPD frontend:
  - Search improvements, including support for multi-word search.
  - Fixed play "-1" and playid "-1" behaviour when playlist is empty or when a current track is set.
  - Support plchanges "-1" to work better with MPDroid.
  - Support pause without arguments to work better with MPDroid.
  - Support plchanges,play,consume,random,repeat, and single without quotes to work better with BitMPC.
  - Fixed deletion of the currently playing track from the current playlist, which crashed several clients.
  - Implement seek and seekid.
  - Fix playlistfind output so the correct song is played when playing songs directly from search results in GMPC.
  - Fix load so that one can append a playlist to the current playlist, and make it return the correct error message if the playlist is not found.
  - Support for single track repeat added. ( Fixes: #4)
  - Relocate from mopidy.mpd to mopidy.frontends.mpd.
– Split gigantic protocol implementation into eleven modules.

– Rename `mopidy.frontends.mpd.{serializer => translator}` to match naming in back-ends.

– Remove setting `mopidy.settings.SERVER` and `mopidy.settings.FRONTEND` in favour of the new `mopidy.settings.FRONTENDS`.

– Run MPD server in its own process.

• Backends:

  – Rename `mopidy.backends.gstreamer` to `mopidy.backends.local`.

  – Remove `mopidy.backends.despotify`, as Desotify is little maintained and the Libspotify back-end is working much better. (Fixes: #9, #10, #13)

  – A Spotify application key is now bundled with the source. `mopidy.settings.SPOTIFY_LIB_APPKEY` is thus removed.

  – If failing to play a track, playback will skip to the next track.

  – Both `mopidy.backends.libspotify` and `mopidy.backends.local` have been rewritten to use the new common GStreamer audio output module, `mopidy.outputs.gstreamer`.

• Mixers:

  – Added new `mopidy.mixers.gstreamer_software.GStreamerSoftwareMixer` which now is the default mixer on all platforms.

  – New setting `mopidy.settings.MIXER_MAX_VOLUME` for capping the maximum output volume.

• Backend API:

  – Relocate from `mopidy.backends` to `mopidy.backends.base`.

  – The `id` field of `mopidy.models.Track` has been removed, as it is no longer needed after the CPID refactoring.

  – `mopidy.backends.base.BaseBackend()` now accepts an `output_queue` which it can use to send messages (i.e. audio data) to the output process.

  – `mopidy.backends.base.BaseLibraryController.find_exact()` now accepts keyword arguments of the form `find_exact(artist=[‘foo’], album=[‘bar’])`.

  – The following fields in `mopidy.backends.base.BasePlaybackController` has been renamed to reflect their relation to methods called on the controller:

    * `next_track` to `track_at_next`
    * `next_cp_track` to `cp_track_at_next`
    * `previous_track` to `track_at_previous`
    * `previous_cp_track` to `cp_track_at_previous`
- mopidy.backends.base.BasePlaybackController.track_at_eot and mopidy.backends.base.BasePlaybackController.cp_track_at_eot has been added to better handle the difference between the user pressing next and the current track ending.

- Rename mopidy.backends.base.BasePlaybackController.new_playlist_loaded_callback() to mopidy.backends.base.BasePlaybackController.on_current_playlist_change().

- Rename mopidy.backends.base.BasePlaybackController.end_of_track_callback() to mopidy.backends.base.BasePlaybackController.on_end_of_track().

- Remove mopidy.backends.base.BaseStoredPlaylistsController.search() since it was barely used, untested, and we got no use case for non-exact search in stored playlists yet. Use mopidy.backends.base.BaseStoredPlaylistsController.get() instead.

26.2.40 v0.1.0a3 (2010-08-03)

In the last two months, Mopidy’s MPD frontend has gotten lots of stability fixes and error handling improvements, proper support for having the same track multiple times in a playlist, and support for IPv6. We have also fixed the choppy playback on the libspotify backend. For the road ahead of us, we got an updated release roadmap with our goals for the 0.1 to 0.3 releases.

Enjoy the best alpha release of Mopidy ever :-)

Changes

- MPD frontend:
  - addid responds properly on errors instead of crashing.
  - commands support, which makes RelaXXPlayer work with Mopidy. (Fixes: #6)
  - Does no longer crash on invalid data, i.e. non-UTF-8 data.
  - ACK error messages are now MPD-compliant, which should make clients handle errors from Mopidy better.
  - Requests to existing commands with wrong arguments are no longer reported as unknown commands.
  - command_list_end before command_list_start now returns unknown command error instead of crashing.
  - list accepts field argument without quotes and capitalized, to work with GMPC and ncmpc.
  - noidle command now returns OK instead of an error. Should make some clients work a bit better.
  - Having multiple identical tracks in a playlist is now working properly. (CPID refactoring)

- Despotify backend:
  - Catch and log spytify.SpytifyError. (Fixes: #11)

- Libspotify backend:
  - Fix choppy playback using the Libspotify backend by using blocking ALSA mode. (Fixes: #7)

- Backend API:
  - A new data structure called cp_track is now used in the current playlist controller and the playback controller. A cp_track is a two-tuple of (CPID integer, mopidy.models.Track), identifying an instance of a track uniquely within the current playlist.
- mopidy.backends.BaseCurrentPlaylistController.load() now accepts lists of mopidy.models.Track instead of mopidy.models.Playlist, as none of the other fields on the Playlist model was in use.

- mopidy.backends.BaseCurrentPlaylistController.add() now returns the cp_track added to the current playlist.

- mopidy.backends.BaseCurrentPlaylistController.remove() now takes criterias, just like mopidy.backends.BaseCurrentPlaylistController.get().

- mopidy.backends.BaseCurrentPlaylistController.tracks is now read-only. Use the methods to change its contents.

- mopidy.backends.BaseCurrentPlaylistController.cp_tracks is a read-only list of cp_track. Use the methods to change its contents.

- mopidy.backends.BasePlaybackController.current_track is now just for convenience and read-only. To set the current track, assign a cp_track to mopidy.backends.BasePlaybackController.current_cp_track.

- mopidy.backends.BasePlaybackController.current_cpid is the read-only CPID of the current track.

- mopidy.backends.BasePlaybackController.next_cp_track is the next cp_track in the playlist.

- mopidy.backends.BasePlaybackController.previous_cp_track is the previous cp_track in the playlist.

- mopidy.backends.BasePlaybackController.play() now takes a cp_track.

26.2.41 v0.1.0a2 (2010-06-02)

It has been a rather slow month for Mopidy, but we would like to keep up with the established pace of at least a release per month.

Changes

- Improvements to MPD protocol handling, making Mopidy work much better with a group of clients, including ncmpc, MPoD, and Theremin.

- New command line flag mopidy --dump for dumping debug log to dump.log in the current directory.

- New setting mopidy.settings.MIXER_ALSA_CONTROL for forcing what ALSA control mopidy.mixers.alsa.AlsaMixer should use.

26.2.42 v0.1.0a1 (2010-05-04)

Since the previous release Mopidy has seen about 300 commits, more than 200 new tests, a libspotify release, and major feature additions to Spotify. The new releases from Spotify have lead to updates to our dependencies, and also to new bugs in Mopidy. Thus, this is primarily a bugfix release, even though the not yet finished work on a GStreamer backend have been merged.

All users are recommended to upgrade to 0.1.0a1, and should at the same time ensure that they have the latest versions of our dependencies: Despotify r508 if you are using DespotifyBackend, and pyspotify 1.1 with libspotify 0.0.4 if you are using LibspotifyBackend.

As always, report problems at our IRC channel or our issue tracker. Thanks!
Changes

- Backend API changes:
  - Removed `backend.playback.volume` wrapper. Use `backend.mixer.volume` directly.
  - Renamed `backend.playback.playlist_position` to `current_playlist_position` to match naming of `current_track`.
  - Replaced `get_by_id()` with a more flexible `get(**criteria)`.
- Merged the `gstreamer` branch from Thomas Adamcik:
  - More than 200 new tests, and thus several bug fixes to existing code.
  - Several new generic features, like shuffle, consume, and playlist repeat. (Fixes: #3)
  - [Work in Progress] A new backend for playing music from a local music archive using the GStreamer library.
- Made `mopidy.mixers.alsa.AlsaMixer` work on machines without a mixer named “Master”.
- Made `mopidy.backends.DespotifyBackend` ignore local files in playlists (feature added in Spotify 0.4.3). Reported by Richard Haugen Olsen.
- And much more.

26.2.43 v0.1.0a0 (2010-03-27)

Three months of development should be more than enough. We have more to do, but Mopidy is working and usable. 0.1.0a0 is an alpha release, which basically means we will still change APIs, add features, etc. before the final 0.1.0 release. But the software is usable as is, so we release it. Please give it a try and give us feedback, either at our IRC channel or through the issue tracker. Thanks!

Changes

- Initial version. No changelog available.
If you want to contribute to Mopidy, here are some tips to get you started.

### 27.1 Asking questions

Please get in touch with us in one of these ways when requesting help with Mopidy and its extensions:

- Our IRC channel: #mopidy on irc.freenode.net. Be prepared to hang around for a while, as we’re not always around to answer straight away.

Before asking for help, it might be worth your time to read the Troubleshooting page, both so you might find a solution to your problem but also to be able to provide useful details when asking for help.

### 27.2 Helping users

If you want to contribute to Mopidy, a great place to start is by helping other users on IRC and in the discussion forum. This is a contribution we value highly. As more people help with user support, new users get faster and better help. For your own benefit, you’ll quickly learn what users find confusing, difficult or lacking, giving you some ideas for where you may contribute improvements, either to code or documentation. Lastly, this may also free up time for other contributors to spend more time on fixing bugs or implementing new features.

### 27.3 Issue guidelines

1. If you need help, see Asking questions above. The GitHub issue tracker is not a support forum.
2. If you are not sure if what you’re experiencing is a bug or not, post in the discussion forum first to verify that it’s a bug.
3. If you are sure that you’ve found a bug or have a feature request, check if there’s already an issue in the issue tracker. If there is, see if there is anything you can add to help reproduce or fix the issue.

4. If there is no existing issue matching your bug or feature request, create a new issue. Please include as much relevant information as possible. If it’s a bug, including how to reproduce the bug and any relevant logs or error messages.

### 27.4 Pull request guidelines

1. Before spending any time on making a pull request:
   - If it’s a bug, [file an issue](https://github.com/mopidy/mopidy/issues).
   - If it’s an enhancement, discuss it with other Mopidy developers first, either in a GitHub issue, on the discussion forum, or on IRC. Making sure your ideas and solutions are aligned with other contributors greatly increases the odds of your pull request being quickly accepted.

2. Create a new branch, based on the develop branch, for every feature or bug fix. Keep branches small and on topic, as that makes them far easier to review. We often use the following naming convention for branches:
   - Features get the prefix `feature/`, e.g. `feature/track-last-modified-as-ms`.
   - Bug fixes get the prefix `fix/`, e.g. `fix/902-consume-track-on-next`.
   - Improvements to the documentation get the prefix `docs/`, e.g. `docs/add-ext-mopidy-spotify-tunigo`.

3. Follow the [code style](https://mopidy.readthedocs.io/en/latest/code_style.html), especially make sure the [flake8](https://flake8.pycqa.org) linter does not complain about anything. Travis CI will check that your pull request is “flake8 clean”. See [Style checking and linting](https://mopidy.readthedocs.io/en/latest/style.html).

4. Include tests for any new feature or substantial bug fix. See [Running tests](https://mopidy.readthedocs.io/en/latest/testing.html).

6. Feel free to include a changelog entry in your pull request. The changelog is in `docs/changelog.rst`.

7. Write good commit messages.
   - Follow the template “topic: description” for the first line of the commit message, e.g. “mpd: Switch list command to using list_distinct”. See the commit history for inspiration.
   - Use the rest of the commit message to explain anything you feel isn’t obvious. It’s better to have the details here than in the pull request description, since the commit message will live forever.
   - Write in the imperative, present tense: “add” not “added”.

For more inspiration, feel free to read these blog posts:

- [Writing Git commit messages](https://medium.com/@david.wildenthal/writing-good-git-commit-messages-3490a53f42e5)
- [A Note About Git Commit Messages](https://trac.gitorious.org/torvalds/git desarrolladores/docs/commitmessage.txt)
- [On commit messages](https://www.mail-archive.com/oss-discuss@oss.gnome.org/msg01204.html)

8. Send a pull request to the `develop` branch. See the [GitHub pull request docs](https://help.github.com/en/articles/pull-requests) for help.

**Note:** If you are contributing a bug fix for a specific minor version of Mopidy you should create the branch based on `release-x.y` instead of `develop`. When the release is done the changes will be merged back into `develop` automatically as part of the normal release process. See [Creating releases](https://mopidy.readthedocs.io/en/latest/releases.html).
This page describes a common development setup for working with Mopidy and Mopidy extensions. Of course, there may be other ways that work better for you and the tools you use, but here’s one recommended way to do it.

- **Initial setup**
  - Install Mopidy the regular way
  - Make a development workspace
  - Make a virtualenv
  - Clone the repo from GitHub
  - Install development tools
  - Install Mopidy from the Git repo
- **Running Mopidy from Git**
- **Running tests**
  - Test it all
  - Running unit tests
  - Continuous integration
  - Style checking and linting
- **Writing documentation**
- **Working on extensions**
  - Installing extensions
  - Upgrading extensions
- **Contribution workflow**
28.1 Initial setup

The following steps help you get a good initial setup. They build on each other to some degree, so if you’re not very familiar with Python development it might be wise to proceed in the order laid out here.

- **Install Mopidy the regular way**
- **Make a development workspace**
- **Make a virtualenv**
- **Clone the repo from GitHub**
- **Install development tools**
- **Install Mopidy from the Git repo**

### 28.1.1 Install Mopidy the regular way

Install Mopidy the regular way. Mopidy has some non-Python dependencies which may be tricky to install. Thus we recommend to always start with a full regular Mopidy install, as described in *Installation*. That is, if you’re running e.g. Debian, start with installing Mopidy from Debian packages.

### 28.1.2 Make a development workspace

Make a directory to be used as a workspace for all your Mopidy development:

```
mkdir ~/mopidy-dev
```

It will contain all the Git repositories you’ll check out when working on Mopidy and extensions.

### 28.1.3 Make a virtualenv

Make a Python virtualenv for Mopidy development. The virtualenv will wall off Mopidy and its dependencies from the rest of your system. All development and installation of Python dependencies, versions of Mopidy, and extensions are done inside the virtualenv. This way your regular Mopidy install, which you set up in the first step, is unaffected by your hacking and will always be working.

Most of us use the virtualenvwrapper to ease working with virtualenvs, so that’s what we’ll be using for the examples here. First, install and setup virtualenvwrapper as described in their docs.

To create a virtualenv named `mopidy` which uses Python 2.7, allows access to system-wide packages like GStreamer, and uses the Mopidy workspace directory as the “project path”, run:
```bash
mkvirtualenv -a ~/mopidy-dev --python `which python2.7` \
   --system-site-packages mopidy
```

Now, each time you open a terminal and want to activate the mopidy virtualenv, run:

```bash
workon mopidy
```

This will both activate the mopidy virtualenv, and change the current working directory to `~/mopidy-dev`.

### 28.1.4 Clone the repo from GitHub

Once inside the virtualenv, it’s time to clone the mopidy/mopidy Git repo from GitHub:

```bash
git clone https://github.com/mopidy/mopidy.git
```

When you’ve cloned the mopidy Git repo, `cd` into it:

```bash
cd ~/mopidy-dev/mopidy/
```

With a fresh clone of the Git repo, you should start out on the develop branch. This is where all features for the next feature release land. To confirm that you’re on the right branch, run:

```bash
git branch
```

### 28.1.5 Install development tools

We use a number of Python development tools. The `dev-requirements.txt` file has comments describing what we use each dependency for, so we might just as well include the file verbatim here:

```bash
# Automate tasks
invoke

# Build documentation
sphinx

# Check code style, errors, etc
flake8
flake8-import-order

# Mock dependencies in tests
mock
responses

# Test runners
pytest>=3.3.0
pytest-cov
pytest-xdist
tox

# Check that MANIFEST.in matches Git repo contents before making a release
check-manifest

# To make wheel packages
wheel
```

(continues on next page)
# Securely upload packages to PyPI

twine

Install them all into the active virtualenv by running pip:

```bash
pip install --upgrade -r dev-requirements.txt
```

To upgrade the tools in the future, just rerun the exact same command.

## 28.1.6 Install Mopidy from the Git repo

Next up, we’ll want to run Mopidy from the Git repo. There’s two reasons for this: first of all, it lets you easily change the source code, restart Mopidy, and see the change take effect. Second, it’s a convenient way to keep at the bleeding edge, testing the latest developments in Mopidy itself or test some extension against the latest Mopidy changes.

Assuming you’re still inside the Git repo, use pip to install Mopidy from the Git repo in an “editable” form:

```bash
pip install --editable .
```

This will not copy the source code into the virtualenv’s `site-packages` directory, but instead create a link there pointing to the Git repo. Using `cdsitepackages` from virtualenvwrapper, we can quickly show that the installed Mopidy.egg-link file points back to the Git repo:

```bash
$ cd sitepackages
$ cat Mopidy.egg-link
/home/user/mopidy-dev/mopidy
$%
$%
```

It will also create a `mopidy` executable inside the virtualenv that will always run the latest code from the Git repo. Using another virtualenvwrapper command, `cdvirtualenv`, we can show that too:

```bash
$ cd virtualenv
$ cat bin/mopidy
...
```

The executable should contain something like this, using `pkg_resources` to look up Mopidy’s “console script” entry point:

```python
#!/home/user/virtualenvs/mopidy/bin/python2
# EASY-INSTALL-ENTRY-SCRIPT: 'Mopidy==0.19.5','console_scripts','mopidy'
__requires__ = 'Mopidy==0.19.5'
import sys
from pkg_resources import load_entry_point

if __name__ == '__main__':
    sys.exit(load_entry_point('Mopidy==0.19.5', 'console_scripts', 'mopidy')() )
```

**Note:** It still works to run `python mopidy` directly on the `~/mopidy-dev/mopidy/mopidy/` Python package directory, but if you don’t run the `pip install` command above, the extensions bundled with Mopidy will not be registered with `pkg_resources`, making Mopidy quite useless.
Third, the `pip install` command will register the bundled Mopidy extensions so that Mopidy may find them through `pkg_resources`. The result of this can be seen in the Git repo, in a new directory called `Mopidy.egg-info`, which is ignored by Git. The `Mopidy.egg-info/entry_points.txt` file is of special interest as it shows both how the above executable and the bundled extensions are connected to the Mopidy source code:

```plaintext
[console_scripts]
mopydy = mopidy.__main__:main

[mopidy_ext]
http = mopidy.http:Extension
local = mopidy.local:Extension
mpd = mopidy.mpd:Extension
softwaremixer = mopidy.softwaremixer:Extension
stream = mopidy.stream:Extension
```

**Warning:** It’s not uncommon to clean up in the Git repo now and then, e.g. by running `git clean`. If you do this, then the `Mopidy.egg-info` directory will be removed, and `pkg_resources` will no longer know how to locate the “console script” entry point or the bundled Mopidy extensions.

The fix is simply to run the install command again:

```
pip install --editable .
```

Finally, we can go back to the workspace, again using a virtualenvwrapper tool:

```
cdproject
```

### 28.2 Running Mopidy from Git

As long as the virtualenv is activated, you can start Mopidy from any directory. Simply run:

```
mopidy
```

To stop it again, press Ctrl+C.

Every time you change code in Mopidy or an extension and want to see it live, you must restart Mopidy.

If you want to iterate quickly while developing, it may sound a bit tedious to restart Mopidy for every minor change. Then it’s useful to have tests to exercise your code…

### 28.3 Running tests

Mopidy has quite good test coverage, and we would like all new code going into Mopidy to come with tests.

- Test it all
- Running unit tests
- Continuous integration
- Style checking and linting
28.3.1 Test it all

You need to know at least one command; the one that runs all the tests:

```bash
 tox
```

This will run exactly the same tests as Travis CI runs for all our branches and pull requests. If this command turns green, you can be quite confident that your pull request will get the green flag from Travis as well, which is a requirement for it to be merged.

As this is the ultimate test command, it’s also the one taking the most time to run; up to a minute, depending on your system. But, if you have patience, this is all you need to know. Always run this command before pushing your changes to GitHub.

If you take a look at the tox config file, `tox.ini`, you’ll see that tox runs tests in multiple environments, including a flake8 environment that lints the source code for issues and a docs environment that tests that the documentation can be built. You can also limit tox to just test specific environments using the `-e` option, e.g. to run just unit tests:

```bash
 tox -e py27
```

To learn more, see the tox documentation.

28.3.2 Running unit tests

Under the hood, `tox -e py27` will use pytest as the test runner. We can also use it directly to run all tests:

```bash
 pytest
```

pytest has lots of possibilities, so you’ll have to dive into their docs and plugins to get full benefit from it. To get you interested, here are some examples.

We can limit to just tests in a single directory to save time:

```bash
 pytest tests/http/
```

With the help of the pytest-xdist plugin, we can run tests with four Python processes in parallel, which usually cuts the test time in half or more:

```bash
 pytest -n 4
```

Another useful feature from pytest-xdist, is the possibility to stop on the first test failure, watch the file system for changes, and then rerun the tests. This makes for a very quick code-test cycle:

```bash
 pytest -f  # or --looponfail
```

With the help of the pytest-cov plugin, we can get a report on what parts of the given module, mopidy in this example, are covered by the test suite:

```bash
 pytest --cov=mopidy --cov-report=term-missing
```

**Note:** Up to date test coverage statistics can also be viewed online at coveralls.io.

If we want to speed up the test suite, we can even get a list of the ten slowest tests:
By now, you should be convinced that running pytest directly during development can be very useful.

### 28.3.3 Continuous integration

Mopidy uses the free service Travis CI for automatically running the test suite when code is pushed to GitHub. This works both for the main Mopidy repo, but also for any forks. This way, any contributions to Mopidy through GitHub will automatically be tested by Travis CI, and the build status will be visible in the GitHub pull request interface, making it easier to evaluate the quality of pull requests.

For each successful build, Travis submits code coverage data to coveralls.io. If you’re out of work, coveralls might help you find areas in the code which could need better test coverage.

### 28.3.4 Style checking and linting

We’re quite pedantic about Code style and try hard to keep the Mopidy code base a very clean and nice place to work in.

Luckily, you can get very far by using the flake8 linter to check your code for issues before submitting a pull request. Mopidy passes all of flake8’s checks, with only a very few exceptions configured in setup.cfg. You can either run the flake8 tox environment, like Travis CI will do on your pull request:

```
tox -e flake8
```

Or you can run flake8 directly:

```
flake8
```

If successful, the command will not print anything at all.

**Note:** In some rare cases it doesn’t make sense to listen to flake8’s warnings. In those cases, ignore the check by appending `# noqa: <warning code>` to the source line that triggers the warning. The `# noqa` part will make flake8 skip all checks on the line, while the warning code will help other developers lookup what you are ignoring.

### 28.4 Writing documentation

To write documentation, we use Sphinx. See their site for lots of documentation on how to use Sphinx.

**Note:** To generate a few graphs which are part of the documentation, you need some additional dependencies. You can install them from APT with:

```
sudo apt-get install python-pygraphviz graphviz
```

To build the documentation, go into the `docs/` directory:

```
cd ~/mopidy-dev/mopidy/docs/
```

Then, to see all available build targets, run:
To generate an HTML version of the documentation, run:

```
make html
```

The generated HTML will be available at `_build/html/index.html`. To open it in a browser you can run either of the following commands, depending on your OS:

```
xdg-open _build/html/index.html  # Linux
open _build/html/index.html      # OS X
```

The documentation at https://docs.mopidy.com/ is hosted by Read the Docs, which automatically updates the documentation when a change is pushed to the mopidy/mopidy repo at GitHub.

### 28.5 Working on extensions

Much of the above also applies to Mopidy extensions, though they’re often a bit simpler. They don’t have documentation sites and their test suites are either small and fast, or sadly missing entirely. Most of them use tox and flake8, and pytest can be used to run their test suites.

- **Installing extensions**
- **Upgrading extensions**

#### 28.5.1 Installing extensions

As always, the `mopidy` virtualenv should be active when working on extensions:

```
workon mopidy
```

Just like with non-development Mopidy installations, you can install extensions using pip:

```
pip install Mopidy-Scrobbler
```

Installing an extension from its Git repo works the same way as with Mopidy itself. First, go to the Mopidy workspace:

```
cdproject    # or cd ~/mopidy-dev/
```

Clone the desired Mopidy extension:

```
git clone https://github.com/mopidy/mopidy-spotify.git
```

Change to the newly created extension directory:

```
 cd mopidy-spotify/
```

Then, install the extension in “editable” mode, so that it can be imported from anywhere inside the virtualenv and the extension is registered and discoverable through `pkg_resources`:

```
pip install --editable .
```
Every extension will have a README.rst file. It may contain information about extra dependencies required, development process, etc. Extensions usually have a changelog in the readme file.

### 28.5.2 Upgrading extensions

Extensions often have a much quicker life cycle than Mopidy itself, often with daily releases in periods of active development. To find outdated extensions in your virtualenv, you can run:

```
pip search mopidy
```

This will list all available Mopidy extensions and compare the installed versions with the latest available ones.

To upgrade an extension installed with pip, simply use pip:

```
pip install --upgrade Mopidy-Scrobblere
```

To upgrade an extension installed from a Git repo, it’s usually enough to pull the new changes in:

```
cd ~/mopidy-dev/mopidy-spotify/
git pull
```

Of course, if you have local modifications, you’ll need to stash these away on a branch or similar first.

Depending on the changes to the extension, it may be necessary to update the metadata about the extension package by installing it in “editable” mode again:

```
pip install --editable .
```

### 28.6 Contribution workflow

Before you begin, make sure you’ve read the Contributing page and the guidelines there. This section will focus more on the practical workflow.

For the examples, we’re making a change to Mopidy. Approximately the same workflow should work for most Mopidy extensions too.

- Setting up Git remotes
- Creating a branch
- Creating a pull request
- Updating a pull request

#### 28.6.1 Setting up Git remotes

Assuming we already have a local Git clone of the upstream Git repo in ~/mopidy-dev/mopidy/, we can run

```
git remote -v
```

```
origin https://github.com/mopidy/mopidy.git (fetch)
origin https://github.com/mopidy/mopidy.git (push)
```
For clarity, we can rename the `origin` remote to `upstream`:

```
$ git remote rename origin upstream
$ git remote -v
upstream https://github.com/mopidy/mopidy.git (fetch)
upstream https://github.com/mopidy/mopidy.git (push)
```

If you haven’t already, fork the repository to your own GitHub account.

Then, add the new fork as a remote to your local clone:

```
git remote add myuser git@github.com:myuser/mopidy.git
```

The end result is that you have both the upstream repo and your own fork as remotes:

```
$ git remote -v
myuser git@github.com:myuser/mopidy.git (fetch)
myuser git@github.com:myuser/mopidy.git (push)
upstream https://github.com/mopidy/mopidy.git (fetch)
upstream https://github.com/mopidy/mopidy.git (push)
```

### 28.6.2 Creating a branch

Fetch the latest data from all remotes without affecting your working directory:

```
git remote update
```

Now, we are ready to create and checkout a new branch off of the upstream `develop` branch for our work:

```
git checkout -b fix/666-crash-on-foo upstream/develop
```

Do the work, while remembering to adhere to code style, test the changes, make necessary updates to the documentation, and making small commits with good commit messages. All as described in `Contributing` and elsewhere in the `Development environment` guide.

### 28.6.3 Creating a pull request

When everything is done and committed, push the branch to your fork on GitHub:

```
git push myuser fix/666-crash-on-foo
```

Go to the repository on GitHub where you want the change merged, in this case `https://github.com/mopidy/mopidy`, and create a pull request.

### 28.6.4 Updating a pull request

When the pull request is created, Travis CI will run all tests on it. If something fails, you’ll get notified by email. You might as well just fix the issues right away, as we won’t merge a pull request without a green Travis build. See `Running tests` on how to run the same tests locally as Travis CI runs on your pull request.

When you’ve fixed the issues, you can update the pull request simply by pushing more commits to the same branch in your fork:
Likewise, when you get review comments from other developers on your pull request, you’re expected to create additional commits which addresses the comments. Push them to your branch so that the pull request is updated.

**Note:** Setup the remote as the default push target for your branch:

```
$ git branch --set-upstream-to myuser/fix/666-crash-on-foo
```

Then you can push more commits without specifying the remote:

```
$ git push
```
Release procedures

Here we try to keep an up to date record of how Mopidy releases are made. This documentation serves both as a checklist, to reduce the project’s dependency on key individuals, and as a stepping stone to more automation.

### 29.1 Creating releases

1. Update changelog and commit it.
2. Bump the version number in `mopidy/__init__.py`.
3. Merge the release branch (develop in the example) into master:

   ```shell
   git checkout master
   git merge --no-ff -m "Release v0.16.0" develop
   ```

4. Install/upgrade tools used for packaging:

   ```shell
   pip install -U twine wheel
   ```

5. Build package and test it manually in a new virtualenv. The following assumes the use of virtualenvwrapper:

   ```shell
   mktmpenv
   python setup.py sdist bdist_wheel
   mktmpenv
   pip install path/to/dist/Mopidy-0.16.0.tar.gz
toggleglobalsitepackages
   # do manual test
deactivate
   mktmpenv
   pip install path/to/dist/Mopidy-0.16.0-py27-none-any.whl
toggleglobalsitepackages
   # do manual test
deactivate
6. Tag the release:

```bash
git tag -a -m "Release v0.16.0" v0.16.0
```

7. Push to GitHub:

```bash
git push --follow-tags
```

8. Upload the previously built and tested sdist and bdist_wheel packages to PyPI:

```bash
twine upload dist/Mopidy-0.16.0*
```

9. Merge `master` back into `develop` and push the branch to GitHub.

10. Make sure the new tag is built by Read the Docs, and that the `latest` version shows the newly released version.

11. Spread the word through the topic on #mopidy on IRC, @mopidy on Twitter, and on the mailing list.

12. Notify distribution packagers, including but not limited to: Debian, Arch Linux, Homebrew.
**Code style**

- Always import `unicode_literals` and use unicode literals for everything except where you’re explicitly working with bytes, which are marked with the `b` prefix.

Do this:

```python
from __future__ import unicode_literals
foo = 'I am a unicode string, which is a sane default'
bar = b'I am a bytestring'
```

Not this:

```python
foo = u'I am a unicode string'
bar = 'I am a bytestring, but was it intentional?'
```

- Follow PEP 8 unless otherwise noted. `flake8` should be used to check your code against the guidelines.

- Use four spaces for indentation, *never* tabs.

- Use CamelCase with initial caps for class names:

```python
ClassNameWithCamelCase
```

- Use underscore to split variable, function and method names for readability. Don’t use CamelCase.

```python
lower_case_withUnderscores
```

- Use the fact that empty strings, lists and tuples are `False` and don’t compare boolean values using `==` and `!=`.

- Follow whitespace rules as described in PEP 8. Good examples:

```python
spam{ham[1], {eggs: 2}}
spam{1}
dict['key'] = list[index]
```
• Limit lines to 80 characters and avoid trailing whitespace. However note that wrapped lines should be one indentation level in from level above, except for if, for, with, and while lines which should have two levels of indentation:

```python
if (foo and bar ...)
    baz and foobar):
    a = 1

from foobar import (foo, bar, ...
    baz)
```

• For consistency, prefer ' over " for strings, unless the string contains ".

• Take a look at PEP 20 for a nice peek into a general mindset useful for Python coding.
Mopidy started as simply an MPD server that could play music from Spotify. Early on, Mopidy got multiple “frontends” to expose Mopidy to more than just MPD clients: for example the scrobble frontend that scrobbles your listening history to your Last.fm account, the MPRIS frontend that integrates Mopidy into the Ubuntu Sound Menu, and the HTTP server and JavaScript player API making web based Mopidy clients possible. In Mopidy 0.9 we added support for multiple music sources without stopping and reconfiguring Mopidy: for example the local backend for playing music from your disk, the stream backend for playing Internet radio streams, and the Spotify and SoundCloud backends, for playing music directly from those services.

All of these are examples of what you can accomplish by creating a Mopidy extension. If you want to create your own Mopidy extension for something that does not exist yet, this guide to extension development will help you get your extension running in no time, and make it feel the way users would expect your extension to behave.

### 31.1 Anatomy of an extension

Extensions are located in a Python package called `mopidy_something` where “something” is the name of the application, library or web service you want to integrate with Mopidy. So, for example, if you plan to add support for a service named Soundspot to Mopidy, you would name your extension’s Python package `mopidy_soundspot`.

The extension must be shipped with a `setup.py` file and be registered on PyPI. The name of the distribution on PyPI would be something like “Mopidy-Soundspot”. Make sure to include the name “Mopidy” somewhere in that name and that you check the capitalization. This is the name users will use when they install your extension from PyPI.

Mopidy extensions must be licensed under an Apache 2.0 (like Mopidy itself), BSD, MIT or more liberal license to be able to be enlisted in the Mopidy documentation. The license text should be included in the LICENSE file in the root of the extension’s Git repo.

Combining this together, we get the following folder structure for our extension, Mopidy-Soundspot:

```
| mopidy-soundspot/       # The Git repo root
| LICENSE                  # The license text
| MANIFEST.in             # List of data files to include in PyPI package
| README.rst              # Document what it is and how to use it
```

(continues on next page)
Example content for the most important files follows below.

### 31.2 cookiecutter project template

We’ve also made a cookiecutter project template for creating new Mopidy extensions. If you install cookiecutter and run a single command, you’re asked a few questions about the name of your extension, etc. This is used to create a folder structure similar to the above, with all the needed files and most of the details filled in for you. This saves you a lot of tedious work and copy-pasting from this howto. See the readme of cookiecutter-mopidy-ext for further details.

### 31.3 Example README.rst

The README file should quickly explain what the extension does, how to install it, and how to configure it. It should also contain a link to a tarball of the latest development version of the extension. It’s important that this link ends with `#egg=Mopidy-Something-dev` for installation using `pip install Mopidy-Something==dev` to work.

```
***************
Mopidy-Soundspot
***************

Mopidy <http://www.mopidy.com/>'__ extension for playing music from
Soundspot <http://soundspot.example.com/>'__.

Requires a Soundspot Platina subscription and the pysoundspot library.

**Installation**

Install by running::

    sudo pip install Mopidy-Soundspot

Or, if available, install the Debian/Ubuntu package from `apt.mopidy.com`
`<http://apt.mopidy.com/>'__.

**Configuration**

Before starting Mopidy, you must add your Soundspot username and password to the Mopidy configuration file::

    [soundspot]
    username = alice
    password = secret
```

Changelog
=========
v0.1.0 (2013-09-17)
------------------- Initial release.

31.4 Example setup.py
The setup.py file must use setuptools, and not distutils. This is because Mopidy extensions use setuptools’ entry
point functionality to register themselves as available Mopidy extensions when they are installed on your system.
The example below also includes a couple of convenient tricks for reading the package version from the source code
so that it is defined in a single place, and to reuse the README file as the long description of the package for the PyPI
registration.
The package must have install_requires on setuptools and Mopidy >= 0.14 (or a newer version, if
your extension requires it), in addition to any other dependencies required by your extension. If you implement a
Mopidy frontend or backend, you’ll need to include Pykka >= 1.1 in the requirements. The entry_points
part must be included. The mopidy.ext part cannot be changed, but the innermost string should be changed. It’s
format is ext_name = package_name:Extension. ext_name should be a short name for your extension,
typically the part after “Mopidy-” in lowercase. This name is used e.g. to name the config section for your extension.
The package_name:Extension part is simply the Python path to the extension class that will connect the rest of
the dots.
from __future__ import absolute_import, unicode_literals
import re
from setuptools import setup, find_packages

def get_version(filename):
content = open(filename).read()
metadata = dict(re.findall("__([a-z]+)__ = '([^']+)'", content))
return metadata['version']

setup(
name='Mopidy-Soundspot',
version=get_version('mopidy_soundspot/__init__.py'),
url='https://github.com/your-account/mopidy-soundspot',
license='Apache License, Version 2.0',
author='Your Name',
(continues on next page)

31.4. Example setup.py

175


To make sure your README, license file and default config file is included in the package that is uploaded to PyPI, we’ll also need to add a `MANIFEST.in` file:

```plaintext
include LICENSE
include MANIFEST.in
include README.rst
include mopidy_soundspot/ext.conf
```

For details on the `MANIFEST.in` file format, check out the distutils docs. `check-manifest` is a very useful tool to check your `MANIFEST.in` file for completeness.

### 31.5 Example __init__.py

The `__init__.py` file should be placed inside the `mopidy_soundspot` Python package.

The root of your Python package should have an `__version__` attribute with a PEP 386 compliant version number, for example “0.1”. Next, it should have a class named `Extension` which inherits from Mopidy’s extension base class, `mopidy.ext.Extension`. This is the class referred to in the `entry_points` part of `setup.py`. Any imports of other files in your extension, outside of Mopidy and it’s core requirements, should be kept inside methods. This ensures that this file can be imported without raising `ImportError` exceptions for missing dependencies, etc.

The default configuration for the extension is defined by the `get_default_config()` method in the `Extension` class which returns a `ConfigParser` compatible config section. The config section’s name must be the same as the extension’s short name, as defined in the `entry_points` part of `setup.py`, for example `soundspot`. All extensions must include an `enabled` config which normally should default to `true`. Provide good defaults for all config values so that as few users as possible will need to change them. The exception is if the config value has security implications; in that case you should default to the most secure configuration. Leave any configurations that don’t have meaningful defaults blank, like `username` and `password`. In the example below, we’ve chosen to
maintain the default config as a separate file named `ext.conf`. This makes it easy to include the default config in documentation without duplicating it.

This is `mopidy_soundspot/__init__.py`:

```python
from __future__ import absolute_import, unicode_literals
import logging
import os
from mopidy import config, exceptions, ext
__version__ = '0.1'
# If you need to log, use loggers named after the current Python module
logger = logging.getLogger(__name__)

class Extension(ext.Extension):
    dist_name = 'Mopidy-Soundspot'
    ext_name = 'soundspot'
    version = __version__

    def get_default_config(self):
        conf_file = os.path.join(os.path.dirname(__file__), 'ext.conf')
        return config.read(conf_file)

    def get_config_schema(self):
        schema = super(Extension, self).get_config_schema()
        schema['username'] = config.String()
        schema['password'] = config.Secret()
        return schema

    def get_command(self):
        from .commands import SoundspotCommand
        return SoundspotCommand()

    def validate_environment(self):
        # Any manual checks of the environment to fail early.
        # Dependencies described by setup.py are checked by Mopidy, so you
        # should not check their presence here.
        pass

    def setup(self, registry):
        # You will typically only do one of the following things in a
        # single extension.

        # Register a frontend
        from .frontend import SoundspotFrontend
        registry.add('frontend', SoundspotFrontend)

        # Register a backend
        from .backend import SoundspotBackend
        registry.add('backend', SoundspotBackend)

        # Or nothing to register e.g. command extension
        pass
```

31.5. Example `__init__.py`
And this is `mopidy_soundspot/ext.conf`:

```conf
[soundspot]
enabled = true
username =
password =
```

For more detailed documentation on the extension class, see the *mopidy.ext — Extension API*.

### 31.6 Example frontend

If you want to use Mopidy's core API from your extension, then you want to implement a frontend.

The skeleton of a frontend would look like this. Notice that the frontend gets passed a reference to the core API when it's created. See the *Frontend API* for more details.

```python
import pykka
from mopidy import core

class SoundspotFrontend(pykka.ThreadingActor, core.CoreListener):
    def __init__(self, config, core):
        super(SoundspotFrontend, self).__init__()
        self.core = core

        # Your frontend implementation
```

### 31.7 Example backend

If you want to extend Mopidy to support new music and playlist sources, you want to implement a backend. A backend does not have access to Mopidy's core API at all, but it does have a bunch of interfaces it can implement to extend Mopidy.

The skeleton of a backend would look like this. See *mopidy.backend — Backend API* for more details.

```python
import pykka
from mopidy import backend

class SoundspotBackend(pykka.ThreadingActor, backend.Backend):
    def __init__(self, config, audio):
        super(SoundspotBackend, self).__init__()
        self.audio = audio

        # Your backend implementation
```

### 31.8 Example command

If you want to extend the Mopidy with a new helper not run from the server, such as scanning for media, adding a command is the way to go. Your top level command name will always match your extension name, but you are free to
add sub-commands with names of your choosing.

The skeleton of a command would look like this. See `mopidy.commands — Commands API` for more details.

```python
from mopidy import commands

class SoundspotCommand(commands.Command):
    help = 'Some text that will show up in --help'

    def __init__(self):
        super(SoundspotCommand, self).__init__()
        self.add_argument('--foo')

    def run(self, args, config, extensions):
        # Your command implementation
        return 0
```

### 31.9 Example web application

As of Mopidy 0.19, extensions can use Mopidy’s built-in web server to host static web clients as well as Tornado and WSGI web applications. For several examples, see the `HTTP server side API` docs or explore with `Mopidy-API-Explorer` extension.

### 31.10 Running an extension

Once your extension is ready to go, to see it in action you’ll need to register it with Mopidy. Typically this is done by running `python setup.py install` from your extension’s Git repo root directory. While developing your extension and to avoid doing this every time you make a change, you can instead run `python setup.py develop` to effectively link Mopidy directly with your development files.

### 31.11 Python conventions

In general, it would be nice if Mopidy extensions followed the same `Code style` as Mopidy itself, as they’re part of the same ecosystem. Among other things, the code style guide explains why all the above examples start with `from __future__ import absolute_import, unicode_literals`.

### 31.12 Use of Mopidy APIs

When writing an extension, you should only use APIs documented at `API reference`. Other parts of Mopidy, like `mopidy.internal`, may change at any time and are not something extensions should use.

Mopidy performs type checking to help catch extension bugs. This applies to both frontend calls into core and return values from backends. Additionally model fields always get validated to further guard against bad data.
31.13 Logging in extensions

For servers like Mopidy, logging is essential for understanding what’s going on. We use the `logging` module from Python’s standard library. When creating a logger, always namespace the logger using your Python package name as this will be visible in Mopidy’s debug log:

```python
import logging

logger = logging.getLogger('mopidy_soundspot')

# Or even better, use the Python module name as the logger name:
logger = logging.getLogger(__name__)
```

When logging at logging level `info` or higher (i.e. `warning`, `error`, and `critical`, but not `debug`) the log message will be displayed to all Mopidy users. Thus, the log messages at those levels should be well written and easy to understand.

As the logger name is not included in Mopidy’s default logging format, you should make it obvious from the log message who is the source of the log message. For example:

```
Loaded 17 Soundspot playlists
```

Is much better than:

```
Loaded 17 playlists
```

If you want to turn on debug logging for your own extension, but not for everything else due to the amount of noise, see the docs for the `loglevels/*` config section.

31.14 Making HTTP requests from extensions

Many Mopidy extensions need to make HTTP requests to use some web API. Here’s a few recommendations to those extensions.

31.14.1 Proxies

If you make HTTP requests please make sure to respect the `proxy configs`, so that all the requests you make go through the proxy configured by the Mopidy user. To make this easier for extension developers, the helper function `mopidy.httpclient.format_proxy()` was added in Mopidy 1.1. This function returns the proxy settings formatted the way Requests expects.

31.14.2 User-Agent strings

When you make HTTP requests, it’s helpful for debugging and usage analysis if the client identifies itself with a proper User-Agent string. In Mopidy 1.1, we added the helper function `mopidy.httpclient.format_user_agent()`. Here’s an example of how to use it:

```python
>>> from mopidy import httpclient
>>> import mopidy_soundspot
>>> httpclient.format_user_agent('%s/%s' %
...    # mopidy_soundspot.Extension.dist_name, mopidy_soundspot.__version__)
'U'Mopidy-SoundSpot/2.0.0 Mopidy/1.0.7 Python/2.7.10''
```
31.14.3 Example using Requests sessions

Most Mopidy extensions that make HTTP requests use the Requests library to do so. When using Requests, the most convenient way to make sure the proxy and User-Agent header is set properly is to create a Requests session object and use that object to make all your HTTP requests:

```python
from mopidy import httpclient
import requests
import mopidy_soundspot

def get_requests_session(proxy_config, user_agent):
    proxy = httpclient.format_proxy(proxy_config)
    full_user_agent = httpclient.format_user_agent(user_agent)

    session = requests.Session()
    session.proxies.update({'http': proxy, 'https': proxy})
    session.headers.update({'user-agent': full_user_agent})

    return session

# ``mopidy_config`` is the config object passed to your frontend/backend
# constructor
session = get_requests_session(
    proxy_config=mopidy_config['proxy'],
    user_agent='{} / {}
        mopidy_soundspot.Extension.dist_name,
        mopidy_soundspot.__version__'))

response = session.get('http://example.com')
# Now do something with ``response`` and/or make further requests using the
# ``session`` object.
```

For further details, see Requests’ docs on session objects.

31.15 Testing extensions

Creating test cases for your extensions makes them much simpler to maintain over the long term. It can also make it easier for you to review and accept pull requests from other contributors knowing that they will not break the extension in some unanticipated way.

Before getting started, it is important to familiarize yourself with the Python mock library. When it comes to running tests, Mopidy typically makes use of testing tools like tox and pytest.

31.15.1 Testing approach

To a large extent the testing approach to follow depends on how your extension is structured, which parts of Mopidy it interacts with, and if it uses any 3rd party APIs or makes any HTTP requests to the outside world.

The sections that follow contain code extracts that highlight some of the key areas that should be tested. For more exhaustive examples, you may want to take a look at the test cases that ship with Mopidy itself which covers everything
from instantiating various controllers, reading configuration files, and simulating events that your extension can listen to.

In general your tests should cover the extension definition, the relevant Mopidy controllers, and the Pykka backend and/or frontend actors that form part of the extension.

### 31.15.2 Testing the extension definition

Test cases for checking the definition of the extension should ensure that:

- the extension provides a `ext.conf` configuration file containing the relevant parameters with their default values,
- that the config schema is fully defined, and
- that the extension’s actor(s) are added to the Mopidy registry on setup.

An example of what these tests could look like is provided below:

```python
def test_get_default_config():
    ext = Extension()
    config = ext.get_default_config()
    assert '[my_extension]' in config
    assert 'enabled = true' in config
    assert 'param_1 = value_1' in config
    assert 'param_2 = value_2' in config
    assert 'param_n = value_n' in config

def test_get_config_schema():
    ext = Extension()
    schema = ext.get_config_schema()
    assert 'enabled' in schema
    assert 'param_1' in schema
    assert 'param_2' in schema
    assert 'param_n' in schema

def test_setup():
    registry = mock.Mock()
    ext = Extension()
    ext.setup(registry)
    calls = [mock.call('frontend', frontend_lib.MyFrontend),
             mock.call('backend', backend_lib.MyBackend)]
    registry.add.assert_has_calls(calls, any_order=True)
```

### 31.15.3 Testing backend actors

Backends can usually be constructed with a small mockup of the configuration file, and mocking the audio actor:

```python
@pytest.fixture
def config():
    return {
        'http': {
            'hostname': '127.0.0.1',
            'port': '6680'
        }
    }

(continues on next page)
The following libraries might be useful for mocking any HTTP requests that your extension makes:

- **responses** - A utility library for mocking out the requests Python library.
- **vcrpy** - Automatically mock your HTTP interactions to simplify and speed up testing.

At the very least, you'll probably want to patch `requests` or any other web API's that you use to avoid any unintended HTTP requests from being made by your backend during testing:

```python
from mock import patch
@mock.patch('requests.get',
            mock.Mock(side_effect=Exception('Intercepted unintended HTTP call')))
```

Backend tests should also ensure that:

- the backend provides a unique URI scheme,
- that it sets up the various providers (e.g. library, playback, etc.)

```python
def test_uri_schemes(config):
    backend = get_backend(config)
    assert 'my_scheme' in backend.uri_schemes

def test_init_sets_up_the_providers(config):
    backend = get_backend(config)
    assert isinstance(backend.library, library.MyLibraryProvider)
    assert isinstance(backend.playback, playback.MyPlaybackProvider)
```

Once you have a backend instance to work with, testing the various playback, library, and other providers is straightforward and should not require any special setup or processing.

### 31.15.4 Testing libraries

Library test cases should cover the implementations of the standard Mopidy API (e.g. `browse`, `lookup`, `refresh`, `get_images`, `search`, etc.)
31.15.5 Testing playback controllers

Testing `change_track` and `translate_uri` is probably the highest priority, since these methods are used to prepare the track and provide its audio URL to Mopidy’s core for playback.

31.15.6 Testing frontends

Because most frontends will interact with the Mopidy core, it will most likely be necessary to have a full core running for testing purposes:

```python
self.core = core.Core.start(
    config, backends=[get_backend(config)]).proxy()
```

It may be advisable to take a quick look at the Pykka API at this point to make sure that you are familiar with `ThreadingActor`, `ThreadingFuture`, and the proxies that allow you to access the attributes and methods of the actor directly.

You’ll also need a list of `Track` and a list of URIs in order to populate the core with some simple tracks that can be used for testing:

```python
class BaseTest(unittest.TestCase):
    tracks = [
        models.Track(uri='my_scheme:track:id1', length=40000),  # Regular track
        models.Track(uri='my_scheme:track:id2', length=None),  # No duration
    ]
    uris = ['my_scheme:track:id1', 'my_scheme:track:id2']
```

In the `setup()` method of your test class, you will then probably need to monkey patch looking up tracks in the library (so that it will always use the lists that you defined), and then populate the core’s tracklist:

```python
def lookup(uris):
    result = {uri: [] for uri in uris}
    for track in self.tracks:
        if track.uri in result:
            result[track.uri].append(track)
    return result

self.core.library.lookup = lookup
self.tl_tracks = self.core.tracklist.add(uris=self.uris).get()
```

With all of that done you should finally be ready to instantiate your frontend:

```python
self.frontend = frontend.MyFrontend.start(config(), self.core).proxy()
```

Keep in mind that the normal core and frontend methods will usually return `pykka.ThreadingFuture` objects, so you will need to add `.get()` at the end of most method calls in order to get to the actual return values.

31.15.7 Triggering events

There may be test case scenarios that require simulating certain event triggers that your extension’s actors can listen for and respond on. An example for patching the listener to store these events, and then play them back for your actor, may look something like this:
self.events = []
self.patcher = mock.patch('mopidy.listener.send')
self.send_mock = self.patcher.start()

def send(cls, event, **kwargs):
    self.events.append((event, kwargs))

self.send_mock.side_effect = send

Once all of the events have been captured, a method like `replay_events()` can be called at the relevant points in the code to have the events fire:

```python
def replay_events(self, my_actor, until=None):
    while self.events:
        if self.events[0][0] == until:
            break
        event, kwargs = self.events.pop(0)
        frontend.on_event(event, **kwargs).get()
```

For further details and examples, refer to the `/tests` directory on the Mopidy development branch.
backend A part of Mopidy providing music library, playlist storage and/or playback capability to the core. Mopidy has a backend for each music store or music service it supports. See mopidy.backend — Backend API for details.

core The part of Mopidy that makes multiple frontends capable of using multiple backends. The core module is also the owner of the tracklist. To use the core module, see mopidy.core — Core API.

extension A Python package that can extend Mopidy with one or more backends, frontends, or GStreamer elements like mixers. See Extensions for a list of existing extensions and Extension development for how to make a new extension.

frontend A part of Mopidy using the core API. Existing frontends include the MPD server, the MPRIS/D-Bus integration, the Last.fm scrobbler, and the HTTP server with JavaScript API. See Frontend API for details.

mixer A GStreamer element that controls audio volume.

tracklist Mopidy’s name for the play queue or current playlist. The name is inspired by the MPRIS specification.
CHAPTER 33

mopidy command

33.1 Synopsis

mopidy [-h] [-version] [-q] [-v] [-save-debug-log] [-c CONFIG_FILES] [-o CONFIG_OVERRIDES] [COMMAND] ...

33.2 Description

Mopidy is a music server which can play music both from multiple sources, like your local hard drive, radio streams, and from Spotify and SoundCloud. Searches combines results from all music sources, and you can mix tracks from all sources in your play queue. Your playlists from Spotify or SoundCloud are also available for use.

The `mopidy` command is used to start the server.

33.3 Options

--help, -h
  Show help message and exit.

--version
  Show Mopidy’s version number and exit.

--quiet, -q
  Show less output: warning level and higher.

--verbose, -v
  Show more output. Repeat up to four times for even more.

--save-debug-log
  Save debug log to the file specified in the `logging/debug_file` config value, typically ./mopidy.log.
--config <file|directory>
    Specify config files and directories to use. To use multiple config files or directories, separate them with a colon. The later files override the earlier ones if there's a conflict. When specifying a directory, all files ending in .conf in the directory are used.

--option <option>, -o <option>
    Specify additional config values in the section/key=value format. Can be provided multiple times.

33.4 Built in commands

config
    Show the current effective config. All configuration sources are merged together to show the effective document. Secret values like passwords are masked out. Config for disabled extensions are not included.

deps
    Show dependencies, their versions and installation location.

33.5 Extension commands

Additionally, extensions can provide extra commands. Run mopidy --help for a list of what is available on your system and command-specific help. Commands for disabled extensions will be listed, but can not be run.

local clear
    Clear local media files from the local library.

local scan
    Scan local media files present in your library.

33.6 Files

/etc/mopidy/mopidy.conf System wide Mopidy configuration file.

~/.config/mopidy/mopidy.conf Your personal Mopidy configuration file. Overrides any configs from the system wide configuration file.

33.7 Examples

To start the music server, run:

mopidy

To start the server with an additional config file, that can override configs set in the default config files, run:

mopidy --config ./my-config.conf

To start the server and change a config value directly on the command line, run:

mopidy --option mpd/enabled=false

The --option flag may be repeated multiple times to change multiple configs:
mopidy -o mpd/enabled=false -o spotify/bitrate=320

The `mopidy config` output shows the effect of the `--option` flags:

mopidy -o mpd/enabled=false -o spotify/bitrate=320 config

## 33.8 Reporting bugs

Report bugs to Mopidy’s issue tracker at <https://github.com/mopidy/mopidy/issues>
34.1 Concepts

34.1.1 Architecture

The overall architecture of Mopidy is organized around multiple frontends and backends. The frontends use the core API. The core actor makes multiple backends work as one. The backends connect to various music sources. The core actor use the mixer actor to control volume, while the backends use the audio actor to play audio.
Frontends

Frontends expose Mopidy to the external world. They can implement servers for protocols like HTTP, MPD and MPRIS, and they can be used to update other services when something happens in Mopidy, like the Last.fm scrobbler frontend does. See Frontend API for more details.
Core

The core is organized as a set of controllers with responsibility for separate sets of functionality.

The core is the single actor that the frontends send their requests to. For every request from a frontend it calls out to one or more backends which does the real work, and when the backends respond, the core actor is responsible for combining the responses into a single response to the requesting frontend.

The core actor also keeps track of the tracklist, since it doesn’t belong to a specific backend.

See `mopidy.core — Core API` for more details.

Backends

The backends are organized as a set of providers with responsibility for separate sets of functionality, similar to the core actor.

Anything specific to i.e. Spotify integration or local storage is contained in the backends. To integrate with new music sources, you just add a new backend. See `mopidy.backend — Backend API` for more details.
Audio

The audio actor is a thin wrapper around the parts of the GStreamer library we use. If you implement an advanced backend, you may need to implement your own playback provider using the `mopidy.audio — Audio API`, but most backends can use the default playback provider without any changes.

Mixer

The mixer actor is responsible for volume control and muting. The default mixer use the audio actor to control volume in software. The alternative implementations are typically independent of the audio actor, but instead use some third party Python library or a serial interface to control other forms of volume controls.

34.1.2 mopidy.models — Data models

These immutable data models are used for all data transfer within the Mopidy backends and between the backends and the MPD frontend. All fields are optional and immutable. In other words, they can only be set through the class constructor during instance creation. Additionally fields are type checked.

If you want to modify a model, use the `replace()` method. It accepts keyword arguments for the parts of the model you want to change, and copies the rest of the data from the model you call it on. Example:

```python
>>> from mopidy.models import Track
>>> track1 = Track(name='Christmas Carol', length=171)
>>> track1
Track(artists=[], length=171, name='Christmas Carol')
>>> track2 = track1.replace(length=37)
>>> track2
Track(artists=[], length=37, name='Christmas Carol')
>>> track1
Track(artists=[], length=171, name='Christmas Carol')
```
Data model relations

Data model API

```python
class mopidy.models.Ref(*args, **kwargs)
```
Model to represent URI references with a human friendly name and type attached. This is intended for use a lightweight object “free” of metadata that can be passed around instead of using full blown models.

**Parameters**

- `uri (string)` – object URI
- `name (string)` – object name
- `type (string)` – object type

**ALBUM** = u'album'
Constant used for comparison with the `type` field.

**ARTIST** = u'artist'
Constant used for comparison with the `type` field.

**DIRECTORY** = u'directory'
Constant used for comparison with the `type` field.
PLAYLIST = u'playlist'
    Constant used for comparison with the type field.

TRACK = u'track'
    Constant used for comparison with the type field.

classmethod album(**kwargs)
    Create a Ref with type ALBUM.

classmethod artist(**kwargs)
    Create a Ref with type ARTIST.

classmethod directory(**kwargs)
    Create a Ref with type DIRECTORY.

name
    The object name. Read-only.

classmethod playlist(**kwargs)
    Create a Ref with type PLAYLIST.

classmethod track(**kwargs)
    Create a Ref with type TRACK.

type
    The object type, e.g. “artist”, “album”, “track”, “playlist”, “directory”. Read-only.

uri
    The object URI. Read-only.

class mopydy.models.Track(*args, **kwargs)

Parameters

• uri (string) – track URI
• name (string) – track name
• artists (list of Artist) – track artists
• album (Album) – track album
• composers (list of Artist) – track composers
• performers (list of Artist) – track performers
• genre (string) – track genre
• track_no (integer or None if unknown) – track number in album
• disc_no (integer or None if unknown) – disc number in album
• date (string) – track release date (YYYY or YYYY-MM-DD)
• length (integer or None if there is no duration) – track length in milliseconds
• bitrate (integer) – bitrate in kbit/s
• comment (string) – track comment
• musicbrainz_id (string) – MusicBrainz ID
• last_modified (integer or None if unknown) – Represents last modification time

album
    The track Album. Read-only.
artists
   A set of track artists. Read-only.

bitrate
   The track’s bitrate in kbit/s. Read-only.

comment
   The track comment. Read-only.

composers
   A set of track composers. Read-only.

date
   The track release date. Read-only.

disc_no
   The disc number in the album. Read-only.

genre
   The track genre. Read-only.

last_modified
   Integer representing when the track was last modified. Exact meaning depends on source of track. For local files this is the modification time in milliseconds since Unix epoch. For other backends it could be an equivalent timestamp or simply a version counter.

length
   The track length in milliseconds. Read-only.

musicbrainz_id
   The MusicBrainz ID of the track. Read-only.

name
   The track name. Read-only.

performers
   A set of track performers’. Read-only.

track_no
   The track number in the album. Read-only.

uri
   The track URI. Read-only.

class mopidy.models.Album(*args, **kwargs)

Parameters
   • uri (string) – album URI
   • name (string) – album name
   • artists (list of Artist) – album artists
   • num_tracks (integer or None if unknown) – number of tracks in album
   • num_discs (integer or None if unknown) – number of discs in album
   • date (string) – album release date (YYYY or YYYY-MM-DD)
   • musicbrainz_id (string) – MusicBrainz ID
   • images (list of strings) – album image URIs

Deprecated since version 1.2: The images field is deprecated. Use mopidy.core.LibraryController.get_images() instead.
artists
A set of album artists. Read-only.

date
The album release date. Read-only.

images
The album image URIs. Read-only.
Deprecation since version 1.2: Use `mopidy.core.LibraryController.get_images()` instead.

musicbrainz_id
The MusicBrainz ID of the album. Read-only.

name
The album name. Read-only.

num_discs
The number of discs in the album. Read-only.

num_tracks
The number of tracks in the album. Read-only.

uri
The album URI. Read-only.

class mopidy.models.Artist(*args, **kwargs)

Parameters
- **uri (string)** – artist URI
- **name (string)** – artist name
- **sortname (string)** – artist name for sorting
- **musicbrainz_id (string)** – MusicBrainz ID

musicbrainz_id
The MusicBrainz ID of the artist. Read-only.

name
The artist name. Read-only.

sortname
Artist name for better sorting, e.g. with articles stripped

uri
The artist URI. Read-only.

class mopidy.models.Playlist(*args, **kwargs)

Parameters
- **uri (string)** – playlist URI
- **name (string)** – playlist name
- **tracks (list of Track elements)** – playlist’s tracks
- **last_modified (int)** – playlist’s modification time in milliseconds since Unix epoch

last_modified
The playlist modification time in milliseconds since Unix epoch. Read-only.

Integer, or `None` if unknown.
### length
The number of tracks in the playlist. Read-only.

### name
The playlist name. Read-only.

### tracks
The playlist’s tracks. Read-only.

### uri
The playlist URI. Read-only.

---

#### mopidy.models.Image(*args, **kwargs)

**Parameters**

- `uri (string)` – URI of the image
- `width (int)` – Optional width of image or `None`
- `height (int)` – Optional height of image or `None`

#### height
Optional height of the image or `None`. Read-only.

#### uri
The image URI. Read-only.

#### width
Optional width of the image or `None`. Read-only.

---

#### mopidy.models.TlTrack(*args, **kwargs)

A tracklist track. Wraps a regular track and its tracklist ID.

The use of `TlTrack` allows the same track to appear multiple times in the tracklist.

This class also accepts its parameters as positional arguments. Both arguments must be provided, and they must appear in the order they are listed here.

This class also supports iteration, so you extract its values like this:

```python
(tlid, track) = tl_track
```

**Parameters**

- `tlid (int)` – tracklist ID
- `track (Track)` – the track

#### tlid
The tracklist ID. Read-only.

#### track
The track. Read-only.

---

#### mopidy.models.SearchResult(*args, **kwargs)

**Parameters**

- `uri (string)` – search result URI
- `tracks` (list of `Track` elements) – matching tracks
- `artists` (list of `Artist` elements) – matching artists
- `albums` (list of `Album` elements) – matching albums
albums
The albums matching the search query. Read-only.

artists
The artists matching the search query. Read-only.

tracks
The tracks matching the search query. Read-only.

uri
The search result URI. Read-only.

Data model helpers

class mopidy.models.ImmutableObject(*args, **kwargs)
    Superclass for immutable objects whose fields can only be modified via the constructor.

    This version of this class has been retained to avoid breaking any clients relying on it’s behavior. Internally in Mopidy we now use ValidatedImmutableObject for type safety and it’s much smaller memory footprint.

    Parameters
    **kwargs (any) -- kwargs to set as fields on the object

    copy(**values)
    Deprecated since version 1.1: Use replace() instead.

    replace(**kwargs)
    Replace the fields in the model and return a new instance

    Examples:

    # Returns a track with a new name
    Track(name='foo').replace(name='bar')
    # Return an album with a new number of tracks
    Album(num_tracks=2).replace(num_tracks=5)

Parameters
    **kwargs (any) -- kwargs to set as fields on the object

Return type
    instance of the model with replaced fields

class mopidy.models.ValidatedImmutableObject(*args, **kwargs)
    Superclass for immutable objects whose fields can only be modified via the constructor. Fields should be Field instances to ensure type safety in our models.

    Note that since these models can not be changed, we heavily memoize them to save memory. So constructing a class with the same arguments twice will give you the same instance twice.

    replace(**kwargs)
    Replace the fields in the model and return a new instance

    Examples:

    # Returns a track with a new name
    Track(name='foo').replace(name='bar')
    # Return an album with a new number of tracks
    Album(num_tracks=2).replace(num_tracks=5)

    Note that internally we memoize heavily to keep memory usage down given our overly repetitive data structures. So you might get an existing instance if it contains the same values.

Parameters
    **kwargs (any) -- kwargs to set as fields on the object
Return type instance of the model with replaced fields

Data model (de)serialization

```
mopidy.models.model_json_decoder(dct)
```
Automatically deserialize Mopidy models from JSON.

Usage:
```
>>> import json
>>> json.loads(
...   '{"a_track": {"__model__": "Track", "name": "name"}},
...   object_hook=model_json_decoder)
{'a_track': Track(artists=[], name=u'name')}
```

```
class mopidy.models.ModelJSONEncoder(
    skipkeys=False, ensure_ascii=True,
    check_circular=True, allow_nan=True,
    sort_keys=False, indent=None, separators=None,
    encoding='utf-8', default=None)
```
Automatically serialize Mopidy models to JSON.

Usage:
```
>>> import json
>>> json.dumps({'a_track': Track(name='name')}, cls=ModelJSONEncoder)
'{"a_track": {"__model__": "Track", "name": "name"}}'
```

Data model field types

```
class mopidy.models.fields.Field(
    default=None, type=None, choices=None)
```
Base field for use in ValidatedImmutableObject. These fields are responsible for type checking and other data sanitation in our models.

For simplicity fields use the Python descriptor protocol to store the values in the instance dictionary. Also note that fields are mutable if the object they are attached to allow it.

Default values will be validated with the exception of None.

Parameters

- **default** – default value for field
- **type** – if set the field value must be of this type
- **choices** – if set the field value must be one of these

```
class mopidy.models.fields.String(
    default=None)
```
Specialized Field which is wired up for bytes and unicode.

Parameters

- **default** – default value for field

```
class mopidy.models.fields.Identifier(
    default=None)
```
Field for storing values such as GUIDs or other identifiers.

Values will be interned.

Parameters

- **default** – default value for field
class mopidy.models.fields.URI (default=None)
    Field for storing URIs
    Values will be interned, currently not validated.

    Parameters
    default – default value for field

class mopidy.models.fields.Date (default=None)
    Field for storing ISO 8601 dates as a string.
    Supported formats are YYYY-MM-DD, YYYY-MM and YYYY, currently not validated.

    Parameters
    default – default value for field

class mopidy.models.fields.Integer (default=None, min=None, max=None)
    Field for storing integer numbers.

    Parameters
    • default – default value for field
    • min – field value must be larger or equal to this value when set
    • max – field value must be smaller or equal to this value when set

class mopidy.models.fields.Collection (type, container=<type 'tuple'>)
    Field for storing collections of a given type.

    Parameters
    • type – all items stored in the collection must be of this type
    • container – the type to store the items in

34.2 Basics

34.2.1 mopidy.core — Core API

The core API is the interface that is used by frontends like mopidy.http and mopidy.mpd. The core layer is in between the frontends and the backends. Don’t forget that you will be accessing core as a Pykka actor. If you are only interested in being notified about changes in core see CoreListener.

Changed in version 1.1: All core API calls are now type checked.

Changed in version 1.1: All backend return values are now type checked.

class mopidy.core.Core (config=None, mixer=None, backends=None, audio=None)

    tracklist
    Manages everything related to the list of tracks we will play. See TracklistController.

    playback
    Manages playback state and the current playing track. See PlaybackController.

    library
    Manages the music library, e.g. searching and browsing for music. See LibraryController.

    playlists
    Manages stored playlists. See PlaylistsController.

    mixer
    Manages volume and muting. See MixerController.
history
Keep record of what tracks have been played. See HistoryController.

get_uri_schemes()
Get list of URI schemes we can handle

get_version()
Get version of the Mopidy core API

Tracklist controller

class mopidy.core.TracklistController(core)

Manipulating

TracklistController.add(tracks=None, at_position=None, uri=None, uris=None)
Add tracks to the tracklist.

If uri is given instead of tracks, the URI is looked up in the library and the resulting tracks are added to the tracklist.

If uris is given instead of uri or tracks, the URIs are looked up in the library and the resulting tracks are added to the tracklist.

If at_position is given, the tracks are inserted at the given position in the tracklist. If at_position is not given, the tracks are appended to the end of the tracklist.

Triggers the mopidy.core.CoreListener.tracklist_changed() event.

Parameters

• tracks (list of mopidy.models.Track or None) – tracks to add
• at_position (int or None) – position in tracklist to add tracks
• uri (string or None) – URI for tracks to add
• uris (list of string or None) – list of URIs for tracks to add

Return type list of mopidy.models.TlTrack

New in version 1.0: The uris argument.

Deprecated since version 1.0: The tracks and uri arguments. Use uris.

TracklistController.remove(criteria=None, **kwargs)
Remove the matching tracks from the tracklist.

Uses filter() to lookup the tracks to remove.

Triggers the mopidy.core.CoreListener.tracklist_changed() event.

Parameters criteria (dict) – on or more criteria to match by

Return type list of mopidy.models.TlTrack that was removed

Deprecated since version 1.1: Providing the criteria via kwargs.

TracklistController.clear()
Clear the tracklist.

Triggers the mopidy.core.CoreListener.tracklist_changed() event.
TracklistController.move(start, end, to_position)

Move the tracks in the slice [start:end] to to_position.

Triggers the mopidy.core.CoreListener.tracklist_changed() event.

Parameters

- **start** (int) – position of first track to move
- **end** (int) – position after last track to move
- **to_position** (int) – new position for the tracks

TracklistController.shuffle(start=None, end=None)

Shuffles the entire tracklist. If start and end is given only shuffles the slice [start:end].

Triggers the mopidy.core.CoreListener.tracklist_changed() event.

Parameters

- **start** (int or None) – position of first track to shuffle
- **end** (int or None) – position after last track to shuffle

Current state

TracklistController.get_tl_tracks()

Get tracklist as list of mopidy.models.TlTrack.

TracklistController.index(tl_track=None, tlid=None)

The position of the given track in the tracklist.

If neither *tl_track* or *tlid* is given we return the index of the currently playing track.

Parameters

- **tl_track** (mopidy.models.TlTrack or None) – the track to find the index of
- **tlid** (int or None) – TLID of the track to find the index of

Return type  int or None

New in version 1.1: The *tlid* parameter

TracklistController.get_version()

Get the tracklist version.

Integer which is increased every time the tracklist is changed. Is not reset before Mopidy is restarted.

TracklistController.get_length()

Get length of the tracklist.

TracklistController.get_tracks()

Get tracklist as list of mopidy.models.Track.

TracklistController.slice(start, end)

Returns a slice of the tracklist, limited by the given start and end positions.

Parameters

- **start** (int) – position of first track to include in slice
- **end** (int) – position after last track to include in slice

Return type  mopidy.models.TlTrack
TracklistController.filter(criteria=None, **kwargs)
Filter the tracklist by the given criterias.

A criteria consists of a model field to check and a list of values to compare it against. If the model field matches
one of the values, it may be returned.

Only tracks that matches all the given criterias are returned.

Examples:

# Returns tracks with TLIDs 1, 2, 3, or 4 (tracklist ID)
filter({'tlid': [1, 2, 3, 4]})

# Returns track with URIs 'xyz' or 'abc'
filter({'uri': ['xyz', 'abc']})

# Returns track with a matching TLIDs (1, 3 or 6) and a
# matching URI ('xyz' or 'abc')
filter({'tlid': [1, 3, 6], 'uri': ['xyz', 'abc']})

Parameters criteria (dict, of (string, list) pairs) – on or more criteria to
match by

Return type list of mopidy.models.TlTrack

Deprecated since version 1.1: Providing the criteria via kwargs.

Future state

TracklistController.get_eot_tlid()
The TLID of the track that will be played after the current track.

Not necessarily the same TLID as returned by get_next_tlid().

Return type int or None

New in version 1.1.

TracklistController.get_next_tlid()
The tlid of the track that will be played if calling mopidy.core.PlaybackController.next().

For normal playback this is the next track in the tracklist. If repeat is enabled the next track can loop around the
tracklist. When random is enabled this should be a random track, all tracks should be played once before the
tracklist repeats.

Return type int or None

New in version 1.1.

TracklistController.get_previous_tlid()
Returns the TLID of the track that will be played if calling mopidy.core.PlaybackController.
previous().

For normal playback this is the previous track in the tracklist. If random and/or consume is enabled it should
return the current track instead.

Return type int or None

New in version 1.1.
TracklistController.eot_track(tl_track)
The track that will be played after the given track.
Not necessarily the same track as next_track().
Parameters **tl_track** *(mopidy.models.TlTrack or None)* – the reference track
Return type *mopidy.models.TlTrack* or None

TracklistController.next_track(tl_track)
The track that will be played if calling mopidy.core.PlaybackController.next().
For normal playback this is the next track in the tracklist. If repeat is enabled the next track can loop around the
tracklist. When random is enabled this should be a random track, all tracks should be played once before the
tracklist repeats.
Parameters **tl_track** *(mopidy.models.TlTrack or None)* – the reference track
Return type *mopidy.models.TlTrack* or None

TracklistController.previous_track(tl_track)
Returns the track that will be played if calling mopidy.core.PlaybackController.previous().
For normal playback this is the previous track in the tracklist. If random and/or consume is enabled it should return the current track instead.
Parameters **tl_track** *(mopidy.models.TlTrack or None)* – the reference track
Return type *mopidy.models.TlTrack* or None

Options

TracklistController.get_consume()
Get consume mode.
**True** Tracks are removed from the tracklist when they have been played.
**False** Tracks are not removed from the tracklist.

TracklistController.set_consume(value)
Set consume mode.
**True** Tracks are removed from the tracklist when they have been played.
**False** Tracks are not removed from the tracklist.

TracklistController.get_random()
Get random mode.
**True** Tracks are selected at random from the tracklist.
**False** Tracks are played in the order of the tracklist.

TracklistController.set_random(value)
Set random mode.
**True** Tracks are selected at random from the tracklist.
**False** Tracks are played in the order of the tracklist.

TracklistController.get_repeat()
Get repeat mode.
**True** The tracklist is played repeatedly.
False The tracklist is played once.

TracklistController.set_repeat(value)
  Set repeat mode.
  To repeat a single track, set both repeat and single.

True The tracklist is played repeatedly.

False The tracklist is played once.

TracklistController.get_single()
  Get single mode.
  True Playback is stopped after current song, unless in repeat mode.
  False Playback continues after current song.

Playback controller

class mopidy.core.PlaybackController (audio, backends, core)

Playback control

PlaybackController.play(tl_track=None, tlid=None)
  Play the given track, or if the given tl_track and tlid is None, play the currently active track.
  Note that the track must already be in the tracklist.

Parameters
  • tl_track (mopidy.models.TLTrack or None) – track to play
  • tlid (int or None) – TLID of the track to play

PlaybackController.next()
  Change to the next track.
  The current playback state will be kept. If it was playing, playing will continue. If it was paused, it will still be paused, etc.

PlaybackController.previous()
  Change to the previous track.
  The current playback state will be kept. If it was playing, playing will continue. If it was paused, it will still be paused, etc.

PlaybackController.stop()
  Stop playing.

PlaybackController.pause()
  Pause playback.

PlaybackController.resume()
  If paused, resume playing the current track.
PlaybackController.\texttt{seek}(\textit{time\_position})
Seeks to time position given in milliseconds.

\textbf{Parameters} \textit{time\_position} (\textit{int}) -- time position in milliseconds

\textbf{Return type} True if successful, else False

\textbf{Current track}

PlaybackController.\texttt{get\_current\_tl\_track}()
Get the currently playing or selected track.

\textbf{Returns} a \texttt{mopidy.models.TlTrack} or None.

PlaybackController.\texttt{get\_current\_track}()
Get the currently playing or selected track.

\textbf{Extracted from} \texttt{get\_current\_tl\_track}() for convenience.

\textbf{Returns} a \texttt{mopidy.models.Track} or None.

PlaybackController.\texttt{get\_stream\_title}()
Get the current stream title or None.

PlaybackController.\texttt{get\_time\_position}()
Get time position in milliseconds.

\textbf{Playback states}

PlaybackController.\texttt{get\_state}()
Get The playback state.

PlaybackController.\texttt{set\_state}(\textit{new\_state})
Set the playback state.

\textbf{Must be} PLAYING, PAUSED, or STOPPED.

Possible states and transitions:
class mopidy.corePlaybackState

    STOPPED = 'stopped'
    PLAYING = 'playing'
    PAUSED = 'paused'

Library controller

class mopidy.core.LibraryController

LibraryController.browse(uri)

    Browse directories and tracks at the given uri.

    uri is a string which represents some directory belonging to a backend. To get the intial root directories for
    backends pass None as the URI.

    Returns a list of mopidy.models.Ref objects for the directories and tracks at the given uri.

    The Ref objects representing tracks keep the track’s original URI. A matching pair of objects can look like this:

    Track(uri='dummy:/foo.mp3', name='foo', artists=..., album=...)
    Ref.track(uri='dummy:/foo.mp3', name='foo')

    The Ref objects representing directories have backend specific URIs. These are opaque values, so no one but
    the backend that created them should try and derive any meaning from them. The only valid exception to this is
    checking the scheme, as it is used to route browse requests to the correct backend.

    For example, the dummy library’s /bar directory could be returned like this:
Ref.directory(uri='dummy:directory:/bar', name='bar')

Parameters
uri (string) – URI to browse

Return type list of mopidy.models.Ref

New in version 0.18.

LibraryController.search(query=None, uris=None, exact=False, **kwargs)

Search the library for tracks where field contains values. field can be one of uri, track_name, album, artist, albumartist, composer, performer, track_no, genre, date, comment or any.

If uris is given, the search is limited to results from within the URI roots. For example passing uris=['file:'] will limit the search to the local backend.

Examples:

```
# Returns results matching 'a' in any backend
search({'any': ['a']})

# Returns results matching artist 'xyz' in any backend
search({'artist': ['xyz']})

# Returns results matching 'a' and 'b' and artist 'xyz' in any backend
search({'any': ['a', 'b'], 'artist': ['xyz']})

# Returns results matching 'a' if within the given URI roots
# "file:///media/music" and "spotify:" 
search({'any': ['a']}, uris=['file:///media/music', 'spotify:'])

# Returns results matching artist 'xyz' and 'abc' in any backend
search({'artist': ['xyz', 'abc']})
```

Parameters

- query (dict) – one or more queries to search for
- uris (list of string or None) – zero or more URI roots to limit the search to
- exact (bool) – if the search should use exact matching

Return type list of mopidy.models.SearchResult

New in version 1.0: The exact keyword argument, which replaces find_exact().

Deprecated since version 1.0: Previously, if the query was empty, and the backend could support it, all available tracks were returned. This has not changed, but it is strongly discouraged. No new code should rely on this behavior.

Deprecated since version 1.1: Providing the search query via kwargs is no longer supported.

LibraryController.lookup(uri=None, uris=None)

Lookup the given URIs.

If the URI expands to multiple tracks, the returned list will contain them all.

Parameters

- uri (string or None) – track URI
- **uris** (list of string or None) – track URIs

  **Return type** list of `mopidy.models.Track` if uri was set or {uri: list of `mopidy.models.Track`} if uris was set.

  New in version 1.0: The `uris` argument.

  Deprecated since version 1.0: The `uri` argument. Use `uris` instead.

  **LibraryController.refresh**( `uri=None`)  
  Refresh library. Limit to URI and below if an URI is given.

  **Parameters**  
  - **uri** (string) – directory or track URI

  **LibraryController.get_images**( `uris`)  
  Lookup the images for the given URIs

  Backends can use this to return image URIs for any URI they know about be it tracks, albums, playlists. The lookup result is a dictionary mapping the provided URIs to lists of images.

  Unknown URIs or URIs the corresponding backend couldn’t find anything for will simply return an empty list for that URI.

  **Parameters**  
  - **uris** (list of string) – list of URIs to find images for

  **Return type** {uri: tuple of `mopidy.models.Image`}  
  New in version 1.0.

  **LibraryController.get_distinct**( `field`, `query=None`)  
  List distinct values for a given field from the library.

  This has mainly been added to support the list commands the MPD protocol supports in a more sane fashion. Other frontends are not recommended to use this method.

  **Parameters**  
  - **field** (string) – One of `track`, `artist`, `albumartist`, `album`, `composer`, `performer`, `date` or `genre`.
  - **query** (dict) – Query to use for limiting results, see `search()` for details about the query format.

  **Return type** set of values corresponding to the requested field type.

  New in version 1.0.

**Playlists controller**

  **class** `mopidy.core.PlaylistsController`

  **PlaylistsController.get_uri_schemes**( )  
  Get the list of URI schemes that support playlists.

  **Return type** list of string  
  New in version 2.0.

**Fetching**

  **PlaylistsController.as_list**( )  
  Get a list of the currently available playlists.
Returns a list of `Ref` objects referring to the playlists. In other words, no information about the playlists’ content is given.

**Return type** list of `mopidy.models.Ref`

New in version 1.0.

**PlaylistsController.get_items(uri)**
Get the items in a playlist specified by `uri`.

Returns a list of `Ref` objects referring to the playlist’s items.

If a playlist with the given `uri` doesn’t exist, it returns `None`.

**Return type** list of `mopidy.models.Ref`, or `None`

New in version 1.0.

**PlaylistsController.lookup(uri)**
Lookup playlist with given URI in both the set of playlists and in any other playlist sources. Returns `None` if not found.

**Parameters**

- **uri** (`string`) – playlist URI

**Return type** `mopidy.models.Playlist` or `None`

**PlaylistsController.refresh(uri_scheme=None)**
Refresh the playlists in `playlists`.

If `uri_scheme` is `None`, all backends are asked to refresh. If `uri_scheme` is an URI scheme handled by a backend, only that backend is asked to refresh. If `uri_scheme` doesn’t match any current backend, nothing happens.

**Parameters**

- **uri_scheme** (`string`) – limit to the backend matching the URI scheme

**Manipulating**

**PlaylistsController.create(name, uri_scheme=None)**
Create a new playlist.

If `uri_scheme` matches an URI scheme handled by a current backend, that backend is asked to create the playlist. If `uri_scheme` is `None` or doesn’t match a current backend, the first backend is asked to create the playlist.

All new playlists must be created by calling this method, and **not** by creating new instances of `mopidy.models.Playlist`.

**Parameters**

- **name** (`string`) – name of the new playlist
- **uri_scheme** (`string`) – use the backend matching the URI scheme

**Return type** `mopidy.models.Playlist` or `None`

**PlaylistsController.save(playlist)**
Save the playlist.

For a playlist to be saveable, it must have the `uri` attribute set. You must not set the `uri` attribute yourself, but use playlist objects returned by `create()` or retrieved from `playlists`, which will always give you saveable playlists.
The method returns the saved playlist. The return playlist may differ from the saved playlist. E.g. if the playlist name was changed, the returned playlist may have a different URI. The caller of this method must throw away the playlist sent to this method, and use the returned playlist instead.

If the playlist’s URI isn’t set or doesn’t match the URI scheme of a current backend, nothing is done and None is returned.

**Parameters**
- **playlist** (`mopidy.models.Playlist`) – the playlist

**Return type**
- `mopidy.models.Playlist` or None

**PlaylistsController.delete(uri)**
Delete playlist identified by the URI.
If the URI doesn’t match the URI schemes handled by the current backends, nothing happens.

Returns True if deleted, False otherwise.

**Parameters**
- **uri** (`string`) – URI of the playlist to delete

**Return type**
- bool

Changed in version 2.2: Return type defined.

### Mixer controller

**class** `mopidy.core.MixerController`

**MixerController.get_mute()**
Get mute state.

- True if muted, False unmuted, None if unknown.

**MixerController.set_mute(mute)**
Set mute state.

- True to mute, False to unmute.

Returns True if call is successful, otherwise False.

**MixerController.get_volume()**
Get the volume.

- Integer in range [0..100] or None if unknown.

The volume scale is linear.

**MixerController.set_volume(volume)**
Set the volume.

- The volume is defined as an integer in range [0..100].
- The volume scale is linear.

Returns True if call is successful, otherwise False.

### History controller

**class** `mopidy.core.HistoryController`

**HistoryController.get_history()**
Get the track history.

The timestamps are milliseconds since epoch.
Returns the track history

Return type list of (timestamp, mopidy.models.Ref) tuples

HistoryController.get_length()
Get the number of tracks in the history.

Returns the history length

Return type int

Core events

class mopidy.core.CoreListener
Marker interface for recipients of events sent by the core actor.

Any Pykka actor that mixes in this class will receive calls to the methods defined here when the corresponding events happen in the core actor. This interface is used both for looking up what actors to notify of the events, and for providing default implementations for those listeners that are not interested in all events.

mute_changed(mute)
Called whenever the mute state is changed.
MAY be implemented by actor.

Parameters mute (boolean) – the new mute state

on_event(event, **kwargs)
Called on all events.
MAY be implemented by actor. By default, this method forwards the event to the specific event methods.

Parameters

• event (string) – the event name
• kwargs – any other arguments to the specific event handlers

options_changed()
Called whenever an option is changed.
MAY be implemented by actor.

playback_state_changed(old_state, new_state)
Called whenever playback state is changed.
MAY be implemented by actor.

Parameters

• old_state (string from mopidy.core.PlaybackState field) – the state before the change
• new_state (string from mopidy.core.PlaybackState field) – the state after the change

playlist_changed(playlist)
Called whenever a playlist is changed.
MAY be implemented by actor.

Parameters playlist (mopidy.models.Playlist) – the changed playlist
playlist_deleted(uri)
Called whenever a playlist is deleted.
MAY be implemented by actor.

Parameters uri (string) – the URI of the deleted playlist

playlists_loaded()
Called when playlists are loaded or refreshed.
MAY be implemented by actor.

seeked(time_position)
Called whenever the time position changes by an unexpected amount, e.g. at seek to a new time position.
MAY be implemented by actor.

Parameters time_position (int) – the position that was seeked to in milliseconds

static send(event, **kwargs)
Helper to allow calling of core listener events

stream_title_changed(title)
Called whenever the currently playing stream title changes.
MAY be implemented by actor.

Parameters title (string) – the new stream title

track_playback_ended(tl_track, time_position)
Called whenever playback of a track ends.
MAY be implemented by actor.

Parameters
• tl_track (mopidy.models.TlTrack) – the track that was played before playback stopped
• time_position (int) – the time position in milliseconds

track_playback_paused(tl_track, time_position)
Called whenever track playback is paused.
MAY be implemented by actor.

Parameters
• tl_track (mopidy.models.TlTrack) – the track that was playing when playback paused
• time_position (int) – the time position in milliseconds

track_playback_resumed(tl_track, time_position)
Called whenever track playback is resumed.
MAY be implemented by actor.

Parameters
• tl_track (mopidy.models.TlTrack) – the track that was playing when playback resumed
• time_position (int) – the time position in milliseconds
track_playback_started(\textit{tl\_track})
Called whenever a new track starts playing.
\textit{MAY} be implemented by actor.

Parameters \textit{tl\_track}(\texttt{mopidy.models.TlTrack}) – the track that just started playing

tracklist_changed()
Called whenever the tracklist is changed.
\textit{MAY} be implemented by actor.

volume_changed(\textit{volume})
Called whenever the volume is changed.
\textit{MAY} be implemented by actor.

Parameters \textit{volume}(\texttt{int}) – the new volume in the range [0..100]

Deprecated API features

\begin{verbatim}
Warning: Though these features still work, they are slated to go away in the next major Mopidy release.
\end{verbatim}

Core

\texttt{Core.version}
Deprecated since version 1.0: Use \texttt{get\_version()} instead.

\texttt{Core.uri\_schemes}
Deprecated since version 1.0: Use \texttt{get\_uri\_schemes()} instead.

TracklistController

\texttt{TracklistController.tl\_tracks}
Deprecated since version 1.0: Use \texttt{get\_tl\_tracks()} instead.

\texttt{TracklistController.tracks}
Deprecated since version 1.0: Use \texttt{get\_tracks()} instead.

\texttt{TracklistController.version}
Deprecated since version 1.0: Use \texttt{get\_version()} instead.

\texttt{TracklistController.length}
Deprecated since version 1.0: Use \texttt{get\_length()} instead.

\texttt{TracklistController.consume}
Deprecated since version 1.0: Use \texttt{get\_consume()} and \texttt{set\_consume()} instead.

\texttt{TracklistController.random}
Deprecated since version 1.0: Use \texttt{get\_random()} and \texttt{set\_random()} instead.

\texttt{TracklistController.repeat}
Deprecated since version 1.0: Use \texttt{get\_repeat()} and \texttt{set\_repeat()} instead.

\texttt{TracklistController.single}
Deprecated since version 1.0: Use \texttt{get\_single()} and \texttt{set\_single()} instead.
**PlaybackController**

PlaybackController.get_mute()
   Deprecated since version 1.0: Use core.mixer.get_mute() instead.

PlaybackController.get_volume()
   Deprecated since version 1.0: Use core.mixer.get_volume() instead.

PlaybackController.current_tl_track
   Deprecated since version 1.0: Use get_current_tl_track() instead.

PlaybackController.current_track
   Deprecated since version 1.0: Use get_current_track() instead.

PlaybackController.state
   Deprecated since version 1.0: Use get_state() and set_state() instead.

PlaybackController.time_position
   Deprecated since version 1.0: Use get_time_position() instead.

PlaybackController.mute
   Deprecated since version 1.0: Use core.mixer.get_mute() and core.mixer.set_mute() instead.

PlaybackController.volume
   Deprecated since version 1.0: Use core.mixer.get_volume() and core.mixer.set_volume() instead.

**LibraryController**

LibraryController.find_exact(query=None, uris=None, **kwargs)
   Search the library for tracks where field is values.
   Deprecated since version 1.0: Use search() with exact set.

**PlaylistsController**

PlaylistsController.filter(criteria=None, **kwargs)
   Filter playlists by the given criterias.

   Examples:

   ```
   # Returns track with name 'a'
   filter({'name': 'a'})

   # Returns track with URI 'xyz'
   filter({'uri': 'xyz'})

   # Returns track with name 'a' and URI 'xyz'
   filter({'name': 'a', 'uri': 'xyz'})
   ```

   Parameters criteria (dict) – one or more criteria to match by

   Return type list of mopidy.models.Playlist

   Deprecated since version 1.0: Use as_list() and filter yourself.

PlaylistsController.get_playlists(include_tracks=True)
   Get the available playlists.
Return type  list of `mopidy.models.Playlist`

Changed in version 1.0: If you call the method with `include_tracks=False`, the `last_modified` field of the returned playlists is no longer set.

Deprecated since version 1.0: Use `as_list()` and `get_items()` instead.

**PlaylistsController.playlists**

Deprecated since version 1.0: Use `as_list()` and `get_items()` instead.

## 34.2.2 Frontend API

The following requirements apply to any frontend implementation:

- A frontend MAY do mostly whatever it wants to, including creating threads, opening TCP ports and exposing Mopidy for a group of clients.
- A frontend MUST implement at least one Pykka actor, called the “main actor” from here on.
- The main actor MUST accept two constructor arguments:
  - `config`, which is a dict structure with the entire Mopidy configuration.
  - `core`, which will be an `ActorProxy` for the core actor. This object gives access to the full `mopidy.core` — Core API.
- It MAY use additional actors to implement whatever it does, and using actors in frontend implementations is encouraged.
- The frontend is enabled if the extension it is part of is enabled. See Extension development for more information.
- The main actor MUST be able to start and stop the frontend when the main actor is started and stopped.
- The frontend MAY require additional config values to be set for it to work.
- Such config values MUST be documented.
- The main actor MUST raise the `mopidy.exceptions.FrontendError` with a descriptive error message if the defined config values are not adequate for the frontend to work properly.
- Any actor which is part of the frontend MAY implement the `mopidy.core.CoreListener` interface to receive notification of the specified events.

**Frontend implementations**

See Frontend extensions.

## 34.2.3 mopidy.backend — Backend API

The backend API is the interface that must be implemented when you create a backend. If you are working on a frontend and need to access the backends, see the mopidy.core — Core API instead.

**URIs and routing of requests to the backend**

When Mopidy’s core layer is processing a client request, it routes the request to one or more appropriate backends based on the URIs of the objects the request touches on. The objects’ URIs are compared with the backends’ `uri_schemes` to select the relevant backends.
An often used pattern when implementing Mopidy backends is to create your own URI scheme which you use for all tracks, playlists, etc. related to your backend. In most cases the Mopidy URI is translated to an actual URI that GStreamer knows how to play right before playback. For example:

- Spotify already has its own URI scheme (spotify:track:..., spotify:playlist:..., etc.) used throughout their applications, and thus Mopidy-Spotify simply uses the same URI scheme. Playback is handled by pushing raw audio data into a GStreamer appsrc element.

- Mopidy-SoundCloud created its own URI scheme, after the model of Spotify, and use URIs of the following forms: soundcloud:search, soundcloud:user-, ..., soundcloud:exp-, ..., and soundcloud:set-.... Playback is handled by converting the custom soundcloud:.. URIs to http:/ / URLs immediately before they are passed on to GStreamer for playback.

- Mopidy differentiates between file://... URIs handled by Mopidy-Stream and local:... URIs handled by Mopidy-Local. Mopidy-Stream can play file://... URIs pointing to tracks and playlists located anywhere on your system, but it doesn’t know a thing about the object before you play it. On the other hand, Mopidy-Local scans a predefined local/media_dir to build a meta data library of all known tracks. It is thus limited to playing tracks residing in the media library, but can provide additional features like directory browsing and search. In other words, we have two different ways of playing local music, handled by two different backends, and have thus created two different URI schemes to separate their handling. The local:... URIs are converted to file://... URIs immediately before they are passed on to GStreamer for playback.

If there isn't an existing URI scheme that fits for your backend's purpose, you should create your own, and name it after your extension's ext_name. Care should be taken not to conflict with already in use URI schemes. It is also recommended to design the format such that tracks, playlists and other entities can be distinguished easily.

**Backend class**

```python
class mopidy.backend.Backend

Backend API

If the backend has problems during initialization it should raise mopidy.exceptions.BackendError with a descriptive error message. This will make Mopidy print the error message and exit so that the user can fix the issue.

Parameters

- config (dict) – the entire Mopidy configuration
- audio (pykka.ActorProxy for mopidy.audio.Audio) – actor proxy for the audio subsystem

audio = None

Actor proxy to an instance of mopidy.audio.Audio.

Should be passed to the backend constructor as the kwarg audio, which will then set this field.

library = None

The library provider. An instance of LibraryProvider, or None if the backend doesn’t provide a library.

ping ()

Called to check if the actor is still alive.

playback = None

The playback provider. An instance of PlaybackProvider, or None if the backend doesn’t provide playback.
```
The playlists provider. An instance of `PlaylistsProvider`, or class: `None` if the backend doesn’t provide playlists.

List of URI schemes this backend can handle.

### Playback provider

```python
class mopidy.backend.PlaybackProvider(audio, backend)
```

**Parameters**

- `audio` (actor proxy to an instance of `mopidy.audio.Audio`) – the audio actor
- `backend` (`mopidy.backend.Backend`) – the backend

**change_track(track)**

Swith to provided track.

*MAY be reimplemented by subclass.*

It is unlikely it makes sense for any backends to override this. For most practical purposes it should be considered an internal call between backends and core that backend authors should not touch.

The default implementation will call `translate_uri()` which is what you want to implement.

**Parameters**

- `track` (`mopidy.models.Track`) – the track to play

**Return type** `True` if successful, else `False`

**get_time_position()**

Get the current time position in milliseconds.

*MAY be reimplemented by subclass.*

**Return type** `int`

**pause()**

Pause playback.

*MAY be reimplemented by subclass.*

**Return type** `True` if successful, else `False`

**play()**

Start playback.

*MAY be reimplemented by subclass.*

**Return type** `True` if successful, else `False`

**prepare_change()**

Indicate that an URI change is about to happen.

*MAY be reimplemented by subclass.*

It is extremely unlikely it makes sense for any backends to override this. For most practical purposes it should be considered an internal call between backends and core that backend authors should not touch.

**resume()**

Resume playback at the same time position playback was paused.

*MAY be reimplemented by subclass.*

**Return type** `True` if successful, else `False`
Mopidy Documentation, Release 2.2.3

**seek** *(time_position)*
Seek to a given time position.

*May be reimplemented by subclass.*

**Parameters**
- `time_position` *(int)* – time position in milliseconds

**Return type** True if successful, else False

**stop** ()
Stop playback.

*May be reimplemented by subclass.*

Should not be used for tracking if tracks have been played or when we are done playing them.

**Return type** True if successful, else False

**translate_uri** *(uri)*
Convert custom URI scheme to real playable URI.

*May be reimplemented by subclass.*

This is very likely the only thing you need to override as a backend author. Typically this is where you convert any Mopidy specific URI to a real URI and then return it. If you can’t convert the URI just return None.

**Parameters**
- `uri` *(string)* – the URI to translate

**Return type** string or None if the URI could not be translated

**Playlists provider**

**class** `mopidy.backend.PlaylistsProvider` *(backend)*
A playlist provider exposes a collection of playlists, methods to create/change/delete playlists in this collection, and lookup of any playlist the backend knows about.

**Parameters**
- `backend` *(mopidy.backend.Backend instance)* – backend the controller is a part of

**as_list** ()
Get a list of the currently available playlists.

Returns a list of `Ref` objects referring to the playlists. In other words, no information about the playlists’ content is given.

**Return type** list of `mopidy.models.Ref`

New in version 1.0.

**create** *(name)*
Create a new empty playlist with the given name.

Returns a new playlist with the given name and an URI, or `None` on failure.

*MUST be implemented by subclass.*

**Parameters**
- `name` *(string)* – name of the new playlist

**Return type** `mopidy.models.Playlist` or `None`

**delete** *(uri)*
Delete playlist identified by the URI.

Returns `True` if deleted, `False` otherwise.
**MUST be implemented by subclass.**

**Parameters** `uri (string)` – URI of the playlist to delete

**Return type** `bool`

Changed in version 2.2: Return type defined.

**get_items** (`uri`)

Get the items in a playlist specified by `uri`.

Returns a list of `Ref` objects referring to the playlist’s items.

If a playlist with the given `uri` doesn’t exist, it returns `None`.

**Return type** list of `mopidy.models.Ref`, or `None`

New in version 1.0.

**lookup** (`uri`)

Lookup playlist with given URI in both the set of playlists and in any other playlist source.

Returns the playlists or `None` if not found.

**MUST be implemented by subclass.**

**Parameters** `uri (string)` – playlist URI

**Return type** `mopidy.models.Playlist` or `None`

**refresh** ()

Refresh the playlists in `playlists`.

**MUST be implemented by subclass.**

**save** (`playlist`)

Save the given playlist.

The playlist must have an `uri` attribute set. To create a new playlist with an URI, use `create()`.

Returns the saved playlist or `None` on failure.

**MUST be implemented by subclass.**

**Parameters** `playlist` (`mopidy.models.Playlist`) – the playlist to save

**Return type** `mopidy.models.Playlist` or `None`

**Library provider**

**class** `mopidy.backend.LibraryProvider` (`backend`)

**Parameters** `backend` (`mopidy.backend.Backend`) – backend the controller is a part of

**browse** (`uri`)

See `mopidy.core.LibraryController.browse()`.

If you implement this method, make sure to also set `root_directory`.

**MAY be implemented by subclass.**

**get_distinct** (`field`, `query=None`)

See `mopidy.core.LibraryController.get_distinct()`.

**MAY be implemented by subclass.**

Default implementation will simply return an empty set.
Note that backends should always return an empty set for unexpected field types.

**get_images** *(uris)*

See `mopidy.core.LibraryController.get_images()`.

*MAY be implemented by subclass.*

Default implementation will simply call lookup and try and use the album art for any tracks returned. Most extensions should replace this with something smarter or simply return an empty dictionary.

**lookup** *(uri)*

See `mopidy.core.LibraryController.lookup()`.

*MUST be implemented by subclass.*

**refresh** *(uri=None)*

See `mopidy.core.LibraryController.refresh()`.

*MAY be implemented by subclass.*

```
root_directory = None
```

`mopidy.models.Ref.directory` instance with a URI and name set representing the root of this library’s browse tree. URIs must use one of the schemes supported by the backend, and name should be set to a human friendly value.

*MUST be set by any class that implements `LibraryProvider.browse()`.*

**search** *(query=None, uris=None, exact=False)*

See `mopidy.core.LibraryController.search()`.

*MAY be implemented by subclass.*

New in version 1.0: The `exact` param which replaces the old `find_exact`.

### Backend listener

**class** `mopidy.backend.BackendListener`

Marker interface for recipients of events sent by the backend actors.

Any Pykka actor that mixes in this class will receive calls to the methods defined here when the corresponding events happen in a backend actor. This interface is used both for looking up what actors to notify of the events, and for providing default implementations for those listeners that are not interested in all events.

Normally, only the Core actor should mix in this class.

**playlists_loaded** ()

Called when playlists are loaded or refreshed.

*MAY be implemented by actor.*

**static send** *(event, **kwargs)*

Helper to allow calling of backend listener events

### Backend implementations

See `Backend extensions`. 
34.2.4 mopidy.ext – Extension API

If you want to learn how to make Mopidy extensions, read Extension development.

```python
class mopidy.ext.Extension
    Base class for Mopidy extensions

    dist_name = None
        The extension’s distribution name, as registered on PyPI
        Example: Mopidy-Soundspot

    ext_name = None
        The extension’s short name, as used in setup.py and as config section name
        Example: soundspot

classmethod get_cache_dir(config)
    Get or create cache directory for the extension.
    Use this directory to cache data that can safely be thrown away.

        Parameters config – the Mopidy config object
        Returns string

get_command()
    Command to expose to command line users running mopidy.

        Returns Instance of a Command class.

classmethod get_config_dir(config)
    Get or create configuration directory for the extension.

        Parameters config – the Mopidy config object
        Returns string

get_config_schema()
    The extension’s config validation schema

        Returns ConfigSchema

classmethod get_data_dir(config)
    Get or create data directory for the extension.
    Use this directory to store data that should be persistent.

        Parameters config – the Mopidy config object
        Returns string

get_default_config()
    The extension’s default config as a bytestring

        Returns bytes or unicode

setup(registry)
    Register the extension’s components in the extension Registry.

    For example, to register a backend:

def setup(self, registry):
    from .backend import SoundspotBackend
    registry.add('backend', SoundspotBackend)
```

See `Registry` for a list of registry keys with a special meaning. Mopidy will instantiate and start any classes registered under the `frontend` and `backend` registry keys.

This method can also be used for other setup tasks not involving the extension registry.

**Parameters**

registry (*Registry*) – the extension registry

**validate_environment()**

Checks if the extension can run in the current environment.

Dependencies described by `setup.py` are checked by Mopidy, so you should not check their presence here.

If a problem is found, raise `ExtensionError` with a message explaining the issue.

**Raises**

`ExtensionError`

**Returns**

`None`

version = `None`

The extension’s version

Should match the `__version__` attribute on the extension’s main Python module and the version registered on PyPI.

**class** `mopidy.ext.ExtensionData` *(extension, entry_point, config_schema, config_defaults, command)*

**command**

Alias for field number 4

**config_defaults**

Alias for field number 3

**config_schema**

Alias for field number 2

**entry_point**

Alias for field number 1

**extension**

Alias for field number 0

**class** `mopidy.ext.Registry`

Registry of components provided by Mopidy extensions.

Passed to the `setup()` method of all extensions. The registry can be used like a dict of string keys and lists.

Some keys have a special meaning, including, but not limited to:

- `backend` is used for Mopidy backend classes.
- `frontend` is used for Mopidy frontend classes.
- `local:library` is used for Mopidy-Local libraries.

Extensions can use the registry for allow other to extend the extension itself. For example the Mopidy-Local use the `local:library` key to allow other extensions to register library providers for Mopidy-Local to use. Extensions should namespace custom keys with the extension’s `ext_name`, e.g. `local:foo` or `http:bar`.

**add**(name, cls)

Add a component to the registry.

Multiple classes can be registered to the same name.
mopidy.ext.load_extensions()
    Find all installed extensions.

Returns list of installed extensions

mopidy.ext.validate_extension_data(data)
    Verify extension’s dependencies and environment.

Parameters extensions – an extension to check

Returns if extension should be run

34.3 Web/JavaScript

34.3.1 HTTP server side API

The Mopidy-HTTP extension comes with an HTTP server to host Mopidy’s HTTP JSON-RPC API. This web server can also be used by other extensions that need to expose something over HTTP.

The HTTP server side API can be used to:

• host static files for e.g. a Mopidy client written in pure JavaScript,
• host a Tornado application, or
• host a WSGI application, including e.g. Flask applications.

To host static files using the web server, an extension needs to register a name and a file path in the extension registry under the http:static key.

To extend the web server with a web application, an extension must register a name and a factory function in the extension registry under the http:app key.

For details on how to make a Mopidy extension, see the Extension development guide.

Static web client example

To serve static files, you just need to register an http:static dictionary in the extension registry. The dictionary must have two keys: name and path. The name is used to build the URL the static files will be served on. By convention, it should be identical with the extension’s ext_name, like in the following example. The path tells Mopidy where on the disk the static files are located.

Assuming that the code below is located in the file mywebclient/__init__.py, the files in the directory mywebclient/static/ will be made available at /mywebclient/ on Mopidy’s web server. For example, mywebclient/static/foo.html will be available at http://localhost:6680/mywebclient/foo.html.

```python
from __future__ import absolute_import, unicode_literals
import os
from mopidy import ext

class MyWebClientExtension(ext.Extension):
    ext_name = 'mywebclient'

    def setup(self, registry):
        registry.add('http:static', {
            'name': 'mywebclient',
            'path': os.path.join('static', 'foo.html')
        })
```

(continues on next page)
Tornado application example

The Mopidy-HTTP extension’s web server is based on the Tornado web framework. Thus, it has first class support for Tornado request handlers.

In the following example, we create a tornado.web.RequestHandler called MyRequestHandler that responds to HTTP GET requests with the string Hello, world! This is Mopidy $version, where it gets the Mopidy version from Mopidy’s core API.

To hook the request handler into Mopidy’s web server, we must register a dictionary under the http:app key in the extension registry. The dictionary must have two keys: name and factory.

The name is used to build the URL the app will be served on. By convention, it should be identical with the extension’s ext_name, like in the following example.

The factory must be a function that accepts two arguments, config and core, respectively a dict structure of Mopidy’s config and a pykka.ActorProxy to the full Mopidy core API. The factory function must return a list of Tornado request handlers. The URL patterns of the request handlers should not include the name, as that will be prepended to the URL patterns by the web server.

When the extension is installed, Mopidy will respond to requests to http://localhost:6680/mywebclient/ with the string Hello, world! This is Mopidy $version.

```python
from __future__ import absolute_import, unicode_literals
import os
import tornado.web
from mopidy import ext

class MyRequestHandler(tornado.web.RequestHandler):
    def initialize(self, core):
        self.core = core
        
        def get(self):
            self.write(
                'Hello, world! This is Mopidy %s
                %s' %
                self.core.get_version().get())

    def my_app_factory(config, core):
        return [
            ('/', MyRequestHandler, {'core': core})
        ]

class MyWebClientExtension(ext.Extension):
    ext_name = 'mywebclient'
```
def setup(self, registry):
    registry.add('http:app', {
        'name': self.ext_name,
        'factory': my_app_factory,
    })

# See the Extension API for the full details on this class

WSGI application example

WSGI applications are second-class citizens on Mopidy’s HTTP server. The WSGI applications are run inside Tornado, which is based on non-blocking I/O and a single event loop. In other words, your WSGI applications will only have a single thread to run on, and if your application is doing blocking I/O, it will block all other requests from being handled by the web server as well.

The example below shows how a WSGI application that returns the string Hello, world! This is Mopidy $version on all requests. The WSGI application is wrapped as a Tornado application and mounted at http://localhost:6680/mywebclient/.

from __future__ import absolute_import, unicode_literals
import os
import tornado.web
import tornado.wsgi
from mopidy import ext

def my_app_factory(config, core):
    def wsgi_app(environ, start_response):
        status = '200 OK'
        response_headers = [('Content-type', 'text/plain')]
        start_response(status, response_headers)
        return [
            'Hello, world! This is Mopidy $version

            self.core.get_version().get()
        ]

        return [
            ('(.*)', tornado.web.FallbackHandler, {
                'fallback': tornado.wsgi.WSGIContainer(wsgi_app),
            }),
        ]

class MyWebClientExtension(ext.Extension):
    ext_name = 'mywebclient'

    def setup(self, registry):
        registry.add('http:app', {
            'name': self.ext_name,
            'factory': my_app_factory,
34.3.2 HTTP JSON-RPC API

The Mopidy-HTTP extension makes Mopidy’s mopidy.core — Core API available using JSON-RPC over HTTP using HTTP POST and WebSockets. We also provide a JavaScript wrapper, called Mopidy.js, around the JSON-RPC over WebSocket API for use both from browsers and Node.js. The Mopidy-API-Explorer extension, can also be used to get you familiarized with HTTP based APIs.

HTTP POST API

The Mopidy web server accepts HTTP requests with the POST method to http://localhost:6680/mopidy/rpc, where the localhost:6680 part will vary with your local setup. Your requests must also set the Content-Type header to application/json. The HTTP POST endpoint gives you access to Mopidy’s full core API, but does not give you notification on events. If you need to listen to events, you should probably use the WebSocket API instead.

Example usage from the command line:

```
$ curl -d '{"jsonrpc": "2.0", "id": 1, "method": "core.playback.get_state"}' -H 'Content-Type: application/json' http://localhost:6680/mopidy/rpc
```

For details on the request and response format, see JSON-RPC 2.0 messages.

WebSocket API

The Mopidy web server exposes a WebSocket at http://localhost:6680/mopidy/ws, where the localhost:6680 part will vary with your local setup. The WebSocket gives you access to Mopidy’s full API and enables Mopidy to instantly push events to the client, as they happen.

On the WebSocket we send two different kind of messages: The client can send JSON-RPC 2.0 requests, and the server will respond with JSON-RPC 2.0 responses. In addition, the server will send event messages when something happens on the server. Both message types are encoded as JSON objects.

If you’re using the API from JavaScript, either in the browser or in Node.js, you should use Mopidy.js JavaScript library which wraps the WebSocket API in a nice JavaScript API.

JSON-RPC 2.0 messages

JSON-RPC 2.0 messages can be recognized by checking for the key named jsonrpc with the string value 2.0. For details on the messaging format, please refer to the JSON-RPC 2.0 spec.

All methods in the mopidy.core — Core API is made available through JSON-RPC calls over the WebSocket. For example, mopidy.core.PlaybackController.play() is available as the JSON-RPC method core.playback.play.
Example JSON-RPC request:

```json
{"jsonrpc": "2.0", "id": 1, "method": "core.playback.get_current_track"}
```

Example JSON-RPC response:

```json
{"jsonrpc": "2.0", "id": 1, "result": {"__model__": "Track", "...": "..."}}
```

The JSON-RPC method `core.describe` returns a data structure describing all available methods. If you’re unsure how the core API maps to JSON-RPC, having a look at the `core.describe` response can be helpful.

**Event messages**

Event objects will always have a key named `event` whose value is the event type. Depending on the event type, the event may include additional fields for related data. The events maps directly to the `mopidy.core.CoreListener` API. Refer to the `CoreListener` method names is the available event types. The `CoreListener` method’s keyword arguments are all included as extra fields on the event objects. Example event message:

```json
{"event": "track_playback_started", "track": {"..."}}
```

### 34.3.3 Mopidy.js JavaScript library

We’ve made a JavaScript library, Mopidy.js, which wraps the WebSocket API and gets you quickly started with working on your client instead of figuring out how to communicate with Mopidy.

**Getting the library for browser use**

Regular and minified versions of Mopidy.js, ready for use, is installed together with Mopidy. When the HTTP extension is enabled, the files are available at:

- http://localhost:6680/mopidy/mopidy.js
- http://localhost:6680/mopidy/mopidy.min.js

You may need to adjust hostname and port for your local setup.

Thus, if you use Mopidy to host your web client, like described in [Static web client example](#), you can load the latest version of Mopidy.js by adding the following script tag to your HTML file:

```html
<script type="text/javascript" src="/mopidy/mopidy.min.js"></script>
```

If you don’t use Mopidy to host your web client, you can find the JS files in the Git repo at:

- mopidy/http/data/mopidy.js
- mopidy/http/data/mopidy.min.js

**Getting the library for Node.js or Browserify use**

If you want to use Mopidy.js from Node.js or on the web through Browserify, you can install Mopidy.js using npm:

```
npm install mopidy
```

After npm completes, you can import Mopidy.js using `require()`:
```javascript
var Mopidy = require("mopidy");
```

### Getting the library for development on the library

If you want to work on the Mopidy.js library itself, you’ll find the source code and a complete development setup in the Mopidy.js Git repo. The instructions in README.md will guide you on your way.

### Creating an instance

Once you have Mopidy.js loaded, you need to create an instance of the wrapper:

```javascript
var mopidy = new Mopidy();
```

When you instantiate `Mopidy()` without arguments, it will connect to the WebSocket at `/mopidy/ws/` on the current host. Thus, if you don’t host your web client using Mopidy’s web server, or if you use Mopidy.js from a Node.js environment, you’ll need to pass the URL to the WebSocket end point:

```javascript
var mopidy = new Mopidy({
  webSocketUrl: "ws://localhost:6680/mopidy/ws/
});
```

It is also possible to create an instance first and connect to the WebSocket later:

```javascript
var mopidy = new Mopidy({autoConnect: false});
// ... do other stuff, like hooking up events ...
mopidy.connect();
```

When creating an instance, you can specify the following settings:

- **autoConnect** Whether or not to connect to the WebSocket on instance creation. Defaults to true.
- **backoffDelayMin** The minimum number of milliseconds to wait after a connection error before we try to reconnect. For every failed attempt, the backoff delay is doubled until it reaches `backoffDelayMax`. Defaults to 1000.
- **backoffDelayMax** The maximum number of milliseconds to wait after a connection error before we try to reconnect. Defaults to 64000.
- **callingConvention** Which calling convention to use when calling methods.
  - If set to “by-position-only”, methods expect to be called with positional arguments, like `mopidy.foo.bar(null, true, 2)`.
  - If set to “by-position-or-by-name”, methods expect to be called either with an array of position arguments, like `mopidy.foo.bar([null, true, 2])`, or with an object of named arguments, like `mopidy.foo.bar({id: 2})`. The advantage of the “by-position-or-by-name” calling convention is that arguments with default values can be left out of the named argument object. Using named arguments also makes the code more readable, and more resistant to future API changes.

**Note:** For backwards compatibility, the default is “by-position-only”. In the future, the default will change to “by-position-or-by-name”. You should explicitly set this setting to your choice, so you won’t be affected when the default changes.

New in version 0.19: (Mopidy.js 0.4)
If set, this object will be used to log errors from Mopidy.js. This is mostly useful for testing Mopidy.js.

**webSocket**
An existing WebSocket object to be used instead of creating a new WebSocket. Defaults to undefined.

**webSocketUrl**
URL used when creating new WebSocket objects. Defaults to `ws://<document.location.host>/mopidy/ws`, or `ws://localhost/mopidy/ws` if `document.location.host` isn’t available, like it is in the browser environment.

### Hooking up to events

Once you have a Mopidy.js object, you can hook up to the events it emits. To explore your possibilities, it can be useful to subscribe to all events and log them:

```javascript
mopidy.on(console.log.bind(console));
```

Several types of events are emitted:

- You can get notified about when the Mopidy.js object is connected to the server and ready for method calls, when it’s offline, and when it’s trying to reconnect to the server by looking at the events `state:online`, `state:offline`, `reconnectionPending`, and `reconnecting`.
- You can get events sent from the Mopidy server by looking at the events with the name prefix `event:`, like `event:trackPlaybackStarted`.
- You can introspect what happens internally on the WebSocket by looking at the events emitted with the name prefix `websocket:`.

Mopidy.js uses the event emitter library BANE, so you should refer to BANE’s short API documentation to see how you can hook up your listeners to the different events.

### Calling core API methods

Once your Mopidy.js object has connected to the Mopidy server and emits the `state:online` event, it is ready to accept core API method calls:

```javascript
mopidy.on("state:online", function () {
  mopidy.playback.next();
});
```

Any calls you make before the `state:online` event is emitted will fail. If you’ve hooked up an errback (more on that a bit later) to the promise returned from the call, the errback will be called with a `Mopidy.ConnectionError` instance.

All methods in Mopidy’s `mopidy.core — Core API` is available via Mopidy.js. For example, the `mopidy.core.PlaybackController.get_state()` method is available in JSON-RPC as the method `core.playback.get_state` and in Mopidy.js as `mopidy.playback.getState()`.

Both the WebSocket API and the JavaScript API are based on introspection of the core Python API. Thus, they will always be up to date and immediately reflect any changes we do to the core API.

The best way to explore the JavaScript API, is probably by opening your browser’s console, and using its tab completion to navigate the API. You’ll find the Mopidy core API exposed under `mopidy.playback`, `mopidy.tracklist`, `mopidy.playlists`, and `mopidy.library`.

All methods in the JavaScript API have an associated data structure describing the Python params it expects, and most methods also have the Python API documentation available. This is available right there in the browser console, by looking at the method’s `description` and `params` attributes:
JSON-RPC 2.0 limits method parameters to be sent either by-position or by-name. Combinations of both, like we’re
used to from Python, isn’t supported by JSON-RPC 2.0.

Obviously, you’ll want to get a return value from many of your method calls. Since everything is happening across
the WebSocket and maybe even across the network, you’ll get the results asynchronously. Instead of having to pass
callbacks and errbacks to every method you call, the methods return “promise” objects, which you can use to pipe the
future result as input to another method, or to hook up callback and errback functions.

```javascript
var track = mopidy.playback.getCurrentTrack();
// => `track` isn’t a track, but a "promise" object
```

Instead, typical usage will look like this:

```javascript
var printCurrentTrack = function (track) {
  if (track) {
    console.log("Currently playing:", track.name, "by",
                track.artists[0].name, "from", track.album.name);
  } else {
    console.log("No current track");
  }
};

mopidy.playback.getCurrentTrack()
  .done(printCurrentTrack);
```

The function passed to `done()`, `printCurrentTrack`, is the callback that will be called if the method call
succeeds. If anything goes wrong, `done()` will throw an exception.

If you want to explicitly handle any errors and avoid an exception being thrown, you can register an error handler
function anywhere in a promise chain. The function will be called with the error object as the only argument:

```javascript
mopidy.playback.getCurrentTrack()
  .catch(console.error.bind(console))
  .done(printCurrentTrack);
```

You can also register the error handler at the end of the promise chain by passing it as the second argument to `done()`:

```javascript
mopidy.playback.getCurrentTrack()
  .done(printCurrentTrack, console.error.bind(console));
```

If you don’t hook up an error handler function and never call `done()` on the promise object, warnings will be logged
to the console complaining that you have unhandled errors. In general, unhandled errors will not go silently missing.

The promise objects returned by Mopidy.js adheres to the CommonJS Promises/A standard. We use the implementa-
tion known as `when.js`, and reexport it as `Mopidy.when` so you don’t have to duplicate the dependency. Please refer
to `when.js`’ documentation or the standard for further details on how to work with promise objects.

**Cleaning up**

If you for some reason want to clean up after Mopidy.js before the web page is closed or navigated away from, you
can close the WebSocket, unregister all event listeners, and delete the object like this:
Example to get started with

1. Make sure that you’ve installed all dependencies required by Mopidy-HTTP.
2. Create an empty directory for your web client.
3. Change the http/static_dir config value to point to your new directory.
4. Start/restart Mopidy.
5. Create a file in the directory named index.html containing e.g. “Hello, world!”.
7. Include Mopidy.js in your web page:

```html
<script type="text/javascript" src="/mopidy/mopidy.min.js"></script>
```

8. Add one of the following Mopidy.js examples of how to queue and start playback of your first playlist either to your web page or a JavaScript file that you include in your web page.

“Imperative” style:

```javascript
var trackDesc = function (track) {
    return track.name + " by " + track.artists[0].name + " from " + track.album.name;
};

var queueAndPlay = function (playlistNum, trackNum) {
    playlistNum = playlistNum || 0;
    trackNum = trackNum || 0;
    mopidy.playlists.getPlaylists().then(function (playlists) {
        var playlist = playlists[playlistNum];
        console.log("Loading playlist:", playlist.name);
        return mopidy.tracklist.add(playlist.tracks).then(function (tlTracks) {
            return mopidy.playback.play(tlTracks[trackNum]).then(function () {
                console.log("Now playing:", trackDesc(tlTracks[trackNum]));
            });
        });
    });
}.catch(console.error.bind(console)) // Handle errors here
.done(); // ...or they'll be thrown here
```
var mopidy = new Mopidy(); // Connect to server
mopidy.on(console.log.bind(console)); // Log all events
mopidy.on("state:online", queueAndPlay);

Approximately the same behavior in a more functional style, using chaining of promises.

var get = function (key, object) {
    return object[key];
};

var printTypeAndName = function (model) {
    console.log(model.__model__ + " : " + model.name);
    // By returning the playlist, this function can be inserted
    // anywhere a model with a name is piped in the chain.
    return model;
};

var trackDesc = function (track) {
    return track.name + " by " + track.artists[0].name + " from " + track.album.name;
};

var printNowPlaying = function () {
    // By returning any arguments we get, the function can be inserted
    // anywhere in the chain.
    var args = arguments;
    return mopidy.playback.getCurrentTrack().then(function (track) {
        console.log("Now playing:", trackDesc(track));
    return args;
    });
};

var queueAndPlay = function (playlistNum, trackNum) {
    playlistNum = playlistNum || 0;
    trackNum = trackNum || 0;
    mopidy.playlists.getPlaylists() // => list of Playlists
    .fold(get, playlistNum) // => Playlist
    .then(printTypeAndName) // => Playlist
    .fold(get, 'tracks') // => list of Tracks
    .then(mopidy.tracklist.add) // => list of TlTracks
    .fold(get, trackNum) // => TlTrack
    .then(mopidy.playback.play) // => null
    .then(printNowPlaying) // => null
    .catch(console.error.bind(console)) // Handle errors here
    .done(); // ...or they'll be thrown here
};

(continues on next page)
9. The web page should now queue and play your first playlist every time you load it. See the browser’s console for output from the function, any errors, and all events that are emitted.

## 34.4 Audio

### 34.4.1 mopidy.audio — Audio API

The audio API is the interface we have built around GStreamer to support our specific use cases. Most backends should be able to get by with simply setting the URI of the resource they want to play, for these cases the default playback provider should be used.

For more advanced cases such as when the raw audio data is delivered outside of GStreamer or the backend needs to add metadata to the currently playing resource, developers should sub-class the base playback provider and implement the extra behaviour that is needed through the following API:

```javascript
class mopidy.audio.Audio(config, mixer)
    Audio output through GStreamer.

    emit_data(buffer_)
    Call this to deliver raw audio data to be played.
    
    If the buffer is None, the end-of-stream token is put on the playbin. We will get a GStreamer message when the stream playback reaches the token, and can then do any end-of-stream related tasks.
    
    Note that the URI must be set to appsrc:// for this to work.
    
    Returns True if data was delivered.
    
    Parameters buffer (Gst.Buffer or None) – buffer to pass to appsrc
    
    Return type boolean

    emit_end_of_stream()
    Put an end-of-stream token on the playbin. This is typically used in combination with emit_data().
    
    We will get a GStreamer message when the stream playback reaches the token, and can then do any end-of-stream related tasks.
    
    Deprecated since version 1.0: Use emit_data() with a None buffer instead.

    enable_sync_handler()
    Enable manual processing of messages from bus.
    
    Should only be used by tests.

    get_current_tags()
    Get the currently playing media’s tags.
    
    If no tags have been found, or nothing is playing this returns an empty dictionary. For each set of tags we collect a tags_changed event is emitted with the keys of the changes tags. After such calls users may call this function to get the updated values.
    
    Return type {key: [values]} dict for the current media.
```
get_position()  
Get position in milliseconds.

**Return type**  int

```python
mixer = None
```

The software mixing interface `mopidy.audio.actor.SoftwareMixer`

```python
on_start()
```

Hook for doing any setup that should be done after the actor is started, but before it starts processing messages.

For ThreadingActor, this method is executed in the actor’s own thread, while `__init__()` is executed in the thread that created the actor.

If an exception is raised by this method the stack trace will be logged, and the actor will stop.

```python
on_stop()
```

Hook for doing any cleanup that should be done after the actor has processed the last message, and before the actor stops.

This hook is not called when the actor stops because of an unhandled exception. In that case, the `on_failure()` hook is called instead.

For ThreadingActor this method is executed in the actor’s own thread, immediately before the thread exits.

If an exception is raised by this method the stack trace will be logged, and the actor will stop.

```python
pause_playback()
```

Notify GStreamer that it should pause playback.

**Return type**  True if successful, else False

```python
prepare_change()
```

Notify GStreamer that we are about to change state of playback.

This function **MUST** be called before changing URIs or doing changes like updating data that is being pushed. The reason for this is that GStreamer will reset all its state when it changes to `Gst.State.READY`.

```python
set_about_to_finish_callback(callback)
```

Configure audio to use an about-to-finish callback.

This should be used to achieve gapless playback. For this to work the callback **MUST** call `set_uri()` with the new URI to play and block until this call has been made. `prepare_change()` is not needed before `set_uri()` in this one special case.

**Parameters**

- **callback (callable)** – Callback to run when we need the next URI.

```python
set_appsrc(caps, need_data=None, enough_data=None, seek_data=None)
```

Switch to using appsrc for getting audio to be played.

You **MUST** call `prepare_change()` before calling this method.

**Parameters**

- **caps (string)** – GStreamer caps string describing the audio format to expect
- **need_data (callable which takes data length hint in ms)** – callback for when appsrc needs data
- **enough_data (callable)** – callback for when appsrc has enough data
- **seek_data** *(callable which takes time position in ms)* – callback for when data from a new position is needed to continue playback

**set_metadata** *(track)*
Set track metadata for currently playing song.

Only needs to be called by sources such as `appsrc` which do not already inject tags in playbin, e.g. when using `emit_data()` to deliver raw audio data to GStreamer.

**Parameters**
- **track** *(mopidy.models.Track)* – the current track

**set_position** *(position)*
Set position in milliseconds.

**Parameters**
- **position** *(int)* – the position in milliseconds

**Return type**
- `True` if successful, `False` otherwise

**set_uri** *(uri)*
Set URI of audio to be played.

You **MUST** call `prepare_change()` before calling this method.

**Parameters**
- **uri** *(string)* – the URI to play

**start_playback** *()*
Notify GStreamer that it should start playback.

**Return type**
- `True` if successful, `False` otherwise

state = u'stopped'
The GStreamer state mapped to `mopidy.audio.PlaybackState`

**stop_playback** *()*
Notify GStreamer that it should stop playback.

**Return type**
- `True` if successful, `False` otherwise

**wait_for_state_change** *()*
Block until any pending state changes are complete.

Should only be used by tests.

### Audio listener

**class** `mopidy.audio.AudioListener`
Marker interface for recipients of events sent by the audio actor.

Any Pykka actor that mixes in this class will receive calls to the methods defined here when the corresponding events happen in the core actor. This interface is used both for looking up what actors to notify of the events, and for providing default implementations for those listeners that are not interested in all events.

**position_changed** *(position)*
Called whenever the position of the stream changes.

**MAY** be implemented by actor.

**Parameters**
- **position** *(int)* – Position in milliseconds.

**reached_end_of_stream** *(*)
Called whenever the end of the audio stream is reached.

**MAY** be implemented by actor.
static send(event, **kwargs)
Helper to allow calling of audio listener events

state_changed(old_state, new_state, target_state)
Called after the playback state have changed.
Will be called for both immediate and async state changes in GStreamer.
Target state is used to when we should be in the target state, but temporarily need to switch to an other state.
A typical example of this is buffering. When this happens an event with old=PLAYING, new=PAUSED, target=PLAYING will be emitted. Once we have caught up a old=PAUSED, new=PLAYING, target=None event will be be generated.
Regular state changes will not have target state set as they are final states which should be stable.
MAY be implemented by actor.

Parameters

• old_state (string from mopidy.core.PlaybackState field) – the state before the change
• new_state (string from mopidy.core.PlaybackState field) – the state after the change
• target_state (string from mopidy.core.PlaybackState field or None if this is a final state.) – the intended state

stream_changed(uri)
Called whenever the audio stream changes.
MAY be implemented by actor.

Parameters uri (string) – URI the stream has started playing.

tags_changed(tags)
Called whenever the current audio stream’s tags change.
This event signals that some track metadata has been updated. This can be metadata such as artists, titles, organization, or details about the actual audio such as bit-rates, numbers of channels etc.
For the available tag keys please refer to GStreamer documentation for tags.
MAY be implemented by actor.

Parameters tags (set of strings) – The tags that have just been updated.

Audio scanner

class mopidy.audio.scan.Scanner(timeout=1000, proxy_config=None)
Helper to get tags and other relevant info from URIs.

Parameters

• timeout – timeout for scanning a URI in ms
• proxy_config – dictionary containing proxy config strings.

scan(uri, timeout=None)
Scan the given uri collecting relevant metadata.

Parameters

• uri (string) – URI of the resource to scan.
timeout (int) – timeout for scanning a URI in ms. Defaults to the timeout value used when creating the scanner.

Returns A named tuple containing (uri, tags, duration, seekable, mime).

tags is a dictionary of lists for all the tags we found. duration is the length of the URI in milliseconds, or None if the URI has no duration. seekable is boolean, indicating if a seek would succeed.

## Audio utils

class mopidy.audio.utils.Signals
Helper for tracking gobject signal registrations

    clear()
    Clear all registered signal handlers.

    connect (element, event, func, *args)
    Connect a function + args to signal event on an element.
    Each event may only be handled by one callback in this implementation.

    disconnect (element, event)
    Disconnect whatever handler we have for an element+event pair.
    Does nothing it the handler has already been removed.

mopidy.audio.utils.calculate_duration (num_samples, sample_rate)
Determine duration of samples using GStreamer helper for precise math.

mopidy.audio.utils.clocktime_to_millisecond (value)
Convert an internal GStreamer time to millisecond time.

mopidy.audio.utils.create_buffer (data, timestamp=None, duration=None)
Create a new GStreamer buffer based on provided data.
Mainly intended to keep gst imports out of non-audio modules.

Changed in version 2.0: capabilities argument was removed.

mopidy.audio.utils.millisecond_to_clocktime (value)
Convert a millisecond time to internal GStreamer time.

mopidy.audio.utils.setup_proxy (element, config)
Configure a GStreamer element with proxy settings.

    Parameters

        * element (Gst.GstElement) – element to setup proxy in.

        * config (dict) – proxy settings to use.

mopidy.audio.utils.supported_uri_schemes (uri_schemes)
Determine which URIs we can actually support from provided whitelist.

    Parameters uri_schemes (list or set or URI schemes as strings.) – list/set of URIs to check support for.

    Return type set of URI schemes we can support via this GStreamer install.
34.4.2 `mopidy.mixer` — Audio mixer API

```python
class mopidy.mixer.Mixer(config)
Audio mixer API

If the mixer has problems during initialization it should raise `mopidy.exceptions.MixerError` with a descriptive error message. This will make Mopidy print the error message and exit so that the user can fix the issue.

Parameters `config` (dict) – the entire Mopidy configuration

get_mute()
Get mute state of the mixer.

`MAY be implemented by subclass.`

Return type `True` if muted, `False` if unmuted, `None` if unknown.

get_volume()
Get volume level of the mixer on a linear scale from 0 to 100.

Example values:

- **0**: Minimum volume, usually silent.
- **100**: Maximum volume.

`None`: Volume is unknown.

`MAY be implemented by subclass.`

Return type `int` in range `[0..100]` or `None`

name = `None`
Name of the mixer.

Used when configuring what mixer to use. Should match the `ext_name` of the extension providing the mixer.

ping()
Called to check if the actor is still alive.

set_mute(mute)
Mute or unmute the mixer.

`MAY be implemented by subclass.`

Parameters `mute` (bool) – True to mute, False to unmute

Return type `True` if success, `False` if failure

set_volume(volume)
Set volume level of the mixer.

`MAY be implemented by subclass.`

Parameters `volume` (int) – Volume in the range `[0..100]`

Return type `True` if success, `False` if failure

trigger_mute_changed(mute)
Send `mute_changed` event to all mixer listeners.

This method should be called by subclasses when the mute state is changed, either because of a call to `set_mute()` or because of any external entity changing the mute state.
```
**trigger_volume_changed**(volume)

Send `volume_changed` event to all mixer listeners.

This method should be called by subclasses when the volume is changed, either because of a call to `set_volume()` or because of any external entity changing the volume.

### class mopidy.mixer.MixerListener

Marker interface for recipients of events sent by the mixer actor.

Any Pykka actor that mixes in this class will receive calls to the methods defined here when the corresponding events happen in the mixer actor. This interface is used both for looking up what actors to notify of the events, and for providing default implementations for those listeners that are not interested in all events.

**mute_changed**(mute)

Called after the mute state has changed.

*MAY* be implemented by actor.

**Parameters**

- `mute` *(bool)* – True if muted, False if not muted

**static send**(event, **kwargs)

Helper to allow calling of mixer listener events

**volume_changed**(volume)

Called after the volume has changed.

*MAY* be implemented by actor.

**Parameters**

- `volume` *(int in range [0..100])* – the new volume

### Mixer implementations

See [Mixer extensions](#).

### 34.5 Utilities

#### 34.5.1 mopidy.commands — Commands API

**class** mopidy.commands.Command

Command parser and runner for building trees of commands.

This class provides a wrapper around `argparse.ArgumentParser` for handling this type of command line application in a better way than `argprases` own sub-parser handling.

**add_argument**(args, **kwargs)

Add an argument to the parser.

This method takes all the same arguments as the `argparse.ArgumentParser` version of this method.

**add_child**(name, command)

Add a child parser to consider using.

**Parameters**

- `name` *(string)* – name to use for the sub-command that is being added.

**exit**(status_code=0, message=None, usage=None)

Optionally print a message and exit.

**format_help**(prog=None)

Format help for current parser and children.
format_usage (prog=None)
Format usage for current parser.

parse (args, prog=None)
Parse command line arguments.
Will recursively parse commands until a final parser is found or an error occurs. In the case of errors we will print a message and exit. Otherwise, any overrides are applied and the current parser stored in the command attribute of the return value.

Parameters
• args (list of strings) – list of arguments to parse
• prog (string) – name to use for program

Return type
argparse.Namespace

run (*args, **kwargs)
Run the command.
Must be implemented by sub-classes that are not simply an intermediate in the command namespace.

set (**kwargs)
Override a value in the finaly result of parsing.

34.5.2 mopidy.config — Config API

class mopidy.config.Proxy (data)
mopidy.config.read (config_file)
Helper to load config defaults in same way across core and extensions

Config section schemas

class mopidy.config.schemas.ConfigSchema (name)
Logical group of config values that correspond to a config section.
Schemas are set up by assigning config keys with config values to instances. Once setup deserialize() can be called with a dict of values to process. For convenience we also support format() method that can used for converting the values to a dict that can be printed and serialize() for converting the values to a form suitable for persistence.

deserialize (values)
Validates the given values using the config schema.
Returns a tuple with cleaned values and errors.

serialize (values, display=False)
Converts the given values to a format suitable for persistence.
If display is True secret config values, like passwords, will be masked out.
Returns a dict of config keys and values.

class mopidy.config.schemas.MapConfigSchema (name, value_type)
Schema for handling multiple unknown keys with the same type.
Does not sub-class ConfigSchema, but implements the same serialize/deserialize interface.
Config value types

```python
class mopidy.config.types.Boolean(optional=False)
    Boolean value.
    Accepts 1, yes, true, and on with any casing as True.
    Accepts 0, no, false, and off with any casing as False.
```

```python
class mopidy.config.types.ConfigValue
    Represents a config key’s value and how to handle it.
    Normally you will only be interacting with sub-classes for config values that encode either deserialization behavior and/or validation.

    Each config value should be used for the following actions:
    1. Deserializing from a raw string and validating, raising ValueError on failure.
    2. Serializing a value back to a string that can be stored in a config.
    3. Formatting a value to a printable form (useful for masking secrets).

    None values should not be deserialized, serialized or formatted, the code interacting with the config should simply skip None config values.

    `deserialize(value)`
    Cast raw string to appropriate type.

    `serialize(value, display=False)`
    Convert value back to string for saving.
```

```python
class mopidy.config.types.Deprecated
    Deprecated value
    Used for ignoring old config values that are no longer in use, but should not cause the config parser to crash.
```

```python
class mopidy.config.types.ExpandedPath
    Original and expanded path value.
```

```python
class mopidy.config.types.Hostname(optional=False)
    Network hostname value.
```

```python
class mopidy.config.types.Integer(minimum=None, maximum=None, choices=None, optional=False)
    Integer value.
```

```python
class mopidy.config.types.List(optional=False)
    List value.
    Supports elements split by commas or newlines. Newlines take precedence and empty list items will be filtered out.
```

```python
class mopidy.config.types.LogLevel
    Log level value.
    Expects one of critical, error, warning, info, debug, or all, with any casing.
```

```python
class mopidy.config.types.Path(optional=False)
    File system path
    The following expansions of the path will be done:
    - ~ to the current user’s home directory
    - $XDG_CACHE_DIR according to the XDG spec
    - $XDG_CONFIG_DIR according to the XDG spec
```

• $XDG\_DATA\_DIR$ according to the XDG spec
• $XDG\_MUSIC\_DIR$ according to the XDG spec

class mopidy.config.types.Port (choices=None, optional=False)
Network port value.

   Expects integer in the range 0-65535, zero tells the kernel to simply allocate a port for us.

class mopidy.config.types.Secret (optional=False, choices=None)
Secret string value.

   Is decoded as utf-8 and n't escapes should work and be preserved.

   Should be used for passwords, auth tokens etc. Will mask value when being displayed.

class mopidy.config.types.String (optional=False, choices=None)
String value.

   Is decoded as utf-8 and n't escapes should work and be preserved.

**Config value validators**

mopidy.config.validators.validate_choice (value, choices)
Validate that value is one of the choices

   Normally called in deserialize().

mopidy.config.validators.validate_maximum (value, maximum)
Validate that value is at most maximum

   Normally called in deserialize().

mopidy.config.validators.validate_minimum (value, minimum)
Validate that value is at least minimum

   Normally called in deserialize().

mopidy.config.validators.validate_required (value, required)
Validate that value is set if required

   Normally called in deserialize() on the raw string, _not_ the converted value.

### 34.5.3 mopidy.httpclient — HTTP Client helpers

mopidy.httpclient.format_proxy (proxy_config, auth=True)
Convert a Mopidy proxy config to the commonly used proxy string format.

   Outputs scheme://host:port, scheme://user:pass@host:port or None depending on the proxy config provided.

   You can also opt out of getting the basic auth by setting auth to False.

   New in version 1.1.

mopidy.httpclient.format_user_agent (name=None)
Construct a User-Agent suitable for use in client code.

   This will identify use by the provided name (which should be on the format dist_name/version), Mopidy version and Python version.

   New in version 1.1.
### 34.5.4 mopidy.zeroconf — Zeroconf API

```python
class mopidy.zeroconf.Zeroconf(name, stype, port, domain=u'', host=u'', text=None)
```

Publish a network service with Zeroconf.

Currently, this only works on Linux using Avahi via D-Bus.

**Parameters**

- `name (str)` – human readable name of the service, e.g. ‘MPD on neptune’
- `stype (str)` – service type, e.g. ‘_mpd._tcp’
- `port (int)` – TCP port of the service, e.g. 6600
- `domain (str)` – local network domain name, defaults to ‘’
- `host (str)` – interface to advertise the service on, defaults to ‘’
- `text (list of str)` – extra information depending on `stype`, defaults to empty list

```python
def publish()
    Publish the service.
```

Call when your service starts.

```python
def unpublish()
    Unpublish the service.
```

Call when your service shuts down.
35.1 mopidy.local — Local backend

For details on how to use Mopidy’s local backend, see Mopidy-Local.

35.1.1 Local library API

class mopidy.local.Library(config)

Local library interface.

Extensions that wish to provide an alternate local library storage backend need to sub-class this class and install and configure it with an extension. Both scanning and library calls will use the active local library.

Parameters

config – Config dictionary

ROOT_DIRECTORY_URI = u'local:directory'

URI of the local backend’s root directory.

This constant should be used by libraries implementing the Library.browse() method.

add(track=None, tags=None, duration=None)

Add the given track to library. Optional args will only be added if add_supports_tags_and_duration has been set.

Parameters

• track (Track) – Track to add to the library
• tags (dictionary of tag keys with a list of values.) – All the tags the scanner found for the media. See mopidy.audio.utils for details about the tags.
• duration (int or None) – Duration of media in milliseconds or None if unknown

add_supports_tags_and_duration = False

Feature marker to indicate that you want add() calls to be called with optional arguments tags and duration.
begin()
    Prepare library for accepting updates. Exactly what this means is highly implementation depended. This
    must however return an iterator that generates all tracks in the library for efficient scanning.

    Return type Track iterator

browse(uri)
    Browse directories and tracks at the given URI.
    The URI for the root directory is a constant available at Library.ROOT_DIRECTORY_URI.

    Parameters path(string) – URI to browse.

    Return type List of Ref tracks and directories.

clear()
    Clear out whatever data storage is used by this backend.

    Return type Boolean indicating if state was cleared.

close()
    Close any resources used for updating, commit outstanding work etc.

flush()
    Called for every n-th track indicating that work should be committed. Sub-classes are free to ignore these
    hints.

    Return type Boolean indicating if state was flushed.

get_distinct(field, query=None)
    List distinct values for a given field from the library.

    Parameters
      • field (string) – One of artist, albumartist, album, composer, performer, date or genre.
      • query (dict) – Query to use for limiting results, see search() for details about the
        query format.

    Return type set of values corresponding to the requested field type.

get_images(uris)
    Lookup the images for the given URIs.
    The default implementation will simply call lookup() and try and use the album art for any tracks
    returned. Most local libraries should replace this with something smarter or simply return an empty dic-
    tionary.

    Parameters uris (list) – list of URIs to find images for

    Return type {uri: tuple of mopidy.models.Image}

load()
    (Re)load any tracks stored in memory, if any, otherwise just return number of available tracks currently
    available. Will be called at startup for both library and update use cases, so if you plan to store tracks in
    memory this is when the should be (re)loaded.

    Return type int representing number of tracks in library.

lookup(uri)
    Lookup the given URI.

    Parameters uri (string) – track URI

    Return type list of Track (or single Track for backward compatibility)
name = None
    Name of the local library implementation, must be overridden.

remove(uri)
    Remove the given track from the library.

    Parameters uri (str) – URI to remove from the library.

search(query=None, limit=100, offset=0, exact=False, uris=None)
    Search the library for tracks where field contains values.

    Parameters
    • query (dict) – one or more queries to search for
    • limit (int) – maximum number of results to return
    • offset (int) – offset into result set to use.
    • exact (bool) – whether to look for exact matches
    • uris (list of strings or None) – zero or more URI roots to limit the search to

    Return type SearchResult

35.1.2 Translation utils

mopidy.local.translator.local_uri_to_file_uri(uri, media_dir)
    Convert local track or directory URI to file URI.

mopidy.local.translator.local_uri_to_path(uri, media_dir)
    Convert local track or directory URI to absolute path.

mopidy.local.translator.path_to_file_uri(abspath)
    Convert absolute path to file URI.

mopidy.local.translator.path_to_local_directory_uri(relpath)
    Convert path relative to local/media_dir to directory URI.

mopidy.local.translator.path_to_local_track_uri(relpath)
    Convert path relative to local/media_dir to local track URI.

35.2 mopidy.mpd — MPD server

For details on how to use Mopidy’s MPD server, see Mopidy-MPD.

35.2.1 MPD tokenizer

mopidy.mpd.tokenize.split(line)
    Splits a line into tokens using same rules as MPD.

    • Lines may not start with whitespace
    • Tokens are split by arbitrary amount of spaces or tabs
    • First token must match [a-z][a-z0-9_.]*
    • Remaining tokens can be unquoted or quoted tokens.
    • Unquoted tokens consist of all printable characters except double quotes, single quotes, spaces and tabs.
• Quoted tokens are surrounded by a matching pair of double quotes.
• The closing quote must be followed by space, tab or end of line.
• Any value is allowed inside a quoted token. Including double quotes, assuming it is correctly escaped.
• Backslash inside a quoted token is used to escape the following character.

For examples see the tests for this function.

35.2.2 MPD dispatcher

class mopidy.mpd.dispatcher.MpdContext (dispatcher, session=None, config=None, core=None, uri_map=None)

This object is passed as the first argument to all MPD command handlers to give the command handlers access to important parts of Mopidy.

browse (path, recursive=True, lookup=True)
Browse the contents of a given directory path.

Returns a sequence of two-tuples (path, data).

If recursive is true, it returns results for all entries in the given path.

If lookup is true and the path is to a track, the returned data is a future which will contain the results from looking up the URI with mopidy.core.LibraryController.lookup(). If lookup is false and the path is to a track, the returned data will be a mopidy.models.Ref for the track.

For all entries that are not tracks, the returned data will be None.

core = None
The Mopidy core API. An instance of mopidy.core.Core.

dispatcher = None
The current MpdDispatcher.

events = None
The active subsystems that have pending events.

lookup_playlist_name_from_uri (uri)
Helper function to retrieve the unique MPD playlist name from its uri.

lookup_playlist_uri_from_name (name)
Helper function to retrieve a playlist from its unique MPD name.

password = None
The MPD password

session = None
The current mopidy.mpd.MpdSession.

subscriptions = None
The subysys that we want to be notified about in idle mode.

class mopidy.mpd.dispatcher.MpdDispatcher (session=None, config=None, core=None, uri_map=None)

The MPD session feeds the MPD dispatcher with requests. The dispatcher finds the correct handler, processes the request and sends the response back to the MPD session.

handle_request (request, current_command_list_index=None)
Dispatch incoming requests to the correct handler.
35.2.3 MPD protocol

rather incomplete with regards to data formats, both for requests and responses. Thus, we have had to talk a great deal
with the the original MPD server using telnet to get the details we need to implement our own MPD server which is
compatible with the numerous existing MPD clients.

mopidy.mpd.protocol.BOOL(value)
Convert the values 0 and 1 into booleans.

class mopidy.mpd.protocol.Commands
Collection of MPD commands to expose to users.

Normally used through the global instance which command handlers have been installed into.

add(name, auth_required=True, list_command=True, **validators)
Create a decorator that registers a handler and validation rules.

Additional keyword arguments are treated as converters/validators to apply to tokens converting them to
proper Python types.

Requirements for valid handlers:
• must accept a context argument as the first arg.
• may not use variable keyword arguments, **kwargs.
• may use variable arguments *args or a mix of required and optional arguments.

Decorator returns the unwrapped function so that tests etc can use the functions with values with correct
python types instead of strings.

Parameters
• name (string) – Name of the command being registered.
• auth_required (bool) – If authorization is required.
• list_command (bool) – If command should be listed in reflection.

call(tokens, context=None)
Find and run the handler registered for the given command.

If the handler was registered with any converters/validators they will be run before calling the real handler.

Parameters
• tokens (list) – List of tokens to process
• context (MpdContext) – MPD context.

mopidy.mpd.protocol.ENCODING = u'UTF-8'
The MPD protocol uses UTF-8 for encoding all data.

mopidy.mpd.protocol.INT(value)
Converts a value that matches \[+-\]?d+ into and integer.

mopidy.mpd.protocol.LINE_TERMINATOR = u'\n'
The MPD protocol uses \n as line terminator.

mopidy.mpd.protocol.RANGE(value)
Convert a single integer or range spec into a slice

n should become slice(n, n+1) n: should become slice(n, None) n:m should become slice(n, m) and m > n must hold
mopidy.mpd.protocol.UINT(value)
Converts a value that matches `d+` into an integer.

mopidy.mpd.protocol.VERSION = u'0.19.0'
The MPD protocol version is 0.19.0.

mopidy.mpd.protocol.commands = <mopidy.mpd.protocol.Commands object>
Global instance to install commands into

mopidy.mpd.protocol.load_protocol_modules()
The protocol modules must be imported to get them registered in commands.

Audio output

mopidy.mpd.protocol.audio_output.disableoutput(context, outputid)
musicpd.org, audio output section:
  disableoutput {ID}
  Turns an output off.

mopidy.mpd.protocol.audio_output.enableoutput(context, outputid)
musicpd.org, audio output section:
  enableoutput {ID}
  Turns an output on.

mopidy.mpd.protocol.audio_output.outputs(context)
musicpd.org, audio output section:
  outputs
  Shows information about all outputs.

mopidy.mpd.protocol.audio_output.toggleoutput(context, outputid)
musicpd.org, audio output section:
  toggleoutput {ID}
  Turns an output on or off, depending on the current state.

Channels

mopidy.mpd.protocol.channels.channels(context)
musicpd.org, client to client section:
  channels
  Obtain a list of all channels. The response is a list of “channel:” lines.

mopidy.mpd.protocol.channels.readmessages(context)
musicpd.org, client to client section:
  readmessages
  Reads messages for this client. The response is a list of “channel:” and “message:” lines.

mopidy.mpd.protocol.channels.sendmessage(context, channel, text)
musicpd.org, client to client section:
  sendmessage {CHANNEL} {TEXT}
  Send a message to the specified channel.
mopidy.mpd.protocol.channels.subscribe(context, channel)

musicpd.org, client to client section:

subscribe {NAME}

Subscribe to a channel. The channel is created if it does not exist already. The name may consist of alphanumeric ASCII characters plus underscore, dash, dot and colon.

mopidy.mpd.protocol.channels.unsubscribe(context, channel)

musicpd.org, client to client section:

unsubscribe {NAME}

Unsubscribe from a channel.

Command list

mopidy.mpd.protocol.command_list.command_list_begin(context)

musicpd.org, command list section:

To facilitate faster adding of files etc. you can pass a list of commands all at once using a command list. The command list begins with command_list_begin or command_list_ok_begin and ends with command_list_end.

It does not execute any commands until the list has ended. The return value is whatever the return for a list of commands is. On success for all commands, OK is returned. If a command fails, no more commands are executed and the appropriate ACK error is returned. If command_list_ok_begin is used, list_OK is returned for each successful command executed in the command list.

mopidy.mpd.protocol.command_list.command_list_end(context)

See command_list_begin().

mopidy.mpd.protocol.command_list.command_list_ok_begin(context)

See command_list_begin().

Connection

mopidy.mpd.protocol.connection.close(context)

musicpd.org, connection section:

close

Closes the connection to MPD.

mopidy.mpd.protocol.connection.kill(context)

musicpd.org, connection section:

kill

Kills MPD.

mopidy.mpd.protocol.connection.password(context, password)

musicpd.org, connection section:

password {PASSWORD}

This is used for authentication with the server. PASSWORD is simply the plaintext password.

mopidy.mpd.protocol.connection.ping(context)

musicpd.org, connection section:
ping
Does nothing but return OK.

Current playlist

mopidy.mpd.protocol.current_playlist.add(context, uri)
musicpd.org, current playlist section:

add {URI}

Adds the file URI to the playlist (directories add recursively). URI can also be a single file.

Clarifications:

• add "" should add all tracks in the library to the current playlist.

mopidy.mpd.protocol.current_playlist.addid(context, uri, songpos=None)
musicpd.org, current playlist section:

addid {URI} [POSITION]

Adds a song to the playlist (non-recursive) and returns the song id.

URI is always a single file or URL. For example:

```
addid "foo.mp3"
Id: 999
OK
```

Clarifications:

• addid "" should return an error.

mopidy.mpd.protocol.current_playlist.addtagid(context, tlid, tag, value)
musicpd.org, current playlist section:

addtagid {SONGID} {TAG} {VALUE}

Adds a tag to the specified song. Editing song tags is only possible for remote songs. This change is
volatile: it may be overwritten by tags received from the server, and the data is gone when the song
gets removed from the queue.

New in version 0.19: New in MPD protocol version 0.19

mopidy.mpd.protocol.current_playlist.clear(context)
musicpd.org, current playlist section:

clear

Clears the current playlist.

mopidy.mpd.protocol.current_playlist.cleartagid(context, tlid, tag)
musicpd.org, current playlist section:

cleartagid {SONGID} [TAG]

Removes tags from the specified song. If TAG is not specified, then all tag values will be removed.
Editing song tags is only possible for remote songs.

New in version 0.19: New in MPD protocol version 0.19

mopidy.mpd.protocol.current_playlist.delete(context, songrange)
musicpd.org, current playlist section:
delete [{POS} | {START:END}]

Deletes a song from the playlist.

```python
mopidy.mpd.protocol.current_playlist.deleteid(context, tlid)
```

musicpd.org, current playlist section:

```
deleteid (SONGID)
```

Deletes the song SONGID from the playlist.

```python
mopidy.mpd.protocol.current_playlist.move_range(context, songrange, to)
```

musicpd.org, current playlist section:

```
move [{FROM} | {START:END}] {TO}
```

Moves the song at FROM or range of songs at START:END to TO in the playlist.

```python
mopidy.mpd.protocol.current_playlist.moveid(context, tlid, to)
```

musicpd.org, current playlist section:

```
moved {FROM} {TO}
```

Moves the song with FROM (songid) to TO (playlist index) in the playlist. If TO is negative, it is relative to the current song in the playlist (if there is one).

```python
mopidy.mpd.protocol.current_playlist.playlist(context)
```

musicpd.org, current playlist section:

```
playlist
```

Displays the current playlist.

**Note:** Do not use this, instead use playlistinfo.

```python
mopidy.mpd.protocol.current_playlist.playlistfind(context, tag, needle)
```

musicpd.org, current playlist section:

```
playlistfind {TAG} {NEEDLE}
```

Finds songs in the current playlist with strict matching.

```python
mopidy.mpd.protocol.current_playlist.playlistid(context, tlid=None)
```

musicpd.org, current playlist section:

```
playlistid {SONGID}
```

Displays a list of songs in the playlist. SONGID is optional and specifies a single song to display info for.

```python
mopidy.mpd.protocol.current_playlist.playlistinfo(context, parameter=None)
```

musicpd.org, current playlist section:

```
playlistinfo [{SONGPOS} | {START:END}]
```

Displays a list of all songs in the playlist, or if the optional argument is given, displays information only for the song SONGPOS or the range of songs START:END.

**ncmpc and mpc:**

- uses negative indexes, like playlistinfo "-1", to request the entire playlist

```python
mopidy.mpd.protocol.current_playlist.playlistsearch(context, tag, needle)
```

musicpd.org, current playlist section:
playlistsearch {TAG} {NEEDLE}
Searches case-sensitively for partial matches in the current playlist.

**GMPC:**
- uses filename and any as tags

mopidy.mpd.protocol.current_playlist.plchanges (context, version)
musicpd.org, current playlist section:
`plchanges {VERSION}`
Displays changed songs currently in the playlist since VERSION.
To detect songs that were deleted at the end of the playlist, use playlistlength returned by status command.

**MPDroid:**
- Calls plchanges "-1" two times per second to get the entire playlist.

mopidy.mpd.protocol.current_playlist.plchangesposid (context, version)
musicpd.org, current playlist section:
`plchangesposid {VERSION}`
Displays changed songs currently in the playlist since VERSION. This function only returns the position and the id of the changed song, not the complete metadata. This is more bandwidth efficient.
To detect songs that were deleted at the end of the playlist, use playlistlength returned by status command.

mopidy.mpd.protocol.current_playlist.prio (context, priority, position)
musicpd.org, current playlist section:
`prio {PRIORITY} {START:END...}`
Set the priority of the specified songs. A higher priority means that it will be played first when “random” mode is enabled.
A priority is an integer between 0 and 255. The default priority of new songs is 0.

mopidy.mpd.protocol.current_playlist.prioid (context, *args)
musicpd.org, current playlist section:
`prioid {PRIORITY} {ID...}`
Same as prio, but address the songs with their id.

mopidy.mpd.protocol.current_playlist.rangeid (context, t1id, songrange)
musicpd.org, current playlist section:
`rangeid {ID} {START:END}`
Specifies the portion of the song that shall be played. START and END are offsets in seconds (fractional seconds allowed); both are optional. Omitting both (i.e. sending just “:”) means “remove the range, play everything”. A song that is currently playing cannot be manipulated this way.

New in version 0.19: New in MPD protocol version 0.19

mopidy.mpd.protocol.current_playlist.shuffle (context, songrange=None)
musicpd.org, current playlist section:
`shuffle [START:END]`
Shuffles the current playlist. START:END is optional and specifies a range of songs.
mopidy.mpd.protocol.current_playlist\[\text{\texttt{swap}}\](\text{context}, \text{songpos1}, \text{songpos2})

\textit{musicpd.org, current playlist section:}

\begin{verbatim}
 swap {SONG1} {SONG2}
\end{verbatim}

Swaps the positions of SONG1 and SONG2.

mopidy.mpd.protocol.current_playlist\[\text{\texttt{swapid}}\](\text{context}, \text{tlid1}, \text{tlid2})

\textit{musicpd.org, current playlist section:}

\begin{verbatim}
 swapid {SONG1} {SONG2}
\end{verbatim}

Swaps the positions of SONG1 and SONG2 (both song ids).

\section*{Mounts and neighbors}

mopidy.mpd.protocol.mount\[\text{\texttt{listmounts}}\](\text{context})

\textit{musicpd.org, mounts and neighbors section:}

\begin{verbatim}
 listmounts
 mount:
 storage: /home/foo/music
 mount: foo
 storage: nfs://192.168.1.4/export/mp3
 OK
\end{verbatim}

New in version 0.19: New in MPD protocol version 0.19

mopidy.mpd.protocol.mount\[\text{\texttt{listneighbors}}\](\text{context})

\textit{musicpd.org, mounts and neighbors section:}

\begin{verbatim}
 listneighbors
 neighbor: smb://FOO
 name: FOO (Samba 4.1.11-Debian)
 OK
\end{verbatim}

New in version 0.19: New in MPD protocol version 0.19

mopidy.mpd.protocol.mount\[\text{\texttt{mount}}\](\text{context}, \text{path}, \text{uri})

\textit{musicpd.org, mounts and neighbors section:}

\begin{verbatim}
 mount {PATH} {URI}
\end{verbatim}

Mount the specified remote storage URI at the given path. Example:

\begin{verbatim}
 mount foo nfs://192.168.1.4/export/mp3
\end{verbatim}

New in version 0.19: New in MPD protocol version 0.19

mopidy.mpd.protocol.mount\[\text{\texttt{unmount}}\](\text{context}, \text{path})

\textit{musicpd.org, mounts and neighbors section:}
unmount {PATH}

Unmounts the specified path. Example:

unmount foo

New in version 0.19: New in MPD protocol version 0.19

Music database

mopidy.mpd.protocol.music_db.count(context, *args)
musicpd.org, music database section:

    count {TAG} {NEEDLE}

Counts the number of songs and their total playtime in the db matching TAG exactly.

GMPC:

• use multiple tag-needle pairs to make more specific searches.

mopidy.mpd.protocol.music_db.find(context, *args)
musicpd.org, music database section:

    find {TYPE} {WHAT}

Finds songs in the db that are exactly WHAT. TYPE can be any tag supported by MPD, or one of the two special parameters - file to search by full path (relative to database root), and any to match against all available tags. WHAT is what to find.

GMPC:

• also uses find album "[ALBUM]" artist "[ARTIST]" to list album tracks.

ncmpc:

• capitalizes the type argument.

ncmpcpp:

• also uses the search type “date”.
• uses “file” instead of “filename”.

mopidy.mpd.protocol.music_db.findadd(context, *args)
musicpd.org, music database section:

    findadd {TYPE} {WHAT}

Finds songs in the db that are exactly WHAT and adds them to current playlist. Parameters have the same meaning as for find.

mopidy.mpd.protocol.music_db.list_(context, *args)
musicpd.org, music database section:

    list {TYPE} [ARTIST]

Lists all tags of the specified type. TYPE should be album, artist, albumartist, date, or genre.

ARTIST is an optional parameter when type is album, date, or genre. This filters the result list by an artist.

Clarifications:
The musicpd.org documentation for list is far from complete. The command also supports the following variant:

\[ \text{list \{TYPE\} \{QUERY\}} \]

Where \text{QUERY} applies to all \text{TYPE}. \text{QUERY} is one or more pairs of a field name and a value. If the \text{QUERY} consists of more than one pair, the pairs are AND-ed together to find the result. Examples of valid queries and what they should return:

\text{list "artist" "artist" "ABBA"}  List artists where the artist name is “ABBA”. Response:

<table>
<thead>
<tr>
<th>Artist: ABBA</th>
</tr>
</thead>
<tbody>
<tr>
<td>OK</td>
</tr>
</tbody>
</table>

\text{list "album" "artist" "ABBA"}  Lists albums where the artist name is “ABBA”. Response:

<table>
<thead>
<tr>
<th>Album: More ABBA Gold: More ABBA Hits</th>
</tr>
</thead>
<tbody>
<tr>
<td>Album: Absolute More Christmas</td>
</tr>
<tr>
<td>Album: Gold: Greatest Hits</td>
</tr>
<tr>
<td>OK</td>
</tr>
</tbody>
</table>

\text{list "artist" "artist" "Gold: Greatest Hits"} Lists artists where the album name is “Gold: Greatest Hits”. Response:

<table>
<thead>
<tr>
<th>Artist: ABBA</th>
</tr>
</thead>
<tbody>
<tr>
<td>OK</td>
</tr>
</tbody>
</table>

\text{list "artist" "artist" "ABBA" "artist" "TLC"} Lists artists where the artist name is “ABBA” and “TLC”. Should never match anything. Response:

| OK |

\text{list "date" "artist" "ABBA"} Lists dates where artist name is “ABBA”. Response:

<table>
<thead>
<tr>
<th>Date:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Date: 1992</td>
</tr>
<tr>
<td>Date: 1993</td>
</tr>
<tr>
<td>OK</td>
</tr>
</tbody>
</table>

\text{list "date" "artist" "ABBA" "album" "Gold: Greatest Hits"} Lists dates where artist name is “ABBA” and album name is “Gold: Greatest Hits”. Response:

| Date: 1992 |
| OK         |

\text{list "genre" "artist" "The Rolling Stones"} Lists genres where artist name is “The Rolling Stones”. Response:

<table>
<thead>
<tr>
<th>Genre:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Genre: Rock</td>
</tr>
<tr>
<td>OK</td>
</tr>
</tbody>
</table>

\text{ncmpc:}

- capitalizes the field argument.

\text{mopidy.mpdp.protocol.music_db.listall\(\text{context, uri=\text{None}}\)}

\text{musicpd.org, music database section:}
listall [URI]

Lists all songs and directories in URI.

Do not use this command. Do not manage a client-side copy of MPD’s database. That is fragile and adds huge overhead. It will break with large databases. Instead, query MPD whenever you need something.

**Warning:** This command is disabled by default in Mopidy installs.

mopidy.mpd.protocol.music_db.listallinfo(context, uri=None)

_musicpd.org, music database section:_

listallinfo [URI]

Same as listall, except it also returns metadata info in the same format as lsinfo.

Do not use this command. Do not manage a client-side copy of MPD’s database. That is fragile and adds huge overhead. It will break with large databases. Instead, query MPD whenever you need something.

**Warning:** This command is disabled by default in Mopidy installs.

mopidy.mpd.protocol.music_db.listfiles(context, uri=None)

_musicpd.org, music database section:_

listfiles [URI]

Lists the contents of the directory URI, including files are not recognized by MPD. URI can be a path relative to the music directory or an URI understood by one of the storage plugins. The response contains at least one line for each directory entry with the prefix “file: ” or “directory: “, and may be followed by file attributes such as “Last-Modified” and “size”.

For example, “smb://SERVER” returns a list of all shares on the given SMB/CIFS server; “nfs://servername/path” obtains a directory listing from the NFS server.

New in version 0.19: New in MPD protocol version 0.19

mopidy.mpd.protocol.music_db.lsinfo(context, uri=None)

_musicpd.org, music database section:_

lsinfo [URI]

Lists the contents of the directory URI.

When listing the root directory, this currently returns the list of stored playlists. This behavior is deprecated; use listplaylists instead.

MPD returns the same result, including both playlists and the files and directories located at the root level, for both lsinfo, lsinfo "", and lsinfo "/".

mopidy.mpd.protocol.music_db.readcomments(context, uri)

_musicpd.org, music database section:_

readcomments [URI]

Read “comments” (i.e. key-value pairs) from the file specified by “URI”. This “URI” can be a path relative to the music directory or a URL in the form “file://foo/bar.ogv”.
This command may be used to list metadata of remote files (e.g. URI beginning with “http://” or “smb://”).

The response consists of lines in the form “KEY: VALUE”. Comments with suspicious characters (e.g. newlines) are ignored silently.

The meaning of these depends on the codec, and not all decoder plugins support it. For example, on Ogg files, this lists the Vorbis comments.

```python
mopidy.mpd.protocol.music_db.rescan(context, uri=None)
```

**musicpd.org, music database section:**

```
rescan [URI]
```

Same as `update`, but also rescans unmodified files.

```python
mopidy.mpd.protocol.music_db.search(context, *args)
```

**musicpd.org, music database section:**

```
search {TYPE} {WHAT} [...]
```

Searches for any song that contains `WHAT`. Parameters have the same meaning as for `find`, except that search is not case sensitive.

**GMPC:**

- uses the undocumented field `any`.
- searches for multiple words like this:

```plaintext
search any "foo" any "bar" any "baz"
```

**ncmpc:**

- capitalizes the field argument.

**ncmpcpp:**

- also uses the search type “date”.
- uses “file” instead of “filename”.

```python
mopidy.mpd.protocol.music_db.searchadd(context, *args)
```

**musicpd.org, music database section:**

```
searchadd {TYPE} {WHAT} [...]
```

Searches for any song that contains `WHAT` in tag `TYPE` and adds them to current playlist.

Parameters have the same meaning as for `find`, except that search is not case sensitive.

```python
mopidy.mpd.protocol.music_db.searchaddpl(context, *args)
```

**musicpd.org, music database section:**

```
searchaddpl {NAME} {TYPE} {WHAT} [...]
```

Searches for any song that contains `WHAT` in tag `TYPE` and adds them to the playlist named `NAME`.

If a playlist by that name doesn’t exist it is created.

Parameters have the same meaning as for `find`, except that search is not case sensitive.

```python
mopidy.mpd.protocol.music_db.update(context, uri=None)
```

**musicpd.org, music database section:**
update [URI]

Updates the music database: find new files, remove deleted files, update modified files.

URI is a particular directory or song/file to update. If you do not specify it, everything is updated.

Prints updating_db: JOBID where JOBID is a positive number identifying the update job. You can read the current job id in the status response.

Playback

mopidy.mpd.protocol.playback.consume(context, state)
musicpd.org, playback section:
 consume {STATE}

Sets consume state to STATE, STATE should be 0 or 1. When consume is activated, each song played is removed from playlist.

mopidy.mpd.protocol.playback.crossfade(context, seconds)
musicpd.org, playback section:
 crossfade {SECONDS}

Sets crossfading between songs.

mopidy.mpd.protocol.playback.mixrampdb(context, decibels)
musicpd.org, playback section:
 mixrampdb {decibels}

Sets the threshold at which songs will be overlapped. Like crossfading but doesn’t fade the track volume, just overlaps. The songs need to have MixRamp tags added by an external tool. 0dB is the normalized maximum volume so use negative values, I prefer -17dB. In the absence of mixramp tags crossfading will be used. See https://sourceforge.net/projects/mixramp/

mopidy.mpd.protocol.playback.mixrampdelay(context, seconds)
musicpd.org, playback section:
 mixrampdelay {SECONDS}

Additional time subtracted from the overlap calculated by mixrampdb. A value of “nan” disables MixRamp overlapping and falls back to crossfading.

mopidy.mpd.protocol.playback.next_(context)
musicpd.org, playback section:
 next

Plays next song in the playlist.

MPD’s behaviour when affected by repeat/random/single/consume:

Given a playlist of three tracks numbered 1, 2, 3, and a currently playing track c. next_track is defined at the track that will be played upon calls to next.

Tests performed on MPD 0.15.4-1ubuntu3.
<table>
<thead>
<tr>

<td>2</td>
<td>3</td>
<td>EOPL</td>
<td></td>
</tr>
</tbody>
</table>

- When end of playlist (EOPL) is reached, the current track is unset.
- [1] When `random` and `single` is combined, `next` selects a track randomly at each invocation, and not just the next track in an internal prerandomized playlist.
- [2] When `random` is active, `next` will skip through all tracks in the playlist in random order, and finally EOPL is reached.
- [3] `single` has no effect in combination with `random` alone, or `random` and `consume`.
- [4] When `random` and `repeat` is active, EOPL is never reached, but the playlist is played again, in the same random order as the first time.

mopidy.mpd.protocol.playback.pause(context, state=None)

`musicpd.org, playback section:`

```
pause (PAUSE)
```

Toggles pause/resumes playing, PAUSE is 0 or 1.

**MPDroid:**
- Calls `pause` without any arguments to toggle pause.

mopidy.mpd.protocol.playback.play(context, songpos=None)

`musicpd.org, playback section:`

```
play [SONGPOS]
```

Beginning playing the playlist at song number SONGPOS.

The original MPD server resumes from the paused state on `play` without arguments.

**Clarifications:**
- `play "-1"` when playing is ignored.
- `play "-1"` when paused resumes playback.
- `play "-1"` when stopped with a current track starts playback at the current track.
• play "-1" when stopped without a current track, e.g. after playlist replacement, starts playback at the first track.

**BitMPC:**

• issues play 6 without quotes around the argument.

```
mopidy.mpd.protocol.playback.playid(context, tlid)
musicpd.org, playback section:
```

```playid [SONGID]
Begins playing the playlist at song SONGID.
```

**Clarifications:**

• playid "-1" when playing is ignored.
• playid "-1" when paused resumes playback.
• playid "-1" when stopped with a current track starts playback at the current track.
• playid "-1" when stopped without a current track, e.g. after playlist replacement, starts playback at the first track.

```
mopidy.mpd.protocol.playback.previous(context)
musicpd.org, playback section:
```

```
previous
Plays previous song in the playlist.
```

**MPD's behaviour when affected by repeat/random/single/consume:**

Given a playlist of three tracks numbered 1, 2, 3, and a currently playing track c. previous_track is defined at the track that will be played upon previous calls.

Tests performed on MPD 0.15.4-1ubuntu3.

<table>
<thead>

</tbody>
</table>

• If time_position of the current track is 15s or more, previous should do a seek to time position 0.
mopidy.mpd.protocol.playback.random\((context, state)\)

musicpd.org, playback section:

random \{STATE\}

Sets random state to STATE, STATE should be 0 or 1.

mopidy.mpd.protocol.playback.repeat\((context, state)\)

musicpd.org, playback section:

repeat \{STATE\}

Sets repeat state to STATE, STATE should be 0 or 1.

mopidy.mpd.protocol.playback.replay_gain_mode\((context, mode)\)

musicpd.org, playback section:

replay_gain_mode \{MODE\}

Sets the replay gain mode. One of off, track, album.

Changing the mode during playback may take several seconds, because the new settings does not affect the buffered data.

This command triggers the options idle event.

mopidy.mpd.protocol.playback.replay_gain_status\((context)\)

musicpd.org, playback section:

replay_gain_status

Prints replay gain options. Currently, only the variable replay_gain_mode is returned.

mopidy.mpd.protocol.playback.seek\((context, songpos, seconds)\)

musicpd.org, playback section:

seek \{SONGPOS\} \{TIME\}

Seeks to the position TIME (in seconds) of entry SONGPOS in the playlist.

**Droid MPD:**

- issues seek 1 120 without quotes around the arguments.

mopidy.mpd.protocol.playback.seekcur\((context, time)\)

musicpd.org, playback section:

seekcur \{TIME\}

Seeks to the position TIME within the current song. If prefixed by ‘+’ or ‘-’, then the time is relative to the current playing position.

mopidy.mpd.protocol.playback.seekid\((context, tlid, seconds)\)

musicpd.org, playback section:

seekid \{SONGID\} \{TIME\}

Seeks to the position TIME (in seconds) of song SONGID.

mopidy.mpd.protocol.playback.setvol\((context, volume)\)

musicpd.org, playback section:

setvol \{VOL\}

Sets volume to VOL, the range of volume is 0-100.

**Droid MPD:**
• issues

```plaintext
mopidy.mpd.protocol.playback.single(context, state)
```

*musicpd.org, playback section:*

```plaintext
single {STATE}
```

Sets single state to `STATE`. `STATE` should be 0 or 1. When single is activated, playback is stopped after current song, or song is repeated if the repeat mode is enabled.

```plaintext
mopidy.mpd.protocol.playback.stop(context)
```

*musicpd.org, playback section:*

```plaintext
stop
```

Stops playing.

```plaintext
mopidy.mpd.protocol.playback.volume(context, change)
```

*musicpd.org, playback section:*

```plaintext
volume {CHANGE}
```

Changes volume by amount `CHANGE`.

Note: `volume` is deprecated, use `setvol` instead.

**Reflection**

```plaintext
mopidy.mpd.protocol.reflection.commands(context)
```

*musicpd.org, reflection section:*

```plaintext
commands
```

Shows which commands the current user has access to.

```plaintext
mopidy.mpd.protocol.reflection.config(context)
```

*musicpd.org, reflection section:*

```plaintext
config
```

Dumps configuration values that may be interesting for the client. This command is only permitted to “local” clients (connected via UNIX domain socket).

```plaintext
mopidy.mpd.protocol.reflection.decoders(context)
```

*musicpd.org, reflection section:*

```plaintext
decoders
```

Print a list of decoder plugins, followed by their supported suffixes and MIME types. Example response:

```plaintext
plugin: mad
suffix: mp3
suffix: mp2
mime_type: audio/mpeg
plugin: mpcdec
suffix: mpc
```

**Clarifications:**

• ncmpcpp asks for decoders the first time you open the browse view. By returning nothing and OK instead of an not implemented error, we avoid “Not implemented” showing up in the ncmpcpp interface, and we get the list of playlists without having to enter the browse interface twice.
mopidy.mpd.protocol.reflection.notcommands(context)
    musicpd.org, reflection section:
    notcommands
    Shows which commands the current user does not have access to.

mopidy.mpd.protocol.reflection.tagtypes(context)
    musicpd.org, reflection section:
    tagtypes
    Shows a list of available song metadata.

mopidy.mpd.protocol.reflection.urlhandlers(context)
    musicpd.org, reflection section:
    urlhandlers
    Gets a list of available URL handlers.

Status

mopidy.mpd.protocol.status.SUBSYSTEMS = [u'database', u'mixer', u'options', u'output', u'playlist', u'stored_playlist', u'update']
    Subsystems that can be registered with idle command.

mopidy.mpd.protocol.status.clearerror(context)
    musicpd.org, status section:
    clearerror
    Clears the current error message in status (this is also accomplished by any command that starts playback).

mopidy.mpd.protocol.status.currentsong(context)
    musicpd.org, status section:
    currentsong
    Displays the song info of the current song (same song that is identified in status).

mopidy.mpd.protocol.status.idle(context, *subsystems)
    musicpd.org, status section:
    idle [SUBSYSTEMS...]
    Waits until there is a noteworthy change in one or more of MPD’s subsystems. As soon as there is one, it lists all changed systems in a line in the format changed: SUBSYSTEM, where SUBSYSTEM is one of the following:
    • database: the song database has been modified after update.
    • update: a database update has started or finished. If the database was modified during the update, the database event is also emitted.
    • stored_playlist: a stored playlist has been modified, renamed, created or deleted
    • playlist: the current playlist has been modified
    • player: the player has been started, stopped or seeked
    • mixer: the volume has been changed
    • output: an audio output has been enabled or disabled
    • options: options like repeat, random, crossfade, replay gain
While a client is waiting for idle results, the server disables timeouts, allowing a client to wait for events as long as MPD runs. The idle command can be canceled by sending the command `noidle` (no other commands are allowed). MPD will then leave idle mode and print results immediately; might be empty at this time.

If the optional `SUBSYSTEMS` argument is used, MPD will only send notifications when something changed in one of the specified subsystems.

```python
mopidy.mpd.protocol.status.noidle(context)
```

See `_status_idle()`.

```python
mopidy.mpd.protocol.status.stats(context)
```

`musicpd.org, status section:

```python
stats
```

Displays statistics.

- `artists`: number of artists
- `songs`: number of albums
- `uptime`: daemon uptime in seconds
- `db_playtime`: sum of all song times in the db
- `db_update`: last db update in UNIX time
- `playtime`: time length of music played

```python
mopidy.mpd.protocol.status.status(context)
```

`musicpd.org, status section:

```python
status
```

Reports the current status of the player and the volume level.

- `volume`: 0-100 or -1
- `repeat`: 0 or 1
- `single`: 0 or 1
- `consume`: 0 or 1
- `playlist`: 31-bit unsigned integer, the playlist version number
- `playlistlength`: integer, the length of the playlist
- `state`: play, stop, or pause
- `song`: playlist song number of the current song stopped on or playing
- `songid`: playlist songid of the current song stopped on or playing
- `nextsong`: playlist song number of the next song to be played
- `nextsongid`: playlist songid of the next song to be played
- `time`: total time elapsed (of current playing/paused song)
- `elapsed`: Total time elapsed within the current song, but with higher resolution.
- `bitrate`: instantaneous bitrate in kbps
- `xfade`: crossfade in seconds
- `audio`: `sampleRate``:``bits``:``channels`
Mopidy Documentation, Release 2.2.3

- `updatings_db`: job id
- `error`: if there is an error, returns message here

**Clarifications based on experience implementing**

- `volume`: can also be -1 if no output is set.
- `elapsed`: Higher resolution means time in seconds with three decimal places for millisecond precision.

**Stickers**

`mopidy.mpd.protocol.stickers.sticker(context, action, field, uri, name=None, value=None)`

*musicpd.org, sticker section:*

```python
sticker list {TYPE} {URI}
Lists the stickers for the specified object.

sticker find {TYPE} {URI} {NAME}
Searches the sticker database for stickers with the specified name, below the specified directory (URI). For each matching song, it prints the URI and that one sticker’s value.

sticker get {TYPE} {URI} {NAME}
Reads a sticker value for the specified object.

sticker set {TYPE} {URI} {NAME} {VALUE}
Adds a sticker value to the specified object. If a sticker item with that name already exists, it is replaced.

sticker delete {TYPE} {URI} [NAME]
Deletes a sticker value from the specified object. If you do not specify a sticker name, all sticker values are deleted.
```

**Stored playlists**

`mopidy.mpd.protocol.stored_playlists.listplaylist(context, name)`

*musicpd.org, stored playlists section:*

```python
listplaylist {NAME}
Lists the files in the playlist NAME.m3u.
```

Output format:

```
file: relative/path/to/file1.flac
file: relative/path/to/file2.ogg
file: relative/path/to/file3.mp3
```

`mopidy.mpd.protocol.stored_playlists.listplaylistinfo(context, name)`

*musicpd.org, stored playlists section:*

```python
listplaylistinfo {NAME}
Lists songs in the playlist NAME.m3u.
```

Output format:
Standard track listing, with fields: file, Time, Title, Date, Album, Artist, Track

```python
mopidy.mpd.protocol.stored_playlists.listplaylists(context)
```

**musicpd.org, stored playlists section:**

```
listplaylists

Prints a list of the playlist directory.

After each playlist name the server sends its last modification time as attribute Last-Modified in ISO 8601 format. To avoid problems due to clock differences between clients and the server, clients should not compare this value with their local clock.

Output format:
```
| playlist: a | Last-Modified: 2010-02-06T02:10:25Z |
| playlist: b | Last-Modified: 2010-02-06T02:11:08Z |
```

**Clarifications:**

- ncmcpp 0.5.10 segfaults if we return ‘playlist: ’ on a line, so we must ignore playlists without names, which isn’t very useful anyway.

```python
mopidy.mpd.protocol.stored_playlists.load(context, name, playlist_slice=slice(0, None, None))
```

**musicpd.org, stored playlists section:**

```
load {NAME} [START:END]

Loads the playlist into the current queue. Playlist plugins are supported. A range may be specified to load only a part of the playlist.

**Clarifications:**

- `load` appends the given playlist to the current playlist.
- MPD 0.17.1 does not support open-ended ranges, i.e. without end specified, for the `load` command, even though MPD’s general range docs allows open-ended ranges.
- MPD 0.17.1 does not fail if the specified range is outside the playlist, in either or both ends.

```python
mopidy.mpd.protocol.stored_playlists.playlistadd(context, name, track_uri)
```

**musicpd.org, stored playlists section:**

```
playlistadd {NAME} {URI}

Adds URI to the playlist `{NAME}.m3u`. `{NAME}.m3u` will be created if it does not exist.
```

```python
mopidy.mpd.protocol.stored_playlists.playlistclear(context, name)
```

**musicpd.org, stored playlists section:**

```
playlistclear {NAME}

Clears the playlist `{NAME}.m3u`.

The playlist will be created if it does not exist.
```

```python
mopidy.mpd.protocol.stored_playlists.playlistdelete(context, name, songpos)
```

**musicpd.org, stored playlists section:**

```
playlistdelete {NAME} {SONGPOS}

Deletes SONGPOS from the playlist `{NAME}.m3u`.
mopidy.mpd.protocol.stored_playlists.playlistmove(context, name, from_pos, to_pos)

```plaintext
playlistmove {NAME} {SONGID} {SONGPOS}
```

Moves SONGID in the playlist NAME.m3u to the position SONGPOS.

Clarifications:
- The second argument is not a SONGID as used elsewhere in the protocol documentation, but just the SONGPOS to move from, i.e. playlistmove {NAME} {FROM_SONGPOS} {TO_SONGPOS}.

mopidy.mpd.protocol.stored_playlists.rename(context, old_name, new_name)

```plaintext
rename {NAME} {NEW_NAME}
```

Renames the playlist NAME.m3u to NEW_NAME.m3u.

mopidy.mpd.protocol.stored_playlists.rm(context, name)

```plaintext
rm {NAME}
```

Removes the playlist NAME.m3u from the playlist directory.

mopidy.mpd.protocol.stored_playlists.save(context, name)

```plaintext
save {NAME}
```

Saves the current playlist to NAME.m3u in the playlist directory.
