This package implements simple mapping functions.

Mapping Functions:

---

## Azimuth

---

Calculates the great circle azimuth from a **point 1** to a **point 2**. The latitude and longitude of these two points can either be given independently or as columns of the matrices **point 1** and **point 2** in the form [latitude longitude].

### 1.1 Forms

```
az = azimuth(lat1, lon1, lat2, lon2)
az = azimuth(lat1, lon1, lat2, lon2, units)
az = azimuth(pt1, pt2)
az = azimuth(pt1, pt2, units)
```

---

**Note:** The units for the input coordinates and output angles can be *degrees* (the default) or *radians*.

---

### 1.2 Examples

Usages:

```
>> azimuth([10, 10], [10, 40])
ans = 87.336
>> azimuth([0, 10], [0, 40])
ans = 90
>> azimuth(pi / 4, 0, pi / 4, -pi / 2, "radians")
ans = 5.3279
```

**See also:**

[Reckon Distance](#)

---

## Reckon

---

Compute the coordinates of the end-point of a displacement on a sphere. **lat** e **lon** are the coordinates of the starting point, **range** is the covered distance of the displacements along a great circle and **azimuth** is the direction of the displacement relative to the North.

This function can also be used to define a spherical coordinate system with rotated poles.

### 2.1 Forms

```
[lato, lono] = reckon(lat, lon, range, azimuth)
```

```
[lato, lono] = reckon(lat, lon, range, azimuth, units)
```

---

**Note:** The units of all input and output parameters can be either *degrees* (default) or *radians*.

---

### 2.2 Examples

Usages:

```
>> [lato, lono] = reckon(0, 10, 30, 90)
lato = 0
lono = 40.000
>> [lato, lono] = reckon(0, 0, pi, pi / 2, "radians")
lato = 0
lono = -3.1416
```

**See also:**

[Azimuth](#)

---

## Distance

---

Calculates the distance (in degrees) between **point 1** and **point 2**.

### 3.1 Forms

```
dist = distance(pt1, pt2)
```

---

**Note:** `pt1` and `pt2` are two-column matrices of the form `[latitude longitude]`.

---

### 3.2 Examples

Usages:

```
>> distance([37,-76], [37,-9])
ans = 52.309
>> distance([37,-76], [67,-76])
ans = 30.000
```

**See also:**

[Azimuth Vincenty](#)

---

## Departure

---

Calculates the distance in **degrees** between longitudes `lon1` and `lon2` at latitude defined by `lat`.

### 4.1 Forms

```
dist = departure(lon1, lon2, lat)
```

### 4.2 Examples

Usages:

```
>> departure(0, 10, 0)
ans = 10
>> departure(0, 10, 60)
ans = 5
```

**See also:**

[Distance](#)

---

## Vincenty

---

Calculates the distance (in kilometers) between **point 1** and **point 2** using the formula devised by Thaddeus Vincenty, with an accurate ellipsoidal model of the earth. The default ellipsoidal model is **WGS-84**, which is the most globally accurate model.

### 5.1 Forms

```
dist = vincenty(pt1, pt2)
```

```
dist = vincenty(pt1, pt2, ellipsoid)
```

```
[dist, az] = vincenty(pt1, pt2)
```

```
[dist, az] = vincenty(pt1, pt2, ellipsoid)
```

---

**Note:** pt1 and pt2 are two-column matrices of the form [latitude longitude]. The units for the input coordinates angles must be *degrees*. ellipsoid defines the reference ellipsoid to use.

---

Sample values for ellipsoid are the following:

- WGS\_84 (default) - referenceEllipsoid(7030)
- GRS\_80 - referenceEllipsoid(7019)
- Airy - referenceEllipsoid(7001)
- Intl - referenceEllipsoid(7022)
- Clarke - referenceEllipsoid(7012)
- GRS - referenceEllipsoid(7003)

The sample values are the following:

Model	Major (km)	Minor (km)	1 / f
WGS 1984	6378.137	6356.7523142	298.257223563
GRS 1980	6378.137	6356.7523141	298.257222101
G.B. Airy 1830	6377.563396	6356.256909	299.3249646
Internacional 1924	6378.388	6356.911946	297.0
Clarke 1880	6378.249145	6356.51486955	293.465
Australian Nat.	6378.1600	6356.774719	298.25

## 5.2 Examples

Usages:

```
>> vincenty([37, -76], [37, -9])
ans = 5830.081
>> vincenty([37, -76], [67, -76], referenceEllipsoid(7019))
ans = 3337.843
```

**See also:**

[Distance Reference Ellipsoid](#)

---

## Vincenty (Direct Form)

---

Compute the coordinates of the end-point of a displacement on a geodesic. The parameters `lat` and `lon` are the coordinates of the starting point, The parameter `range` is the covered distance of the displacements along a specified geodesic and `azi` is the direction of the displacement relative to the North.

### 6.1 Forms

```
[lato, lono] = vincentyDirect(lat, lon, range, azi)
[lato, lono, azo] = vincentyDirect(lat, lon, range, azi)
[lato, lono] = vincentyDirect(lat, lon, range, azi, dim)
[lato, lono, azo] = vincentyDirect(lat, lon, range, azi, dim)
[lato, lono] = vincentyDirect(lat, lon, range, azi}, dim, ellipsoid)
[lato, lono, azo] = vincentyDirect(lat, lon, range, azi, dim, ellipsoid)
```

---

**Note:** The units of all input and output parameters must be ‘radians’ and/or ‘kilometers’. `dim` defines the range dimension to use. `ellipsoid` defines the reference ellipsoid to use.

---

The possible values for `dim` are ‘angle’ (default) or ‘length’.

Sample values for `ellipsoid` are the following:

- WGS\_84 (default) - referenceEllipsoid(7030)
- GRS\_80 - referenceEllipsoid(7019)
- Airy - referenceEllipsoid(7001)
- Intl - referenceEllipsoid(7022)
- Clarke - referenceEllipsoid(7012)
- GRS - referenceEllipsoid(7003)

The sample values are the following:

Model	Major (km)	Minor (km)	1 / f
WGS 1984	6378.137	6356.7523142	298.257223563
GRS 1980	6378.137	6356.7523141	298.257222101
G.B. Airy 1830	6377.563396	6356.256909	299.3249646
Internacional 1924	6378.388	6356.911946	297.0
Clarke 1880	6378.249145	6356.51486955	293.465
Australian Nat.	6378.1600	6356.774719	298.25

## 6.2 Examples

Usages:

```
>> [lat, lon] = vincentyDirect(0, 0, pi, pi / 2)
lat = 0
lon = 3.1311
>> [lat, lon, az] = vincentyDirect(0, 0, pi, pi / 2)
lat = 0
lon = 3.1311
az = 1.5708
```

**See also:**

[Vincenty Reference Ellipsoid](#)

---

## Great-Circle to Small-Circle

---

Converts a great circle to small circle notation.

### 7.1 Forms

```
[lato, lono, range] = gc2sc(lat, lon, azi)
```

```
[lato, lono] = gc2sc(lat, lon, azi, units)
```

```
mat = gc2sc(lat, lon, azi)
```

```
mat = gc2sc(lat, lon, azi, units)
```

---

## Degree to Kilometer

---

Convert a distance along a great circle of the Earth from degrees to kilometer. Great-circle distance uses a spherical model of the earth, using the average great-circle radius of 6372.795 kilometers, resulting in an error of up to about 0.5%.

### 8.1 Forms

**x = deg2km(a)**

**See also:**

[Kilometer to Degree](#)

---

## Kilometer to Degree

---

Convert a distance along a great circle of the Earth from kilometer to degrees. A radius Great-circle distance uses a spherical model of the earth, using the average great-circle radius of 6372.795 kilometers, resulting in an error of up to about 0.5%.

### 9.1 Forms

**a = km2deg (x)**

**See also:**

[Degree to Kilometer](#)

---

## Degree to Radians

---

Converts angles input in degrees to the equivalent in radians.

### 10.1 Forms

`anglout = deg2rad(anglin)`

**See also:**

[Radians to Degree](#)

---

## Radians to Degree

---

Converts angles input in radians to the equivalent in degrees.

### 11.1 Forms

`anglout = rad2deg(anglin)`

**See also:**

[Degree to Radians](#)

---

## Geocode

---

Geolocation service from Google Maps API. Define a geocode method for resolving a location from a string.

Geocoding is the process of converting addresses (like “1600 Amphitheatre Parkway, Mountain View, CA”) into geographic coordinates (like latitude 37.423021 and longitude -122.083739), which you can use to place markers or position the map.

Reverse geocoding is the process of converting geographic coordinates into a human-readable address.

### 12.1 Forms

```
[lato, lono] = geocode(addr)
```

```
[lato, lono, xml] = geocode(addr)
```

### 12.2 Examples

Usages:

```
>> [lat, lon] = geocode('new york,ny')
lat = 40.714
lon = -74.006
>> [lat, lon] = geocode('brasilia,df')
lat = -15.827
lon = -47.922
```

**See also:**

[Reverse](#)

---

## Reverse

---

Geolocation service from Google Maps API. Define a geocode method for resolving a address from a location.

The term geocoding generally refers to translating a human-readable address into a location on a map. The process of doing the converse, translating a location on the map into a human-readable address, is known as reverse geocoding.

### 13.1 Forms

```
addr = reverse([lat lon])  
[addr, xml] = reverse([lat lon])
```

### 13.2 Examples

Usages:

```
>> reverse([40.714 -74.006])  
ans = '58-68 Chambers Street, Nova York, NY 10007, EUA'  
>> reverse([-15.827 -47.922])  
ans = 'Asa Sul, Brasília, DF, 70383-070, Brasil'
```

**See also:**

[Geocode](#)

This brings the `angin` into the  $[-\pi, \pi]$  interval.

## 14.1 Forms

`angout = npi2pi(angin)`

**See also:**

[ZERO to 2PI](#)

This brings the `angin` into the  $[0, 2 * \pi[$  interval.

## 15.1 Forms

`angout = zero22pi(angin)`

**See also:**

[nPI to PI](#)

---

## Reference Ellipsoid

---

This function returns a reference ellipsoid object corresponding to the specified `code` (numerical EPSG). The values of the `SemimajorAxis` and `SemiminorAxis` properties are in kilometers. The reference ellipsoid has five properties: `Code`, `Name`, `SemimajorAxis`, `SemiminorAxis` and `Flattening`.

The form `code` can receive a valid EPSG code. 46 codes are currently implemented between 7001 and 7053 (except for 7017, 7023, 7026 and 7037-7040).

The valid values for name form are as follows: `sphere`, `unitsphere`, `earth`, `moon`, `mercury`, `venus`, `mars`, `jupiter`, `saturn`, `uranus`, `neptune` and `pluto`.

### 16.1 Forms

```
ref = referenceEllipsoid(code)
```

```
ref = referenceEllipsoid(name)
```
