Welcome to OpenImageIO!

I kinda like “Oy-e-oh” with a bit of a groaning Yiddish accent, as in “OIIO, did you really write yet another file I/O library?”

Dan Wexler

1.1 Overview

OpenImageIO provides simple but powerful ImageInput and ImageOutput APIs that abstract the reading and writing of 2D image file formats. They don’t support every possible way of encoding images in memory, but for a reasonable and common set of desired functionality, they provide an exceptionally easy way for an application using the APIs support a wide — and extensible — selection of image formats without knowing the details of any of these formats.

Concrete instances of these APIs, each of which implements the ability to read and/or write a different image file format, are stored as plugins (i.e., dynamic libraries, DLL’s, or DSO’s) that are loaded at runtime. The OpenImageIO distribution contains such plugins for several popular formats. Any user may create conforming plugins that implement reading and writing capabilities for other image formats, and any application that uses OpenImageIO would be able to use those plugins.

The library also implements the helper class ImageBuf, which is a handy way to store and manipulate images in memory. ImageBuf itself uses ImageInput and ImageOutput for its file I/O, and therefore is also agnostic as to image file formats. A variety of functions in the ImageBufAlgo namespace are available to perform common image processing operations on ImageBuf’s.

The ImageCache class transparently manages a cache so that it can access truly vast amounts of image data (thousands of image files totaling hundreds of GB to several TBs) very efficiently using only a tiny amount (tens of megabytes to a few GB at most) of runtime memory. Additionally, a TextureSystem class provides filtered MIP-map texture lookups, atop the nice caching behavior of ImageCache.

Finally, the OpenImageIO distribution contains several utility programs that operate on images, each of which is built atop this functionality, and therefore may read or write any image file type for which an appropriate plugin is found at runtime. Paramount among these utilities oiiotool, a command-line image processing engine, and iv, an image
viewing application. Additionally, there are programs for converting images among different formats, comparing image data between two images, and examining image metadata.

All of this is released as “open source” software using the very permissive “BSD 3-clause” license. So you should feel free to use any or all of OpenImageIO in your own software, whether it is private or public, open source or proprietary, free or commercial. You may also modify it on your own. You are encouraged to contribute to the continued development of OpenImageIO and to share any improvements that you make on your own, though you are by no means required to do so.

1.2 Simplifying Assumptions

OpenImageIO is not the only image library in the world. Certainly there are many fine libraries that implement a single image format (including the excellent libtiff, libjpeg, and OpenEXR that OpenImageIO itself relies on). Many libraries attempt to present a uniform API for reading and writing multiple image file formats. Most of these support a fixed set of image formats, though a few of these also attempt to provide an extensible set by using the plugin approach.

But in our experience, these libraries are all flawed in one or more ways: (1) They either support only a few formats, or many formats but with the majority of them somehow incomplete or incorrect. (2) Their APIs are not sufficiently expressive as to handle all the image features we need (such as tiled images, which is critical for our texture library). (3) Their APIs are too complete, trying to handle every possible permutation of image format features, and as a result are horribly complicated.

The third sin is the most severe, and is almost always the main problem at the end of the day. Even among the many open source image libraries that rely on extensible plugins, we have not found one that is both sufficiently flexible and has APIs anywhere near as simple to understand and use as those of OpenImageIO.

Good design is usually a matter of deciding what not to do, and OpenImageIO is no exception. We achieve power and elegance only by making simplifying assumptions. Among them:

- OpenImageIO only deals with ordinary 2D images, and to a limited extent 3D volumes, and image files that contain multiple (but finite) independent images within them. OpenImageIO’s support of “movie” files is limited to viewing them as a sequence of separate frames within the file, but not as movies per se (for example, no support for dealing with audio or synchronization).

- Pixel data are presented as 8- 16- or 32-bit int (signed or unsigned), 16- 32- or 64-bit float. NOTHING ELSE. No < 8 bit images, or pixel value boundaries that aren’t byte boundaries. Files with < 8 will appear to the client application as 8-bit unsigned grayscale images.

- Only fully elaborated, non-compressed data are accepted and returned by the API. Compression or special encodings are handled entirely within an OpenImageIO plugin.

- Color space is by default converted to grayscale or RGB. Non-spectral color models, such as XYZ, CMYK, or YUV, are converted to RGB upon reading. (There is a way to override this and ask for raw pixel values.)

- All color channels can be treated (by apps or readers/writers) as having the same data format (though there is a way to deal with per-channel formats for apps and readers/writers that truly need it).

- All image channels in a subimage are sampled at the same resolution. For file formats that allow some channels to be subsampled, they will be automatically up-sampled to the highest resolution channel in the subimage.

- Color information is always in the order R, G, B, and the alpha channel, if any, always follows RGB, and Z channel (if any) always follows alpha. So if a file actually stores ABGR, the plugin is expected to rearrange it as RGBA.

It’s important to remember that these restrictions apply to data passed through the APIs, not to the files themselves. It’s perfectly fine to have an OpenImageIO plugin that supports YUV data, or 4 bits per channel, or any other exotic feature. You could even write a movie-reading ImageInput (despite OpenImageIO’s claims of not supporting movies)
and make it look to the client like it's just a series of images within the file. It's just that all the nonconforming details are handled entirely within the OpenImageIO plugin and are not exposed through the main OpenImageIO APIs.

1.3 Historical Origins

OpenImageIO is the evolution of concepts and tools I've been working on for two decades.

In the 1980’s, every program I wrote that output images would have a simple, custom format and viewer. I soon graduated to using a standard image file format (TIFF) with my own library implementation. Then I switched to Sam Leffler’s stable and complete libtiff.

In the mid-to-late-1990’s, I worked at Pixar as one of the main implementors of PhotoRealistic RenderMan, which had display drivers that consisted of an API for opening files and outputting pixels, and a set of DSO/DLL plugins that each implement image output for each of a dozen or so different file format. The plugins all responded to the same API, so the renderer itself did not need to know how to the details of the image file formats, and users could (in theory, but rarely in practice) extend the set of output image formats the renderer could use by writing their own plugins.

This was the seed of a good idea, but PRMan’s display driver plugin API was abstruse and hard to use. So when I started Exluna in 2000, Matt Pharr, Craig Kolb, and I designed a new API for image output for our own renderer, Entropy. This API, called “ExDisplay,” was C++, and much simpler, clearer, and easier to use than PRMan’s display drivers.

NVIDIA's Gelato (circa 2002), whose early work was done by myself, Dan Wexler, Jonathan Rice, and Eric Enderton, had an API called “ImageIO.” ImageIO was much more powerful and descriptive than ExDisplay, and had an API for reading as well as writing images. Gelato was not only “format agnostic” for its image output, but also for its image input (textures, image viewer, and other image utilities). We released the API specification and headers (though not the library implementation) using the BSD open source license, firmly repudiating any notion that the API should be specific to NVIDIA or Gelato.

For Gelato 3.0 (circa 2007), we refined ImageIO again (by this time, Philip Nemec was also a major influence, in addition to Dan, Eric, and myself1). This revision was not a major overhaul but more of a fine tuning. Our ideas were clearly approaching stability. But, alas, the Gelato project was canceled before Gelato 3.0 was released, and despite our prodding, NVIDIA executives would not open source the full ImageIO code and related tools.

After I left NVIDIA, I was determined to recreate this work once again – and ONLY once more – and release it as open source from the start. Thus, OpenImageIO was born. I started with the existing Gelato ImageIO specification and headers (which were BSD licensed all along), and made further refinements since I had to rewrite the entire implementation from scratch anyway. I think the additional changes are all improvements.

Over the years and with the help of dozens of open source contributors, OpenImageIO has expanded beyond the original simple image format input/output to encompass a wide range of image-related functionality. It has grown into a foundational technology in many products and tools, particularly for the production of animation and visual effects for motion pictures (but also many other uses and fields). This is the software you have in your hands today.

1 Gelato as a whole had many other contributors; those I’ve named here are the ones I recall contributing to the design or implementation of the ImageIO APIs.
1.4 Acknowledgments

OpenImageIO incorporates, depends upon, or dynamically links against several other open source packages, detailed below. These other packages are all distributed under licenses that allow them to be used by OpenImageIO. Where not specifically noted, they are all using the same BSD license that OpenImageIO uses. Any omissions or inaccuracies in this list are inadvertent and will be fixed if pointed out. The full original licenses can be found in the relevant parts of the source code.

OpenImageIO incorporates, distributes, or contains derived works of:

2.1 Data Type Descriptions: TypeDesc

There are two kinds of data that are important to OpenImageIO:

- Internal data is in the memory of the computer, used by an application program.
- Native file data is what is stored in an image file itself (i.e., on the “other side” of the abstraction layer that OpenImageIO provides).

Both internal and file data is stored in a particular data format that describes the numerical encoding of the values. OpenImageIO understands several types of data encodings, and there is a special class, TypeDesc, that allows their enumeration and is described in the header file OpenImageIO/typedesc.h. A TypeDesc describes a base data format type, aggregation into simple vector and matrix types, and an array length (if it’s an array).

The remainder of this section describes the C++ API for TypeDesc. See Section Python Bindings for the corresponding Python bindings.

**struct OIIIO::TypeDesc**

A TypeDesc describes simple data types.

It frequently comes up (in my experience, with renderers and image handling programs) that you want a way to describe data that is passed through APIs through blind pointers. These are some simple classes that provide a simple type descriptor system. This is not meant to be comprehensive for example, there is no provision for structs, unions, pointers, const, or ‘nested’ type definitions. Just simple integer and floating point, common aggregates such as 3-points, and reasonably-lengthed arrays thereof.

**Public Types**

**enum BASETYPE**

BASETYPE is a simple enum describing the base data types that correspond (mostly) to the C/C++ built-in types.

Values:

- **enumerator UNKNOWN**
  - unknown type
- **enumerator NONE**
  - void/no type
- **enumerator UINT8**
  - 8-bit unsigned int values ranging from 0..255, (C/C++ unsigned char).
- **enumerator UCHAR**
enumerator INT8
8-bit int values ranging from -128..127, (C/C++ char).

enumerator CHAR

denumerator UINT16
16-bit int values ranging from 0..65535, (C/C++ unsigned short).

denumerator USHORT

denumerator INT16
16-bit int values ranging from -32768..32767, (C/C++ short).

enumerator SHORT

denumerator UINT32
32-bit unsigned int values (C/C++ unsigned int).

denumerator UINT

denumerator INT32
signed 32-bit int values (C/C++ int).

denumerator INT

denumerator UINT64
64-bit unsigned int values (C/C++ unsigned long long on most architectures).

denumerator ULONGLONG

denumerator INT64
signed 64-bit int values (C/C++ long long on most architectures).

denumerator LONGLONG

denumerator HALF
16-bit IEEE floating point values (OpenEXR half).

denumerator FLOAT
32-bit IEEE floating point values, (C/C++ float).

denumerator DOUBLE
64-bit IEEE floating point values, (C/C++ double).

enumerator STRING
Character string.

enumerator PTR
A pointer value.

enumerator LASTBASE

denum AGGREGATE
AGGREGATE describes whether our TypeDesc is a simple scalar of one of the BASETYPE’s, or one of several simple aggregates. Note that aggregates and arrays are different. A TypeDesc(FLOAT,3) is an array of three floats, a TypeDesc(FLOAT,VEC3) is a single 3-component vector comprised of floats, and TypeDesc(FLOAT,3,VEC3) is an array of 3 vectors, each of which is comprised of 3 floats.

Values:

enumerator SCALAR
A single scalar value (such as a raw int or float in C). This is the default.
enumerator VEC2
   2 values representing a 2D vector.
enumerator VEC3
   3 values representing a 3D vector.
enumerator VEC4
   4 values representing a 4D vector.
enumerator MATRIX33
   9 values representing a 3x3 matrix.
enumerator MATRIX44
   16 values representing a 4x4 matrix.

dependant VECSEMANTICS
   VECSEMANTICS gives hints about what the data represent (for example, if a spatial vector quantity
   should transform as a point, direction vector, or surface normal).
Values:

enumerator NOXFORM
   No semantic hints.
enumerator NOSEMANTICS
   No semantic hints.
enumerator COLOR
   Color.
enumerator POINT
   Point: a spatial location.
enumerator VECTOR
   Vector: a spatial direction.
enumerator NORMAL
   Normal: a surface normal.
enumerator TIMECODE
   indicates an int[2] representing the standard 4-byte encoding of an SMPTE timecode.
enumerator KEYCODE
enumerator RATIONAL
   A VEC2 representing a rational number val[0] / val[1]
enumerator BOX
   A VEC2[2] or VEC3[2] that represents a 2D or 3D bounds (min/max)

Public Functions

inline constexpr TypeDesc(BASETYPE btype = UNKNOWN, AGGREGATE agg = SCALAR,
   VECSEMANTICS semantics = NOSEMANTICS, int arraylen = 0)
   noexcept
   Construct from a BASETYPE and optional aggregateness, semantics, and arrayness.

inline constexpr TypeDesc(BASETYPE btype, int arraylen) noexcept
   Construct an array of a non-aggregate BASETYPE.

2.1. Data Type Descriptions: TypeDesc
inline constexpr TypeDesc (BASETYPE btype, AGGREGATE agg, int arraylen) noexcept
Construct an array from BASETYPE, AGGREGATE, and array length, with unspecified (or moot) semantic hints.

TypeDesc (string_view typestring)
Construct from a string (e.g., "float[3]"). If no valid type could be assembled, set base to UNKNOWN.

Examples:

```
TypeDesc("int") == TypeDesc(TypeDesc::INT) // C++ int32_t
TypeDesc("float") == TypeDesc(TypeDesc::FLOAT) // C++ float
TypeDesc("uint16") == TypeDesc(TypeDesc::UINT16) // C++ uint16_t
TypeDesc("float[4]") == TypeDesc(TypeDesc::FLOAT, 4) // array
TypeDesc("point") == TypeDesc(TypeDesc::FLOAT,
    TypeDesc::VEC3, TypeDesc::POINT)
```

inline constexpr TypeDesc (const TypeDesc & t) noexcept
Copy constructor.

const char *c_str () const
Return the name, for printing and whatnot. For example, “float”, “int[5]”, “normal”

inline constexpr size_t numelements () const noexcept
Return the number of elements: 1 if not an array, or the array length. Invalid to call this for arrays of undetermined size.

inline constexpr size_t basevalues () const noexcept
Return the number of basetype values: the aggregate count multiplied by the array length (or 1 if not an array). Invalid to call this for arrays of undetermined size.

inline constexpr bool is_array () const noexcept
Does this TypeDesc describe an array?

inline constexpr bool is_unsized_array () const noexcept
Does this TypeDesc describe an array, but whose length is not specified?

inline constexpr bool is_sized_array () const noexcept
Does this TypeDesc describe an array, whose length is specified?

inline size_t size () const noexcept
Return the size, in bytes, of this type.

inline constexpr TypeDesc elementtype () const noexcept
Return the type of one element, i.e., strip out the array-ness.

inline size_t elementsize () const noexcept
Return the size, in bytes, of one element of this type (that is, ignoring whether it’s an array).

inline constexpr TypeDesc scalartype () const
Return just the underlying C scalar type, i.e., strip out the array-ness and the aggregateness.

size_t basesize () const noexcept
Return the base type size, i.e., stripped of both array-ness and aggregateness.

bool is_floating_point () const noexcept
True if it’s a floating-point type (versus a fundamentally integral type or something else like a string).

bool is_signed () const noexcept
True if it’s a signed type that allows for negative values.

inline constexpr bool is_unknown () const noexcept
Shortcut: is it UNKNOWN?
inline constexpr operator bool () const noexcept
    if (typedesc) is the same as asking whether it's not UNKNOWN.

size_t fromstring(string_view typestring)
    Set *this to the type described in the string. Return the length of the part of the string that describes the
type. If no valid type could be assembled, return 0 and do not modify *this.

inline constexpr bool operator==(const TypeDesc &t) const noexcept
    Compare two TypeDesc values for equality.

inline constexpr bool operator!=(const TypeDesc &t) const noexcept
    Compare two TypeDesc values for inequality.

inline constexpr bool equivalent(const TypeDesc &b) const noexcept
    Member version of equivalent.

inline constexpr bool is_vec2(BASETYPE b = FLOAT) const noexcept
    Is this a 2-vector aggregate (of the given type, float by default)?

inline constexpr bool is_vec3(BASETYPE b = FLOAT) const noexcept
    Is this a 3-vector aggregate (of the given type, float by default)?

inline constexpr bool is_vec4(BASETYPE b = FLOAT) const noexcept
    Is this a 4-vector aggregate (of the given type, float by default)?

inline constexpr bool is_box2(BASETYPE b = FLOAT) const noexcept
    Is this an array of aggregates that represents a 2D bounding box?

inline constexpr bool is_box3(BASETYPE b = FLOAT) const noexcept
    Is this an array of aggregates that represents a 3D bounding box?

inline void unarray(void) noexcept
    Demote the type to a non-array

bool operator<(const TypeDesc &x) const noexcept
    Test for lexicographic ‘less’, comes in handy for lots of STL containers and algorithms.

Public Members

unsigned char basetype
    C data type at the heart of our type.

unsigned char aggregate
    What kind of AGGREGATE is it?

unsigned char vecsemantics
    Hint: What does the aggregate represent?

unsigned char reserved
    Reserved for future expansion.

int arraylen
    Array length, 0 = not array, -1 = unsized.
Public Static Functions

static BASETYPE basetype_merge (TypeDesc a, TypeDesc b)
Given base data types of a and b, return a basetype that is a best guess for one that can handle both without any loss of range or precision.

Friends

inline friend friend constexpr bool operator== (const TypeDesc &t, BASETYPE b) noexcept
Compare a TypeDesc to a basetype (it’s the same if it has the same base type and is not an aggregate or an array).

inline friend friend constexpr bool operator!= (const TypeDesc &t, BASETYPE b) noexcept
Compare a TypeDesc to a basetype (it’s the same if it has the same base type and is not an aggregate or an array).

inline friend friend constexpr bool equivalent (const TypeDesc &a, const TypeDesc &b) noexcept
TypeDesc’s are equivalent if they are equal, or if their only inequality is differing vector semantics.

A number of static constexpr TypeDesc aliases for common types exist in the outer OpenImageIO scope:

</table>

The only types commonly used to store pixel values in image files are scalars of UINT8, UINT16, float, and half (the last only used by OpenEXR, to the best of our knowledge).

Note that the TypeDesc (which is also used for applications other than images) can describe many types not used by OpenImageIO. Please ignore this extra complexity; only the above simple types are understood by OpenImageIO as pixel storage data types, though a few others, including string and MATRIX44 aggregates, are occasionally used for metadata for certain image file formats (see Sections sec-imageoutput-metadata, sec-imageinput-metadata, and the documentation of individual ImageIO plugins for details).

2.2 Non-owning string views: string_view

Warning: doxygenclass: Cannot find class “OIIO::string_view” in doxygen xml output for project “oiio” from directory: ../build/doxygen/xml
2.3 Efficient unique strings: ustring

**class OIIIO::ustring**

A ustring is an alternative to char* or std::string for storing strings, in which the character sequence is unique (allowing many speed advantages for assignment, equality testing, and inequality testing).

The implementation is that behind the scenes there is a hash set of allocated strings, so the characters of each string are unique. A ustring itself is a pointer to the characters of one of these canonical strings. Therefore, assignment and equality testing is just a single 32- or 64-bit int operation, the only mutex is when a ustring is created from raw characters, and the only malloc is the first time each canonical ustring is created.

The internal table also contains a std::string version and the length of the string, so converting a ustring to a std::string (via `ustring::string()`) or querying the number of characters (via `ustring::size()` or `ustring::length()`) is extremely inexpensive, and does not involve creation/allocation of a new std::string or a call to strlen.

We try very hard to completely mimic the API of std::string, including all the constructors, comparisons, iterations, etc. Of course, the characters of a ustring are non-modifiable, so we do not replicate any of the non-const methods of std::string. But in most other ways it looks and acts like a std::string and so most templated algorithms that would work on a “const std::string &” will also work on a ustring.

Note that like a char*, but unlike a std::string, a ustring is not allowed to contain any embedded NUL (‘\0’) characters. When constructing ustrings from a std::string or a string_view, the contents will be truncated at the point of any NUL character. This is done to ensure that `ustring::c_str()` refers to the same C-style character sequence as the ustring itself or `ustring::string()`.

Usage guidelines:

Compared to standard strings, ustrings have several advantages:

- Each individual ustring is very small in fact, we guarantee that a ustring is the same size and memory layout as an ordinary char*.
- Storage is frugal, since there is only one allocated copy of each unique character sequence, throughout the lifetime of the program.
- Assignment from one ustring to another is just copy of the pointer; no allocation, no character copying, no reference counting.
- Equality testing (do the strings contain the same characters) is a single operation, the comparison of the pointer.
- Memory allocation only occurs when a new ustring is constructed from raw characters the FIRST time subsequent constructions of the same string just finds it in the canonical string set, but doesn’t need to allocate new storage. Destruction of a ustring is trivial, there is no de-allocation because the canonical version stays in the set. Also, therefore, no user code mistake can lead to memory leaks.

But there are some problems, too. Canonical strings are never freed from the table. So in some sense all the strings “leak”, but they only leak one copy for each unique string that the program ever comes across. Also, creation of unique strings from raw characters is more expensive than for standard strings, due to hashing, table queries, and other overhead.

On the whole, ustrings are a really great string representation

- if you tend to have (relatively) few unique strings, but many copies of those strings;
- if the creation of strings from raw characters is relatively rare compared to copying or comparing to existing strings;
- if you tend to make the same strings over and over again, and if it’s relatively rare that a single unique character sequence is used only once in the entire lifetime of the program;
• if your most common string operations are assignment and equality testing and you want them to be as fast as possible;
• if you are doing relatively little character-by-character assembly of strings, string concatenation, or other “string manipulation” (other than equality testing).

ustrings are not so hot
• if your program tends to have very few copies of each character sequence over the entire lifetime of the program;
• if your program tends to generate a huge variety of unique strings over its lifetime, each of which is used only a short time and then discarded, never to be needed again;
• if you don’t need to do a lot of string assignment or equality testing, but lots of more complex string manipulation.

Public Functions

```cpp
inline ustring (void) noexcept
Default ctr for ustring make an empty string.
```

```cpp
inline explicit ustring (const char *str)
Construct a ustring from a null-terminated C string (char *).
```

```cpp
inline explicit ustring (string_view str)
Construct a ustring from a string_view, which can be auto-converted from either a null-terminated C string (char *) or a C++ std::string.
```

```cpp
inline ustring (const char *str, size_type pos, size_type n)
Construct a ustring from at most n characters of str, starting at position pos.
```

```cpp
inline ustring (const char *str, size_type n)
Construct a ustring from the first n characters of str.
```

```cpp
inline ustring (size_type n, char c)
Construct a ustring from n copies of character c.
```

```cpp
inline ustring (const std::string &str, size_type pos, size_type n = npos)
Construct a ustring from an indexed substring of a std::string.
```

```cpp
inline ustring (const ustring &str) noexcept
Copy construct a ustring from another ustring.
```

```cpp
inline ustring (const ustring &str, size_type pos, size_type n = npos)
Construct a ustring from an indexed substring of a ustring.
```

```cpp
inline ~ustring () noexcept
ustring destructor.
```

```cpp
inline operator string_view () const noexcept
Conversion to an OIIO::string_view.
```

```cpp
inline explicit operator std::string () const noexcept
Conversion to std::string (explicit only!).
```

```cpp
inline const ustring &assign (const ustring &str)
Assign a ustring to *this.
```

```cpp
inline const ustring &assign (const ustring &str, size_type pos, size_type n = npos)
Assign a substring of a ustring to *this.
```
inline const ustring &assign (const std::string &str)
    Assign a std::string to *this.

inline const ustring &assign (const std::string &str, size_type pos, size_type n = npos)
    Assign a substring of a std::string to *this.

inline const ustring &assign (const char *str)
    Assign a null-terminated C string (char*) to *this.

inline const ustring &assign (const char *str, size_type n)
    Assign the first n characters of str to *this.

inline const ustring &assign (size_type n, char c)
    Assign n copies of c to *this.

inline const ustring &assign (string_view str)
    Assign a string_view to *this.

inline const ustring &operator= (const ustring &str)
    Assign a ustring to another ustring.

inline const ustring &operator= (const char *str)
    Assign a null-terminated C string (char*) to a ustring.

inline const ustring &operator= (const std::string &str)
    Assign a C++ std::string to a ustring.

inline const ustring &operator= (string_view str)
    Assign a string_view to a ustring.

inline const ustring &operator= (char c)
    Assign a single char to a ustring.

inline char *c_str () const noexcept
    Return a C string representation of a ustring.

inline char *data () const noexcept
    Return a C string representation of a ustring.

inline std::string &string () const noexcept
    Return a C++ std::string representation of a ustring.

inline void clear (void) noexcept
    Reset to an empty string.

inline size_t length (void) const noexcept
    Return the number of characters in the string.

inline size_t hash (void) const noexcept
    Return a hashed version of the string.

inline size_t size (void) const noexcept
    Return the number of characters in the string.

inline bool empty (void) const noexcept
    Is the string empty i.e., is it nullptr or does it point to an empty string?

inline const_iterator begin () const noexcept
    Return a const_iterator that references the first character of the string.

inline const_iterator end () const noexcept
    Return a const_iterator that references the end of a traversal of the characters of the string.

2.3. Efficient unique strings: ustring

17
inline const_reverse_iterator rbegin () const noexcept
    Return a const_reverse_iterator that references the last character of the string.

inline const_reverse_iterator rend () const noexcept
    Return a const_reverse_iterator that references the end of a reverse traversal of the characters of the string.

inline const_reference operator[] (size_type pos) const noexcept
    Return a reference to the character at the given position. Note that it’s up to the caller to be sure pos is within the size of the string.

inline size_type copy (char *, size_type n, size_type pos = 0) const
    Dump into character array s the characters of this ustring, beginning with position pos and copying at most n characters.

inline ustring substr (size_type pos = 0, size_type n = npos) const
    Returns a substring of the ustring object consisting of n characters starting at position pos.

inline int compare (string_view str) const noexcept
    Return 0 if *this is lexicographically equal to str, -1 if *this is lexicographically earlier than str, 1 if *this is lexicographically after str.

inline int compare (const char *str) const noexcept
    Return 0 if *this is lexicographically equal to str, -1 if *this is lexicographically earlier than str, 1 if *this is lexicographically after str.

inline bool operator== (const ustring &str) const noexcept
    Test two ustrings for equality are they comprised of the same sequence of characters. Note that because ustrings are unique, this is a trivial pointer comparison, not a char-by-char loop as would be the case with a char* or a std::string.

inline bool operator!= (const ustring &str) const noexcept
    Test two ustrings for inequality are they comprised of different sequences of characters. Note that because ustrings are unique, this is a trivial pointer comparison, not a char-by-char loop as would be the case with a char* or a std::string.

inline bool operator== (const std::string &x) const noexcept
    Test a ustring (*this) for lexicographic equality with std::string x.

inline bool operator== (string_view x) const noexcept
    Test a ustring (*this) for lexicographic equality with string_view x.

inline bool operator== (const char *x) const noexcept
    Test a ustring (this) for lexicographic equality with char x.

inline bool operator!= (const std::string &x) const noexcept
    Test a ustring (*this) for lexicographic inequality with std::string x.

inline bool operator!= (string_view x) const noexcept
    Test a ustring (*this) for lexicographic inequality with string_view x.

inline bool operator!= (const char *x) const noexcept
    Test a ustring (this) for lexicographic inequality with char x.

inline bool operator<(const ustring &x) const noexcept
    Test for lexicographic ‘less’, comes in handy for lots of STL containers and algorithms.
Public Static Functions

```cpp
template<typename ... Args>
static inline ustring sprintf(const char *fmt, const Args&... args)
    Construct a ustring in a printf-like fashion. In other words, something like: ustring s = ustring::sprintf("blah %d %g", (int)foo, (float)bar); The argument list is fully typesafe. The formatting of the string will always use the classic “C” locale conventions (in particular, ‘.’ as decimal separator for float values).

template<typename ... Args>
static inline ustring fmtformat(const char *fmt, const Args&... args)
    Construct a ustring in a fmt::format-like fashion. In other words, something like: ustring s = ustring::fmtformat("blah {} {}", (int)foo, (float)bar); The argument list is fully typesafe. The formatting of the string will always use the classic “C” locale conventions (in particular, ‘.’ as decimal separator for float values).

template<typename ... Args>
static inline ustring format(const char *fmt, const Args&... args)
    NOTE: Semi-DEPRECATED! This will someday switch to behave like fmt::format (or future std::format) but for now, it is back compatible and equivalent to sprintf.

static ustring concat(string_view s, string_view t)
    Concatenate two strings, returning a ustring, implemented carefully to not perform any redundant copies or allocations. This is semantically equivalent to ustring::sprintf("%s%s", s, t), but is more efficient.

static std::string getstats(bool verbose = true)
    Return the statistics output as a string.

static size_t memory()
    Return the amount of memory consumed by the ustring table.

static size_t total_ustrings()
    Return the total number of ustrings in the internal table.

static size_t hash_collisions(std::vector<ustring> *collisions = nullptr)
    Return the total number ustrings that have the exact hash as another ustring. If collisions is passed, store all the colliding ustrings in the vector.

static const char *make_unique(string_view str)
    Given a string_view, return a pointer to the unique version kept in the internal table (creating a new table entry if we haven’t seen this sequence of characters before). N.B.: this is equivalent to ustring(str).c_str(). It’s also the routine that is used directly by ustring’s internals to generate the canonical unique copy of the characters.

static inline bool is_unique(const char *str)
    Is this character pointer a unique ustring representation of those characters? Useful for diagnostics and debugging.

static inline ustring from_unique(const char *unique)
    Create a ustring from characters guaranteed to already be ustring-clean, without having to run through the hash yet again. Use with extreme caution!!!
```
**Friends**

```cpp
inline friend friend int compare (const std::string &a, const ustring &b) noexcept
    Return 0 if a is lexicographically equal to b, -1 if a is lexicographically earlier than b, 1 if a is lexicographically after b.
inline friend friend bool operator== (const std::string &a, const ustring &b) noexcept
    Test for lexicographic equality between std::string a and ustring b.
inline friend friend bool operator== (string_view a, const ustring &b) noexcept
    Test for lexicographic equality between string_view a and ustring b.
inline friend friend bool operator== (const char *a, const ustring &b) noexcept
    Test for lexicographic equality between char* a and ustring b.
inline friend friend bool operator!= (const std::string &a, const ustring &b) noexcept
    Test for lexicographic inequality between std::string a and ustring b.
inline friend friend bool operator!= (string_view a, const ustring &b) noexcept
    Test for lexicographic inequality between string_view a and ustring b.
inline friend friend bool operator!= (const char *a, const ustring &b) noexcept
    Test for lexicographic inequality between char* a and ustring b.
inline friend friend std::ostream & operator<< (std::ostream &out, const ustring &str)
    Generic stream output of a ustring.
```

```cpp
struct TableRep
```

### 2.4 Non-owning array views: span / cspan

```cpp
template<typename T, oiio_span_size_type Extent = dynamic_extent>
class OIIO::span
    span<T> is a non-owning, non-copying, non-allocating reference to a contiguous array of T objects known length. A ‘span’ encapsulates both a pointer and a length, and thus is a safer way of passing pointers around (because the function called knows how long the array is). A function that might ordinarily take a T* and a length could indeed just take a span<T>.

A span<T> is mutable (the values in the array may be modified). A non-mutable (i.e., read-only) reference would be span<const T>. Thus, a function that might ordinarily take a const T* and a length could instead take a span<const T>.

For convenience, we also define cspan<T> as equivalent to span<const T>.

A span may be initialized explicitly from a pointer and length, by initializing with a std::vector<T>, or by initializing with a constant (treated as an array of length 1). For all of these cases, no extra allocations are performed, and no extra copies of the array contents are made.

Important caveat: The span merely refers to items owned by another array, so the span should not be used beyond the lifetime of the array it refers to. Thus, span is great for parameter passing, but it’s not a good idea to use a span to store values in a data structure (unless you are really sure you know what you’re doing).
Public Functions

```cpp
inline constexpr span() noexcept
Default constructor the span points to nothing.
```

```cpp
inline constexpr span(const U &copy) noexcept
Copy constructor (copies the span pointer and length, NOT the data).
```

```cpp
constexpr span(const span &copy)
Copy constructor (copies the span pointer and length, NOT the data).
```

```cpp
inline constexpr span(pointer data, size_type size) noexcept
Construct from T* and length.
```

```cpp
inline constexpr span(pointer b, pointer e) noexcept
Construct from begin and end pointers.
```

```cpp
inline constexpr span(T &data)
Construct from a single T&.
```

```cpp
template<size_t N>
inline constexpr span(T (&data)[N])
Construct from a fixed-length C array. Template magic automatically finds the length from the declared
type of the array.
```

```cpp
template<class Allocator>
inline constexpr span(std::vector<T, Allocator> &v)
Construct from std::vector<T>.
```

```cpp
template<class Allocator>
inline span(const std::vector<value_type, Allocator> &v)
Construct from const std::vector<T>.
```

```cpp
template<size_t N>
inline constexpr span(const std::array<value_type, N> &arr)
Construct from read-only element std::array.
```

```cpp
inline constexpr span(element_type, Count) first() const
Subview containing the first Count elements of the span.
```

```cpp
inline constexpr span(element_type, Count) last() const
Subview containing the last Count elements of the span.
```

Additionally, there is a convenience template:

```cpp
template<typename T>
using cspan = span<const T> cspan<T> is a synonym for a non-mutable span<const T>.
```

2.4. Non-owning array views: span / cspan
2.5 Rectangular region of interest: ROI

**struct OIIIO::ROI**

*ROI* is a small helper struct describing a rectangular region of interest in an image. The region is \([x_{\text{begin}}, x_{\text{end}}) \times [y_{\text{begin}}, y_{\text{end}}) \times [z_{\text{begin}}, z_{\text{end}}),\) with the “end” designators signifying one past the last pixel in each dimension, a la STL style.

**ROI data members**

The data members are:

```cpp
int xbegin, xend, ybegin, yend, zbegin, zend;
int chbegin, chend;
```

These describe the spatial extent \([x_{\text{begin}}, x_{\text{end}}) \times [y_{\text{begin}}, y_{\text{end}}) \times [z_{\text{begin}}, z_{\text{end}})\) And the channel extent: \([ch_{\text{begin}}, ch_{\text{end}}]\)

**Spatial size functions.**

The width, height, and depth of the region.

```cpp
inline constexpr int width () const noexcept
    { return xend - xbegin; }
inline constexpr int height () const noexcept
    { return yend - ybegin; }
inline constexpr int depth () const noexcept
    { return zend - zbegin; }
```

**Public Functions**

```cpp
inline constexpr ROI () noexcept
    { return {}; }
inline constexpr ROI (int xbegin, int xend, int ybegin, int yend, int zbegin = 0, int zend = 1, int chbegin = 0, int chend = 10000) noexcept
    { (void) xbegin, (void) xend, (void) ybegin, (void) yend, (void) zbegin, (void) zend, (void) chbegin, (void) chend; }
inline constexpr bool defined () const noexcept
    { return xbegin != 0; }
inline constexpr int nchannels () const noexcept
    { return std::min(imagebuf.nchannels(), roi.nchannels()); }
inline constexpr imagesize_t npixels () const noexcept
    { return (xend - xbegin) \* (yend - ybegin) \* (zend - zbegin); }
```
inline constexpr bool contains (int x, int y, int z = 0, int ch = 0) const noexcept
    Test if the coordinate is within the ROI.
inline constexpr bool contains (const ROI &other) const noexcept
    Test if another ROI is entirely within our ROI.

Public Static Functions

static inline constexpr ROI All () noexcept
    All() is an alias for the default constructor, which indicates that it means “all” of the image, or no region restriction. For example, float myfunc (ImageBuf &buf, ROI roi = ROI::All()); Note that this is equivalent to: float myfunc (ImageBuf &buf, ROI roi = {});

Friends

inline friend friend constexpr bool operator== (const ROI &a, const ROI &b) noexcept
    Test equality of two ROIs.
inline friend friend constexpr bool operator!= (const ROI &a, const ROI &b) noexcept
    Test inequality of two ROIs.
inline friend friend std::ostream & operator<< (std::ostream &out, const ROI &roi)
    Stream output of the range.

In addition, there are several related helper functions that involve ROI:
inline constexpr ROI OIIIO::roi_union (const ROI &A, const ROI &B) noexcept
    Union of two regions, the smallest region containing both.
inline constexpr ROI OIIIO::roi_intersection (const ROI &A, const ROI &B) noexcept
    Intersection of two regions.
ROI get_roi (const ImageSpec &spec)
ROI get_roi_full (const ImageSpec &spec)
Return the ROI describing spec’s pixel data window (the x, y, z, width, height, depth fields) or the full (display) window (the full_x, full_y, full_z, full_width, full_height, full_depth fields), respectively.
void set_roi (const ImageSpec &spec, const ROI &newroi)
void set_roi_full (const ImageSpec &spec, const ROI &newroi)
    Alters the spec so to make its pixel data window or the full (display) window match newroi.

2.6 Image Specification: ImageSpec

An ImageSpec is a structure that describes the complete format specification of a single image. It contains:

- The image resolution (number of pixels) and origin. This specifies what is often called the “pixel data window.”
- The full size and offset of an abstract “full” or “display” window. Differing full and data windows can indicate that the pixels are a crop region or a larger image, or contain overscan pixels.
- Whether the image is organized into tiles, and if so, the tile size.
- The native data format of the pixel values (e.g., float, 8-bit integer, etc.).
- The number of color channels in the image (e.g., 3 for RGB images), names of the channels, and whether any particular channels represent alpha and depth.
A user-extensible (and format-extensible) list of any other arbitrarily-named and -typed data that may help describe the image or its disk representation.

The remainder of this section describes the C++ API for ImageSpec. See Section ImageSpec for the corresponding Python bindings.

class OIIIO::ImageSpec

ImageSpec describes the data format of an image dimensions, layout, number and meanings of image channels.

The width, height, depth are the size of the data of this image, i.e., the number of pixels in each dimension. A depth greater than 1 indicates a 3D “volumetric” image. The x, y, z fields indicate the origin of the pixel data of the image. These default to (0,0,0), but setting them differently may indicate that this image is offset from the usual origin. Therefore the pixel data are defined over pixel coordinates [x … x+width-1] horizontally, [y … y+height-1] vertically, and [z … z+depth-1] in depth.

The analogous full_width, full_height, full_depth and full_x, full_y, full_z fields define a “full” or “display” image window over the region [full_x … full_x+full_width-1] horizontally, [full_y … full_y+full_height-1] vertically, and [full_z … full_z+full_depth-1] in depth.

Having the full display window different from the pixel data window can be helpful in cases where you want to indicate that your image is a crop window of a larger image (if the pixel data window is a subset of the full display window), or that the pixels include overscan (if the pixel data is a superset of the full display window), or may simply indicate how different non-overlapping images piece together.

For tiled images, tile_width, tile_height, and tile_depth specify that the image is stored in a file organized into rectangular tiles of these dimensions. The default of 0 value for these fields indicates that the image is stored in scanline order, rather than as tiles.

ImageSpec data members

The ImageSpec contains data fields for the values that are required to describe nearly any image, and an extensible list of arbitrary attributes that can hold metadata that may be user-defined or specific to individual file formats.

Here are the hard-coded data fields:

int x
    origin (upper left corner) of pixel data

int y
    origin (upper left corner) of pixel data

int z
    origin (upper left corner) of pixel data

int width
    width of the pixel data window

int height
    height of the pixel data window

int depth
    depth of pixel data, >1 indicates a “volume”

int full_x
    origin of the full (display) window

int full_y
    origin of the full (display) window
int **full_z**
origin of the full (display) window

int **full_width**
width of the full (display) window

int **full_height**
height of the full (display) window

int **full_depth**
depth of the full (display) window

int **tile_width**
tile width (0 for a non-tiled image)

int **tile_height**
tile height (0 for a non-tiled image)

int **tile_depth**
tile depth (0 for a non-tiled image, 1 for a non-volume image)

int **nchannels**
number of image channels, e.g., 4 for RGBA

**TypeDesc** **format**
Data format of the channels. Describes the native format of the pixel data values themselves, as a TypeDesc. Typical values would be TypeDesc::UINT8 for 8-bit unsigned values, TypeDesc::FLOAT for 32-bit floating-point values, etc.

std::vector<TypeDesc> **channelformats**
Optional per-channel data formats. If all channels of the image have the same data format, that will be described by format and channelformats will be empty (zero length). If there are different data formats for each channel, they will be described in the channelformats vector, and the format field will indicate a single default data format for applications that don’t wish to support per-channel formats (usually this will be the format of the channel that has the most precision).

std::vector<std::string> **channelnames**
The names of each channel, in order. Typically this will be “R”, “G”, “B”, “A” (alpha), “Z” (depth), or other arbitrary names.

int **alpha_channel**
The index of the channel that represents alpha (pixel coverage and/or transparency). It defaults to -1 if no alpha channel is present, or if it is not known which channel represents alpha.

int **z_channel**
The index of the channel that represents z or depth (from the camera). It defaults to -1 if no depth channel is present, or if it is not known which channel represents depth.

bool **deep**
True if the image contains deep data. If true, this indicates that the image describes contains “deep” data consisting of multiple samples per pixel. If false, it’s an ordinary image with one data value (per channel) per pixel.

ParamValueList **extra_attrs**
A list of arbitrarily-named and arbitrarily-typed additional attributes of the image, for any metadata not described by the hard-coded fields described above. This list may be manipulated with the attribute() and find_attribute() methods.
Public Functions

**ImageSpec** *(TypeDesc format = TypeDesc::UNKNOWN) noexcept*
Constructor: given just the data format, set all other fields to something reasonable.

**inline ImageSpec**(string_view format) noexcept
Constructor: given just the data format (as any type name recognized by the TypeDesc constructor), set all other fields to something reasonable.

**ImageSpec**(int xres, int yres, int nchans, TypeDesc fmt = TypeUInt8) noexcept
Constructs an ImageSpec with the given x and y resolution, number of channels, and pixel data format. All other fields are set to the obvious defaults the image is an ordinary 2D image (not a volume), the image is not offset or a crop of a bigger image, the image is scanline-oriented (not tiled), channel names are “R”, “G”, “B” and “A” (up to and including 4 channels, beyond that they are named “channel *n*”), the fourth channel (if it exists) is assumed to be alpha.

**inline ImageSpec**(int xres, int yres, int nchans, string_view fmt) noexcept
Construct an ImageSpec with the given x and y resolution, number of channels, and pixel data format name (as any type name recognized by the TypeDesc constructor).

**explicit ImageSpec**(const ROI &roi, TypeDesc fmt = TypeUInt8) noexcept
Construct an ImageSpec whose dimensions (both data and “full”) and number of channels are given by the ROI, pixel data type by fmt, and other fields are set to their default values.

**inline explicit ImageSpec**(const ROI &roi, string_view fmt) noexcept
Construct an ImageSpec from an ROI giving dimensions, and the name of a data type that will be recognized by the TypeDesc constructor.

**void set_format**(TypeDesc fmt) noexcept
Set the data format, and clear any per-channel format information in channelformats.

**inline void set_format**(string_view fmt) noexcept
Set the data format, and clear any per-channel format information in channelformats. The fmt may be a string such as "uint8", or any other type name recognized by the TypeDesc constructor.

**void default_channel_names ()** noexcept
Sets the channelnames to reasonable defaults for the number of channels. Specifically, channel names are set to “R”, “G”, “B,” and “A” (up to and including 4 channels, beyond that they are named “channel *n*”).

**inline size_t channel_bytes () const noexcept**
Returns the number of bytes comprising each channel of each pixel (i.e., the size of a single value of the type described by the format field).

**size_t channel_bytes**(int chan, bool native = false) const noexcept
Return the number of bytes needed for the single specified channel. If native is false (default), compute the size of one channel of this->format, but if native is true, compute the size of the channel in terms of the “native” data format of that channel as stored in the file.

**size_t pixel_bytes**(bool native = false) const noexcept
Return the number of bytes for each pixel (counting all channels). If native is false (default), assume all channels are in this->format, but if native is true, compute the size of a pixel in the “native” data format of the file (these may differ in the case of per-channel formats).

**size_t pixel_bytes**(int chbegin, int chend, bool native = false) const noexcept
Return the number of bytes for just the subset of channels in each pixel described by [chbegin,chend]. If native is false (default), assume all channels are in this->format, but if native is true, compute the size of a pixel in the “native” data format of the file (these may differ in the case of per-channel formats).
imagesize_t scanline_bytes (bool native = false) const noexcept
Returns the number of bytes comprising each scanline, i.e., pixel_bytes(native) * width. This will return std::numeric_limits<imagesize_t>::max() in the event of an overflow where it’s not representable in an imagesize_t.

imagesize_t tile_pixels() const noexcept
Return the number of pixels comprising a tile (or 0 if it is not a tiled image). This will return std::numeric_limits<imagesize_t>::max() in the event of an overflow where it’s not representable in an imagesize_t.

imagesize_t tile_bytes (bool native = false) const noexcept
Returns the number of bytes comprising an image tile, i.e., pixel_bytes(native) * tile_width * tile_height * tile_depth. If native is false (default), assume all channels are in this->format, but if native is true, compute the size of a pixel in the “native” data format of the file (these may differ in the case of per-channel formats).

imagesize_t image_pixels () const noexcept
Return the number of pixels for an entire image. This will return std::numeric_limits<imagesize_t>::max() in the event of an overflow where it’s not representable in an imagesize_t.

imagesize_t image_bytes (bool native = false) const noexcept
Returns the number of bytes comprising an entire image of these dimensions, i.e., pixel_bytes(native) * width * height * depth. This will return std::numeric_limits<image size_t>::max() in the event of an overflow where it’s not representable in an imagesize_t. If native is false (default), assume all channels are in this->format, but if native is true, compute the size of a pixel in the “native” data format of the file (these may differ in the case of per-channel formats).

inline bool size_t_safe () const noexcept
Verify that on this platform, a size_t is big enough to hold the number of bytes (and pixels) in a scanline, a tile, and the whole image. If this returns false, the image is much too big to allocate and read all at once, so client apps beware and check these routines for overflows!

void attribute (string_view name, TypeDesc type, const void *value)
Add a metadata attribute to extra_attribs, with the given name and data type. The value pointer specifies the address of the data to be copied.

inline void attribute (string_view name, unsigned int value)
Add an unsigned int attribute to extra_attribs.

inline void attribute (string_view name, int value)
Add an int attribute to extra_attribs.

inline void attribute (string_view name, float value)
Add a float attribute to extra_attribs.

void attribute (string_view name, string_view value)
Add a string attribute to extra_attribs.

void attribute (string_view name, ustring value)
Add a string attribute (passed as a ustring) to extra_attribs.

void attribute (string_view name, TypeDesc type, string_view value)
Parse a string containing a textual representation of a value of the given type, and add that as an attribute to extra_attribs. Example:

spec.attribute ("temperature", TypeFloat, "-273.15");
void **\texttt{erase\_attribute}\* (\texttt{string\_view name, TypeDesc searchtype = TypeDesc::UNKNOWN, bool caseSensitive = false})

Searches \texttt{extra\_attrs} for any attributes matching \texttt{name} (as a regular expression), removing them entirely from \texttt{extra\_attrs}. If \texttt{searchtype} is anything other than \texttt{TypeDesc::UNKNOWN}, matches will be restricted only to attributes with the given type. The name comparison will be case-sensitive if \texttt{caseSensitive} is true, otherwise in a case-insensitive manner.

**ParamValue** *\texttt{find\_attribute}\* (\texttt{string\_view name, TypeDesc searchtype = TypeDesc::UNKNOWN, bool caseSensitive = false})

Searches \texttt{extra\_attrs} for an attribute matching \texttt{name}, returning a pointer to the attribute record, or NULL if there was no match. If \texttt{searchtype} is anything other than \texttt{TypeDesc::UNKNOWN}, matches will be restricted only to attributes with the given type. The name comparison will be exact if \texttt{caseSensitive} is true, otherwise in a case-insensitive manner if \texttt{caseSensitive} is false.

**const** ParamValue *\texttt{find\_attribute}\* (\texttt{string\_view name, ParamValue &tmp\_param, TypeDesc searchtype = TypeDesc::UNKNOWN, bool caseSensitive = false})\texttt{ const}

Search for the named attribute and return the pointer to its \texttt{ParamValue} record, or NULL if not found. This variety of \texttt{find\_attribute()} can retrieve items such as “width”, which are data members of the \texttt{ImageSpec}, but not in \texttt{extra\_attrs}. The \texttt{tmp\_param} is a storage area owned by the caller, which is used as temporary buffer in cases where the information does not correspond to an actual \texttt{extra\_attrs} (in this case, the return value will be \texttt{&tmp\_param}). The extra names it understands are:

- **"x" "y" "z" "width" "height" "depth" "full\_x" "full\_y" "full\_z" "full\_width" "full\_height" "full\_depth"**

  Returns the \texttt{ImageSpec} fields of those names (despite the fact that they are technically not arbitrary named attributes in \texttt{extra\_attrs}). All are of type \texttt{int}.

- **"datawindow"**

  Without a type, or if requested explicitly as an \texttt{int\[4\]}, returns the OpenEXR-like pixel data min and max coordinates, as a 4-element integer array: \{ \texttt{x, y, x+width-1, y+height-1} \}. If instead you specifically request as an \texttt{int\[6\]}, it will return the volumetric data window, \{ \texttt{x, y, z, x+width-1, y+height-1, z+depth-1} \}.

- **"displaywindow"**

  Without a type, or if requested explicitly as an \texttt{int\[4\]}, returns the OpenEXR-like pixel display min and max coordinates, as a 4-element integer array: \{ \texttt{full\_x, full\_y, full\_x+full\_width-1, full\_y+full\_height-1} \}. If instead you specifically request as an \texttt{int\[6\]}, it will return the volumetric display window, \{ \texttt{full\_x, full\_y, full\_z, full\_x+full\_width-1, full\_y+full\_height-1, full\_z+full\_depth-1} \}.

**EXAMPLES**

```cpp
ImageSpec spec; // has the info
Imath::Box2i dw; // we want the displaywindow here
ParamValue tmp; // so we can retrieve pseudo-values
TypeDesc int4("int\[4\]"); // Equivalent: TypeDesc int4(TypeDesc::INT,4);
const ParamValue* p = spec.find_attribute("displaywindow", int4);
if (p)
    dw = Imath::Box2i(p->get<int>(0), p->get<int>(1), p->get<int>(2), p->get<int>(3));

p = spec.find_attribute("temperature", TypeFloat);
```

(continues on next page)
if (p)
    float temperature = p->get<float>();

**TypeDesc getattributetype** (string_view name, bool casesensitive = false) **const**

If the named attribute can be found in the *ImageSpec*, return its data type. If no such attribute exists, return *TypeUnknown*.

This was added in version 2.1.

**bool getattribute** (string_view name, TypeDesc type, void *value, bool casesensitive = false) **const**

If the *ImageSpec* contains the named attribute and its type matches *type*, copy the attribute value into the memory pointed to by *val* (it is up to the caller to ensure there is enough space) and return true. If no such attribute is found, or if it doesn’t match the type, return false and do not modify *val*.

**EXAMPLES:**

```cpp
ImageSpec spec;
...
// Retrieving an integer attribute:
int orientation = 0;
spec.getattribute ("orientation", TypeInt, &orientation);

// Retrieving a string attribute with a char*:
const char* compression = nullptr;
spec.getattribute ("compression", TypeString, &compression);

// Alternately, retrieving a string with a ustring:
ustring compression;
spec.getattribute ("compression", TypeString, &compression);
```

Note that when passing a string, you need to pass a pointer to the char*, not a pointer to the first character. Also, the char* will end up pointing to characters owned by the *ImageSpec*; the caller does not need to ever free the memory that contains the characters.

This was added in version 2.1.

**int get_int_attribute** (string_view name, int defaultval = 0) **const**

Retrieve the named metadata attribute and return its value as an int. Any integer type will convert to int by truncation or expansion, string data will parsed into an int if its contents consist of of the text representation of one integer. Floating point data will not succeed in converting to an int. If no such metadata exists, or are of a type that cannot be converted, the defaultval will be returned.

**float get_float_attribute** (string_view name, float defaultval = 0) **const**

Retrieve the named metadata attribute and return its value as a float. Any integer or floating point type will convert to float in the obvious way (like a C cast), and so will string metadata if its contents consist of of the text representation of one floating point value. If no such metadata exists, or are of a type that cannot be converted, the defaultval will be returned.

**string_view get_string_attribute** (string_view name, string_view defaultval = string_view()) **const**

Retrieve any metadata attribute, converted to a string. If no such metadata exists, the defaultval will be returned.

**std::string serialize** (SerialFormat format, SerialVerbose verbose = SerialDetailed) **const**

Returns, as a string, a serialized version of the *ImageSpec*. The format may be either *ImageSpec::SerialText* or *ImageSpec::SerialXML*. The verbose argument may be one of: *ImageSpec::SerialBrief* (just resolution and other vital statistics, one line for *SerialText*, *ImageSpec::SerialDetailed* (contains all metadata in original form), or
ImageSpec::SerialDetailedHuman (contains all metadata, in many cases with human-readable explanation).

std::string to_xml() const
Converting the contents of the ImageSpec as an XML string.

void from_xml(const char *xml)
Populates the fields of the ImageSpec based on the XML passed in.

std::pair<string_view, int> decode_compression_metadata(string_view defaultcomp = "", int defaultqual = -1) const
Hunt for the “Compression” and “CompressionQuality” settings in the spec and turn them into the compression name and quality. This handles compression name/qual combos of the form “name:quality”.

inline bool valid_tile_range(int xbegin, int xend, int ybegin, int yend, int zbegin, int zend)
noexcept
Helper function to verify that the given pixel range exactly covers a set of tiles. Also returns false if the spec indicates that the image isn’t tiled at all.

inline TypeDesc channelformat(int chan) const
Return the channelformat of the given channel. This is safe even if channelformats is not filled out.

inline string_view channel_name(int chan) const
Return the channel name of the given channel. This is safe even if channelnames is not filled out.

inline void get_channelformats(std::vector<TypeDesc> &formats) const
Fill in an array of channel formats describing all channels in the image. (Note that this differs slightly from the member data channelformats, which is empty if there are not separate per-channel formats.)

int channelindex(string_view name) const
Return the index of the channel with the given name, or -1 if no such channel is present in channelnames.

inline ROI roi() const noexcept
Return pixel data window for this ImageSpec expressed as a ROI.

inline ROI roi_full() const noexcept
Return full/display window for this ImageSpec expressed as a ROI.

inline void set_roi(const ROI &r) noexcept
Set pixel data window parameters (x, y, z, width, height, depth) for this ImageSpec from an ROI. Does NOT change the channels of the spec, regardless of r.

inline void set_roi_full(const ROI &r) noexcept
Set full/display window parameters (full_x, full_y, full_z, full_width, full_height, full_depth) for this ImageSpec from an ROI. Does NOT change the channels of the spec, regardless of r.

inline void copy_dimensions(const ImageSpec &other)
Copy from other the image dimensions (x, y, z, width, height, depth, full*, nchannels, format) and data types. It does not copy arbitrary named metadata or channel names (thus, for an ImageSpec with lots of metadata, it is much less expensive than copying the whole thing with operator=()).

inline bool undefined() const noexcept
Returns true for a newly initialized (undefined) ImageSpec. (Designated by no channels and undefined data type true of the uninitialized state of an ImageSpec, and presumably not for any ImageSpec that is useful or purposefully made.)

inline AttrDelegate<ImageSpec> operator[](string_view name)
Array indexing by string will create an AttrDelegate that enables a convenient shorthand for adding and retrieving values from the spec:
i. Assigning to the delegate adds a metadata attribute:

```cpp
ImageSpec spec;
spec["foo"] = 42;   // int
spec["pi"] = float(M_PI);   // float
spec["oiio:ColorSpace"] = "sRGB";   // string
spec["cameratoworld"] = Imath::Matrix44(...);   // matrix
```

Be very careful, the attribute’s type will be implied by the C++ type of what you assign.

ii. String data may be retrieved directly, and for other types, the delegate supports a get<T>() that retrieves an item of type T:

```cpp
std::string colorspace = spec["oiio:ColorSpace"];  
int dither = spec["oiio:dither"].get<int>();
```

This was added in version 2.1.

**Public Static Functions**

```cpp
static inline void auto_stride(stride_t &xstride, stride_t &ystride, stride_t &zstride, stride_t channelsize, int nchannels, int width, int height) noexcept
```

Adjust the stride values, if set to AutoStride, to be the right sizes for contiguous data with the given format, channels, width, height.

```cpp
static inline void auto_stride(stride_t &xstride, stride_t &ystride, stride_t &zstride, TypeDesc format, int nchannels, int width, int height) noexcept
```

Adjust the stride values, if set to AutoStride, to be the right sizes for contiguous data with the given format, channels, width, height.

```cpp
static inline void auto_stride(stride_t &xstride, TypeDesc format, int nchannels) noexcept
```

Adjust xstride, if set to AutoStride, to be the right size for contiguous data with the given format and channels.

```cpp
static std::string metadata_val(const ParamValue &p, bool human = false)
```

For a given parameter p, format the value nicely as a string. If human is true, use especially human-readable explanations (units, or decoding of values) for certain known metadata.

### 2.7 “Deep” pixel data: DeepData

```cpp
class OIIO::DeepData
```

A **DeepData** holds the contents of an image of “deep” pixels (multiple depth samples per pixel).
Public Functions

**DeepData ()**
Construct an empty DeepData.

**DeepData (const ImageSpec &spec)**
Construct and init from an ImageSpec.

**DeepData (const DeepData &src)**
Copy constructor.

**DeepData (const DeepData &src, cspan<TypeDesc> channeltypes)**
Copy constructor with change of channel types.

**DeepData (DeepData &&src)**
Move constructor.

**const DeepData &operator=(const DeepData &d)**
Copy assignment.

void **clear ()**
Reset the DeepData to be equivalent to its empty initial state.

void **free ()**
In addition to performing the tasks of clear(), also ensure that all allocated memory has been truly freed.

void **init (int64_t npix, int nchan, cspan>TypeDesc> channeltypes, cspan<std::string> channelnames)**
Initialize the DeepData with the specified number of pixels, channels, channel types, and channel names, and allocate memory for all the data.

void **init (const ImageSpec &spec)**
Initialize the DeepData based on the ImageSpec’s total number of pixels, number and types of channels. At this stage, all pixels are assumed to have 0 samples, and no sample data is allocated.

**bool initialized () const**
Is the DeepData initialized?

**bool allocated () const**
Has the DeepData fully allocated? If no, it is still very inexpensive to call set_capacity().

**int64_t pixels () const**
Retrieve the total number of pixels.

**int channels () const**
Retrieve the number of channels.

**string_view channelname (int c) const**
Return the name of channel c.

**TypeDesc channeltype (int c) const**
Retrieve the data type of channel c.

**size_t channelsize (int c) const**
Return the size (in bytes) of one sample datum of channel c.

**size_t samplesize () const**
Return the size (in bytes) for all channels of one sample.

**bool same_channeltypes (const DeepData &other) const**
Does this DeepData have the same channel types as other?
int samples (int64_t pixel) const
    Retrieve the number of samples for the given pixel index.

void set_samples (int64_t pixel, int samps)
    Set the number of samples for the given pixel. This must be called after init().

void set_all_samples (cspan<unsigned int> samples)
    Set the number of samples for all pixels. The samples.size() is required to match pixels().

void set_capacity (int64_t pixel, int samps)
    Set the capacity of samples for the given pixel. This must be called after init().

int capacity (int64_t pixel) const
    Retrieve the capacity (number of allocated samples) for the given pixel index.

void insert_samples (int64_t pixel, int samplepos, int n = 1)
    Insert n samples of the specified pixel, beginning at the sample position index. After insertion, the new samples will have uninitialized values.

void erase_samples (int64_t pixel, int samplepos, int n = 1)
    Erase n samples of the specified pixel, beginning at the sample position index.

float deep_value (int64_t pixel, int channel, int sample) const
    Retrieve the value of the given pixel, channel, and sample index, cast to a float.

uint32_t deep_value_uint (int64_t pixel, int channel, int sample) const
    Retrieve the value of the given pixel, channel, and sample index, cast to a uint32.

void set_deep_value (int64_t pixel, int channel, int sample, float value)
    Set the value of the given pixel, channel, and sample index, for floating-point channels.

void set_deep_value (int64_t pixel, int channel, int sample, uint32_t value)
    Set the value of the given pixel, channel, and sample index, for integer channels.

void * data_ptr (int64_t pixel, int channel, int sample)
    Retrieve the pointer to a given pixel/channel/sample, or NULL if there are no samples for that pixel. Use with care, and note that calls to insert_samples and erase_samples can invalidate pointers returned by prior calls to data_ptr.

void get_pointers (std::vector<void*> &pointers) const
    Fill in the vector with pointers to the start of the first channel for each pixel.

bool copy_deep_sample (int64_t pixel, int sample, const DeepData &src, int64_t srcpixel, int srccsample)
    Copy a deep sample from src to this DeepData. They must have the same channel layout. Return true if ok, false if the operation could not be performed.

bool copy_deep_pixel (int64_t pixel, const DeepData &src, int64_t srcpixel)
    Copy an entire deep pixel from src to this DeepData, completely replacing any pixel data for that pixel. They must have the same channel layout. Return true if ok, false if the operation could not be performed.

bool split (int64_t pixel, float depth)
    Split all samples of that pixel at the given depth zsplit. Samples that span z (i.e. z < zsplit < zback) will be split into two samples with depth ranges [z,zsplit] and [zsplit,zback] with appropriate changes to their color and alpha values. Samples not spanning zsplit will remain intact. This operation will have no effect if there are not Z and Zback channels present. Return true if any splits occurred, false if the pixel was not modified.

void sort (int64_t pixel)
    Sort the samples of the pixel by their Z depth.

2.7. “Deep” pixel data: DeepData
void `merge_overlaps` (int64_t `pixel`)
    Merge any adjacent samples in the pixel that exactly overlap in z range. This is only useful if the pixel has
    previously been split at all sample starts and ends, and sorted by Z. Note that this may change the number
    of samples in the pixel.

void `merge_deep_pixels` (int64_t `pixel`, const DeepData &`.src`, int `srcpixel`)
    Merge the samples of `src`'s pixel into this DeepData's pixel. Return `true` if ok, `false` if the operation
could not be performed.

float `opaque_z` (int64_t `pixel`) const
    Return the z depth at which the pixel reaches full opacity.

void `occlusion_cull` (int64_t `pixel`)
    Remove any samples hidden behind opaque samples.

### 2.8 Global Attributes

These helper functions are not part of any other OpenImageIO class, they just exist in the OpenImageIO namespace
as general utilities. (See Miscellaneous Utilities for the corresponding Python bindings.)

bool `OIIO::attribute` (string_view `name`, TypeDesc `type`, const void *`val`)
    `OIIO::attribute()` sets a global attribute (i.e., a property or option) of OpenImageIO. The `name`
designates the name of the attribute, `type` describes the type of data, and `val` is a pointer to memory containing the
new value for the attribute.

    If the name is known, valid attribute that matches the type specified, the attribute will be set to the new value
and `attribute()` will return `true`. If `name` is not recognized, or if the types do not match (e.g., `type` is
`TypeFloat` but the named attribute is a string), the attribute will not be modified, and `attribute()` will
return `false`.

    The following are the recognized attributes:

    • string `options`
        This catch-all is simply a comma-separated list of `name=value` settings of named options, which will be
        parsed and individually set. For example,
        
        `OIIO::attribute ("options", "threads=4,log_times=1");`
        
        Note that if an option takes a string value that must itself contain a comma, it is permissible to enclose the
value in either ‘single’ or “double” quotes.

    • int `threads`
        How many threads to use for operations that can be sped up by being multithreaded. (Examples: simul-
        taneous format conversions of multiple scanlines read together, or many ImageBufAlgo operations.) The
default is 0, meaning to use the full available hardware concurrency detected.

        Situations where the main application logic is essentially single threaded (i.e., one top-level call into OIIO
        at a time) should leave this at the default value, or some reasonable number of cores, thus allowing lots of
threads to fill the cores when OIIO has big tasks to complete. But situations where you have many threads
at the application level, each of which is expected to be making separate OIIO calls simultaneously, should set this to 1, thus having each calling thread do its own work inside of OIIO rather than spawning new threads with a high overall “fan out.”

- **int exr_threads**
  Sets the internal OpenEXR thread pool size. The default is to use as many threads as the amount of hardware concurrency detected. Note that this is separate from the OIIO "threads" attribute.

- **string font_searchpath**
  Colon-separated (or semicolon-separated) list of directories to search if fonts are needed. (Such as for `ImageBufAlgo::render_text()`)

- **string plugin_searchpath**
  Colon-separated (or semicolon-separated) list of directories to search for dynamically-loaded format plugins.

- **int try_all_readers**
  When nonzero (the default), a call to `ImageInput::create()` or `ImageInput::open()` that does not succeed in opening the file with the format reader implied by the file extension will try all available format readers to see if one of them can open the file. If this is zero, the only reader that will be tried is the one implied by the file extension.

- **int read_chunk**
  When performing a `read_image()`, this is the number of scanlines it will attempt to read at a time (some formats are more efficient when reading and decoding multiple scanlines). The default is 256. The special value of 0 indicates that it should try to read the whole image if possible.

- **float[] missingcolor, string missingcolor**
  This attribute may either be an array of float values, or a string containing a comma-separated list of the values. Setting this option globally is equivalent to always passing an `ImageInput` open-with-configuration hint "oiio:missingcolor" with the value.

  When set, it gives some `ImageInput` readers the option of ignoring any missing tiles or scanlines in the file, and instead of treating the read failure of an individual tile as a full error, will interpret it as an intentionally missing tile and proceed by simply filling in the missing pixels with the color specified. If the first element is negative, it will use the absolute value, but draw alternating diagonal stripes of the color. For example,

  ```
float missing[4] = { -1.0, 0.0, 0.0, 0.0 }; // striped red
OIIO::attribute ("missingcolor", TypeDesc("float[4]"), &missing);
  ```

  Note that only some file formats support files with missing tiles or scanlines, and this is only taken as a hint. Please see chap-bundledplugins_ for details on which formats accept a "missingcolor" configuration hint.

- **int debug**
  When nonzero, various debug messages may be printed. The default is 0 for release builds, 1 for DEBUG builds (values > 1 are for OIIO developers to print even more debugging information). This attribute but also may be overridden by the OPENIMAGEIO_DEBUG environment variable.

- **int tiff:half**
  When nonzero, allows TIFF to write half pixel data. N.B. Most apps may not read these correctly, but OIIO will. That’s why the default is not to support it.
• **int openexr:core**
  When nonzero, use the new “OpenEXR core C library” when available, for OpenEXR >= 3.1. This is experimental, and currently defaults to 0.

• **int limits:channels (1024)**
  When nonzero, the maximum number of color channels in an image. Image files whose headers indicate they have more channels might be assumed to be corrupted or malicious files. In situations when more channels are expected to be encountered, the application should raise this limit. The default is 1024 channels.

• **int limits:image_size_MB (32768)**
  When nonzero, the maximum size in MB of the uncompressed pixel data of a single 2D image. Images whose headers indicate that they are larger than this might be assumed to be corrupted or malicious files. The default is 32768 (32 GB of uncompressed pixel data equivalent to 64k x 64k x 4 channel x half). In situations when images larger than this are expected to be encountered, you should raise this limit.

• **int log_times**
  When the "log_times" attribute is nonzero, ImageBufAlgo functions are instrumented to record the number of times they were called and the total amount of time spent executing them. It can be overridden by environment variable OPENIMAGEIO_LOG_TIMES. The totals will be recorded and can be retrieved as a string by using OIIO::getattribute("timing_report", ...). Additionally, if the value is 2 or more, the timing report will be printed to stdout upon application exit (not advised in contexts where it isn’t ok to print to the terminal via stdout, such as GUI apps or libraries).

  When enabled, there is a slight runtime performance cost due to checking the time at the start and end of each of those function calls, and the locking and recording of the data structure that holds the log information. When the log_times attribute is disabled, there is no additional performance cost.

```cpp
bool OIIO::attribute(string_view name, int val)
bool OIIO::attribute(string_view name, float val)
bool OIIO::attribute(string_view name, string_view val)
```
Shortcuts for setting an attribute to a single int, float, or string.

```cpp
bool OIIO::getattribute(string_view name, TypeDesc type, void *val)
```
Get the named global attribute of OpenImageIO, store it in *val. Return true if found and it was compatible with the type specified, otherwise return false and do not modify the contents of *val. It is up to the caller to ensure that val points to the right kind and size of storage for the given type.

In addition to being able to retrieve all the attributes that are documented as settable by the OIIO::attribute() call, getattribute() can also retrieve the following read-only attributes:

• **string format_list**
• **string input_format_list**
• **string output_format_list**
A comma-separated list of all the names of, respectively, all supported image formats, all formats accepted as inputs, and all formats accepted as outputs.

• **string extension_list**
For each format, the format name, followed by a colon, followed by a comma-separated list of all extensions that are presumed to be used for that format. Semicolons separate the lists for formats. For example,
• string library_list
   For each format that uses a dependent library, the format name, followed by a colon, followed by the name
   and version of the dependency. Semicolons separate the lists for formats. For example,

   "tiff:LIBTIFF 4.0.4;gif:gif_lib 4.2.3;openexr:OpenEXR 2.2.0"

• string “timing_report” A string containing the report of all the log_times.
• string hw:simd
• string oiio:simd (read-only)
   A comma-separated list of hardware CPU features for SIMD (and some other things). The "oiio:simd"
   attribute is similarly a list of which features this build of OIIO was compiled to support.

   This was added in OpenImageIO 1.8.
• float resident_memory_used_MB
   This read-only attribute can be used for debugging purposes to report the approximate process memory
   used (resident) by the application, in MB.
• string timing_report
   Retrieving this attribute returns the timing report generated by the log_timing attribute (if it was en-
   abled). The report is sorted alphabetically and for each named instrumentation region, prints the number
   of times it executed, the total runtime, and the average per call, like this:

<table>
<thead>
<tr>
<th>Region</th>
<th>Calls</th>
<th>Total Time (ms)</th>
<th>Average Time (ms)</th>
</tr>
</thead>
<tbody>
<tr>
<td>IBA::computePixelStats</td>
<td>2</td>
<td>2.69</td>
<td>1.34</td>
</tr>
<tr>
<td>IBA::make_texture</td>
<td>1</td>
<td>74.05</td>
<td>74.05</td>
</tr>
<tr>
<td>IBA::mul</td>
<td>8</td>
<td>2.42</td>
<td>0.30</td>
</tr>
<tr>
<td>IBA::over</td>
<td>10</td>
<td>23.82</td>
<td>2.38</td>
</tr>
<tr>
<td>IBA::resize</td>
<td>20</td>
<td>0.24</td>
<td>12.18</td>
</tr>
<tr>
<td>IBA::zero</td>
<td>8</td>
<td>0.66</td>
<td>0.08</td>
</tr>
</tbody>
</table>

bool getattribute (string_view name, int &val)
bool getattribute (string_view name, float &val)
bool getattribute (string_view name, char **val)
bool getattribute (string_view name, std::string &val)

   Specialized versions of getattribute() in which the data type is implied by the type of the argument (for
   single int, float, or string). Two string versions exist: one that retrieves it as a std::string and another that
   retrieves it as a char *. In all cases, the return value is true if the attribute is found and the requested data
   type conversion was legal.

   EXAMPLES:

   int threads;
   OIIO::getattribute ("threads", &threads);
   std::string path;
   OIIO::getattribute ("plugin_searchpath", path);

   int get_int_attribute (string_view name, int defaultvalue = 0)
   float get_float_attribute (string_view name, float defaultvalue = 0)
   string_view get_string_attribute (string_view name, string_view defaultvalue = "")

   Specialized versions of getattribute() for common types, in which the data is returned directly,
   and a supplied default value is returned if the attribute was not found.

   EXAMPLES:
2.9 Miscellaneous Utilities

These helper functions are not part of any other OpenImageIO class, they just exist in the OIIO namespace as general utilities. (See Miscellaneous Utilities for the corresponding Python bindings.)

```cpp
int OIIO::openimageio_version()

Returns a numeric value for the version of OpenImageIO, 10000 for each major version, 100 for each minor version, 1 for each patch. For example, OpenImageIO 1.2.3 would return a value of 10203. One example of how this is useful is for plugins to query the version to be sure they are linked against an adequate version of the library.

bool OIIO::has_error()

Is there a pending global error message waiting to be retrieved?

std::string OIIO::geterror(bool clear = true)

Returns any error string describing what went wrong if ImageInput::create() or ImageOutput::create() failed (since in such cases, the ImageInput or ImageOutput itself does not exist to have its own geterror() function called). This function returns the last error for this particular thread, and clear the pending error message unless clear is false; separate threads will not clobber each other's global error messages.

void OIIO::declare_imageio_format(const std::string &format_name, ImageInput::Creator input_creator, const char **input_extensions, ImageOutput::Creator output_creator, const char **output_extensions, const char *lib_version)

Register the input and output 'create' routines and list of file extensions for a particular format.

bool OIIO::is_imageio_format_name(string_view name)

Is name one of the known format names?

inline std::map<std::string, std::vector<std::string>> OIIO::get_extension_map()

Utility: Parse the "extension_list" attribute into a std::map string keys are the names of all the file formats OIIO knows how to read, and whose values are vectors of strings of the file extensions associated with the file format. (Added in OIIO 2.2.13.)
```

2.10 Environment variables

There are a few special environment variables that can be used to control OpenImageIO at times that it is not convenient to set options individually from inside the source code.

**OPENIMAGEIO_FONTS**

A searchpath for finding fonts (for example, when using by ImageBufAlgo::render_text or oiiotool --text). This may contain a list of directories separated by "::" or ":::'

**OPENIMAGEIO_OPTIONS**
Allows you to seed the global OpenImageIO-wide options.

The value of the environment variable should be a comma-separated list of \texttt{name=value} settings. If a value is a string that itself needs to contain commas, it may be enclosed in single or double quotes.

Upon startup, the contents of this environment variable will be passed to a call to:

\begin{verbatim}
OIIO::attribute ("options", value);
\end{verbatim}

\textbf{OPENIMAGEIO\_IMAGECACHE\_OPTIONS}

Allows you to seed the options for any ImageCache created.

The value of the environment variable should be a comma-separated list of \texttt{name=value} settings. If a value is a string that itself needs to contain commas, it may be enclosed in single or double quotes.

Upon creation of any ImageCache, the contents of this environment variable will be passed to a call to:

\begin{verbatim}
imagecache->attribute ("options", value);
\end{verbatim}

\textbf{OPENIMAGEIO\_TEXTURE\_OPTIONS}

Allows you to seed the options for any TextureSystem created.

The value of the environment variable should be a comma-separated list of \texttt{name=value} settings. If a value is a string that itself needs to contain commas, it may be enclosed in single or double quotes.

Upon creation of any TextureSystem, the contents of this environment variable will be passed to a call to:

\begin{verbatim}
texturesys->attribute ("options", value);
\end{verbatim}

\textbf{OPENIMAGEIO\_THREADS, CUE\_THREADS}

Either of these sets the default number of threads that OpenImageIO will use for its thread pool. If both are set, \texttt{OPENIMAGEIO\_THREADS} will take precedence. If neither is set, the default will be 0, which means to use as many threads as there are physical cores on the machine.
3.1 Image Output Made Simple

Here is the simplest sequence required to write the pixels of a 2D image to a file:

C++

```cpp
#include <OpenImageIO/imageio.h>
using namespace OIIO;
...
const char *filename = "foo.jpg";
const int xres = 640, yres = 480;
const int channels = 3; // RGB
unsigned char pixels[xres * yres * channels];
std::unique_ptr<ImageOutput> out = ImageOutput::create (filename);
if (! out)
    return;
ImageSpec spec (xres, yres, channels, TypeDesc::UINT8);
out->open (filename, spec);
out->write_image (TypeDesc::UINT8, pixels);
out->close();
```

Python

```python
import OpenImageIO as oiio
import numpy as np

filename = "foo.jpg"
xres = 640
yres = 480
channels = 3  # RGB
pixels = np.zeros((yres, xres, channels), dtype=np.uint8)

out = oiio.ImageOutput.create (filename)
if out is None:
    return
spec = ImageSpec(xres, yres, channels, 'uint8')
out.open (filename, spec)
out.write_image (pixels)
out.close ()
```

This little bit of code does a surprising amount of useful work:
Search for an ImageIO plugin that is capable of writing the file foo.jpg, deducing the format from the file extension. When it finds such a plugin, it creates a subclass instance of `ImageOutput` that writes the right kind of file format.

```c++
std::unique_ptr<ImageOutput> out = ImageOutput::create(filename);
```

```python
out = ImageOutput.create(filename)
```

Open the file, write the correct headers, and in all other important ways prepare a file with the given dimensions (640 x 480), number of color channels (3), and data format (unsigned 8-bit integer).

```c++
ImageSpec spec (xres, yres, channels, TypeDesc::UINT8);
out->open (filename, spec);
```

```python
spec = ImageSpec (xres, yres, channels, 'uint8')
out.open (filename, spec)
```

Write the entire image, hiding all details of the encoding of image data in the file, whether the file is scanline- or tile-based, or what is the native format of data in the file (in this case, our in-memory data is unsigned 8-bit and we’ve requested the same format for disk storage, but if they had been different, write_image() would do all the conversions for us).

```c++
out->write_image (TypeDesc::UINT8, &pixels);
```

```python
out.write_image (pixels)
```

Close the file.

```c++
out->close ();
```

```python
out.close ()
```

What happens when the file format doesn’t support the spec?

The `open()` call will fail (returning an empty pointer and set an appropriate error message) if the output format cannot accommodate what is requested by the `ImageSpec`. This includes:

- Dimensions (width, height, or number of channels) exceeding the limits supported by the file format.\(^1\)
- Volumetric (depth > 1) if the format does not support volumetric data.
- Tile size >1 if the format does not support tiles.

---

\(^1\) One exception to the rule about number of channels is that a file format that supports only RGB, but not alpha, is permitted to silently drop the alpha channel without considering that to be an error.
• Multiple subimages or MIP levels if not supported by the format.

However, several other mismatches between requested ImageSpec and file format capabilities will be silently ignored, allowing open() to succeed:

• If the pixel data format is not supported (for example, a request for half pixels when writing a JPEG/JFIF file), the format writer may substitute another data format (generally, whichever commonly-used data format supported by the file type will result in the least reduction of precision or range).

• If the ImageSpec requests different per-channel data formats, but the format supports only a single format for all channels, it may just choose the most precise format requested and use it for all channels.

• If the file format does not support arbitrarily-named channels, the channel names may be lost when saving the file.

• Any other metadata in the ImageSpec may be summarily dropped if not supported by the file format.

3.2 Advanced Image Output

Let’s walk through many of the most common things you might want to do, but that are more complex than the simple example above.

3.2.1 Writing individual scanlines, tiles, and rectangles

The simple example of Section Image Output Made Simple wrote an entire image with one call. But sometimes you are generating output a little at a time and do not wish to retain the entire image in memory until it is time to write the file. OpenImageIO allows you to write images one scanline at a time, one tile at a time, or by individual rectangles.

Writing individual scanlines

Individual scanlines may be written using the writescanline() API call:

C++

```cpp
unsigned char scanline[xres*channels];
out->open (filename, spec);
int z = 0;  // Always zero for 2D images
for (int y = 0; y < yres; ++y) {
    ... generate data in scanline[0..xres*channels-1] ...
    out->write_scanline (y, z, TypeDesc::UINT8, scanline);
}
out->close ();
```

Python

```python
out.open (filename, spec)
z = 0  # Always zero for 2D images
for y in range(yres):
    # generate data in scanline[0..xres*channels-1] ...
    scanline = ...
    out.write_scanline (y, z, scanline)
out.close ()
```
The first two arguments to `writescanline()` specify which scanline is being written by its vertical (y) scanline number (beginning with 0) and, for volume images, its slice (z) number (the slice number should be 0 for 2D non-volume images). This is followed by a `TypeDesc` describing the data you are supplying, and a pointer to the pixel data itself. Additional optional arguments describe the data stride, which can be ignored for contiguous data (use of strides is explained in Section Data Strides).

All `ImageOutput` implementations will accept scanlines in strict order (starting with scanline 0, then 1, up to `yres-1`, without skipping any). See Section Random access and repeated transmission of pixels for details on out-of-order or repeated scanlines.

The full description of the `writescanline()` function may be found in Section `ImageOutput Class Reference`.

**Writing individual tiles**

Not all image formats (and therefore not all `ImageOutput` implementations) support tiled images. If the format does not support tiles, then `writetile()` will fail. An application using OpenImageIO should gracefully handle the case that tiled output is not available for the chosen format.

Once you `create()` an `ImageOutput`, you can ask if it is capable of writing a tiled image by using the `supports("tiles")` query:

**C++**

```cpp
std::unique_ptr<ImageOutput> out = ImageOutput::create (filename);
if (! out->supports ("tiles")) {
    // Tiles are not supported
}
```

**Python**

```python
out = ImageOutput.create (filename)
if not out.supports ("tiles") :
    # Tiles are not supported
```

Assuming that the `ImageOutput` supports tiled images, you need to specifically request a tiled image when you `open()` the file. This is done by setting the tile size in the `ImageSpec` passed to `open()`. If the tile dimensions are not set, they will default to zero, which indicates that scanline output should be used rather than tiled output.

**C++**

```cpp
int tilesize = 64;
ImageSpec spec (xres, yres, channels, TypeDesc::UINT8);
spec.tile_width = tilesize;
spec.tile_height = tilesize;
out->open (filename, spec);
```

**Python**

```python
tilesize = 64
spec = ImageSpec (xres, yres, channels, 'uint8')
spec.tile_width = tilesize
spec.tile_height = tilesize
out.open (filename, spec)
```

In this example, we have used square tiles (the same number of pixels horizontally and vertically), but this is not a requirement of OpenImageIO. However, it is possible that some image formats may only support square tiles, or only certain tile sizes (such as restricting tile sizes to powers of two). Such restrictions should be documented by each individual plugin.
C++

```cpp
unsigned char tile[tilesize*tilesize*channels];
int z = 0;  // Always zero for 2D images
for (int y = 0; y < yres; y += tileSize) {
    for (int x = 0; x < xres; x += tileSize) {
        ... generate data in tile[]..
        out->write_tile (x, y, z, TypeDesc::UINT8, tile);
    }
}
out->close ();
```

Python

```python
z = 0  # Always zero for 2D images
for y in range(0, yres, tileSize) :
    for x in range(0, xres, tileSize) :
        # ... generate data in tile[]
        out.write_tile (x, y, z, tile)
out.close ()
```

The first three arguments to `write_tile()` specify which tile is being written by the pixel coordinates of any pixel contained in the tile: x (column), y (scanline), and z (slice, which should always be 0 for 2D non-volume images). This is followed by a `TypeDesc` describing the data you are supplying, and a pointer to the tile’s pixel data itself, which should be ordered by increasing slice, increasing scanline within each slice, and increasing column within each scanline. Additional optional arguments describe the data stride, which can be ignored for contiguous data (use of strides is explained in Section Data Strides).

All `ImageOutput` implementations that support tiles will accept tiles in strict order of increasing y rows, and within each row, increasing x column, without missing any tiles. See

The full description of the `write_tile()` function may be found in Section `ImageOutput Class Reference`.

Writing arbitrary rectangles

Some `ImageOutput` implementations — such as those implementing an interactive image display, but probably not any that are outputting directly to a file — may allow you to send arbitrary rectangular pixel regions. Once you create() an `ImageOutput`, you can ask if it is capable of accepting arbitrary rectangles by using the supports("rectangles") query:

C++

```cpp
std::unique_ptr<ImageOutput> out = ImageOutput::create (filename);
if (! out->supports ("rectangles")) {
    // Rectangles are not supported
}
```

Python

```python
out = ImageOutput.create (filename)
if not out.supports ("rectangles") :
    # Rectangles are not supported
```

If rectangular regions are supported, they may be sent using the `write_rectangle()` API call:

C++
The first six arguments to `write_rectangle()` specify the region of pixels that is being transmitted by supplying the minimum and one-past-maximum pixel indices in \(x\) (column), \(y\) (scanline), and \(z\) (slice, always 0 for 2D non-volume images).

**Note:** OpenImageIO nearly always follows the C++ STL convention of specifying ranges as the half-open interval \([\text{begin}, \text{end})\) specifying the sequence \(\text{begin}, \text{begin}+1, \ldots, \text{end}−1\) (but the sequence does not contain the \(\text{end}\) value itself).

The total number of pixels being transmitted is therefore:

\[(x_{\text{end}} - x_{\text{begin}}) \times (y_{\text{end}} - y_{\text{begin}}) \times (z_{\text{end}} - z_{\text{begin}})\]

This is followed by a `TypeDesc` describing the data you are supplying, and a pointer to the rectangle’s pixel data itself, which should be ordered by increasing slice, increasing scanline within each slice, and increasing column within each scanline. Additional optional arguments describe the data stride, which can be ignored for contiguous data (use of strides is explained in Section *Data Strides*).

### 3.2.2 Converting pixel data types

The code examples of the previous sections all assumed that your internal pixel data is stored as unsigned 8-bit integers (i.e., 0-255 range). But OpenImageIO is significantly more flexible.

You may request that the output image pixels be stored in any of several data types. This is done by setting the `format` field of the `ImageSpec` prior to calling `open`. You can do this upon construction of the `ImageSpec`, as in the following example that requests a spec that stores pixel values as 16-bit unsigned integers:

```cpp
ImageSpec spec (xres, yres, channels, TypeDesc::UINT16);
```

Or, for an `ImageSpec` that has already been constructed, you may reset its format using the `set_format()` method.

```cpp
ImageSpec spec(...);
spec.set_format (TypeDesc::UINT16);
```

```python
spec = ImageSpec(...)
spec.set_format("uint16")
```

Note that resetting the pixel data type must be done before passing the spec to `open()`, or it will have no effect on the file.
Individual file formats, and therefore ImageOutput implementations, may only support a subset of the pixel data
types understood by the OpenImageIO library. Each ImageOutput plugin implementation should document which
data formats it supports. An individual ImageOutput implementation is expected to always succeed, but if the file
format does not support the requested pixel data type, it is expected to choose a data type that is supported, usually
the data type that best preserves the precision and range of the originally-requested data type.

The conversion from floating-point formats to integer formats (or from higher to lower integer, which is done by first
converting to float) is always done by rescaling the value so that 0.0 maps to integer 0 and 1.0 to the maximum value
representable by the integer type, then rounded to an integer value for final output. Here is the code that implements
this transformation (T is the final output integer type):

```c
float value = quant_max * input;
T output = (T) clamp ((int)(value + 0.5), quant_min, quant_max);
```

Quantization limits for each integer type is as follows:

<table>
<thead>
<tr>
<th>Data Format</th>
<th>min</th>
<th>max</th>
</tr>
</thead>
<tbody>
<tr>
<td>UINT8</td>
<td>0</td>
<td>255</td>
</tr>
<tr>
<td>INT8</td>
<td>-128</td>
<td>127</td>
</tr>
<tr>
<td>UINT16</td>
<td>0</td>
<td>65535</td>
</tr>
<tr>
<td>INT16</td>
<td>-32768</td>
<td>32767</td>
</tr>
<tr>
<td>UINT</td>
<td>0</td>
<td>4294967295</td>
</tr>
<tr>
<td>INT</td>
<td>-2147483648</td>
<td>2147483647</td>
</tr>
</tbody>
</table>

Note that the default is to use the entire positive range of each integer type to represent the floating-point (0.0 - 1.0)
range. Floating-point types do not attempt to remap values, and do not clamp (except to their full floating-point range).

It is not required that the pixel data passed to writeimage(), writescanline(), writetile(), or
write_rectangle() actually be in the same data type as that requested as the native pixel data type of the file.
You can fully mix and match data you pass to the various “write” routines and OpenImageIO will automatically con-
vert from the internal format to the native file format. For example, the following code will open a TIFF file that stores
pixel data as 16-bit unsigned integers (values ranging from 0 to 65535), compute internal pixel values as floating-point
values, with writeimage() performing the conversion automatically:

**C++**

```c
std::unique_ptr<ImageOutput> out = ImageOutput::create ("myfile.tif");
ImageSpec spec (xres, yres, channels, TypeDesc::UINT16);
out->open (filename, spec);
...
float pixels [xres*yres*channels];
...
out->write_image (TypeDesc::FLOAT, pixels);
```

**Python**

```python
out = ImageOutput.create ("myfile.tif")
spec = ImageSpec (xres, yres, channels, "uint16")
out.open (filename, spec)
...
pixels = (...)
...
out.write_image (pixels)
```

Note that writescanline(), writetile(), and write_rectangle() have a parameter that works in a
corresponding manner.
3.2.3 Data Strides

In the preceding examples, we have assumed that the block of data being passed to the “write” functions are contiguous, that is:

- each pixel in memory consists of a number of data values equal to the declared number of channels that are being written to the file;
- successive column pixels within a row directly follow each other in memory, with the first channel of pixel $x$ immediately following last channel of pixel $x-1$ of the same row;
- for whole images, tiles or rectangles, the data for each row immediately follows the previous one in memory (the first pixel of row $y$ immediately follows the last column of row $y-1$);
- for 3D volumetric images, the first pixel of slice $z$ immediately follows the last pixel of of slice $z-1$.

Please note that this implies that data passed to write_tile() be contiguous in the shape of a single tile (not just an offset into a whole image worth of pixels), and that data passed to write_rectangle() be contiguous in the dimensions of the rectangle.

The writescanline() function takes an optional xstride argument, and the writeimage(), write_tile(), and write_rectangle() functions take optional xstride, ystride, and zstride values that describe the distance, in bytes, between successive pixel columns, rows, and slices, respectively, of the data you are passing. For any of these values that are not supplied, or are given as the special constant AutoStride, contiguity will be assumed.

By passing different stride values, you can achieve some surprisingly flexible functionality. A few representative examples follow:

- Flip an image vertically upon writing, by using negative y stride:

```c
unsigned char pixels[xres*yres*channels];
int scanlinesize = xres * channels * sizeof(pixels[0]);
...
out->write_image (TypeDesc::UINT8,
    (char *)pixels+(yres-1)*scanlinesize, // offset to last
    AutoStride, // default x stride
    -scanlinesize, // special y stride
    AutoStride); // default z stride
```

- Write a tile that is embedded within a whole image of pixel data, rather than having a one-tile-only memory layout:

```c
unsigned char pixels[xres*yres*channels];
int pixelsize = channels * sizeof(pixels[0]);
int scanlinesize = xres * pixelsize;
...
out->write_tile (x, y, 0, TypeDesc::UINT8,
    (char *)pixels + y*scanlinesize + x*pixelsize,
    pixelsize, scanlinesize);
```

- Write only a subset of channels to disk. In this example, our internal data layout consists of 4 channels, but we write just channel 3 to disk as a one-channel image:

```c
// In-memory representation is 4 channel
const int xres = 640, yres = 480;
const int channels = 4; // RGBA
const int channelsize = sizeof(unsigned char);
(continues on next page)
unsigned char pixels[xres*yres*channels];

// File representation is 1 channel
std::unique_ptr<ImageOutput> out = ImageOutput::create(filename);
ImageSpec spec (xres, yres, 1, TypeDesc::UINT8);
out->open (filename, spec);

// Use strides to write out a one-channel "slice" of the image
out->write_image (TypeDesc::UINT8,
    (char *)pixels+3*channelsize, // offset to chan 3
    channels*channelsize, // 4 channel x stride
    AutoStride, // default y stride
    AutoStride); // default z stride

...
3.2.5 Writing metadata

The ImageSpec passed to open() can specify all the common required properties that describe an image: data format, dimensions, number of channels, tiling. However, there may be a variety of additional metadata that should be carried along with the image or saved in the file.

Note: Metadata refers to data about data, in this case, data about the image that goes beyond the pixel values and description thereof.

The remainder of this section explains how to store additional metadata in the ImageSpec. It is up to the ImageOutput to store these in the file, if indeed the file format is able to accept the data. Individual ImageOutput implementations should document which metadata they respect.
**Channel names**

In addition to specifying the number of color channels, it is also possible to name those channels. Only a few ImageOutput implementations have a way of saving this in the file, but some do, so you may as well do it if you have information about what the channels represent.

By convention, channel names for red, green, blue, and alpha (or a main image) should be named "R", "G", "B", and "A", respectively. Beyond this guideline, however, you can use any names you want.

The ImageSpec has a vector of strings called channelnames. Upon construction, it starts out with reasonable default values. If you use it at all, you should make sure that it contains the same number of strings as the number of color channels in your image. Here is an example:

C++

```cpp
int channels = 3;
ImageSpec spec (width, length, channels, TypeDesc::UINT8);
spec.channelnames.assign ("R", "G", "B");
```

Python

```python
channels = 3
spec = ImageSpec(width, length, channels, "uint8")
spec.channelnames = ("R", "G", "B")
```

Here is another example in which custom channel names are used to label the channels in an 8-channel image containing beauty pass RGB, per-channel opacity, and texture s,t coordinates for each pixel.

C++

```cpp
int channels = 8;
ImageSpec spec (width, length, channels, TypeDesc::UINT8);
spec.channelnames.clear ();
```

Python

```python
channels = 8
spec = ImageSpec(width, length, channels, "uint8")
spec.channelnames = ("R", "G", "B", "opacityR", "opacityG", "opacityB", "texture_s", "texture_t")
```

The main advantage to naming color channels is that if you are saving to a file format that supports channel names, then any application that uses OpenImageIO to read the image back has the option to retain those names and use them for helpful purposes. For example, the iv image viewer will display the channel names when viewing individual channels or displaying numeric pixel values in “pixel view” mode.
Specially-designated channels

The ImageSpec contains two fields, alpha_channel and z_channel, which can be used to designate which channel indices are used for alpha and z depth, if any. Upon construction, these are both set to -1, indicating that it is not known which channels are alpha or depth. Here is an example of setting up a 5-channel output that represents RGBAZ:

```cpp
int channels = 5;
ImageSpec spec (width, length, channels, format);
spec.channelnames.assign({ "R", "G", "B", "A", "Z" });
spec.alpha_channel = 3;
spec.z_channel = 4;
```

```python
channels = 5
spec = ImageSpec(width, length, channels, "uint8")
spec.channelnames = ("R", "G", "B", "A", "Z")
spec.alpha_channel = 3
spec.z_channel = 4
```

There are advantages to designating the alpha and depth channels in this manner: Some file formats may require that these channels be stored in a particular order, with a particular precision, or the ImageOutput may in some other way need to know about these special channels.

Arbitrary metadata

For all other metadata that you wish to save in the file, you can attach the data to the ImageSpec using the attribute() methods. These come in polymorphic varieties that allow you to attach an attribute name and a value consisting of a single int, unsigned int, float, char*, or std::string, as shown in the following examples:

```cpp
ImageSpec spec (...);

int i = 1;
spec.attribute ("Orientation", i);

float f = 72.0f;
spec.attribute ("dotsize", f);

std::string s = "Fabulous image writer 1.0";
spec.attribute ("Software", s);
```

```python
spec = ImageSpec(...)  
int i = 1
spec.attribute ("Orientation", i)

x = 72.0  
spec.attribute ("dotsize", x)
```

(continues on next page)
s = "Fabulous image writer 1.0"
spec.attribute ("Software", s)

These are convenience routines for metadata that consist of a single value of one of these common types. For other data
types, or more complex arrangements, you can use the more general form of attribute(), which takes arguments
giving the name, type (as a TypeDesc), number of values (1 for a single value, >1 for an array), and then a pointer to
the data values. For example,

C++

```cpp
ImageSpec spec (...);

// Attach a 4x4 matrix to describe the camera coordinates
float mymatrix[16] = { ... };
spec.attribute ("worldtocamera", TypeMatrix, &mymatrix);

// Attach an array of two floats giving the CIE neutral color
float neutral[2] = { 0.3127, 0.329 };
spec.attribute ("adoptedNeutral", TypeDesc(TypeDesc::FLOAT, 2), &neutral);
```

Python

```python
spec = ImageSpec(...)

# Attach a 4x4 matrix to describe the camera coordinates
mymatrix = (1, 0, 0, 0, 0, 1, 0, 0, 0, 1, 0, 0, 0, 1)
spec.attribute ("worldtocamera", "matrix", mymatrix)

# Attach an array of two floats giving the CIE neutral color
neutral = (0.3127, 0.329)
spec.attribute ("adoptedNeutral", "float[2]", neutral)
```

Additionally, the ["key"] notation may be used to set metadata in the spec as if it were an associative array or
dictionary:

C++

```cpp
// spec["key"] = value sets the value of the metadata, using
// the type of value as a guide for the type of the metadata.
spec["Orientation"] = 1; // int
spec["PixelAspectRatio"] = 1.0f; // float
spec["ImageDescription"] = "selfie"; // string
spec["worldtocamera"] = Imath::M44f(...) // matrix
```

Python

```python
# spec["key"] = value sets the value of the metadata, just
# like a Python dict.
spec["Orientation"] = 1
spec["PixelAspectRatio"] = 1.0
spec["ImageDescription"] = "selfie"
spec["worldtocamera"] = (1, 0, 0, 0, 0, 1, 0, 0, 0, 1, 0, 0, 0, 1)
```

In general, most image file formats (and therefore most ImageOutput implementations) are aware of only a small
number of name/value pairs that they redefine and will recognize. Some file formats (OpenEXR, notably) do accept
arbitrary user data and save it in the image file. If an ImageOutput does not recognize your metadata and does not support arbitrary metadata, that metadatum will be silently ignored and will not be saved with the file.

Each individual ImageOutput implementation should document the names, types, and meanings of all metadata attributes that they understand.

**Color space hints**

We certainly hope that you are using only modern file formats that support high precision and extended range pixels (such as OpenEXR) and keeping all your images in a linear color space. But you may have to work with file formats that dictate the use of nonlinear color values. This is prevalent in formats that store pixels only as 8-bit values, since 256 values are not enough to linearly represent colors without banding artifacts in the dim values.

Since this can (and probably will) happen, we have a convention for explaining what color space your image pixels are in. Each individual ImageOutput should document how it uses this (or not).

The ImageSpec::extra_attribs field should store metadata that reveals the color space of the pixels you are sending the ImageOutput (see Section Color information metadata for explanations of particular values).

The color space hints only describe color channels. You should always pass alpha, depth, or other non-color channels with linear values.

Here is a simple example of setting up the ImageSpec when you know that the pixel values you are writing are linear:

**C++**

```cpp
ImageSpec spec (width, length, channels, format);
spec.attribute ("oiio:ColorSpace", "Linear");
```

**Python**

```python
spec = ImageSpec(width, length, channels, format)
spec.attribute ("oiio:ColorSpace", "Linear")
```

If a particular ImageOutput implementation is required (by the rules of the file format it writes) to have pixels in a particular color space, then it should try to convert the color values of your image to the right color space if it is not already in that space. For example, JPEG images must be in sRGB space, so if you declare your pixels to be "Linear", the JPEG ImageOutput will convert to sRGB.

If you leave the "oiio:ColorSpace" unset, the values will not be transformed, since the plugin can’t be sure that it’s not in the correct space to begin with.

### 3.2.6 Random access and repeated transmission of pixels

All ImageOutput implementations that support scanlines and tiles should write pixels in strict order of increasing z slice, increasing y scanlines/rows within each slice, and increasing x column within each row. It is generally not safe to skip scanlines or tiles, or transmit them out of order, unless the plugin specifically advertises that it supports random access or rewrites, which may be queried using:

**C++**

```cpp
auto out = ImageOutput::create (filename);
if (out->supports ("random_access"))
    ...
```

**Python**

```python
```
Similarly, you should assume the plugin will not correctly handle repeated transmissions of a scanline or tile that has already been sent, unless it advertises that it supports rewrites, which may be queried using:

C++

```cpp
if (out->supports("rewrite"))
    ...
```

Python

```python
if out.supports("rewrite") :
    ...
```

### 3.2.7 Multi-image files

Some image file formats support storing multiple images within a single file. Given a created `ImageOutput`, you can query whether multiple images may be stored in the file:

C++

```cpp
auto out = ImageOutput::create(filename);
if (out->supports("multiimage"))
    ...
```

Python

```python
out = ImageOutput.create(filename)
if out->supports("multiimage") :
    ...
```

Some image formats allow you to do the initial `open()` call without declaring the specifics of the subimages, and simply append subimages as you go. You can detect this by checking

C++

```cpp
if (out->supports("appendsubimage"))
    ...
```

Python

```python
if out.supports("appendsubimage") :
    ...
```

In this case, all you have to do is, after writing all the pixels of one image but before calling `close()`, call `open()` again for the next subimage and pass `AppendSubimage` as the value for the `mode` argument (see Section `ImageOutput Class Reference` for the full technical description of the arguments to `open()`). The `close()` routine is called just once, after all subimages are completed. Here is an example:

C++

```cpp
const char* filename = "foo.tif";
int nsubimages; // assume this is set
```
ImageSpec specs[]; // assume these are set for each subimage
unsigned char *pixels[]; // assume a buffer for each subimage

// Create the ImageOutput
auto out = ImageOutput::create (filename);

// Be sure we can support subimages
if (subimages > 1 && (! out->supports("multiimage") ||
    ! out->supports("appendsubimage"))) {
    std::cerr << "Does not support appending of subimages\n";
    return;
}

// Use Create mode for the first level.
ImageOutput::OpenMode appendmode = ImageOutput::Create;

// Write the individual subimages
for (int s = 0; s < nsubimages; ++s) {
    out->open (filename, specs[s], appendmode);
    out->write_image (TypeDesc::UINT8, pixels[s]);
    // Use AppendSubimage mode for subsequent levels
    appendmode = ImageOutput::AppendSubimage;
}
out->close ();

Python

filename = "foo.tif"  # assume this is set
nsubimages = ...  # assume these are set for each subimage
ImageSpec specs = (...)  # assume these are set for each subimage
pixels = (...)  # assume a buffer for each subimage

# Create the ImageOutput
out = ImageOutput.create(filename)

# Be sure we can support subimages
if subimages > 1 and (not out->supports("multiimage") or
    not out->supports("appendsubimage")) :
    print("Does not support appending of subimages")
    return

# Use Create mode for the first level.
appendmode = "Create"

# Write the individual subimages
for s in range(nsubimages) :
    out.open (filename, specs[s], appendmode)
    out.write_image (pixels[s])
    # Use AppendSubimage mode for subsequent levels
    appendmode = "AppendSubimage"
out.close ()

On the other hand, if out->supports("appendsubimage") returns false, then you must use a different open() variety that allows you to declare the number of subimages and their specifications up front.

Below is an example of how to write a multi-subimage file, assuming that you know all the image specifications ahead of time. This should be safe for any file format that supports multiple subimages, regardless of whether it supports
appending, and thus is the preferred method for writing subimages, assuming that you are able to know the number and specification of the subimages at the time you first open the file.

C++

```c++
const char* filename = "foo.tif";
int nsubimages; // assume this is set
ImageSpec specs[]; // assume these are set for each subimage
unsigned char* pixels[]; // assume a buffer for each subimage

// Create the ImageOutput
auto out = ImageOutput::create(filename);

// Be sure we can support subimages
if (subimages > 1 && (! out->supports("multiimage") ||
                   ! out->supports("appendsubimage"))) {
    std::cerr << "Does not support appending of subimages\n";
    return;
}

// Open and declare all subimages
out->open(filename, nsubimages, specs);

// Write the individual subimages
for (int s = 0; s < nsubimages; ++s) {
    if (s > 0) // Not needed for the first, which is already open
        out->open(filename, specs[s], ImageInput::AppendSubimage);
    out->write_image(TypeDesc::UINT8, pixels[s]);
}
out->close();
```

Python

```python
filename = "foo.tif"
nsubimages = ...  # assume this is set
ImageSpec specs = (...)  # assume these are set for each subimage
pixels = (...)       # assume a buffer for each subimage

# Create the ImageOutput
out = ImageOutput.create(filename)

# Be sure we can support subimages
if subimages > 1 and (not out->supports("multiimage") or
                      not out->supports("appendsubimage")):
    print("Does not support appending of subimages")
    return

# Open and declare all subimages
out.open (filename, nsubimages, specs)

# Write the individual subimages
for s in range(nsubimages):
    if s > 0:
        out.open (filename, specs[s], "AppendSubimage")
        out.write_image (pixels[s])
out.close()
```

In both of these examples, we have used `writeimage()`, but of course `writescanline()`, `writetile()`, and `write_rectangle()` work as you would expect, on the current subimage.
3.2.8 MIP-maps

Some image file formats support multiple copies of an image at successively lower resolutions (MIP-map levels, or an “image pyramid”). Given a created ImageOutput, you can query whether MIP-maps may be stored in the file:

C++

```cpp
auto out = ImageOutput::create (filename);
if (out->supports ("mipmap")
```

Python

```python
out = ImageOutput.create(filename)
if out.supports("mipmap") :
```

If you are working with an ImageOutput that supports MIP-map levels, it is easy to write these levels. After writing all the pixels of one MIP-map level, call open() again for the next MIP level and pass ImageInput::AppendMIPLevel as the value for the mode argument, and then write the pixels of the subsequent MIP level. (See Section ImageOutput Class Reference for the full technical description of the arguments to open().) The close() routine is called just once, after all subimages and MIP levels are completed.

Below is pseudocode for writing a MIP-map (a multi-resolution image used for texture mapping):

C++

```cpp
const char *filename = "foo.tif";
const int xres = 512, yres = 512;
const int channels = 3; // RGB
unsigned char *pixels = new unsigned char [xres*yres*channels];

// Create the ImageOutput
auto out = ImageOutput::create (filename);

// Be sure we can support either mipmaps or subimages
if (! out->supports ("mipmap") && ! out->supports ("multiimage")) {
    std::cerr << "Cannot write a MIP-map\n";
    return;
}

// Set up spec for the highest resolution
ImageSpec spec (xres, yres, channels, TypeDesc::UINT8);

// Use Create mode for the first level.
ImageOutput::OpenMode appendmode = ImageOutput::Create;

// Write images, halving every time, until we're down to
// 1 pixel in either dimension
while (spec.width >= 1 && spec.height >= 1) {
    out->open (filename, spec, appendmode);
    out->write_image (TypeDesc::UINT8, pixels);
    // Assume halve() resamples the image to half resolution
    halve (pixels, spec.width, spec.height);
    // Don't forget to change spec for the next iteration
    spec.width /= 2;
    spec.height /= 2;

    // For subsequent levels, change the mode argument to
```
// open(). If the format doesn't support MIPmaps directly, // try to emulate it with subimages.
if (out->supports("mipmap"))
    appendmode = ImageOutput::AppendMIPLevel;
else
    appendmode = ImageOutput::AppendSubimage;
}
out->close ();

Python

filename = "foo.tif"
xres = 512
yres = 512
channels = 3 # RGB
pixels = numpy.array([yres, xres, channels], dtype='uint8')

# Create the ImageOutput
out = ImageOutput.create (filename)

# Be sure we can support either mipmaps or subimages
if not out.supports ("mipmap") and not out.supports ("multiimage") :
    print("Cannot write a MIP-map")
    return

# Set up spec for the highest resolution
spec = ImageSpec(xres, yres, channels, "uint8")

# Use Create mode for the first level.
appendmode = "Create"

# Write images, halving every time, until we're down to # 1 pixel in either dimension
while spec.width >= 1 and spec.height >= 1 :
    out.open (filename, spec, appendmode)
    out.write_image (pixels)
    # Assume halve() resamples the image to half resolution
    halve (pixels, spec.width, spec.height)
    # Don't forget to change spec for the next iteration
    spec.width = spec.width // 2
    spec.height = spec.height // 2

    # For subsequent levels, change the mode argument to # open(). If the format doesn't support MIPmaps directly, # try to emulate it with subimages.
    if (out.supports("mipmap"))
        appendmode = ImageOutput.AppendMIPLevel
    else
        appendmode = ImageOutput.AppendSubimage
    out.close ()

In this example, we have used writeimage(), but of course writescanline(), writetile(), and write_rectangle() work as you would expect, on the current MIP level.
3.2.9 Per-channel formats

Some image formats allow separate per-channel data formats (for example, `half` data for colors and `float` data for depth). When this is desired, the following steps are necessary:

1. Verify that the writer supports per-channel formats by checking `supports("channelformats")`.
2. The `ImageSpec` passed to `open()` should have its `channelformats` vector filled with the types for each channel.
3. The call to `write_scanline()`, `read_scanlines()`, `write_tile()`, `write_tiles()`, or `write_image()` should pass a `data` pointer to the raw data, already in the native per-channel format of the file and contiguously packed, and specify that the data is of type `TypeUnknown`.

For example, the following code fragment will write a 5-channel image to an OpenEXR file, consisting of R/G/B/A channels in `half` and a Z channel in `float`:

```c++
// Mixed data type for the pixel
struct Pixel { half r, g, b, a; float z; }
Pixel pixels[xres*yres];

auto out = ImageOutput::create("foo.exr");

// Double check that this format accepts per-channel formats
if (! out->supports("channelformats")) {
    return;
}

// Prepare an ImageSpec with per-channel formats
ImageSpec spec (xres, yres, 5, TypeDesc::FLOAT);
spec.channelformats.assign(
    { TypeHalf, TypeHalf, TypeHalf, TypeHalf, TypeFloat });
spec.channelnames.assign({ "R", "G", "B", "A", "Z" });
spec.alpha_channel = 3;
spec.z_channel = 4;
out->open (filename, spec);
out->write_image (TypeDesc::UNKNOWN, /* use channel formats */
    pixels, /* data buffer */
    sizeof(Pixel)); /* pixel stride */
```

3.2.10 Writing “deep” data

Some image file formats (OpenEXR only, at this time) support the concept of “deep” pixels – those containing multiple samples per pixel (and a potentially differing number of them in each pixel). You can tell if a format supports deep images by checking `supports("deepdata")`, and you can specify a deep data in an `ImageSpec` by setting its `deep` field will be `true`.

Deep files cannot be written with the usual `write_scanline()`, `write_scanlines()`, `write_tile()`, `write_tiles()`, `write_image()` functions, due to the nature of their variable number of samples per pixel. Instead, `ImageOutput` has three special member functions used only for writing deep data:

```c++
bool write_deep_scanlines (int ybegin, int yend, int z,
    const DeepData &deepdata);

bool write_deep_tiles (int xbegin, int xend, int ybegin, int yend,
    int zbegin, int zend, const DeepData &deepdata);
```

(continues on next page)
bool write_deep_image (const DeepData &deepdata);

It is only possible to write “native” data types to deep files; that is, there is no automatic translation into arbitrary data types as there is for ordinary images. All three of these functions are passed deep data in a special DeepData structure, described in detail in Section “Deep” pixel data: DeepData.

Here is an example of using these methods to write a deep image:

C++

```cpp
// Prepare the spec for 'half' RGBA, 'float' z
int nchannels = 5;
ImageSpec spec (xres, yres, nchannels);
spec.channelnames.assign ("R", "G", "B", "A", "Z");
spec.channeltypes.assign (TypeHalf, TypeHalf, TypeHalf, TypeHalf, TypeFloat);
spec.alpha_channel = 3;
spec.z_channel = 4;
spec.deep = true;

// Prepare the data (sorry, complicated, but need to show the gist)
DeepData deepdata;
deepdata.init (spec);
for (int y = 0; y < yres; ++y)
    for (int x = 0; x < xres; ++x)
        deepdata.set_samples (y * xres + x, ...samples for that pixel...);
deepdata.alloc (); // allocate pointers and data
int pixel = 0;
for (int y = 0; y < yres; ++y)
    for (int x = 0; x < xres; ++x, ++pixel)
        for (int chan = 0; chan < nchannels; ++chan)
            for (int samp = 0; samp < deepdata.samples (pixel); ++samp)
                deepdata.set_deep_value (pixel, chan, samp, ...value...);

// Create the output
auto out = ImageOutput::create (filename);
if (! out)
    return;
// Make sure the format can handle deep data and per-channel formats
if (! out->supports ("deepdata") || ! out->supports ("channelformats"))
    return;
// Do the I/O (this is the easy part!)
out->open (filename, spec);
out->write_deep_image (deepdata);
out->close ();
```

Python

```python
# Prepare the spec for 'half' RGBA, 'float' z
int nchannels = 5
spec = ImageSpec(xres, yres, nchannels)
spec.channelnames = ("R", "G", "B", "A", "Z")
spec.channeltypes = ("half", "half", "half", "half", "float")
spec.z_channel = 3
```

(continues on next page)
spec.deep = True

# Prepare the data (sorry, complicated, but need to show the gist)
depdata = DeepData()
depdata.init (spec)
for y in range(yres) :
    for x in range(xres) :
        depdata.set_samples(y*xres+x, ...samples for that pixel...)
depdata.alloc()  # allocate pointers and data
pixel = 0
for y in range(yres) :
    for x in range(xres) :
        for chan in range(nchannels) :
            for samp in range(deepdata.samples(pixel)) :
                depdata.set_deep_value (pixel, chan, samp, ...value...)
pixel += 1

# Create the output
out = ImageOutput.create (filename)
if out is None :
    return

# Make sure the format can handle deep data and per-channel formats
if not out.supports("deepdata") or not out.supports("channelformats") :
    return

# Do the I/O (this is the easy part!)
out.open (filename, spec)
out.write_deep_image (deepdata)
out.close ()

3.2.11 Copying an entire image

Suppose you want to copy an image, perhaps with alterations to the metadata but not to the pixels. You could open an ImageInput and perform a read_image(), and open another ImageOutput and call write_image() to output the pixels from the input image. However, for compressed images, this may be inefficient due to the unnecessary decompression and subsequent re-compression. In addition, if the compression is lossy, the output image may not contain pixel values identical to the original input.

A special copy_image() method of ImageOutput is available that attempts to copy an image from an open ImageInput (of the same format) to the output as efficiently as possible with without altering pixel values, if at all possible.

Not all format plugins will provide an implementation of copy_image() (in fact, most will not), but the default implementation simply copies pixels one scanline or tile at a time (with decompression/recompression) so it’s still safe to call. Furthermore, even a provided copy_image() is expected to fall back on the default implementation if the input and output are not able to do an efficient copy. Nevertheless, this method is recommended for copying images so that maximal advantage will be taken in cases where savings can be had.

The following is an example use of copy_image() to transfer pixels without alteration while modifying the image description metadata:

C++

```cpp
// Open the input file
auto in = ImageInput::open ("input.jpg");
```
// Make an output spec, identical to the input except for metadata
ImageSpec out_spec = in->spec();
out_spec.attribute("ImageDescription", "My Title");

// Create the output file and copy the image
auto out = ImageOutput::create("output.jpg");
out->open(output, out_spec);
out->copy_image(in);

// Clean up
out->close();
in->close();

Python

# Open the input file
inp = ImageInput.open("input.jpg")

# Make an output spec, identical to the input except for metadata
out_spec = inp.spec()
out_spec.attribute("ImageDescription", "My Title")

# Create the output file and copy the image
out = ImageOutput.create("output.jpg")
out.open(output, out_spec)
out.copy_image(inp)

# Clean up
out.close()
inp.close()

3.2.12 Opening for output with configuration settings/hints

Sometimes you will want to give the image file writer hints or requests related to *how to write the data*, hints which must be made in time for the initial opening of the file. For example, when writing to a file format that requires unassociated alpha, you may already have unpremultiplied colors to pass, rather than the more customary practice of passing associated colors and having them converted to unassociated while being output.

This is accomplished by setting certain metadata in the `ImageSpec` that is passed to `ImageOutput::open()`. These particular metadata entries will be understood to be hints that control choices about how to write the file, rather than as metadata to store in the file header.

Configuration hints are optional and advisory only – meaning that not all image file writers will respect them (and indeed, many of them are only sensible for certain file formats).

Some common output configuration hints that tend to be respected across many writers (but not all, check Chapter *Bundled ImageIO Plugins* to see what hints are supported by each writer, as well as writer-specific settings) are:
<table>
<thead>
<tr>
<th>Input Configuration Attribute</th>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compression</td>
<td>string</td>
<td>Compression method (and sometimes quality level) to be used. Each output file format may have a different set of possible compression methods that are accepted.</td>
</tr>
<tr>
<td>olio:ioproxy</td>
<td>ptr</td>
<td>Pointer to a <code>Filesystem::IOProxy</code> that will handle the I/O, for example by writing to a memory buffer.</td>
</tr>
<tr>
<td>olio:BitsPerSample</td>
<td>int</td>
<td>Requests that the data in the file use a particular bits-per-sample that is not directly expressible by the <code>ImageSpec::format</code> or any of the usual C data types, for example, requesting 10 bits per sample in the output file.</td>
</tr>
<tr>
<td>olio:dither</td>
<td>int</td>
<td>If nonzero and writing UINT8 values to the file from a source buffer of higher bit depth, will add a small amount of random dither to combat the appearance of banding.</td>
</tr>
<tr>
<td>olio:RawColor</td>
<td>int</td>
<td>If nonzero, when writing images to certain formats that support or dictate non-RGB color models (such as YCbCr), this indicates that the input passed by the app will already be in this color model, and should not be automatically converted from RGB to the designated color space as the pixels are written.</td>
</tr>
<tr>
<td>olio:UnassociatedAlpha</td>
<td>int</td>
<td>If nonzero and writing to a file format that allows or dictates unassociated alpha/color values, this hint indicates that the pixel data that will be passed are already in unassociated form and should not automatically be “un-premultiplied” by the writer in order to conform to the file format’s need for unassociated data.</td>
</tr>
</tbody>
</table>

Examples:

Below is an example where we are writing to a PNG file, which dictates that RGBA data is always unassociated (i.e., the color channels are not already premultiplied by alpha), and we already have unassociated pixel values we wish to write unaltered, without it assuming that it’s associated and automatically converting to unassociated alpha:

**C++**

```cpp
unsigned char unassociated_pixels[xres*yres*channels];

ImageSpec spec (xres, yres, channels, TypeDesc::UINT8);
spec["oiio:UnassociatedAlpha"] = 1;

auto out = ImageOutput::create ("foo.png");
out->open ("foo.png", spec);
out->write_image (TypeDesc::UINT8, unassociated_pixels);
out->close ();
```

**Python**

```python
# Prepare the spec that describes the file, but also add to it # the hint that says that the pixel data we will send it will # be already unassociated.
spec = ImageSpec (xres, yres, channels, "uint8")
spec["oiio:UnassociatedAlpha"] = 1

out = ImageOutput.create ("foo.png")
out.open ("foo.png", spec)
```

(continues on next page)
3.2.13 Custom I/O proxies (and writing the file to a memory buffer)

Some file format writers allow you to supply a custom I/O proxy object that can allow bypassing the usual file I/O with custom behavior, including the ability to fill an in-memory buffer with a byte-for-byte representation of the correctly formatted file that would have been written to disk.

Only some output format writers support this feature. To find out if a particular file format supports this feature, you can create an ImageOutput of the right type, and check if it supports the feature name "ioproxy":

```cpp
auto out = ImageOutput::create (filename);
if (! out || ! out->supports ("ioproxy")) { return; }
```

ImageOutput writers that support "ioproxy" will respond to a special attribute, "oiio:ioproxy", which passes a pointer to a Filesystem::IOProxy* (see OpenImageIO's filesystem.h for this type and its subclasses). IOProxy is an abstract type, and concrete subclasses include IOFile (which wraps I/O to an open FILE*) and IOVecOutput (which sends output to a std::vector<unsigned char>).

Here is an example of using a proxy that writes the “file” to a std::vector<unsigned char>:

```cpp
// ImageSpec describing the image we want to write.
ImageSpec spec (xres, yres, channels, TypeDesc::UINT8);

std::vector<unsigned char> file_buffer; // bytes will go here
Filesystem::IOVecOutput vecout (file_buffer); // I/O proxy object

auto out = ImageOutput::create ("out.exr", &vecout);
out->open ("out.exr", spec);
out->write_image (...);
out->close ();

// At this point, file_buffer will contain the "file"
```

3.2.14 Custom search paths for plugins

When you call ImageOutput::create(), the OpenImageIO library will try to find a plugin that is able to write the format implied by your filename. These plugins are alternately known as DLL’s on Windows (with the .dll extension), DSO’s on Linux (with the .so extension), and dynamic libraries on Mac OS X (with the .dylib extension).

OpenImageIO will look for matching plugins according to search paths, which are strings giving a list of directories to search, with each directory separated by a colon :. Within a search path, any substrings of the form $\{\{FOO\}\}$ will be replaced by the value of environment variable FOO. For example, the searchpath "$\{HOME\}/plugins:/shared/plugins" will first check the directory /home/tom/plugins (assuming the user’s home directory is /home/tom), and if not found there, will then check the directory /shared/plugins.

The first search path it will check is that stored in the environment variable OIIO_LIBRARY_PATH. It will check each directory in turn, in the order that they are listed in the variable. If no adequate plugin is found in any of the directories listed in this environment variable, then it will check the custom searchpath passed as the optional second argument to ImageOutput::create(), searching in the order that the directories are listed. Here is an example:
3.2.15 Error checking

Nearly every `ImageOutput` API function returns a `bool` indicating whether the operation succeeded (`true`) or failed (`false`). In the case of a failure, the `ImageOutput` will have saved an error message describing in more detail what went wrong, and the latest error message is accessible using the `ImageOutput` method `geterror()`, which returns the message as a `std::string`.

The exception to this rule is `ImageOutput::create()`, which returns `NULL` if it could not create an appropriate `ImageOutput`. And in this case, since no `ImageOutput` exists for which you can call its `geterror()` function, there exists a global `geterror()` function (in the `OpenImageIO` namespace) that retrieves the latest error message resulting from a call to `create()`.

Here is another version of the simple image writing code from Section *Image Output Made Simple*, but this time it is fully elaborated with error checking and reporting:

```cpp
#include <OpenImageIO/imageio.h>
using namespace OIIO;
...
const char *filename = "foo.jpg";
const int xres = 640, yres = 480;
const int channels = 3;  // RGB
unsigned char pixels[xres*yres*channels];

auto out = ImageOutput::create (filename);
if (! out) {
    std::cerr << "Could not create an ImageOutput for " << filename << ", error = " << OpenImageIO::geterror() << "\n";
    return;
}

ImageSpec spec (xres, yres, channels, TypeDesc::UINT8);
if (! out->open (filename, spec)) {
    std::cerr << "Could not open " << filename << ", error = " << out->geterror() << "\n";
    return;
}

if (! out->write_image (TypeDesc::UINT8, pixels)) {
    std::cerr << "Could not write pixels to " << filename << ", error = " << out->geterror() << "\n";
    return;
}

if (! out->close ()) {
    std::cerr << "Error closing " << filename << ", error = " << out->geterror() << "\n";
    return;
}
```
Python

```python
from OpenImageIO import ImageOutput, ImageSpec
import numpy as np

filename = "foo.jpg"
xres = 640
yres = 480
channels = 3  # RGB
pixels = np.zeros((yres, xres, channels), dtype=np.uint8)

out = ImageOutput.create(filename)
if not out:
    print("Could not create an ImageOutput for", filename,
          ", error = ", OpenImageIO.geterror())
    return

spec = ImageSpec(xres, yres, channels, 'uint8')
if not out.open(filename, spec):
    print("Could not open", filename, ", error = ", out.geterror())
    return

if not out.write_image(pixels):
    print("Could not write pixels to", filename, ", error = ", out.geterror())
    return

if not out.close():
    print("Error closing", filename, ", error = ", out.geterror())
    return
```

### 3.3 ImageOutput Class Reference

**class OIIIO::ImageOutput**

*ImageOutput* abstracts the writing of an image file in a file format-agnostic manner.

Users don’t directly declare these. Instead, you call the *create()* static method, which will return a *unique_ptr* holding a subclass of *ImageOutput* that implements writing the particular format.

**Creating an ImageOutput**

```
static unique_ptr create (string_view filename, Filesystem::IOProxy *ioprodxy = nullptr, string_view plugin_searchpath = "")
```

Create an *ImageOutput* that can be used to write an image file. The type of image file (and hence, the particular subclass of *ImageOutput* returned, and the plugin that contains its methods) is inferred from the name, if it appears to be a full filename, or it may also name the format.

**Return** A *unique_ptr* that will close and free the *ImageOutput* when it exits scope or is reset. The pointer will be empty if the required writer was not able to be created.

**Parameters**

- *filename*: The name of the file format (e.g., “openexr”), a file extension (e.g., “exr”), or a filename from which the the file format can be inferred from its extension (e.g., “hawaii.exr”). The filename is UTF-8 encoded.
• plugin_searchpath: An optional colon-separated list of directories to search for OpenImageIO plugin DSO/DLL’s.

• ioproxy: Optional pointer to an IOProxy to use (not supported by all formats, see supports("ioproxy")) The caller retains ownership of the proxy.

static inline unique_ptr create (const std::wstring & filename, Filesystem::IOProxy * ioproxy = nullptr, const std::wstring & plugin_searchpath = {})

Create an ImageOutput using a UTF-16 encoded wstring filename and plugin searchpath.

Opening and closing files for output

denum OpenMode

Modes passed to the open() call.

Values:

enumerator Create

eenumerator AppendSubimage

eenumerator AppendMIPLevel

inline virtual int supports (string_view feature) const

Given the name of a “feature”, return whether this ImageOutput supports output of images with the given properties. Most queries will simply return 0 for “doesn’t support” and 1 for “supports it,” but it is acceptable to have queries return other nonzero integers to indicate varying degrees of support or limits (but should be clearly documented as such).

Feature names that ImageOutput implementations are expected to recognize include:

* "tiles": Is this format writer able to write tiled images?

* "rectangles": Does this writer accept arbitrary rectangular pixel regions (via write_rectangle())? Returning 0 indicates that pixels must be transmitted via write_scanline() (if scanline-oriented) or write_tile() (if tile-oriented, and only if supports("tiles") returns true).

* "random_access": May tiles or scanlines be written in any order (0 indicates that they must be in successive order)?

* "multiimage": Does this format support multiple subimages within a file?

* "appendsubimage": Does this format support multiple subimages that can be successively appended at will via open(name, spec, AppendSubimage)? A value of 0 means that the format requires pre-declaring the number and specifications of the subimages when the file is first opened, with open(name, subimages, specs).

* "mipmap": Does this format support multiple resolutions for an image/subimage?

* "volumes": Does this format support “3D” pixel arrays (a.k.a. volume images)?

* "alpha": Can this format support an alpha channel?

* "nchannels": Can this format support arbitrary number of channels (beyond RGBA)?

* "rewrite": May the same scanline or tile be sent more than once? Generally, this is true for plugins that implement interactive display, rather than a saved image file.

* "empty": Does this plugin support passing a NULL data pointer to the various write routines to indicate that the entire data block is composed of pixels with value zero? Plugins that support this
achieve a speedup when passing blank scanlines or tiles (since no actual data needs to be transmitted or converted).

- "channelformats" : Does this format writer support per-channel data formats, respecting the ImageSpec's channelformats field? If not, it only accepts a single data format for all channels and will ignore the channelformats field of the spec.

- "displaywindow" : Does the format support display ("full") windows distinct from the pixel data window?

- "origin" : Does the image format support specifying a pixel window origin (i.e., nonzero ImageSpec x, y, z)?

- "negativeorigin" : Does the image format allow data and display window origins (i.e., ImageSpec x, y, z, full_x, full_y, full_z) to have negative values?

- "deepdata" : Does the image format allow "deep" data consisting of multiple values per pixel (and potentially a differing number of values from pixel to pixel)?

- "arbitrary_metadata" : Does the image file format allow metadata with arbitrary names (and either arbitrary, or a reasonable set of, data types)? (Versus the file format supporting only a fixed list of specific metadata names/values.)

- "exif" Does the image file format support Exif camera data (either specifically, or via arbitrary named metadata)?

- "iptc" Does the image file format support IPTC data (either specifically, or via arbitrary named metadata)?

- "ioproxy" Does the image file format support writing to an IOProxy?

- "procedural" : Is this a purely procedural output that doesn't write an actual file?

- "thumbnail" : Does this format writer support adding a reduced resolution copy of the image via the thumbnail() method?

- "thumbnail_after_write" : Does this format writer support calling thumbnail() after the scanlines or tiles have been specified? (Supporting "thumbnail" but not "thumbnail_after_write" means that any thumbnail must be supplied immediately after open(), prior to any of the write_*() calls.)

This list of queries may be extended in future releases. Since this can be done simply by recognizing new query strings, and does not require any new API entry points, addition of support for new queries does not break "link compatibility" with previously-compiled plugins.

```cpp
virtual bool open(const std::string &filename, const ImageSpec &newspec, OpenMode mode = Create) = 0;
```

Open the file with given name, with resolution and other format data as given in newspec. It is legal to call open multiple times on the same file without a call to close(), if it supports multiimage and mode is AppendSubimage, or if it supports MIP-maps and mode is AppendMIPLevel this is interpreted as appending a subimage, or a MIP level to the current subimage, respectively.

Return true upon success, or false upon failure.

Parameters

- filename: The name of the image file to open, UTF-8 encoded.

- newspec: The ImageSpec describing the resolution, data types, etc.
• mode: Specifies whether the purpose of the open is to create/truncate the file (default: Create), append another subimage (AppendSubimage), or append another MIP level (AppendMIPLevel).

```cpp
inline bool open (const std::wstring &filename, const ImageSpec &newspec, OpenMode mode = Create)
Open an ImageOutput using a UTF-16 encoded wstring filename.
```

```cpp
inline virtual bool open (const std::string &filename, int subimages, const ImageSpec *specs)
Open a multi-subimage file with given name and specifications for each of the subimages. Upon success, the first subimage will be open and ready for transmission of pixels. Subsequent subimages will be denoted with the usual call of open(name, spec, AppendSubimage) (and MIP levels by open(name, spec, AppendMIPLevel)).

The purpose of this call is to accommodate format-writing libraries that must know the number and specifications of the subimages upon first opening the file; such formats can be detected by: supports("multiimage") && !supports("appendsubimage") The individual specs passed to the appending open() calls for subsequent subimages must match the ones originally passed.
```

Return true upon success, or false upon failure.

Parameters

• filename: The name of the image file to open, UTF-8 encoded.
• subimages: The number of subimages (and therefore the length of the specs[] array.
• specs[]: Pointer to an array of ImageSpec objects describing each of the expected subimages.

```cpp
inline const ImageSpec &spec (void) const
Return a reference to the image format specification of the current subimage. Note that the contents of the spec are invalid before open() or after close().
```

```cpp
virtual bool close () = 0
Closes the currently open file associated with this ImageOutput and frees any memory or resources associated with it.
```

Writing pixels

Common features of all the write methods:

• The format parameter describes the data type of the data[]. The write methods automatically convert the data from the specified format to the actual output data type of the file (as was specified by the ImageSpec passed to open()). If format is TypeUnknown, then rather than converting from format, it will just copy pixels assumed to already be in the file’s native data layout (including, possibly, per-channel data formats as specified by the ImageSpec’s channelformats field).

• The stride values describe the layout of the data buffer: xstride is the distance in bytes between successive pixels within each scanline. ystride is the distance in bytes between successive scanlines. For volumetric images zstride is the distance in bytes between successive “volumetric planes”. Strides set to the special value AutoStride imply contiguous data, i.e.,

```cpp
xstride = format.size() * nchannels
ystride = xstride * width
zstride = ystride * height
```
- Any range parameters (such as ybegin and yend) describe a “half open interval”, meaning that begin is the first item and end is one past the last item. That means that the number of items is end - begin.

- For ordinary 2D (non-volumetric) images, any z or zbegin coordinates should be 0 and any zend should be 1, indicating that only a single image “plane” exists.

- Scanlines or tiles must be written in successive increasing coordinate order, unless the particular output file driver allows random access (indicated by supports("random_access").

- All write functions return true for success, false for failure (after which a call to geterror() may retrieve a specific error message).

virtual bool write_scanline(int y, int z, TypeDesc format, const void *data, stride_t xstride = AutoStride)
Write the full scanline that includes pixels (*,y,z). For 2D non-volume images, z should be 0. The xstride value gives the distance between successive pixels (in bytes). Strides set to AutoStride imply “contiguous” data.

Return true upon success, or false upon failure.

Parameters

- y/z: The y & z coordinates of the scanline.
- format: A TypeDesc describing the type of data.
- data: Pointer to the pixel data.
- xstride: The distance in bytes between successive pixels in data (or AutoStride).

virtual bool write_scanlines(int ybegin, int yend, int z, TypeDesc format, const void *data,
stride_t xstride = AutoStride, stride_t ystride = AutoStride)
Write multiple scanlines that include pixels (*,y,z) for all ybegin <= y < yend, from data. This is analogous to write_scanline(y,z,format,data,xstride) repeatedly for each of the scanlines in turn (the advantage, though, is that some image file types may be able to write multiple scanlines more efficiently or in parallel, than it could with one scanline at a time).

Return true upon success, or false upon failure.

Parameters

- ybegin/yend: The y range of the scanlines being passed.
- z: The z coordinate of the scanline.
- format: A TypeDesc describing the type of data.
- data: Pointer to the pixel data.
- xstride/ystride: The distance in bytes between successive pixels and scanlines (or AutoStride).

virtual bool write_tile(int x, int y, int z, TypeDesc format, const void *data, stride_t xstride =
AutoStride, stride_t ystride = AutoStride, stride_t zstride = AutoStride)
Write the tile with (x,y,z) as the upper left corner. The three stride values give the distance (in bytes) between successive pixels, scanlines, and volumetric slices, respectively. Strides set to AutoStride imply ‘contiguous’ data in the shape of a full tile, i.e.,

\[
xstride = \text{format.size()} \times \text{spec.nchannels} \\
ystride = xstride \times \text{spec.tile_width} \\
zstride = ystride \times \text{spec.tile_height}
\]
Return true upon success, or false upon failure.

Note This call will fail if the image is not tiled, or if (x,y,z) is not the upper left corner coordinates of a tile.

Parameters

- x/y/z: The upper left coordinate of the tile being passed.
- format: A TypeDesc describing the type of data.
- data: Pointer to the pixel data.
- xstride/ystride/zstride: The distance in bytes between successive pixels, scanlines, and image planes (or AutoStride to indicate a "contiguous" single tile).

virtual bool write_tiles(int xbegin, int xend, int ybegin, int yend, int zbegin, int zend, TypeDesc format, const void *data, stride_t xstride = AutoStride, stride_t ystride = AutoStride, stride_t zstride = AutoStride)

Write the block of multiple tiles that include all pixels in

\[ [xbegin, xend) \times [ybegin, yend) \times [zbegin, zend) \]

This is analogous to calling write_tile(x,y,z,...) for each tile in turn (but for some file formats, passing multiple tiles may allow it to write more efficiently or in parallel).

The begin/end pairs must correctly delineate tile boundaries, with the exception that it may also be the end of the image data if the image resolution is not a whole multiple of the tile size. The stride values give the data spacing of adjacent pixels, scanlines, and volumetric slices (measured in bytes). Strides set to AutoStride imply contiguous data in the shape of the [begin,end) region, i.e.,

\[
\begin{align*}
xstride & = \text{format.size()} \times \text{spec.nchannels} \\
ystride & = xstride \times (xend-xbegin) \\
zstride & = ystride \times (yend-ybegin)
\end{align*}
\]

Return true upon success, or false upon failure.

Note The call will fail if the image is not tiled, or if the pixel ranges do not fall along tile (or image) boundaries, or if it is not a valid tile range.

Parameters

- xbegin/xend: The x range of the pixels covered by the group of tiles passed.
- ybegin/yend: The y range of the pixels covered by the tiles.
- zbegin/zend: The z range of the pixels covered by the tiles (for a 2D image, zbegin=0 and zend=1).
- format: A TypeDesc describing the type of data.
- data: Pointer to the pixel data.
- xstride/ystride/zstride: The distance in bytes between successive pixels, scanlines, and image planes (or AutoStride).

virtual bool write_rectangle(int xbegin, int xend, int ybegin, int yend, int zbegin, int zend, TypeDesc format, const void *data, stride_t xstride = AutoStride, stride_t ystride = AutoStride, stride_t zstride = AutoStride)

Write a rectangle of pixels given by the range
The stride values give the data spacing of adjacent pixels, scanlines, and volumetric slices (measured in bytes). Strides set to AutoStride imply contiguous data in the shape of the \([\text{begin}, \text{end})\) region, i.e.,

\[
xstride = \text{format.size()} \times \text{spec.nchannels} \\
ystride = xstride \times (\text{end}-\text{begin}) \\
zstride = ystride \times (\text{end}-\text{begin})
\]

Return true upon success, or false upon failure.

Note The call will fail for a format plugin that does not return true for `supports("rectangles")`.

Parameters

- \(\text{xbegin}/\text{xend}\): The x range of the pixels being passed.
- \(\text{ybegin}/\text{yend}\): The y range of the pixels being passed.
- \(\text{zbegin}/\text{zend}\): The z range of the pixels being passed (for a 2D image, \(\text{zbegin}=0\) and \(\text{zend}=1\)).
- `format`: A `TypeDesc` describing the type of data.
- `data`: Pointer to the pixel data.
- `xstride/ystride/zstride`: The distance in bytes between successive pixels, scanlines, and image planes (or AutoStride).

```
virtual bool write_image (TypeDesc format, const void *data, stride_t xstride = AutoStride, stride_t ystride = AutoStride, stride_t zstride = AutoStride, ProgressCallback progress_callback = nullptr, void *progress_callback_data = nullptr)
```

Write the entire image of \(\text{spec.width} \times \text{spec.height} \times \text{spec.depth}\) pixels, from a buffer with the given strides and in the desired format.

Depending on the spec, this will write either all tiles or all scanlines. Assume that data points to a layout in row-major order.

Because this may be an expensive operation, a progress callback may be passed. Periodically, it will be called as follows:

```
progress_callback (progress_callback_data, float done);
```

where done gives the portion of the image (between 0.0 and 1.0) that has been written thus far.

Return true upon success, or false upon failure.

Parameters

- `format`: A `TypeDesc` describing the type of data.
- `data`: Pointer to the pixel data.
- `xstride/ystride/zstride`: The distance in bytes between successive pixels, scanlines, and image planes (or AutoStride).
- `progress_callback/progress_callback_data`: Optional progress callback.
virtual bool write_deep_scanlines (int ybegin, int yend, int z, const DeepData &deepdata)
Write deep scanlines containing pixels (*,y,z), for all y in the range [ybegin,yend), to a deep file. This will fail if it is not a deep file.

Return true upon success, or false upon failure.

Parameters
- ybegin/yend: The y range of the scanlines being passed.
- z: The z coordinate of the scanline.
- deepdata: A DeepData object with the data for these scanlines.

virtual bool write_deep_tiles (int xbegin, int xend, int ybegin, int yend, int zbegin, int zend, const DeepData &deepdata)
Write the block of deep tiles that include all pixels in the range

\([xbegin, xend) \times [ybegin, yend) \times [zbegin, zend]\)

The begin/end pairs must correctly delineate tile boundaries, with the exception that it may also be the end of the image data if the image resolution is not a whole multiple of the tile size.

Return true upon success, or false upon failure.

Note The call will fail if the image is not tiled, or if the pixel ranges do not fall along tile (or image) boundaries, or if it is not a valid tile range.

Parameters
- xbegin/xend: The x range of the pixels covered by the group of tiles passed.
- ybegin/yend: The y range of the pixels covered by the tiles.
- zbegin/zend: The z range of the pixels covered by the tiles (for a 2D image, zbegin=0 and zend=1).
- deepdata: A DeepData object with the data for the tiles.

virtual bool write_deep_image (const DeepData &deepdata)
Write the entire deep image described by deepdata. Depending on the spec, this will write either all tiles or all scanlines.

Return true upon success, or false upon failure.

Parameters
- deepdata: A DeepData object with the data for the image.

inline virtual bool set_thumbnail (const ImageBuf &thumb)
Specify a reduced-resolution (“thumbnail”) version of the image. Note that many image formats may require the thumbnail to be specified prior to writing the pixels.

Return true upon success, false if it was not possible to write the thumbnail, or if this file format (or writer) does not support thumbnails.

Note This method was added to OpenImageIO 2.3.

Parameters
• thumb: A reference to an ImageBuf containing the thumbnail image.

**IOPROxy aids for ImagInput implementations.**

This set of utility functions are not meant to be called by user code. They are protected methods of ImageInput, and are used internally by the ImageInput implementation to help it properly implement support of IOPROxy.

**Public Types**

```cpp
using unique_ptr = std::unique_ptr<ImageOutput>

typedef ImageOutput *(*Creator)()
```

Call signature of a function that creates and returns an ImageOutput*.

**Public Functions**

```cpp
virtual const char *format_name (void) const = 0
```

Return the name of the format implemented by this class.

```cpp
virtual bool copy_image (ImageInput *in)
```

Read the pixels of the current subimage of in, and write it as the next subimage of *this, in a way that is efficient and does not alter pixel values, if at all possible. Both in and this must be a properly-opened ImageInput and ImageOutput, respectively, and their current images must match in size and number of channels.

If a particular ImageOutput implementation does not supply a copy_image method, it will inherit the default implementation, which is to simply read scanlines or tiles from in and write them to *this. However, some file format implementations may have a special technique for directly copying raw pixel data from the input to the output, when both are the same file type and the same pixel data type. This can be more efficient than in->read_image() followed by out->write_image(), and avoids any unintended pixel alterations, especially for formats that use lossy compression.

Note: this method is NOT thread-safe, since it depends on persistent state in the ImageInput.

Return true upon success, or false upon failure.

Parameters

• in: A pointer to the open ImageInput to read from.

```cpp
virtual bool set_ioproxy (Filesystem::IOProxy *ioproxy)
```

Set an IOPROxy for this writer. This must be called prior to open(), and only for writers that support them (supports("ioproxy")). The caller retains ownership of the proxy.

Return true for success, false for failure.

```cpp
bool has_error () const
```

Is there a pending error message waiting to be retrieved, that resulted from an ImageOutput API call made by the this thread?

Note that any error() calls issued are thread-specific, and the geterror()/has_error() are expected to be called by the same thread that called whichever API function encountered an error.
std::string geterror (bool clear = true) const
Return the text of all pending error messages issued against this ImageOutput by the calling thread, and clear the pending error message unless clear is false. If no error message is pending, it will return an empty string.

Note that any error() calls issued are thread-specific, and the geterror()/has_error() are expected to be called by the same thread that called whichever API function encountered an error.

template<typename ... Args>
inline void error (const char *fmt, const Args&... args) const
Error reporting for the plugin implementation: call this with Strutil::format-like arguments. It is not necessary to have the error message contain a trailing newline. Use with caution! Some day this will change to be fmt-like rather than printf-like.

template<typename ... Args>
inline void errorf (const char *fmt, const Args&... args) const
Error reporting for the plugin implementation: call this with printf-like arguments. It is not necessary to have the error message contain a trailing newline.

template<typename ... Args>
inline void errorfmt (const char *fmt, const Args&... args) const
Error reporting for the plugin implementation: call this with std::format-like arguments. It is not necessary to have the error message contain a trailing newline.

void threads (int n)
Set the threading policy for this ImageOutput, controlling the maximum amount of parallelizing thread “fan-out” that might occur during large write operations. The default of 0 means that the global attribute("threads") value should be used (which itself defaults to using as many threads as cores; see Section Global Attributes_).

The main reason to change this value is to set it to 1 to indicate that the calling thread should do all the work rather than spawning new threads. That is probably the desired behavior in situations where the calling application has already spawned multiple worker threads.

int threads () const
Retrieve the current thread-spawning policy.

See threads(int)
4.1 Image Input Made Simple

Here is the simplest sequence required to open an image file, find out its resolution, and read the pixels (converting them into 8-bit values in memory, even if that’s not the way they’re stored in the file):

C++

```cpp
#include <OpenImageIO/imageio.h>
using namespace OIIO;
...

auto inp = ImageInput::open(filename);
if (!inp)
    return;
const ImageSpec &spec = inp->spec();
int xres = spec.width;
int yres = spec.height;
int channels = spec.nchannels;
std::vector<unsigned char> pixels(xres * yres * channels);
inp->read_image(TypeDesc::UINT8, &pixels[0]);
inp->close();
```

Python

```python
import OpenImageIO as oiio
import numpy as np

inp = ImageInput.open(filename)
if inp is None:
    return
spec = inp.spec()
xres = spec.width
yres = spec.height
channels = spec.nchannels
pixels = inp.read_image("uint8")
inp.close()
```

Here is a breakdown of what work this code is doing:

- Search for an ImageIO plugin that is capable of reading the file (foo.jpg), first by trying to deduce the correct plugin from the file extension, but if that fails, by opening every ImageIO plugin it can find until one will open the file without error. When it finds the right plugin, it creates a subclass instance of ImageInput that reads the right kind of file format, and tries to fully open the file. The open() method returns a std::unique_ptr<ImageInput> that will be automatically freed when it exits scope.
C++

```cpp
auto inp = ImageInput::open(filename);
```

Python

```python
inp = ImageInput.open(filename)
```

- The specification, accessible as `inp->spec()`, contains vital information such as the dimensions of the image, number of color channels, and data type of the pixel values. This is enough to allow us to allocate enough space for the image in C++ (for Python, this is unnecessary, since `read_image()` will return a NumPy array to us).

  C++

```cpp
const ImageSpec &spec = inp->spec();
int xres = spec.width;
int yres = spec.height;
int channels = spec.nchannels;
std::vector<unsigned char> pixels (xres*yres*channels);
```

Python

```python
spec = inp.spec()
xres = spec.width
yres = spec.height
channels = spec.nchannels
```

Note that in this example, we don’t care what data format is used for the pixel data in the file — we will request unsigned 8 bit integers and rely on OpenImageIO’s ability to convert to our requested format from the native data format of the file.

- Read the entire image, hiding all details of the encoding of image data in the file, whether the file is scanline- or tile-based, or what is the native format of the data in the file (in this case, we request that it be automatically converted to unsigned 8-bit integers).

  C++

```cpp
inp->read_image(TypeDesc::UINT8, &pixels[0]);
```

Python

```python
pixels = inp->read_image("uint8")
# Note: pixels now contains a NumPy array of the image data.
```

- Close the file.

  C++

```cpp
inp->close();
```

Python

```python
inp.close()
```

- When `inp` exits its scope, the ImageInput will automatically be destroyed and any resources used by the plugin will be released.
4.2 Advanced Image Input

Let’s walk through some of the most common things you might want to do, but that are more complex than the simple example above.

4.2.1 Reading individual scanlines and tiles

The simple example of Section Image Input Made Simple read an entire image with one call. But sometimes you want to read a large image a little at a time and do not wish to retain the entire image in memory as you process it. OpenImageIO allows you to read images one scanline at a time or one tile at a time.

Examining the ImageSpec reveals whether the file is scanline or tile-oriented: a scanline image will have spec.tile_width and spec.tile_height set to 0, whereas a tiled images will have nonzero values for the tile dimensions.

Reading scanlines

Individual scanlines may be read using the read_scanline() API call:

C++

```cpp
auto inp = ImageInput::open (filename);
const ImageSpec &spec = inp->spec();
if (spec.tile_width == 0) {
  std::vector<unsigned char> scanline (spec.width*spec.channels);
  for (int y = 0; y < yres; ++y) {
    inp->read_scanline (y, 0, TypeDesc::UINT8, &scanline[0]);
    // ... process data in scanline[0..width*channels-1] ...
  }
} else {
  //... handle tiles, or reject the file ...
}
inp->close ();
```

Python

```python
inp = ImageInput.open (filename)
spec = inp.spec()
if spec.tile_width == 0 :
  for y in range(yres) :
    scanline = inp.read_scanline (y, 0, "uint8")
    # ... process data in scanline[0..width*channels-1] ...
else :
  # ... handle tiles, or reject the file ...
inp.close ()
```

The first two arguments to read_scanline() specify which scanline is being read by its vertical (y) scanline number (beginning with 0) and, for volume images, its slice (z) number (the slice number should be 0 for 2D non-volume images). This is followed by a TypeDesc describing the data type of the pixel buffer you are supplying, and a pointer to the pixel buffer itself. Additional optional arguments describe the data stride, which can be ignored for contiguous data (use of strides is explained in Section Data Strides).

Nearly all ImageInput implementations will be most efficient reading scanlines in strict order (starting with scanline 0, then 1, up to yres-1, without skipping any). An ImageInput is required to accept read_scanline() requests
in arbitrary order, but depending on the file format and reader implementation, out-of-order scanline reads may be inefficient.

There is also a `read_scanlines()` function that operates similarly, except that it takes a `ybegin` and `yend` that specify a range, reading all scanlines `ybegin <= y < yend`. For most image format readers, this is implemented as a loop over individual scanlines, but some image format readers may be able to read a contiguous block of scanlines more efficiently than reading each one individually.

The full descriptions of the `read_scanline()` and `read_scanlines()` functions may be found in Section ImageInput Class Reference.

Reading tiles

Once you open() an image file, you can find out if it is a tiled image (and the tile size) by examining the ImageSpec’s `tile_width`, `tile_height`, and `tile_depth` fields. If they are zero, it’s a scanline image and you should read pixels using `read_scanline()`, not `read_tile()`.

C++

```cpp
auto inp = ImageInput::open(filename);
const ImageSpec &spec = inp->spec();
if (spec.tile_width == 0) {
    // ... read scanline by scanline ...
} else {
    // Tiles
    int tilesize = spec.tile_width * spec.tile_height;
    std::vector<unsigned char> tile(tilesize * spec.channels);
    for (int y = 0; y < yres; y += spec.tile_height) {
        for (int x = 0; x < xres; x += spec.tile_width) {
            inp->read_tile(x, y, 0, TypeDesc::UINT8, &tile[0]);
            // ... process the pixels in tile[] ...
        }
    }
    inp->close();
}
```

Python

```python
inp = ImageInput.open(filename)
spec = inp.spec()
if spec.tile_width == 0 :
    # ... read scanline by scanline ...
else :
    # Tiles
tilesize = spec.tile_width * spec.tile_height;
    for y in range(0, yres, spec.tile_height) :
        for x in range(0, xres, spec.tile_width) :
            tile = inp.read_tile (x, y, 0, "uint8")
            # ... process the pixels in tile[] ...
    inp.close();
```

The first three arguments to `read_tile()` specify which tile is being read by the pixel coordinates of any pixel contained in the tile: `x` (column), `y` (scanline), and `z` (slice, which should always be 0 for 2D non-volume images). This is followed by a `TypeDesc` describing the data format of the pixel buffer you are supplying, and a pointer to the pixel buffer. Pixel data will be written to your buffer in order of increasing slice, increasing scanline within each slice, and increasing column within each scanline. Additional optional arguments describe the data stride, which can be ignored for contiguous data (use of strides is explained in Section Data Strides).
All ImageInput implementations are required to support reading tiles in arbitrary order (i.e., not in strict order of increasing \( y \) rows, and within each row, increasing \( x \) column, without missing any tiles).

The full description of the `read_tile()` function may be found in Section *ImageInput Class Reference*.

### 4.2.2 Converting formats

The code examples of the previous sections all assumed that your internal pixel data is stored as unsigned 8-bit integers (i.e., 0-255 range). But OpenImageIO is significantly more flexible.

You may request that the pixels be stored in any of several formats. This is done merely by passing the `read` function the data type of your pixel buffer, as one of the enumerated type `TypeDesc`.

It is not required that the pixel data buffer passed to `read_image()`, `read_scanline()`, or `read_tile()` actually be in the same data format as the data in the file being read. OpenImageIO will automatically convert from native data type of the file to the internal data format of your choice. For example, the following code will open a TIFF and read pixels into your internal buffer represented as `float` values. This will work regardless of whether the TIFF file itself is using 8-bit, 16-bit, or float values.

**C++**

```cpp
std::unique_ptr<ImageInput> inp = ImageInput::open("myfile.tif");
const ImageSpec &spec = inp->spec();
int numpixels = spec.image_pixels();
float pixels = new float [numpixels * channels];
inp->read_image (TypeDesc::FLOAT, pixels);
```

**Python**

```python
inp = ImageInput.open("myfile.tif")
pixels = inp.read_image("float")
```

Note that `read_scanline()` and `read_tile()` have a parameter that works in a corresponding manner.

You can, of course, find out the native type of the file simply by examining `spec.format`. If you wish, you may then allocate a buffer big enough for an image of that type and request the native type when reading, therefore eliminating any translation among types and seeing the actual numerical values in the file.

### 4.2.3 Data Strides

In the preceding examples, we have assumed that the buffer passed to the `read` functions (i.e., the place where you want your pixels to be stored) is *contiguous*, that is:

- each pixel in memory consists of a number of data values equal to the number of channels in the file;
- successive column pixels within a row directly follow each other in memory, with the first channel of pixel \( x \) immediately following last channel of pixel \( x-1 \) of the same row;
- for whole images or tiles, the data for each row immediately follows the previous one in memory (the first pixel of row \( y \) immediately follows the last column of row \( y-1 \));
- for 3D volumetric images, the first pixel of slice \( z \) immediately follows the last pixel of of slice \( z-1 \).

Please note that this implies that `read_tile()` will write pixel data into your buffer so that it is contiguous in the shape of a single tile, not just an offset into a whole image worth of pixels.
The `read_scanline()` function takes an optional `xstride` argument, and the `read_image()` and `read_tile()` functions take optional `xstride`, `ystride`, and `zstride` values that describe the distance, in bytes, between successive pixel columns, rows, and slices, respectively, of your pixel buffer. For any of these values that are not supplied, or are given as the special constant `AutoStride`, contiguity will be assumed.

By passing different stride values, you can achieve some surprisingly flexible functionality. A few representative examples follow:

- Flip an image vertically upon reading, by using negative `y` stride:

  ```c
  unsigned char pixels[spec.width * spec.height * spec.nchannels];
  int scanlinesize = spec.width * spec.nchannels * sizeof(pixels[0]);
  ...
  in->read_image (TypeDesc::UINT8,
                  (char *)pixels+(yres-1)*scanlinesize,  // offset to last
                  AutoStride,   // default x stride
                  -scanlinesize, // special y stride
                  AutoStride);  // default z stride
  ```

- Read a tile into its spot in a buffer whose layout matches a whole image of pixel data, rather than having a one-tile-only memory layout:

  ```c
  int pixelsize = spec.nchannels * sizeof(pixels[0]);
  int scanlinesize = spec.width * pixelsize;
  ...
  in->read_tile (x, y, 0, TypeDesc::UINT8,
                 (char *)pixels + y*scanlinesize + x*pixelsize,
                 pixelsize,
                 scanlinesize);
  ```

Please consult Section *ImageInput Class Reference* for detailed descriptions of the stride parameters to each `read` function.

### 4.2.4 Reading channels to separate buffers

While specifying data strides allows writing entire pixels to buffers with arbitrary layouts, it is not possible to separate those pixels into multiple buffers (i.e. to write image data to a separate or planar memory layout: RRRRGGGGBBBB instead of the interleaved RGBRGBRGRGB).

A workaround for this is to call `read_scanlines`, `read_tiles` or `read_image` repeatedly with arguments `chbegin` and `chend` of `0 <= chbegin < spec.nchannels` and `chend == chbegin + 1`:

**C++**

```c
// one buffer for all three channels
unsigned char pixels[spec.width * spec.height * spec.nchannels];

for (int channel = 0; channel < spec.nchannels; ++channel) {
    file->read_image(
        // reading one channel at a time
        channel, channel + 1,
        TypeDesc::UINT8,
        // writing the data to offsets spaced `spec.width * spec.height`
        // apart
        &pixels[spec.width * spec.height * channel]);
}
```

**Python**
pixels = numpy.zeros((spec.nchannels, spec.height, spec.width), "uint8")
for channel in range(spec.nchannels):
    pixels[channel] = file.read_image(channel, channel + 1, "uint8")

For many formats, this is nearly as fast as reading the image with interleaved pixel data if the format stores the pixels in an interleaved layout and even slightly faster if the pixels are stored in separate planes in the file.

4.2.5 Reading metadata

The ImageSpec that is filled in by `ImageInput::open()` specifies all the common properties that describe an image: data format, dimensions, number of channels, tiling. However, there may be a variety of additional metadata that are present in the image file and could be queried by your application.

The remainder of this section explains how to query additional metadata in the ImageSpec. It is up to the ImageInput to read these from the file, if indeed the file format is able to carry additional data. Individual ImageInput implementations should document which metadata they read.

**Channel names**

In addition to specifying the number of color channels, the ImageSpec also stores the names of those channels in its `channelnames` field, which is a `std::vector<std::string>` in C++, or a tuple of strings in Python. Its length should always be equal to the number of channels (it’s the responsibility of the ImageInput to ensure this).

Only a few file formats (and thus ImageInput implementations) have a way of specifying custom channel names, so most of the time you will see that the channel names follow the default convention of being named "R", "G", "B", and "A", for red, green, blue, and alpha, respectively.

Here is example code that prints the names of the channels in an image:

C++

```cpp
auto inp = ImageInput::open (filename);
const ImageSpec &spec = inp->spec();
for (int i = 0; i < spec.nchannels; ++i)
    std::cout << "Channel " << i << " is "
                << spec.channelnames[i] << "\n";
```

Python

```python
inp = ImageInput.open (filename)
spec = inp.spec()
for i in range(spec.nchannels):
    print("Channel", i, "is", spec.channelnames[i])
```

**Specially-designated channels**

The ImageSpec contains two fields, `alpha_channel` and `z_channel`, which designate which channel numbers represent alpha and z depth, if any. If either is set to -1, it indicates that it is not known which channel is used for that data.

If you are doing something special with alpha or depth, it is probably safer to respect the `alpha_channel` and `z_channel` designations (if not set to -1) rather than merely assuming that, for example, channel 3 is always the alpha channel.
Arbitrary metadata

All other metadata found in the file will be stored in the ImageSpec’s `extra_attribs` field, which is a Param-ValueList, which is itself essentially a vector of ParamValue instances. Each ParamValue stores one meta-datum consisting of a name, type (specified by a `TypeDesc`), number of values, and data pointer.

If you know the name and type of a specific piece of metadata you want to use, you can retrieve it using the `ImageSpec::getattribute()` method. In C++, this copies the value into your variable and returns true if the attribute was found, or false if it was not. In Python, `getattribute()` simply returns the value of the attribute itself, or None if no match was found.

```cpp
auto in; = ImageInput::open(filename);
const ImageSpec &spec = inp->spec();
...
int orientation = 0;
bool ok = spec.getattribute("Orientation", TypeInt, &orientation);
if (!ok) {
    std::cout << "No integer orientation in the file\n";
}
```

```python
inp = ImageInput.open(filename)
spec = inp.spec()
orientation = spec.getattribute("Orientation")
if orientation.is None:
    print("No integer orientation in the file")
```

By convention, ImageInput plugins will save all integer metadata as 32-bit integers (`TypeDesc::INT` or `TypeDesc::UINT`), even if the file format dictates that a particular item is stored in the file as a 8- or 16-bit integer. This is just to keep client applications from having to deal with all the types. Since there is relatively little metadata compared to pixel data, there’s no real memory waste of promoting all integer types to int32 metadata. Floating-point metadata and string metadata may also exist, of course.

For certain common types, there is an even simpler method for retrieving the metadata:

```cpp
int i = spec.get_int_attribute ("Orientation", 0);
float f = spec.get_float_attribute ("PixelAspectRatio", 1.0f);
std::string s = spec.get_string_attribute ("ImageDescription", "");
```

```python
i = spec.get_int_attribute ("Orientation", 0)
f = spec.get_float_attribute ("PixelAspectRatio", 1.0)
s = spec.get_string_attribute ("ImageDescription", ")
```

This method simply returns the value. The second argument is the default value to use if the attribute named is not found. These versions will do automatic type conversion as well — for example, if you ask for a float and the attribute is really an int, it will return the proper float for it; or if the attribute is a UINT16 and you call `get_int_attribute()`, it will succeed, promoting to an int.

And finally, another convenience method lets you treat the spec itself as an associative array or dictionary:

```cpp
```
// spec["key"].get<TYPE> tries to retrieve that type, or a default
// value (generally 0 or empty string) if not found.
int i = spec["Orientation"].get<int>();
float f = spec["PixelAspectRatio"].get<float>();
std::string s = spec["ImageDescription"].get<std::string>();

// An optional argument to get() lets you specify a different default
// value to return if the attribute is not found.
float f = spec["PixelAspectRatio"].get<float>(1.0f);

Python

# spec["key"] returns the attribute if present, or raises KeyError
# if not found.
i = spec["Orientation"]
f = spec["PixelAspectRatio"]
s = spec["ImageDescription"]

# spec.get("key", default=None) returns the attribute if present,
# or the default value if not found.
val = spec.get("Orientation", 1)

Note that when retrieving with this “dictionary” syntax, the C++ and Python behaviors are different: C++ requires a
get<TYPE>() call to retrieve the full value, and a missing key will return a default value. Python will return the
value directly (no get() needed), and a missing key will raise a KeyError exception.

It is also possible to step through all the metadata, item by item. This can be accomplished using the technique of the
following example:

C++

for (const auto &p : spec.extra_attribs) {
    printf("%s: %s
", p.name().c_str(), p.get_string().c_str());
}

Python

for p in spec.attribs:
    printf(" %", p.name, ":", p.value)

Each individual ImageInput implementation should document the names, types, and meanings of all metadata at-
tributes that they understand.

Color space hints

We certainly hope that you are using only modern file formats that support high precision and extended range pixels
(such as OpenEXR) and keeping all your images in a linear color space. But you may have to work with file formats
that dictate the use of nonlinear color values. This is prevalent in formats that store pixels only as 8-bit values, since
256 values are not enough to linearly represent colors without banding artifacts in the dim values.

The ImageSpec::extra_attribs field may store metadata that reveals the color space the image file in the
"oiio:ColorSpace" attribute (see Section Color information for explanations of particular values).

The ImageInput sets the "oiio:ColorSpace" metadata in a purely advisory capacity — the read will not con-
vert pixel values among color spaces. Many image file formats only support nonlinear color spaces (for example,
JPEG/JFIF dictates use of sRGB). So your application should intelligently deal with gamma-corrected and sRGB
input, at the very least.
The color space hints only describe color channels. You should assume that alpha or depth (z) channels (designated by the alpha_channel and z_channel fields, respectively) always represent linear values and should never be transformed by your application.

### 4.2.6 Multi-image files and MIP-maps

Some image file formats support multiple discrete subimages to be stored in one file, and/or multiple resolutions for each image to form a MIP-map. When you open an ImageInput, it will by default point to the first (i.e., number 0) subimage in the file, and the highest resolution (level 0) MIP-map level. You can switch to viewing another subimage or MIP-map level using the seek_subimage() function:

```cpp
auto inp = ImageInput::open (filename);
int subimage = 1;
int miplevel = 0;
if (inp->seek_subimage (subimage, miplevel)) {
    // process the subimage/miplevel ...
} else {
    // no such subimage/miplevel ...
}
```

```python
inp = ImageInput.open(filename)
subimage = 1
miplevel = 0
if inp.seek_subimage (subimage, miplevel) :
    # ... process the subimage/miplevel ...
else :
    # ... no such subimage/miplevel ...
```

The seek_subimage() function takes three arguments: the index of the subimage to switch to (starting with 0), the MIPMap level (starting with 0 for the highest-resolution level), and a reference to an ImageSpec, into which will be stored the spec of the new subimage/mipmap. The seek_subimage() function returns true upon success, and false if no such subimage or MIP level existed. It is legal to visit subimages and MIP levels out of order; the ImageInput is responsible for making it work properly. It is also possible to find out which subimage and MIP level is currently being viewed, using the current_subimage() and current_miplevel() functions, which return the index of the current subimage and MIP levels, respectively.

Below is pseudocode for reading all the levels of a MIP-map (a multi-resolution image used for texture mapping) that shows how to read multi-image files:

```cpp
auto inp = ImageInput::open (filename);
int num_miplevels = 0;
while (inp->seek_subimage (0, num_miplevels, spec)) {
    const ImageSpec &spec = inp->spec();
    int npixels = spec.width * spec.height;
    int nchannels = spec.nchannels;
    unsigned char *pixels = new unsigned char [npixels * nchannels];
    inp->read_image(TypeDesc::UINT8, pixels);
    // ... do whatever you want with this level, in pixels ...
    delete [] pixels;
}
```

(continues on next page)
++num_miplevels;
}
// Note: we break out of the while loop when seek_subimage fails
// to find a next MIP level.
inp->close();

Python

inp = ImageInput::open (filename)
num_miplevels = 0
while inp.seek_subimage(0, num_miplevels, spec) :
    spec = inp.spec()
    npixels = spec.width * spec.height
    nchannels = spec.nchannels
    pixels = inp.read_image ("uint8")

    # ... do whatever you want with this level, in pixels ...
    num_miplevels += 1
}
# Note: we break out of the while loop when seek_subimage fails
# to find a next MIP level.
inp.close()

In this example, we have used read_image(), but of course read_scanline() and read_tile() work as you would expect, on the current subimage and MIP level.

### 4.2.7 Per-channel formats

Some image formats allow separate per-channel data formats (for example, half data for colors and float data for depth). If you want to read the pixels in their true native per-channel formats, the following steps are necessary:

1. Check the ImageSpec's channelformats vector. If non-empty, the channels in the file do not all have the same format.

2. When calling read_scanline, read_scanlines, read_tile, read_tiles, or read_image, pass a format of TypeUnknown to indicate that you would like the raw data in native per-channel format of the file written to your data buffer.

For example, the following code fragment will read a 5-channel image to an OpenEXR file, consisting of R/G/B/A channels in half and a Z channel in float:

```cpp
auto inp = ImageInput::open (filename);
const ImageSpec &spec = inp->spec();

// Allocate enough space
unsigned char *pixels = new unsigned char [spec.image_bytes(true)];

inp->read_image(TypeDesc::UNKNOWN, /* use native channel formats */
    pixels); /* data buffer */

if (spec.channelformats.size() > 0) {
    ... the buffer contains packed data in the native
    per-channel formats ...
```

(continues on next page)
4.2.8 Reading “deep” data

Some image file formats (OpenEXR only, at this time) support the concept of “deep” pixels – those containing multiple samples per pixel (and a potentially differing number of them in each pixel). You can tell an image is “deep” from its ImageSpec: the deep field will be true.

Deep files cannot be read with the usual read_scanline(), read_scanlines(), read_tile(), read_tiles(), read_image() functions, due to the nature of their variable number of samples per pixel. Instead, ImageInput has three special member functions used only for reading deep data:

C++

```cpp
bool read_native_deep_scanlines (int subimage, int mipmaplevel,
                                 int ybegin, int yend, int z,
                                 int chbegin, int chend,
                                 DeepData &deepdata);
bool read_native_deep_tiles (int subimage, int mipmaplevel,
                             int xbegin, int xend, int ybegin int yend,
                             int zbegin, int zend,
                             int chbegin, int chend, DeepData &deepdata);
bool read_native_deep_image (int subimage, int mipmaplevel,
                             DeepData &deepdata);
```

Python

```python
ImageInput.read_native_deep_scanlines (subimage, mipmaplevel,
                                        ybegin, yend, z, chbegin, chend)
ImageInput.read_native_deep_tiles (subimage, mipmaplevel, xbegin, xend,
                                    ybegin yend, zbegin, zend, chbegin, chend)
ImageInput.read_native_deep_image (subimage, mipmaplevel)
```

It is only possible to read “native” data types from deep files; that is, there is no automatic translation into arbitrary data types as there is for ordinary images. All three of these functions store the resulting deep data in a special DeepData structure, described in detail in Section Reading “deep” data.

Here is an example of using these methods to read a deep image from a file and print all its values:

C++

```cpp
auto inp = ImageInput::open (filename);
if (! inp)
    return;
const ImageSpec &spec = inp.spec();
if (spec.deep) {
    DeepData deepdata;
    inp.read_native_deep_image (0, 0, deepdata);
    int p = 0; // absolute pixel number
    for (int y = 0; y < spec.height; ++y) {
        ...
```
for (int x = 0; x < spec.width; ++x, ++p) {
    std::cout << "Pixel " << x << "," << y << ":\n";
    if (deepdata.samples(p) == 0)
        std::cout << " no samples\n";
    else
        for (int c = 0; c < spec.nchannels; ++c) {
            TypeDesc type = deepdata.channeltype(c);
            std::cout << " " << spec.channelnames[c] << ":";
            void *ptr = deepdata.pointers[p*spec.nchannels+c]
            for (int s = 0; s < deepdata.samples(p); ++s) {
                if (type.basetype == TypeDesc::FLOAT ||
                    type.basetype == TypeDesc::HALF)
                    std::cout << deepdata.deep_value(p, c, s) << ' ';
                else if (type.basetype == TypeDesc::UINT32)
                    std::cout << deepdata.deep_value_uint(p, c, s) << ' ';
            }
            std::cout << "\n";
        }
}
inp.close();

Python

inp = ImageInput::open (filename)
if inp is None :
    return
spec = inp.spec()
if spec.deep :
    deepdata = inp.read_native_deep_image (0, 0)
    p = 0  # absolute pixel number
    for y in range(spec.height) :
        for x in range(spec.width) :
            print ("Pixel", x, ",", y, ":")
            if deepdata.samples(p) == 0 :
                print(" no samples")
            else :
                for c in range(spec.nchannels) :
                    type = deepdata.channeltype(c)
                    print (" ", spec.channelnames[c], ":")
                    for s in range(deepdata.samples(p) :
                        print (deepdata.deep_value(p, c, s), end="")
                    print("")
inp.close()
## 4.2.9 Opening for input with configuration settings/hints

Sometimes you will want to give the image file reader hints or requests for how to open the file or present its data, hints which must be made in time for the initial opening of the file. For example, in specific circumstances, you might want to request that an image with unassociated alpha *not* be automatically converted to associated alpha by multiplying the color channel values by the alpha (as would be customary by OIIO convention).

This is accomplished by using the `ImageInput::open()` or `ImageInput::create()` method varieties that take an additional `config` parameter. This is an `ImageSpec` object whose metadata contains the configuration hints.

Configuration hints are optional and advisory only – meaning that not all image file readers will respect them (and indeed, many of them are only sensible for certain file formats).

Some common input configuration hints that tend to be respected across many readers (but not all, check Chapter **Bundled ImageIO Plugins** to see what hints are supported by each reader) are:

<table>
<thead>
<tr>
<th>Input Attribute</th>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>oiio:ioproxy</code></td>
<td>ptr</td>
<td>Pointer to a <code>Filesystem::IOProxy</code> that will handle the I/O, for example by reading from memory rather than the file system.</td>
</tr>
<tr>
<td><code>oiio:RawColor</code></td>
<td>int</td>
<td>If nonzero, reading images with non-RGB color models (such as YCbCr) will return unaltered pixel values (versus the default OIIO behavior of automatically converting to RGB).</td>
</tr>
<tr>
<td><code>oiio:UnassociatedAlpha</code></td>
<td>int</td>
<td>If nonzero, and the file contains unassociated alpha, this will cause the reader to leave alpha unassociated (versus the default of premultiplying color channels by alpha if the alpha channel is unassociated).</td>
</tr>
</tbody>
</table>

Examples:

Below is an example where we wish to read in an RGBA image in a format that tends to store it as unassociated alpha, but we DON’T want it to automatically be converted to associated alpha.

**C++**

```cpp
// Set up an ImageSpec that holds the configuration hints.
ImageSpec config;
config["oiio:UnassociatedAlpha"] = 1;

// Open the file, passing in the config.
auto inp = ImageInput::open (filename, config);
const ImageSpec &spec = inp->spec();
std::vector<unsigned char> pixels (spec.image_pixels() * spec.nchannels);
inp->read_image (TypeDesc::UINT8, pixels.data());
if (spec.get_int_attribute("oiio:UnassociatedAlpha"))
    printf("pixels holds unassociated alpha\n");
else
    printf("pixels holds associated alpha\n");
```

**Python**

```python
# Set up an ImageSpec that holds the configuration hints.
config = ImageSpec()
config["oiio:UnassociatedAlpha"] = 1

# Open the file, passing in the config.
inp = ImageInput.open (filename, config)
```
4.2.10 Custom I/O proxies (and reading the file from a memory buffer)

Some file format readers allow you to supply a custom I/O proxy object that can allow bypassing the usual file I/O with custom behavior, including the ability to read the file form an in-memory buffer rather than reading from disk.

Only some input format readers support this feature. To find out if a particular file format supports this feature, you can create an ImageInput of the right type, and check if it supports the feature name "ioproxy":

```cpp
auto in = ImageInput::create(filename);
if (! in || ! in->supports ("ioproxy")) {
    return;
}
```

ImageInput readers that support "ioproxy" will respond to a special attribute, "oiio:ioproxy", which passes a pointer to a Filesystem::IOProxy* (see OpenImageIO's filesystem.h for this type and its subclasses). IOProxy is an abstract type, and concrete subclasses include IOFile (which wraps I/O to an open FILE*) and IOMemReader (which reads input from a block of memory).

Here is an example of using a proxy that reads the “file” from a memory buffer:

```cpp
const void* buf = ...;  // pointer to memory block
size_t size = ...;      // length of memory block
Filesystem::IOMemReader memreader (buf, size);  // I/O proxy object
auto in = ImageInput::open ("in.exr", nullptr, &memreader);
in->read_image (...);
in->close();
// That will have read the "file" from the memory buffer
```

4.2.11 Custom search paths for plugins

Please see Section Global Attributes for discussion about setting the plugin search path via the attribute() function. For example:

C++

```cpp
std::string mysearch = "/usr/myapp/lib:/home/jane/plugins";
IOIO::attribute ("plugin_searchpath", mysearch);
auto inp = ImageInput::open (filename);
// ...
```

Python

```python
mysearch = "/usr/myapp/lib:/home/jane/plugins"
OpenImageIO.attribute ("plugin_searchpath", mysearch)
inp = ImageInput.open(filename)
// ...
```
4.2.12 Error checking

Nearly every ImageInput API function returns a bool indicating whether the operation succeeded (true) or failed (false). In the case of a failure, the ImageInput will have saved an error message describing in more detail what went wrong, and the latest error message is accessible using the ImageInput method geterror(), which returns the message as a std::string.

The exceptions to this rule are static methods such as the static ImageInput::open() and ImageInput::create(), which return an empty pointer if it could not create an appropriate ImageInput (and open it, in the case of open()). In such a case, since no ImageInput is returned for which you can call its geterror() function, there exists a global geterror() function (in the OpenImageIO namespace) that retrieves the latest error message resulting from a call to static open() or create().

Here is another version of the simple image reading code from Section Image Input Made Simple, but this time it is fully elaborated with error checking and reporting:

C++

```cpp
#include <OpenImageIO/imageio.h>
using namespace OIIO;
...

const char *filename = "foo.jpg";
auto inp = ImageInput::open(filename);
if (! inp) {
    std::cerr << "Could not open " << filename
              << ", error = " << OIIO::geterror() << "\n";
    return;
}
const ImageSpec &spec = inp->spec();
int xres = spec.width;
int yres = spec.height;
int channels = spec.nchannels;
std::vector<unsigned char> pixels(xres * yres * channels);
if (! inp->read_image (TypeDesc::UINT8, &pixels[0])) {
    std::cerr << "Could not read pixels from " << filename
              << ", error = " << inp->geterror() << "\n";
    return;
}
if (! inp->close ()) {
    std::cerr << "Error closing " << filename
              << ", error = " << inp->geterror() << "\n";
    return;
}
```

Python

```python
import OpenImageIO as oiio
import numpy as np
filename = "foo.jpg"
inp = ImageInput::open(filename)
if inp is None:
    print("Could not open", filename, ", error =", oiio.geterror())
    return
spec = inp.spec()
(continues on next page)```
xres = spec.width
yres = spec.height
channels = spec.nchannels

pixels = inp.read_image("uint8")
if pixels is None :
    print("Could not read pixels from", filename, ", error =", inp.geterror())
    return
if not inp.close() :
    print("Error closing", filename, ", error =", inp.geterror())
    return

4.3 ImageInput Class Reference

class OIIO::ImageInput

ImageInput abstracts the reading of an image file in a file format-agnostic manner.

Creating an ImageInput

static unique_ptr open (const std::string &filename, const ImageSpec *config = nullptr, Filesys-

tem::IOProxy *ioproxy = nullptr)

Create an ImageInput subclass instance that is able to read the given file and open it, returning a
unique_ptr to the ImageInput if successful. The unique_ptr is set up with an appropriate deleter
so the ImageInput will be properly closed and deleted when the unique_ptr goes out of scope or
is reset. If the open fails, return an empty unique_ptr and set an error that can be retrieved by
OIIO::geterror().

The config, if not nullptr, points to an ImageSpec giving hints, requests, or special instructions. Im-
ageInput implementations are free to not respond to any such requests, so the default implementation is
just to ignore config.

open() will first try to make an ImageInput corresponding to the format implied by the file extension
(for example, "foo.tif" will try the TIFF plugin), but if one is not found or if the inferred one does not
open the file, every known ImageInput type will be tried until one is found that will open the file.

Return A unique_ptr that will close and free the ImageInput when it exits scope or is reset. The
pointer will be empty if the required writer was not able to be created.

Parameters

• filename: The name of the file to open, UTF-8 encoded.
• config: Optional pointer to an ImageSpec whose metadata contains “configuration hints.”
• ioproxy: Optional pointer to an IOProxy to use (not supported by all formats, see
  supports("ioproxy")). The caller retains ownership of the proxy.

static inline unique_ptr open (const std::wstring &filename, const ImageSpec *config =

nullptr, Filesystem::IOProxy *ioproxy = nullptr)

Create and open an ImageInput using a UTF-16 encoded wstring filename.
static unique_ptr create(string_view filename, bool do_open = false, const ImageSpec *config = nullptr, Filesystem::IOProxy *ioproxy = nullptr, string_view plugin_searchpath = "")

Create and return an ImageInput implementation that is able to read the given file or format. If do_open is true (and the filename is the name of a file, not just a format), fully open it if possible (using the optional config configuration spec, if supplied), otherwise just create the ImageInput but don’t open it. The plugin_searchpath parameter is an override of the searchpath, colon-separated list of directories to search for ImageIO plugin DSO/DLL’s (not a searchpath for the image itself!).

If the filename parameter is the name of a file format (such as “openexr”), it will create an ImageInput that reads that particular format. If the name is a file extension (such as “exr” or “.exr”), it will guess the file format from the extension and return that type of ImageInput.

If filename is a full file name (such as “hawaii.exr”), it will create an ImageInput that reads the format implied by the file extension (“.tif”) and try to open the file with that reader. If the file can be opened and appears to be of the correct type, then that ImageInput (after being closed) will be returned to the caller. But if it fails (say, because the file type does not match the extension), then every known kind of image reader will be tried in turn, until one can be found that succeeds in opening that file. The create() file will fail entirely only if no known image reader type succeeds.

If the caller intends to immediately open the file, then it is often simpler to call static ImageInput::open().

Return A unique_ptr that will close and free the ImageInput when it exits scope or is reset. The pointer will be empty if the required writer was not able to be created.

Parameters

- filename: The name of an image file, or a file extension, or the name of a file format. The filename is UTF-8 encoded.
- do_open: If true, not only create but also open the file.
- config: Optional pointer to an ImageSpec whose metadata contains “configuration hints” for the ImageInput implementation.
- ioproxy: Optional pointer to an IOProxy to use (not supported by all formats, see supports("ioproxy")). The caller retains ownership of the proxy. If this is not supplied, it is still possible to set the proxy with a call to set_proxy() prior to open().
- plugin_searchpath: An optional colon-separated list of directories to search for OpenImageIO plugin DSO/DLL’s.

static inline unique_ptr create(const std::wstring &filename, bool do_open = false, const ImageSpec *config = nullptr, Filesystem::IOProxy *ioproxy = nullptr, string_view plugin_searchpath = "")

Create an ImageInput using a UTF-16 encoded wstring filename.
**Reading pixels**

Common features of all the read methods:

- The format parameter describes the data type of the data[] buffer. The read methods automatically convert the data from the data type it is stored in the file into the format of the data buffer. If format is TypeUnknown it will just copy pixels of file’s native data layout (including, possibly, per-channel data formats as specified by the ImageSpec’s channelformats field).

- The stride values describe the layout of the data buffer: xstride is the distance in bytes between successive pixels within each scanline. ystride is the distance in bytes between successive scanlines. For volumetric images zstride is the distance in bytes between successive “volumetric planes”. Strides set to the special value AutoStride imply contiguous data, i.e.,

```
xstride = format.size() * nchannels
ystride = xstride * width
zstride = ystride * height
```

- Any range parameters (such as ybegin and yend) describe a “half open interval”, meaning that begin is the first item and end is one past the last item. That means that the number of items is end - begin.

- For ordinary 2D (non-volumetric) images, any z or zbegin coordinates should be 0 and any zend should be 1, indicating that only a single image “plane” exists.

- Some read methods take a channel range [chbegin, chend) to allow reading of a contiguous subset of channels (chbegin=0, chend=spec.nchannels reads all channels).

- ImageInput readers are expected to give the appearance of random access in other words, if it can’t randomly seek to the given scanline or tile, it should transparently close, reopen, and sequentially read through prior scanlines.

- All read functions return true for success, false for failure (after which a call to geterror() may retrieve a specific error message).

```
virtual bool read_scanline(int y, int z, TypeDesc format, void *data, stride_t xstride = AutoStride)
```

Read the scanline that includes pixels (*, y, z) from the “current” subimage and MIP level. The xstride value gives the distance between successive pixels (in bytes). Strides set to AutoStride imply “contiguous” data.

**Note** This variety of read_scanline is not re-entrant nor thread-safe. If you require concurrent reads to the same open ImageInput, you should use read_scanlines that has the subimage and miplevel passed explicitly.

**Return** true upon success, or false upon failure.

**Parameters**

- y/z: The y & z coordinates of the scanline. For 2D images, z should be 0.
- format: A TypeDesc describing the type of data.
- data: Pointer to the pixel data buffer.
- xstride: The distance in bytes between successive pixels in data (or AutoStride).

```
inline bool read_scanline(int y, int z, float *data)
```

Simple read_scanline reads into contiguous float pixels.

4.3. ImageInput Class Reference 95
virtual bool read_scanlines(int subimage, int mipmap, int ybegin, int yend, int z, int chbegin, int chend, TypeDesc format, void *data, stride_t xstride = AutoStride, stride_t ystride = AutoStride)

Read multiple scanlines that include pixels (*,y,z) for all ybegin <= y < yend in the specified subimage and mip level, into data, using the strides given and converting to the requested data format (TypeUnknown indicates no conversion, just copy native data types). Only channels [chbegin,chend) will be read/copied (chbegin=0, chend=spec.nchannels reads all channels, yielding equivalent behavior to the simpler variant of read_scanlines).

This version of read_scanlines, because it passes explicit subimage/mipmap, does not require a separate call to seek_subimage, and is guaranteed to be thread-safe against other concurrent calls to any of the read_* methods that take an explicit subimage/mipmap (but not against any other ImageInput methods).

Return true upon success, or false upon failure.

Note This call was changed for OpenImageIO 2.0 to include the explicit subimage and mipmap parameters. The previous versions, which lacked subimage and mipmap parameters (thus were dependent on a prior call to seek_subimage) are considered deprecated.

Parameters

• subimage: The subimage to read from (starting with 0).
• mipmap: The MIP level to read (0 is the highest resolution level).
• ybegin/yend: The y range of the scanlines being passed.
• z: The z coordinate of the scanline.
• chbegin/chend: The channel range to read.
• format: A TypeDesc describing the type of data.
• data: Pointer to the pixel data.
• xstride/ystride: The distance in bytes between successive pixels and scanlines (or AutoStride).

virtual bool read_tile(int x, int y, int z, TypeDesc format, void *data, stride_t xstride = AutoStride, stride_t ystride = AutoStride, stride_t zstride = AutoStride)

Read the tile whose upper-left origin is (x,y,z) into data[], converting if necessary from the native data format of the file into the format specified. The stride values give the data spacing of adjacent pixels, scanlines, and volumetric slices (measured in bytes). Strides set to AutoStride imply 'contiguous' data in the shape of a full tile, i.e.,

\[
\begin{align*}
\text{xstride} &= \text{format.size()} \times \text{spec.nchannels} \\
\text{ystride} &= \text{xstride} \times \text{spec.tile_width} \\
\text{zstride} &= \text{ystride} \times \text{spec.tile_height}
\end{align*}
\]

Note This variety of read_tile is not re-entrant nor thread-safe. If you require concurrent reads to the same open ImageInput, you should use read_tiles() that has the subimage and mipmap passed explicitly.

Return true upon success, or false upon failure.

Note This call will fail if the image is not tiled, or if (x,y,z) is not the upper left corner coordinates of a tile.

Parameters
• x/y/z: The upper left coordinate of the tile being passed.
• format: A TypeDesc describing the type of data.
• data: Pointer to the pixel data.
• xstride/ystride/zstride: The distance in bytes between successive pixels, scanlines, and image planes (or AutoStride to indicate a “contiguous” single tile).

**inline** bool **read_tile**(int x, int y, int z, float *data)

Simple read_tile reads into contiguous float pixels.

**virtual** bool **read_tiles**(int subimage, int mipmap, int xbegin, int xend, int ybegin, int yend, int zbegin, int zend, int chbegin, int chend, TypeDesc format, void *data, stride_t xstride = AutoStride, stride_t ystride = AutoStride, stride_t zstride = AutoStride)

Read the block of multiple tiles that include all pixels in

\[ \{xbegin, xend\} \times \{ybegin, yend\} \times \{zbegin, zend\} \]

This is analogous to calling read_tile(x,y,z,...) for each tile in turn (but for some file formats, reading multiple tiles may allow it to read more efficiently or in parallel).

The begin/end pairs must correctly delineate tile boundaries, with the exception that it may also be the end of the image data if the image resolution is not a whole multiple of the tile size. The stride values give the data spacing of adjacent pixels, scanlines, and volumetric slices (measured in bytes). Strides set to AutoStride imply contiguous data in the shape of the [begin,end) region, i.e.,

\[
xstride = \text{format.size()} \times \text{spec.nchannels} \\
ystride = \text{xstride} \times (xend-xbegin) \\
zstride = \text{ystride} \times (yend-ybegin)
\]

This version of read_tiles, because it passes explicit subimage and mipmap, does not require a separate call to seek_subimage, and is guaranteed to be thread-safe against other concurrent calls to any of the read_* methods that take an explicit subimage/mipmap (but not against any other ImageInput methods).

**Return** true upon success, or false upon failure.

**Note** The call will fail if the image is not tiled, or if the pixel ranges do not fall along tile (or image) boundaries, or if it is not a valid tile range.

**Parameters**

• subimage: The subimage to read from (starting with 0).
• mipmap: The MIP level to read (0 is the highest resolution level).
• xbegin/xend: The x range of the pixels covered by the group of tiles being read.
• ybegin/yend: The y range of the pixels covered by the tiles.
• zbegin/zend: The z range of the pixels covered by the tiles (for a 2D image, zbegin=0 and zend=1).
• chbegin/chend: The channel range to read.
• format: A TypeDesc describing the type of data.
• data: Pointer to the pixel data.
• xstride/ystride/zstride: The distance in bytes between successive pixels, scanlines, and image planes (or AutoStride).
virtual bool read_image (int subimage, int mipmap, int chbegin, int chend, TypeDesc format, void *data, stride_t xstride = AutoStride, stride_t ystride = AutoStride, stride_t zstride = AutoStride, ProgressCallback progress_callback = NULL, void *progress_callback_data = NULL)

Read the entire image of spec.width x spec.height x spec.depth pixels into a buffer with the given strides and in the desired data format.

Depending on the spec, this will read either all tiles or all scanlines. Assume that data points to a layout in row-major order.

This version of read_image, because it passes explicit subimage and mipmap, does not require a separate call to seek_subimage, and is guaranteed to be thread-safe against other concurrent calls to any of the read_* methods that take an explicit subimage/mipmap (but not against any other ImageInput methods).

Because this may be an expensive operation, a progress callback may be passed. Periodically, it will be called as follows:

```
progress_callback (progress_callback_data, float done);
```

where done gives the portion of the image (between 0.0 and 1.0) that has been written thus far.

Return true upon success, or false upon failure.

Parameters

- subimage: The subimage to read from (starting with 0).
- mipmap: The MIP level to read (0 is the highest resolution level).
- chbegin/chend: The channel range to read. If chend is -1, it will be set to spec.nchannels.
- format: A TypeDesc describing the type of data.
- data: Pointer to the pixel data.
- xstride/ystride/zstride: The distance in bytes between successive pixels, scanlines, and image planes (or AutoStride).
- progress_callback/progress_callback_data: Optional progress callback.

virtual bool read_native_deep_scanlines (int subimage, int mipmap, int ybegin, int yend, int z, int chbegin, int chend, DeepData &deepdata)

Read deep scanlines containing pixels (*,y,z), for all y in the range [ybegin,yend) into deepdata. This will fail if it is not a deep file.

Return true upon success, or false upon failure.

Parameters

- subimage: The subimage to read from (starting with 0).
- mipmap: The MIP level to read (0 is the highest resolution level).
- chbegin/chend: The channel range to read.
- ybegin/yend: The y range of the scanlines being passed.
- z: The z coordinate of the scanline.
- deepdata: A DeepData object into which the data for these scanlines will be placed.
virtual bool read_native_deep_tiles (int subimage, int mipmap, int xbegin, int xend, int ybegin, int yend, int zbegin, int zend, DeepData &deepdata)

Read into deepdata the block of native deep data tiles that include all pixels and channels specified by pixel range.

Return true upon success, or false upon failure.

Note The call will fail if the image is not tiled, or if the pixel ranges do not fall along tile (or image) boundaries, or if it is not a valid tile range.

Parameters

• subimage: The subimage to read from (starting with 0).
• mipmap: The MIP level to read (0 is the highest resolution level).
• xbegin/xend: The x range of the pixels covered by the group of tiles being read.
• ybegin/yend: The y range of the pixels covered by the tiles.
• zbegin/zend: The z range of the pixels covered by the tiles (for a 2D image, zbegin=0 and zend=1).
• chbegin/chend: The channel range to read.
• deepdata: A DeepData object into which the data for these tiles will be placed.

virtual bool read_native_deep_image (int subimage, int mipmap, DeepData &deepdata)

Read the entire deep data image of spec.width x spec.height x spec.depth pixels, all channels, into deepdata.

Return true upon success, or false upon failure.

Parameters

• subimage: The subimage to read from (starting with 0).
• mipmap: The MIP level to read (0 is the highest resolution level).
• deepdata: A DeepData object into which the data for the image will be placed.

Reading native pixels – implementation overloads

Note read_native_* methods are usually not directly called by user code (except for read_native_deep_* varieties). These are the methods that are overloaded by the ImageInput subclasses that implement the individual file format readers.

virtual bool read_native_scanline (int subimage, int mipmap, int y, int z, void *data) = 0

Read a single scanline (all channels) of native data into contiguous memory.

virtual bool read_native_scanlines (int subimage, int mipmap, int ybegin, int yend, int z, void *data)

Read a range of scanlines (all channels) of native data into contiguous memory.

virtual bool read_native_scanlines (int subimage, int mipmap, int ybegin, int yend, int z, int chbegin, int chend, void *data)

Read a range of scanlines (with optionally a subset of channels) of native data into contiguous memory.
virtual bool read_native_tile(int subimage, int mipmap, int x, int y, int z, void *data)
Read a single tile (all channels) of native data into contiguous memory. The base class read_native_tile
fails. A format reader that supports tiles MUST overload this virtual method that reads a single tile (all
channels).

virtual bool read_native_tiles(int subimage, int mipmap, int xbegin, int xend, int ybegin, int
yend, int zbegin, int zend, void *data)
Read multiple tiles (all channels) of native data into contiguous memory. A format reader that supports
reading multiple tiles at once (in a way that’s more efficient than reading the tiles one at a time) is advised
(but not required) to overload this virtual method. If an ImageInput subclass does not overload this, the
default implementation here is simply to loop over the tiles, calling the single-tile read_native_tile() for
each one.

virtual bool read_native_tiles(int subimage, int mipmap, int xbegin, int xend, int ybegin, int
yend, int zbegin, int zend, int chbegin, int chend, void *data)
Read multiple tiles (potentially a subset of channels) of native data into contiguous memory. A format
reader that supports reading multiple tiles at once, and can handle a channel subset while doing so, is
advised (but not required) to overload this virtual method. If an ImageInput subclass does not overload this,
the default implementation here is simply to loop over the tiles, calling the single-tile read_native_tile()
for each one (and copying carefully to handle the channel subset issues).

IOProxy aids for ImageInput implementations.
This set of utility functions are not meant to be called by user code. They are protected methods of ImageInput,
and are used internally by the ImageInput implementation to help it properly implement support of IOProxy.

Public Types

using unique_ptr = std::unique_ptr<ImageInput>
unique_ptr to an ImageInput

typedef std::lock_guard<const ImageInput&> lock_guard
The presence of lock() and unlock() establish an ImageInput itself as having the BasicLockable concept
and therefore can be used by std::lock_guard.

typedef ImageInput *(Creator)()
Call signature of a function that creates and returns an ImageInput*.

Public Functions

virtual const char *format_name (void) const = 0
Return the name of the format implemented by this class.

inline virtual int supports (string_view feature) const
Given the name of a “feature”, return whether this ImageInput supports output of images with the given
properties. Most queries will simply return 0 for “doesn’t support” and 1 for “supports it,” but it is ac-
ceptable to have queries return other nonzero integers to indicate varying degrees of support or limits (but
should be clearly documented as such).

Feature names that ImageInput implementations are expected to recognize include:

- "arbitrary_metadata": Does this format allow metadata with arbitrary names and types?
- "exif": Can this format store Exif camera data?
• "ioproxy" : Does this format reader support reading from an IOProxy?
• "iptc" : Can this format store IPTC data?
• "procedural" : Can this format create images without reading from a disk file?
• "thumbnail" : Does this format reader support retrieving a reduced resolution copy of the image via the thumbnail() method?

This list of queries may be extended in future releases. Since this can be done simply by recognizing new query strings, and does not require any new API entry points, addition of support for new queries does not break “link compatibility” with previously-compiled plugins.

**virtual bool valid_file(const std::string &filename) const**  
Return true if the filename names a file of the type for this ImageInput. The implementation will try to determine this as efficiently as possible, in most cases much less expensively than doing a full open(). Note that there can be false positives: a file can appear to be of the right type (i.e., valid_file() returning true) but still fail a subsequent call to open(), such as if the contents of the file are truncated, nonsensical, or otherwise corrupted. The filename is UTF-8 encoded.

**virtual bool valid_file(const std::wstring &filename) const**  
Check valid vile using a UTF-16 encoded wstring filename.

**virtual bool open(const std::string &name, ImageSpec &newspec) = 0**  
Opens the file with given name and seek to the first subimage in the file. Various file attributes are put in newspec and a copy is also saved internally to the ImageInput (retrievable via spec()). From examining newspec or spec(), you can discern the resolution, if it’s tiled, number of channels, native data format, and other metadata about the image.

**Return** true if the file was found and opened successfully.

**Parameters**
• name: Filename to open, UTF-8 encoded.
• newspec: Reference to an ImageSpec in which to deposit a full description of the contents of the first subimage of the file.

**inline bool open(const std::wstring &name, ImageSpec &newspec)**  
Open the ImageInput using a UTF-16 encoded wstring filename.

**inline virtual bool open(const std::string &name, ImageSpec &newspec, const ImageSpec &config)**  
Open file with given name, similar to open(name,newspec). The config is an ImageSpec giving requests or special instructions. ImageInput implementations are free to not respond to any such requests, so the default implementation is just to ignore config and call regular open(name,newspec).

**Return** true if the file was found and opened successfully.

**Parameters**
• name: Filename to open, UTF-8 encoded.
• newspec: Reference to an ImageSpec in which to deposit a full description of the contents of the first subimage of the file.
OpenImageIO, Release 2.4.1

• config: An ImageSpec whose metadata contains “configuration hints” for the ImageInput implementation.

```cpp
inline bool open (const std::wstring &name, ImageSpec &newspec, const ImageSpec &config)
    Open the ImageInput using a UTF-16 encoded wstring filename.

inline virtual const ImageSpec &spec(void) const
    Return a reference to the image specification of the current subimage/MIPlevel. Note that the contents of the spec are invalid before open() or after close(), and may change with a call to seek_subimage(). It is thus not thread-safe, since the spec may change if another thread calls seek_subimage, or any of the read_*() functions that take explicit subimage/miplevel.

virtual ImageSpec spec(int subimage, int mipmap = 0)
    Return a full copy of the ImageSpec of the designated subimage and MIPlevel. This method is thread-safe, but it is potentially expensive, due to the work that needs to be done to fully copy an ImageSpec if there is lots of named metadata to allocate and copy. See also the less expensive spec_dimensions(). Errors (such as having requested a nonexistent subimage) are indicated by returning an ImageSpec with format==TypeUnknown.

virtual ImageSpec spec_dimensions(int subimage, int mipmap = 0)
    Return a copy of the ImageSpec of the designated subimage and miplevel, but only the dimension and type fields. Just as with a call to ImageSpec::copy_dimensions(), neither the channel names nor any of the arbitrary named metadata will be copied, thus this is a relatively inexpensive operation if you don’t need that information. It is guaranteed to be thread-safe. Errors (such as having requested a nonexistent subimage) are indicated by returning an ImageSpec with format==TypeUnknown.

inline virtual bool get_thumbnail(ImageBuf &thumb, int subimage)
    Retrieve a reduced-resolution (“thumbnail”) version of the given subimage. It is guaranteed to be thread-safe.

Return true upon success, false if no thumbnail was available, or if this file format (or reader) does not support thumbnails.

Note This method was added to OpenImageIO 2.3.

Parameters
• thumb: A reference to an ImageBuf which will be overwritten with the thumbnail image.
• subimage: The index of the subimage in the file whose thumbnail is to be retrieved.

virtual bool close() = 0
    Close an open ImageInput. The call to close() is not strictly necessary if the ImageInput is destroyed immediately afterwards, since it is required for the destructor to close if the file is still open.

Return true upon success, or false upon failure.

inline virtual int current_subimage(void) const
    Returns the index of the subimage that is currently being read. The first subimage (or the only subimage, if there is just one) is number 0.

inline virtual int current_mipmap(void) const
    Returns the index of the MIPmap image that is currently being read. The highest-res MIP level (or the only level, if there is just one) is number 0.

inline virtual bool seek_subimage(int subimage, int mipmap)
    Seek to the given subimage and MIP-map level within the open image file. The first subimage of the file has index 0, the highest-resolution MIP level has index 0. The new subimage’s vital statistics may
be retrieved by \texttt{this->spec()}. The reader is expected to give the appearance of random access to subimages and MIP levels in other words, if it can’t randomly seek to the given subimage/level, it should transparently close, reopen, and sequentially read through prior subimages and levels.

\textbf{Return} \textit{true} upon success, or \textit{false} upon failure. A failure may indicate that no such subimage or MIP level exists in the file.

\texttt{virtual bool set_ioproxy (Filesystem::IOProxy *ioproxy)}

Set an IOProxy for this reader. This must be called prior to \texttt{open()}, and only for readers that support them (\texttt{supports("ioproxy")}). The caller retains ownership of the proxy.

\textbf{Return} \textit{true} for success, \textit{false} for failure.

\texttt{bool has_error () const}

Is there a pending error message waiting to be retrieved, that resulted from an \texttt{ImageInput} API call made by the this thread?

Note that any \texttt{error()} calls issued are thread-specific, and the \texttt{geterror()/has_error()} are expected to be called by the same thread that called whichever API function encountered an error.

\texttt{std::string geterror (bool clear = true) const}

Return the text of all pending error messages issued against this \texttt{ImageInput} by the calling thread, and clear the pending error message unless \texttt{clear} is false. If no error message is pending, it will return an empty string.

Note that any \texttt{error()} calls issued are thread-specific, and the \texttt{geterror()/has_error()} are expected to be called by the same thread that called whichever API function encountered an error.

\texttt{template<typename ... Args> inline void error (const char *fmt, const Args&... args) const}

Error reporting for the plugin implementation: call this with Strutil::format-like arguments. It is not necessary to have the error message contain a trailing newline. Use with caution! Some day this will change to be fmt-like rather than printf-like.

\texttt{template<typename ... Args> inline void errorf (const char *fmt, const Args&... args) const}

Error reporting for the plugin implementation: call this with printf-like arguments. It is not necessary to have the error message contain a trailing newline.

\texttt{template<typename ... Args> inline void errorfmt (const char *fmt, const Args&... args) const}

Error reporting for the plugin implementation: call this with std::format-like arguments. It is not necessary to have the error message contain a trailing newline.

\texttt{void threads (int n)}

Set the threading policy for this \texttt{ImageInput}, controlling the maximum amount of parallelizing thread “fan-out” that might occur during large read operations. The default of 0 means that the global \texttt{attribute("threads")} value should be used (which itself defaults to using as many threads as cores; see Section \textbf{Global Attributes}).

The main reason to change this value is to set it to 1 to indicate that the calling thread should do all the work rather than spawning new threads. That is probably the desired behavior in situations where the calling application has already spawned multiple worker threads.

\texttt{int threads () const}

Retrieve the current thread-spawning policy.

\textbf{See} \texttt{threads(int)}
void lock() const

There is a (hidden) internal recursive mutex to each ImageInput that can be used by the II to enforce thread safety. This is exposed via the obvious lock()/unlock()/try_lock() semantics.
WRITING IMAGEIO PLUGINS

5.1 Plugin Introduction

As explained in Chapters *ImageInput: Reading Images* and *ImageOutput: Writing Images*, the ImageIO library does not know how to read or write any particular image formats, but rather relies on plugins located and loaded dynamically at run-time. This set of plugins, and therefore the set of image file formats that OpenImageIO or its clients can read and write, is extensible without needing to modify OpenImageIO itself.

This chapter explains how to write your own OpenImageIO plugins. We will first explain separately how to write image file readers and writers, then tie up the loose ends of how to build the plugins themselves.

5.2 Image Reader Plugins

A plugin that reads a particular image file format must implement a *subclass* of ImageInput (described in Chapter *ImageInput: Reading Images*). This is actually very straightforward and consists of the following steps, which we will illustrate with a real-world example of writing a JPEG/JFIF plug-in.

1. Read the base class definition from `imageio.h`. It may also be helpful to enclose the contents of your plugin in the same namespace that the OpenImageIO library uses:

```cpp
#include <OpenImageIO/imageio.h>
OIIO_PLUGIN_NAMESPACE_BEGIN
// ... everything else ...
OIIO_PLUGIN_NAMESPACE_END
```

2. Declare these public items:
   a. An integer called *name_imageio_version* that identifies the version of the ImageIO protocol implemented by the plugin, defined in `imageio.h` as the constant `OIIO_PLUGIN_VERSION`. This allows the library to be sure it is not loading a plugin that was compiled against an incompatible version of OpenImageIO.
   b. An function named *name_imageio_library_version* that identifies the underlying dependent library that is responsible for reading or writing the format (it may return `nullptr` to indicate that there is no dependent library being used for this format).
   c. A function named *name_input_imageio_create* that takes no arguments and returns an `ImageInput *` constructed from a new instance of your ImageInput subclass and a deleter. (Note that *name* is the name of your format, and must match the name of the plugin itself.)
d. An array of char * called name_input_extensions that contains the list of file extensions that are likely to indicate a file of the right format. The list is terminated by a nullptr.

All of these items must be inside an extern "C" block in order to avoid name mangling by the C++ compiler, and we provide handy macros OIIO_PLUGIN_EXPORTS_BEGIN and OIIO_PLUGIN_EXPORTS_END to make this easy. Depending on your compiler, you may need to use special commands to dictate that the symbols will be exported in the DSO; we provide a special OIIO_EXPORT macro for this purpose, defined in export.h.

Putting this all together, we get the following for our JPEG example:

```cpp
OIIO_PLUGIN_EXPORTS_BEGIN
OIIO_EXPORT int jpeg_imageio_version = OIIO_PLUGIN_VERSION;
OIIO_EXPORT ImageInput *jpeg_input_imageio_create () {
    return new JpgInput;
}
OIIO_EXPORT const char *jpeg_input_extensions[] = {
    "jpg", "jpe", "jpeg", "jif", "jfif", "jfi", nullptr
};
OIIO_EXPORT const char * jpeg_imageio_library_version () {
    #define STRINGIZE2(a) #a
    #define STRINGIZE(a) STRINGIZE2(a)
    #ifdef LIBJPEG_TURBO_VERSION
        return "jpeg-turbo " STRINGIZE(LIBJPEG_TURBO_VERSION);
    #else
        return "jpeglib " STRINGIZE(JPEG_LIB_VERSION_MAJOR) "." STRINGIZE(JPEG_LIB_VERSION_MINOR);
    #endif
}
OIIO_PLUGIN_EXPORTS_END
```

3. The definition and implementation of an ImageInput subclass for this file format. It must publicly inherit ImageInput, and must overload the following methods which are “pure virtual” in the ImageInput base class:

a. format_name() should return the name of the format, which ought to match the name of the plugin and by convention is strictly lower-case and contains no whitespace.

b. open() should open the file and return true, or should return false if unable to do so (including if the file was found but turned out not to be in the format that your plugin is trying to implement).

c. close() should close the file, if open.

d. read_native_scanline() should read a single scanline from the file into the address provided, uncompressing it but keeping it in its naive data format without any translation.

e. The virtual destructor, which should close() if the file is still open, addition to performing any other tear-down activities.

Additionally, your ImageInput subclass may optionally choose to overload any of the following methods, which are defined in the ImageInput base class and only need to be overloaded if the default behavior is not appropriate for your plugin:

f. supports(), only if your format supports any of the optional features described in the section describing ImageInput::supports.

g. valid_file(), if your format has a way to determine if a file is of the given format in a way that is less expensive than a full open().

h. seek_subimage(), only if your format supports reading multiple subimages within a single file.

i. read_native_scanlines(), only if your format has a speed advantage when reading multiple scanlines at once. If you do not supply this function, the default implementation will simply call
read_scanline() for each scanline in the range.

j. read_native_tile(), only if your format supports reading tiled images.

k. read_native_tiles(), only if your format supports reading tiled images and there is a speed advantage when reading multiple tiles at once. If you do not supply this function, the default implementation will simply call read_native_tile() for each tile in the range.

l. Channel subset' versions of `read_native_scanlines() and/or read_native_tiles(), only if your format has a more efficient means of reading a subset of channels. If you do not supply these methods, the default implementation will simply use read_native_scanlines() or read_native_tiles() to read into a temporary all-channel buffer and then copy the channel subset into the user’s buffer.

m. read_native_deep_scanlines() and/or read_native_deep_tiles(), only if your format supports “deep” data images.

Here is how the class definition looks for our JPEG example. Note that the JPEG/JFIF file format does not support multiple subimages or tiled images.

class JpgInput final : public ImageInput {
    public:
    JpgInput () { init(); }
    virtual ~JpgInput () { close(); }
    virtual const char * format_name () override { return "jpeg"; }
    virtual bool open (const std::string &name, ImageSpec &spec) override;
    virtual bool read_native_scanline (int y, int z, void *data) override;
    virtual bool close () override;

    private:
    FILE *m_fd;
    bool m_first_scanline;
    struct jpeg_decompress_struct m_cinfo;
    struct jpeg_error_mgr m_jerr;
    void init () { m_fd = NULL; }
};

Your subclass implementation of open(), close(), and read_native_scanline() are the heart of an ImageInput implementation. (Also read_native_tile() and seek_subimage(), for those image formats that support them.)

The remainder of this section simply lists the full implementation of our JPEG reader, which relies heavily on the open source jpeg-6b library to perform the actual JPEG decoding.

5.3 Image Writers

A plugin that writes a particular image file format must implement a subclass of ImageOutput (described in Chapter ImageOutput: Writing Images). This is actually very straightforward and consists of the following steps, which we will illustrate with a real-world example of writing a JPEG/JFIF plug-in.

1. Read the base class definition from imageio.h, just as with an image reader (see Section Image Reader Plugins).

2. Declare four public items:

   a. An integer called name_imageio_version that identifies the version of the ImageIO protocol implemented by the plugin, defined in imageio.h as the constant OIIO_PLUGIN_VERSION. This allows the library to be sure it is not loading a plugin that was compiled against an incompatible version of OpenImageIO. Note that if your plugin has both a reader and writer and they are compiled as separate modules (C++ source files), you don’t want to declare this in both modules; either one is fine.

   b. A function named name_output_imageio_create that takes no arguments and returns an ImageOutput * constructed from a new instance of your ImageOutput subclass and a deleter. (Note that name is the name of your format, and must match the name of the plugin itself.)

   c. An array of char * called name_output_extensions that contains the list of file extensions that are likely to indicate a file of the right format. The list is terminated by a nullptr pointer.

   All of these items must be inside an extern "C" block in order to avoid name mangling by the C++ compiler, and we provide handy macros OIIO_PLUGIN_EXPORTS_BEGIN and OIIO_PLUGIN_EXPORTS_END to make this easy. Depending on your compiler, you may need to use special commands to dictate that the symbols will be exported in the DSO; we provide a special OIIO_EXPORT macro for this purpose, defined in export.h.

   Putting this all together, we get the following for our JPEG example:

   ```
   OIIO_PLUGIN_EXPORTS_BEGIN
   OIIO_EXPORT int jpeg_imageio_version = OIIO_PLUGIN_VERSION;
   OIIO_EXPORT ImageOutput *jpeg_output_imageio_create () {
   return new JpgOutput;
   }
   OIIO_EXPORT const char *jpeg_input_extensions[] = {
   "jpg", "jpe", "jpeg", nullptr
   };
   OIIO_PLUGIN_EXPORTS_END
   ```

3. The definition and implementation of an ImageOutput subclass for this file format. It must publicly inherit ImageOutput, and must overload the following methods which are “pure virtual” in the ImageOutput base class:

   a. format_name() should return the name of the format, which ought to match the name of the plugin and by convention is strictly lower-case and contains no whitespace.
b. supports() should return true if its argument names a feature supported by your format plugin, false if it names a feature not supported by your plugin. See the description of ImageOutput::supports() for the list of feature names.

c. open() should open the file and return true, or should return false if unable to do so (including if the file was found but turned out not to be in the format that your plugin is trying to implement).

d. close() should close the file, if open.

e. write_scanline() should write a single scanline to the file, translating from internal to native data format and handling strides properly.

f. The virtual destructor, which should close() if the file is still open, addition to performing any other tear-down activities.

Additionally, your ImageOutput subclass may optionally choose to overload any of the following methods, which are defined in the ImageOutput base class and only need to be overloaded if the default behavior is not appropriate for your plugin:

g. write_scanlines(), only if your format supports writing scanlines and you can get a performance improvement when outputting multiple scanlines at once. If you don’t supply write_scanlines(), the default implementation will simply call write_scanline() separately for each scanline in the range.

h. write_tile(), only if your format supports writing tiled images.

i. write_tiles(), only if your format supports writing tiled images and you can get a performance improvement when outputting multiple tiles at once. If you don’t supply write_tiles(), the default implementation will simply call write_tile() separately for each tile in the range.

j. write_rectangle(), only if your format supports writing arbitrary rectangles.

k. write_image(), only if you have a more clever method of doing so than the default implementation that calls write_scanline() or write_tile() repeatedly.

l. write_deep_scanlines() and/or write_deep_tiles(), only if your format supports “deep” data images.

It is not strictly required, but certainly appreciated, if a file format does not support tiles, to nonetheless accept an ImageSpec that specifies tile sizes by allocating a full-image buffer in open(), providing an implementation of write_tile() that copies the tile of data to the right spots in the buffer, and having close() then call write_scanlines() to process the buffer now that the image has been fully sent.

Here is how the class definition looks for our JPEG example. Note that the JPEG/JFIF file format does not support multiple subimages or tiled images.

class JpgOutput final : public ImageOutput {
public:
    JpgOutput () { init(); }  // Call this instead of the virtual destructor.
    virtual ~JpgOutput () { close(); }
    virtual const char * format_name () const override { return "jpeg"; }
    virtual int supports (string_view property) const override { return false; }
    virtual bool open (const std::string &name, const ImageSpec &spec,
        bool append=false) override;
    virtual bool write_scanline (int y, int z, TypeDesc format,
        const void *data, stride_t xstride);
    virtual close();
private:
    FILE *m_fd;
};

(continues on next page)
Your subclass implementation of `open()`, `close()`, and `write_scanline()` are the heart of an ImageOutput implementation. (Also `write_tile()` for those image formats that support tiled output.)

An ImageOutput implementation must properly handle all data formats and strides passed to `write_scanline()` or `write_tile()`, unlike an ImageInput implementation, which only needs to read scanlines or tiles in their native format and then have the super-class handle the translation. But don’t worry, all the heavy lifting can be accomplished with the following helper functions provided as protected member functions of ImageOutput that convert a scanline, tile, or rectangular array of values from one format to the native format(s) of the file.

```cpp
const void *to_native_scanline(TypeDesc format, const void *data, stride_t xstride, std::vector<unsigned char> &scratch, unsigned int dither = 0, int yorigin = 0, int zorigin = 0)
```

Convert a full scanline of pixels (pointed to by `data` with the given `format` and strides into contiguous pixels in the native format (described by the ImageSpec returned by the `spec()` member function). The location of the newly converted data is returned, which may either be the original `data` itself if no data conversion was necessary and the requested layout was contiguous (thereby avoiding unnecessary memory copies), or may point into memory allocated within the `scratch` vector passed by the user. In either case, the caller doesn’t need to worry about thread safety or freeing any allocated memory (other than eventually destroying the scratch vector).

```cpp
const void *to_native_tile(TypeDesc format, const void *data, stride_t xstride, stride_t ystride, stride_t zstride, std::vector<unsigned char> &scratch, unsigned int dither = 0, int xorigin = 0, int yorigin = 0, int zorigin = 0)
```

Convert a full tile of pixels (pointed to by `data` with the given `format` and strides into contiguous pixels in the native format (described by the ImageSpec returned by the `spec()` member function). The location of the newly converted data is returned, which may either be the original `data` itself if no data conversion was necessary and the requested layout was contiguous (thereby avoiding unnecessary memory copies), or may point into memory allocated within the `scratch` vector passed by the user. In either case, the caller doesn’t need to worry about thread safety or freeing any allocated memory (other than eventually destroying the scratch vector).

```cpp
const void *to_native_rectangle(int xbegin, int xend, int ybegin, int yend, int zbegin, int zend, TypeDesc format, const void *data, stride_t xstride, stride_t ystride, stride_t zstride, std::vector<unsigned char> &scratch, unsigned int dither = 0, int xorigin = 0, int yorigin = 0, int zorigin = 0)
```

Convert a rectangle of pixels (pointed to by `data` with the given `format`, dimensions, and strides into contiguous pixels in the native format (described by the ImageSpec returned by the `spec()` member function). The location of the newly converted data is returned, which may either be the original `data` itself if no data conversion was necessary and the requested layout was contiguous (thereby avoiding unnecessary memory copies), or may point into memory allocated within the `scratch` vector passed by the user. In either case, the caller doesn’t need to worry about thread safety or freeing any allocated memory (other than eventually destroying the scratch vector).

For `float` to 8 bit integer conversions only, if `dither` parameter is nonzero, random dither will be added to reduce quantization banding artifacts; in this case, the specific nonzero `dither` value is used as a seed for the hash function that produces the per-pixel dither amounts, and the optional `origin` parameters help it to align the pixels to the right position in the dither pattern.
The remainder of this section simply lists the full implementation of our JPEG writer, which relies heavily on the open source jpeg-6b library to perform the actual JPEG encoding.

}
5.4 Tips and Conventions

OpenImageIO’s main goal is to hide all the pesky details of individual file formats from the client application. This inevitably leads to various mismatches between a file format’s true capabilities and requests that may be made through the OpenImageIO APIs. This section outlines conventions, tips, and rules of thumb that we recommend for image file support.

Readers

- If the file format stores images in a non-spectral color space (for example, YUV), the reader should automatically convert to RGB to pass through the OIIO APIs. In such a case, the reader should signal the file’s true color space via a "Foo:colorspace" attribute in the ImageSpec.
- “Palette” images should be automatically converted by the reader to RGB.
- If the file supports thumbnail images in its header, the reader should provide an `ImageInput::get_thumbnail()` method, as well as store the thumbnail dimensions in the ImageSpec as attributes "thumbnail_width", "thumbnail_height", and "thumbnail_nchannels" (all of which should be int).

Writers

The overall rule of thumb is: try to always “succeed” at writing the file, outputting the closest approximation of the user’s data as possible. But it is permissible to fail the `open()` call if it is clearly nonsensical or there is no possible way to output a decent approximation of the user’s data. Some tips:

- If the client application requests a data format not directly supported by the file type, silently write the supported data format that will result in the least precision or range loss.
- It is customary to fail a call to `open()` if the ImageSpec requested a number of color channels plainly not supported by the file format. As an exception to this rule, it is permissible for a file format that does not support alpha channels to silently drop the fourth (alpha) channel of a 4-channel output request.
- If the app requests a "Compression" not supported by the file format, you may choose as a default any lossless compression supported. Do not use a lossy compression unless you are fairly certain that the app wanted a lossy compression.
- If the file format is able to store images in a non-spectral color space (for example, YUV), the writer may accept a "Foo:colorspace" attribute in the ImageSpec as a request to automatically convert and store the data in that format (but it will always be passed as RGB through the OIIO APIs).
- If the file format can support thumbnail images in its header, and the ImageSpec contain attributes "thumbnail_width", "thumbnail_height", "thumbnail_nchannels", and "thumbnail_image", the writer should attempt to store the thumbnail if possible.
This chapter lists all the image format plugins that are bundled with OpenImageIO. For each plugin, we delineate any limitations, custom attributes, etc. The plugins are listed alphabetically by format name.

### 6.1 BMP

BMP is a bitmap image file format used mostly on Windows systems. BMP files use the file extension `.bmp`. BMP is not a nice format for high-quality or high-performance images. It only supports unsigned integer 1-, 2-, 4-, and 8-bit per channel; only grayscale, RGB, and RGBA; does not support MIPmaps, multiimage, or tiles.

#### BMP Attributes

<table>
<thead>
<tr>
<th>ImageSpec Attribute</th>
<th>Type</th>
<th>BMP header data or explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>compression</td>
<td>string</td>
<td>The compression of the BMP file (&quot;rle4&quot; or &quot;rle8&quot;, if RLE compression is used).</td>
</tr>
<tr>
<td>XResolution</td>
<td>float</td>
<td>hres</td>
</tr>
<tr>
<td>YResolution</td>
<td>float</td>
<td>vres</td>
</tr>
<tr>
<td>ResolutionUnit</td>
<td>string</td>
<td>always &quot;m&quot; (pixels per meter)</td>
</tr>
<tr>
<td>bmp:bitsperpixel</td>
<td>int</td>
<td>When not a whole number of bytes per channel, this describes the bits per pixel in the file (16 for R4G4B4, 8 for a 256-color palette image, 4 for a 16-color palette image, 1 for a 2-color palette image).</td>
</tr>
<tr>
<td>bmp:version</td>
<td>int</td>
<td>Version of the BMP file format</td>
</tr>
</tbody>
</table>

#### Configuration settings for BMP input

When opening a BMP ImageInput with a *configuration* (see Section *Opening for input with configuration settings/hints*), the following special configuration options are supported:

<table>
<thead>
<tr>
<th>Input Configuration Attribute</th>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>bmp:monochrome_detect</td>
<td>int</td>
<td>If nonzero, try to detect when all palette entries are gray and pretend that it’s a 1-channel image to allow the calling app to save memory and time (even though the BMP format does not actually support grayscale images per se. It is 1 by default, but by setting the hint to 0, you can disable this behavior.</td>
</tr>
<tr>
<td>oiiio:ioproxy</td>
<td>ptr</td>
<td>Pointer to a Filesystem::IOProxy that will handle the I/O, for example by reading from memory rather than the file system.</td>
</tr>
</tbody>
</table>
Configuration settings for BMP output

When opening an BMP ImageOutput, the following special metadata tokens control aspects of the writing itself:

<table>
<thead>
<tr>
<th>Output Configuration Attribute</th>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>oiiio:ioproxy</td>
<td>ptr</td>
<td>Pointer to a Filesystem::IOProxy that will handle the I/O, for example by writing to a memory buffer.</td>
</tr>
<tr>
<td>oiiio:dither</td>
<td>int</td>
<td>If nonzero and outputting UINT8 values in the file from a source of higher bit depth, will add a small amount of random dither to combat the appearance of banding.</td>
</tr>
</tbody>
</table>

Custom I/O Overrides

BMP input and output both support the “custom I/O” feature via the special "oiiio:ioproxy" attributes (see Sections Custom I/O proxies (and writing the file to a memory buffer) and Custom I/O proxies (and reading the file from a memory buffer)) as well as the set_ioproxy() methods.

BMP Limitations

- OIIIO’s current implementation will only write uncompressed 8bpp (from a 1-channel source), 24bpp (if 3 channel), or 32bpp (if 4 channel). Reads, however, can handle RLE compression as well as 1, 4, or 16 bpp input.
- Only 1, 3, and 4-channel images are supported with BMP due to limitations of the file format itself.
- BMP only supports uint8 pixel data types. Requests for other pixel data types will automatically be converted to uint8.

6.2 Cineon

Cineon is an image file format developed by Kodak that is commonly used for scanned motion picture film and digital intermediates. Cineon files use the file extension .cin.

6.3 DDS

DDS (Direct Draw Surface) is an image file format designed by Microsoft for use in Direct3D graphics. DDS files use the extension .dds.

DDS is an awful format, with several compression modes that are all so lossy as to be completely useless for high-end graphics. Nevertheless, they are widely used in games and graphics hardware directly supports these compression modes. Alas.

OpenImageIO currently only supports reading DDS files, not writing them.
**ImageSpec Attribute** | **Type** | **DDS header data or explanation**
---|---|---
compression | string | Compression type
oiio:BitsPerSample | int | Bits per sample
textureformat | string | Set correctly to one of "Plain Texture", "Volume Texture", or "CubeFace Environment".
dds:CubeMapSides | string | For environment maps, which cube faces are present (e.g., "+x -x +y -y" if x & y faces are present, but not z).

### Configuration settings for DDS input

When opening an DDS ImageInput with a configuration (see Section *Opening for input with configuration settings/hints*), the following special configuration attributes are supported:

<table>
<thead>
<tr>
<th>Input Configuration Attribute</th>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
</table>
oiio:ioproxy | ptr | Pointer to a Filesystem::IOProxy that will handle the I/O, for example by reading from memory rather than the file system. |

### Configuration settings for DDS output

When opening an DDS ImageOutput, the following special metadata tokens control aspects of the writing itself:

<table>
<thead>
<tr>
<th>Output Configuration Attribute</th>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
</table>
oiio:ioproxy | ptr | Pointer to a Filesystem::IOProxy that will handle the I/O, for example by writing to a memory buffer. |

### Custom I/O Overrides

DDS supports the “custom I/O” feature via the special "oiio:ioproxy" attributes (see Sections *Custom I/O proxies (and writing the file to a memory buffer)* and *Custom I/O proxies (and reading the file from a memory buffer)*) as well as the set_ioproxy() methods.

### 6.4 DICOM

DICOM (Digital Imaging and Communications in Medicine) is the standard format used for medical images. DICOM files usually have the extension .dcm.

OpenImageIO currently only supports reading DICOM files, not writing them.

<table>
<thead>
<tr>
<th>ImageSpec Attribute</th>
<th>Type</th>
<th>DDS header data or explanation</th>
</tr>
</thead>
</table>
oiio:BitsPerSample | int | Bits per sample. |
dicom:* | any | DICOM header information and metadata is currently all preceded by the dicom: prefix. |

## 6.5 DPX

DPX (Digital Picture Exchange) is an image file format used for motion picture film scanning, output, and digital intermediates. DPX files use the file extension `.dpx`.

### Configuration settings for DPX input

When opening a DPX ImageInput with a configuration (see Section Opening for input with configuration settings/hints), the following special configuration options are supported:

<table>
<thead>
<tr>
<th>Input Configuration Attribute</th>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>oiio:RawColor</code></td>
<td>int</td>
<td>If nonzero, reading images with non-RGB color models (such as YCbCr) will return unaltered pixel values (versus the default OIIO behavior of automatically converting to RGB).</td>
</tr>
<tr>
<td><code>oiio:ioproxy</code></td>
<td>ptr</td>
<td>Pointer to a <code>Filesystem::IOProxy</code> that will handle the I/O, for example by reading from memory rather than the file system.</td>
</tr>
</tbody>
</table>

### Configuration settings for DPX output

When opening a DPX ImageOutput, the following special metadata tokens control aspects of the writing itself:

<table>
<thead>
<tr>
<th>Output configuration Attribute</th>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>oiio:RawColor</code></td>
<td>int</td>
<td>If nonzero, writing images with non-RGB color models (such as YCbCr) will keep unaltered pixel values (versus the default OIIO behavior of automatically converting from RGB to the designated color space as the pixels are written).</td>
</tr>
<tr>
<td><code>oiio:ioproxy</code></td>
<td>ptr</td>
<td>Pointer to a <code>Filesystem::IOProxy</code> that will handle the I/O, for example by writing to memory rather than the file system.</td>
</tr>
<tr>
<td><code>oiio:dither</code></td>
<td>int</td>
<td>If nonzero and outputting UINT8 values in the file from a source of higher bit depth, will add a small amount of random dither to combat the appearance of banding.</td>
</tr>
</tbody>
</table>

### Custom I/O Overrides

DPX input and output both support the “custom I/O” feature via the special "`oiio:ioproxy`" attributes (see Sections Custom I/O proxies (and writing the file to a memory buffer) and Custom I/O proxies (and reading the file from a memory buffer)) as well as the `set_ioproxy()` methods.

### DPX Attributes

<table>
<thead>
<tr>
<th>ImageSpec Attribute</th>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ImageDescription</code></td>
<td>string</td>
<td>Description of image element</td>
</tr>
<tr>
<td><code>Copyright</code></td>
<td>string</td>
<td>Copyright statement</td>
</tr>
<tr>
<td><code>Software</code></td>
<td>string</td>
<td>Creator</td>
</tr>
<tr>
<td><code>DocumentName</code></td>
<td>string</td>
<td>Project name</td>
</tr>
<tr>
<td><code>DateTime</code></td>
<td>string</td>
<td>Creation date/time</td>
</tr>
<tr>
<td><code>Orientation</code></td>
<td>int</td>
<td>the orientation of the DPX image data (see <code>metadata:orientation</code>)</td>
</tr>
<tr>
<td><code>compression</code></td>
<td>string</td>
<td>The compression type</td>
</tr>
<tr>
<td><code>PixelFormat</code></td>
<td>float</td>
<td>pixel aspect ratio</td>
</tr>
<tr>
<td><code>oiio:BitsPerSample</code></td>
<td>int</td>
<td>the true bits per sample of the DPX file.</td>
</tr>
</tbody>
</table>

<tr>
<td>dpx:EndOfImagePadding</td>
<td>int</td>
<td>Padded bytes at the end of each image</td>
</tr>
</tbody>
</table>
6.6 FITS

FITS (Flexible Image Transport System) is an image file format used for scientific applications, particularly professional astronomy. FITS files use the file extension `.fits`. Official FITS specs and other info may be found at: http://fits.gsfc.nasa.gov/

OpenImageIO supports multiple images in FITS files, and supports the following pixel data types: UINT8, UINT16, UINT32, FLOAT, DOUBLE.

FITS files can store various kinds of arbitrary data arrays, but OpenImageIO’s support of FITS is mostly limited using FITS for image storage. Currently, OpenImageIO only supports 2D FITS data (images), not 3D (volume) data, nor 1-D or higher-dimensional arrays.

<table>
<thead>
<tr>
<th>ImageSpec Attribute</th>
<th>Type</th>
<th>FITS header data or explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Orientation</td>
<td>int</td>
<td>derived from FITS “ORIENTAT” field.</td>
</tr>
<tr>
<td>DateTime</td>
<td>string</td>
<td>derived from the FITS “DATE” field.</td>
</tr>
<tr>
<td>Comment</td>
<td>string</td>
<td>FITS “COMMENT” (*)</td>
</tr>
<tr>
<td>History</td>
<td>string</td>
<td>FITS “HISTORY” (*)</td>
</tr>
<tr>
<td>Hierarch</td>
<td>string</td>
<td>FITS “HIERARCH” (*)</td>
</tr>
<tr>
<td>other</td>
<td></td>
<td>all other FITS keywords will be added to the ImageSpec as arbitrary named metadata.</td>
</tr>
</tbody>
</table>

Note: If the file contains multiple COMMENT, HISTORY, or HIERARCH fields, their text will be appended to form a single attribute (of each) in OpenImageIO’s ImageSpec.

6.7 GIF

GIF (Graphics Interchange Format) is an image file format developed by CompuServe in 1987. Nowadays it is widely used to display basic animations despite its technical limitations.

<table>
<thead>
<tr>
<th>ImageSpec Attribute</th>
<th>Type</th>
<th>GIF header data or explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>gif:Interlacing</td>
<td>int</td>
<td>Specifies if image is interlaced (0 or 1).</td>
</tr>
<tr>
<td>FramesPerSecond</td>
<td>int[2]</td>
<td>Frames per second</td>
</tr>
<tr>
<td>(rational)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>oiiio:Movie</td>
<td>int</td>
<td>If nonzero, indicates that it’s a multi-subimage file intended to represent an animation.</td>
</tr>
<tr>
<td>oiiio:LoopCount</td>
<td>int</td>
<td>Number of times the animation should be played (0-65535, 0 stands for infinity).</td>
</tr>
<tr>
<td>gif:LoopCount</td>
<td>int</td>
<td>Deprecated synonym for oiiio:LoopCount.</td>
</tr>
<tr>
<td>ImageDescription</td>
<td>string</td>
<td>The GIF comment field.</td>
</tr>
</tbody>
</table>

Configuration settings for GIF input
When opening a GIF ImageInput with a configuration (see Section Opening for input with configuration settings/hints), the following special configuration options are supported:

<table>
<thead>
<tr>
<th>Input Configuration Attribute</th>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>oiio:ioproxy</td>
<td>ptr</td>
<td>Pointer to a Filesystem::IOProxy that will handle the I/O, for example by reading from memory rather than the file system.</td>
</tr>
</tbody>
</table>

**Configuration settings for GIF output**

When opening a GIF ImageOutput, the following special metadata tokens control aspects of the writing itself:

<table>
<thead>
<tr>
<th>Output configuration Attribute</th>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>oiio:ioproxy</td>
<td>ptr</td>
<td>Pointer to a Filesystem::IOProxy that will handle the I/O, for example by writing to memory rather than the file system.</td>
</tr>
</tbody>
</table>

**Custom I/O Overrides**

GIF supports the "custom I/O" feature via the special "oiio:ioproxy" attributes (see Sections Custom I/O proxies (and writing the file to a memory buffer) and Custom I/O proxies (and reading the file from a memory buffer)) as well as the set_ioproxy() methods.

**Limitations**

- GIF only supports 3-channel (RGB) images and at most 8 bits per channel.
- Each subimage can include its own palette or use global palette. Palettes contain up to 256 colors of which one can be used as background color. It is then emulated with additional Alpha channel by OpenImageIO’s reader.

**6.8 HDR/RGBE**

HDR (High Dynamic Range), also known as RGBE (rgb with extended range), is a simple format developed for the Radiance renderer to store high dynamic range images. HDR/RGBE files commonly use the file extensions .hdr. The format is described in this section of the Radiance documentation: [http://radsite.lbl.gov/radiance/refer/filefmts.pdf](http://radsite.lbl.gov/radiance/refer/filefmts.pdf)

RGBE does not support tiles, multiple subimages, mipmapping, true half or float pixel values, or arbitrary metadata. Only RGB (3 channel) files are supported.

RGBE became important because it was developed at a time when no standard file formats supported high dynamic range, and is still used for many legacy applications and to distribute HDR environment maps. But newer formats with native HDR support, such as OpenEXR, are vastly superior and should be preferred except when legacy file access is required.

<table>
<thead>
<tr>
<th>ImageSpec Attribute</th>
<th>Type</th>
<th>RGBE header data or explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Orientation</td>
<td>int</td>
<td>encodes the orientation (see Section Display hints)</td>
</tr>
<tr>
<td>oiio:ColorSpace</td>
<td>string</td>
<td>Color space (see Section Color information).</td>
</tr>
<tr>
<td>oiio:Gamma</td>
<td>float</td>
<td>the gamma correction specified in the RGBE header (if it’s gamma corrected).</td>
</tr>
</tbody>
</table>

**Configuration settings for HDR input**
When opening an HDR ImageInput with a configuration (see Section Opening for input with configuration settings/hints), the following special configuration options are supported:

<table>
<thead>
<tr>
<th>Input Configuration Attribute</th>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>oiio:ioproxy</td>
<td>ptr</td>
<td>Pointer to a Filesystem::IOProxy that will handle the I/O, for example by reading from memory rather than the file system.</td>
</tr>
</tbody>
</table>

Configuration settings for HDR output

When opening a HDR ImageOutput, the following special metadata tokens control aspects of the writing itself:

<table>
<thead>
<tr>
<th>Output configuration Attribute</th>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>oiio:ioproxy</td>
<td>ptr</td>
<td>Pointer to a Filesystem::IOProxy that will handle the I/O, for example by writing to memory rather than the file system.</td>
</tr>
</tbody>
</table>

Custom I/O Overrides

HDR supports the “custom I/O” feature via the special "oiio:ioproxy" attributes (see Sections Custom I/O proxies (and writing the file to a memory buffer) and Custom I/O proxies (and reading the file from a memory buffer)) as well as the set_ioproxy() methods.

6.9 HEIF/HEIC/AVIF

HEIF is a container format for images compressed with various compression standards (HEIC is based on HEVC/H.265, AVIF is based on AV1). HEIC is used commonly for iPhone camera pictures, but it is not Apple-specific and will probably become more popular on other platforms in coming years. HEIF files usually use the file extension .HEIC or .AVIF depending on their main compression type.

HEIC and AVIF compression formats are lossy, but are higher visual quality than JPEG while taking <= half the file size. Currently, OIIIO’s HEIF reader supports reading files as RGB or RGBA, uint8 pixel values. Multi-image files are currently supported for reading, but not yet writing. All pixel data is uint8, though we hope to add support for HDR (more than 8 bits) in the future.

Configuration settings for HEIF input

When opening an HEIF ImageInput with a configuration (see Section Opening for input with configuration settings/hints), the following special configuration attributes are supported:

<table>
<thead>
<tr>
<th>Input Configuration Attribute</th>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>oiio:UnassociatedAlpha</td>
<td>int</td>
<td>If nonzero, and the file contains unassociated alpha, this will cause the reader to leave alpha unassociated (versus the default of premultiplying color channels by alpha if the alpha channel is unassociated).</td>
</tr>
</tbody>
</table>

Configuration settings for HEIF output

When opening an HEIF ImageOutput, the following special metadata tokens control aspects of the writing itself:
6.10 ICO

ICO is an image file format used for small images (usually icons) on Windows. ICO files use the file extension `.ico`.

Attributes

<table>
<thead>
<tr>
<th>ImageSpec Attribute</th>
<th>Type</th>
<th>ICO header data or explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>ioio:BitsPerSample</td>
<td>int</td>
<td>the true bits per sample in the ICO file.</td>
</tr>
<tr>
<td>ico:PNG</td>
<td>int</td>
<td>if nonzero, will cause the ICO to be written out using PNG format.</td>
</tr>
</tbody>
</table>

Configuration settings for ICO output

When opening an ICO ImageOutput, the following special metadata tokens control aspects of the writing itself:

<table>
<thead>
<tr>
<th>Output Configuration Attribute</th>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>ioio:dither</td>
<td>int</td>
<td>If nonzero and outputting UINT8 values in the file from a source of higher bit depth, will add a small amount of random dither to combat the appearance of banding.</td>
</tr>
</tbody>
</table>

Limitations

- ICO only supports UINT8 and UINT16 formats; all output images will be silently converted to one of these.
- ICO only supports small images, up to 256 x 256. Requests to write larger images will fail their open() call.

6.11 IFF

IFF files are used by Autodesk Maya and use the file extension `.iff`.

<table>
<thead>
<tr>
<th>ImageSpec Attribute</th>
<th>Type</th>
<th>IFF header data or explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Artist</td>
<td>string</td>
<td>The IFF “author”</td>
</tr>
<tr>
<td>DateTime</td>
<td>string</td>
<td>Creation date/time</td>
</tr>
<tr>
<td>compression</td>
<td>string</td>
<td>The compression type (&quot;none&quot; or &quot;rle&quot; [default])</td>
</tr>
<tr>
<td>ioio:BitsPerSample</td>
<td>int</td>
<td>the true bits per sample of the IFF file.</td>
</tr>
</tbody>
</table>

Configuration settings for IFF output

When opening an IFF ImageOutput, the following special metadata tokens control aspects of the writing itself:
### 6.12 JPEG

JPEG (Joint Photographic Experts Group), or more properly the JFIF file format containing JPEG-compressed pixel data, is one of the most popular file formats on the Internet, with applications, and from digital cameras, scanners, and other image acquisition devices. JPEG/JFIF files usually have the file extension `.jpg`, `.jpe`, `.jpeg`, `.jif`, `.jfif`, or `.jfi`. The JFIF file format is described by [http://www.w3.org/Graphics/JPEG/jfif3.pdf](http://www.w3.org/Graphics/JPEG/jfif3.pdf).

Although we strive to support JPEG/JFIF because it is so widely used, we acknowledge that it is a poor format for high-end work: it supports only 1- and 3-channel images, has no support for alpha channels, no support for high dynamic range or even 16 bit integer pixel data, by convention stores sRGB data and is ill-suited to linear color spaces, and does not support multiple subimages or MIPmap levels. There are newer formats also blessed by the Joint Photographic Experts Group that attempt to address some of these issues, such as JPEG-2000, but these do not have anywhere near the acceptance of the original JPEG/JFIF format.

**Attributes**

<table>
<thead>
<tr>
<th>ImageSpec Attribute</th>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>ImageDescription</td>
<td>string</td>
<td>the JPEG Comment field</td>
</tr>
<tr>
<td>Orientation</td>
<td>int</td>
<td>the image orientation</td>
</tr>
<tr>
<td>XResolution, YResolution, ResolutionUnit</td>
<td>string</td>
<td>The resolution and units from the Exif header</td>
</tr>
<tr>
<td>Compression</td>
<td>string</td>
<td>If supplied, must be &quot;jpeg&quot;, but may optionally have a quality value appended, like &quot;jpeg:90&quot;. Quality can be 1-100, with 100 meaning lossless.</td>
</tr>
<tr>
<td>ICCProfile</td>
<td>uint8[]</td>
<td>The ICC color profile</td>
</tr>
<tr>
<td>jpeg:subsampling</td>
<td>string</td>
<td>Describes the chroma subsampling, e.g., &quot;4:2:0&quot; (the default), &quot;4:4:4&quot;, &quot;4:2:2&quot;, &quot;4:2:1&quot;.</td>
</tr>
<tr>
<td>Exif:<em>, IPTC:</em>, XMP:<em>, GPS:</em></td>
<td>string</td>
<td>Extensive Exif, IPTC, XMP, and GPS data are supported by the reader/writer, and you should assume that nearly everything described Appendix Metadata conventions is properly translated when using JPEG files.</td>
</tr>
</tbody>
</table>

**Configuration settings for JPEG input**

When opening a JPEG ImageInput with a configuration (see Section Opening for input with configuration settings/hints), the following special configuration attributes are supported:

<table>
<thead>
<tr>
<th>Input Attribute</th>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>oiio:ioproxy</td>
<td>ptr</td>
<td>Pointer to a Filesystem::IOProxy that will handle the I/O, for example by reading from memory rather than the file system.</td>
</tr>
</tbody>
</table>
Configuration settings for JPEG output

When opening a JPEG ImageOutput, the following special metadata tokens control aspects of the writing itself:

<table>
<thead>
<tr>
<th>Output Configuration Attribute</th>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>oiio:dither</td>
<td>int</td>
<td>If nonzero and outputting UINT8 values in the file from a source of higher bit depth, will add a small amount of random dither to combat the appearance of banding.</td>
</tr>
<tr>
<td>oiio:ioproxy</td>
<td>ptr</td>
<td>Pointer to a Filesystem::IOProxy that will handle the I/O, for example by writing to a memory buffer.</td>
</tr>
<tr>
<td>jpeg:progressive</td>
<td>int</td>
<td>If nonzero, will write a progressive JPEG file.</td>
</tr>
</tbody>
</table>

Custom I/O Overrides

JPEG supports the “custom I/O” feature via the ImageInput::set_ioproxy() method and the special "oiio:ioproxy" attributes (see Section Custom I/O proxies (and reading the file from a memory buffer)).

Limitations

- JPEG/JFIF only supports 1- (grayscale) and 3-channel (RGB) images. As a special case, OpenImageIO’s JPEG writer will accept n-channel image data, but will only output the first 3 channels (if n >= 3) or the first channel (if n <= 2), silently drop any extra channels from the output.
- Since JPEG/JFIF only supports 8 bits per channel, OpenImageIO’s JPEG/JFIF writer will silently convert to UINT8 upon output, regardless of requests to the contrary from the calling program.
- OpenImageIO’s JPEG/JFIF reader and writer always operate in scanline mode and do not support tiled image input or output.

6.13 JPEG-2000

JPEG-2000 is a successor to the popular JPEG/JFIF format, that supports better (wavelet) compression and a number of other extensions. It’s geared toward photography. JPEG-2000 files use the file extensions .jp2 or .j2k. The official JPEG-2000 format specification and other helpful info may be found at: http://www.jpeg.org/JPEG2000.htm

JPEG-2000 is not yet widely used, so OpenImageIO’s support of it is preliminary. In particular, we are not yet very good at handling the metadata robustly.

Attributes

<table>
<thead>
<tr>
<th>ImageSpec Attribute</th>
<th>Type</th>
<th>JPEG-2000 header data or explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>jpeg2000:streamformat</td>
<td>string</td>
<td>specifies the JPEG-2000 stream format (&quot;none&quot; or &quot;jpc&quot;)</td>
</tr>
<tr>
<td>oiio:ColorSpace</td>
<td>string</td>
<td>Color space (see Section Color information).</td>
</tr>
<tr>
<td>ICCProfile</td>
<td>uint8[]</td>
<td>The ICC color profile</td>
</tr>
</tbody>
</table>

Configuration settings for JPEG-2000 input

When opening an JPEG-2000 ImageInput with a configuration (see Section Opening for input with configuration settings/hints), the following special configuration attributes are supported:
OpenImageIO, Release 2.4.1

<table>
<thead>
<tr>
<th>Input Configuration Attribute</th>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>oiio:UnassociatedAlpha</code></td>
<td>int</td>
<td>If nonzero, will leave alpha unassociated (versus the default of premultiplying color channels by alpha if the alpha channel is unassociated).</td>
</tr>
<tr>
<td><code>oiio:ioproxy</code></td>
<td>ptr</td>
<td>Pointer to a <code>Filesystem::IOProxy</code> that will handle the I/O, for example by reading from memory rather than the file system.</td>
</tr>
</tbody>
</table>

### Configuration settings for JPEG-2000 output

When opening a JPEG-2000 ImageOutput, the following special metadata tokens control aspects of the writing itself:

<table>
<thead>
<tr>
<th>Output Configuration Attribute</th>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>oiio:dither</code></td>
<td>int</td>
<td>If nonzero and outputting UINT8 values in the file from a source of higher bit depth, will add a small amount of random dither to combat the appearance of banding.</td>
</tr>
<tr>
<td><code>oiio:ioproxy</code></td>
<td>ptr</td>
<td>Pointer to a <code>Filesystem::IOProxy</code> that will handle the I/O, for example by writing to a memory buffer.</td>
</tr>
<tr>
<td><code>oiio:UnassociatedAlpha</code></td>
<td>int</td>
<td>If nonzero, indicates that the data being passed is already in unassociated form (non-premultiplied colors) and should stay that way for output rather than being assumed to be associated and get automatic un-association to store in the file.</td>
</tr>
</tbody>
</table>

### Custom I/O Overrides

JPEG-2000 input and output both support the “custom I/O” feature via the special "`oiio:ioproxy`" attributes (see Sections Custom I/O proxies (and writing the file to a memory buffer) and Custom I/O proxies (and reading the file from a memory buffer)) as well as the `set_ioproxy()` methods.

### 6.14 Movie formats (using ffmpeg)

The `ffmpeg`-based reader is capable of reading the individual frames from a variety of movie file formats, including:

<table>
<thead>
<tr>
<th>Format</th>
<th>Extensions</th>
</tr>
</thead>
<tbody>
<tr>
<td>AVI</td>
<td>.avi</td>
</tr>
<tr>
<td>QuickTime</td>
<td>.qt,.mov</td>
</tr>
<tr>
<td>MPEG-4</td>
<td>.mp4,.m4a,.m4v</td>
</tr>
<tr>
<td>3GPP files</td>
<td>.3gp,.3g2</td>
</tr>
<tr>
<td>Motion JPEG-2000</td>
<td>.mj2</td>
</tr>
<tr>
<td>Apple M4V</td>
<td>.m4v</td>
</tr>
<tr>
<td>MPEG-1/MPEG-2</td>
<td>.mpg</td>
</tr>
</tbody>
</table>

Currently, these files may only be read. Write support may be added in a future release. Also, currently, these files simply look to OIIO like simple multi-image files and not much support is given to the fact that they are technically `movies` (for example, there is no support for reading audio information).

Some special attributes are used for movie files:
<table>
<thead>
<tr>
<th>ImageSpec Attribute</th>
<th>Type</th>
<th>Header data or explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>oiio:Movie</td>
<td>int</td>
<td>Nonzero value for movie files</td>
</tr>
<tr>
<td>oiio:subimages</td>
<td>int</td>
<td>The number of frames in the movie, positive if it can be known without reading the entire file. Zero or not present if the number of frames cannot be determined from reading from just the file header.</td>
</tr>
<tr>
<td>FramesPerSecond</td>
<td>int[2] (rational)</td>
<td>Frames per second</td>
</tr>
</tbody>
</table>

### 6.15 Null format

The `nullptr` reader/writer is a mock-up that does not perform any actual I/O. The reader just returns constant-colored pixels, and the writer just returns directly without saving any data. This has several uses:

- Benchmarking, if you want to have OIIO’s input or output truly take as close to no time whatsoever.
- “Dry run” of applications where you don’t want it to produce any real output (akin to a Unix command that you redirect output to `/dev/null`).
- Make “fake” input that looks like a file, but the file doesn’t exist (if you are happy with constant-colored pixels).

The filename allows a REST-ful syntax, where you can append modifiers that specify things like resolution (of the non-existent file), etc. For example:

```plaintext
foo.null?RES=640x480&CHANNELS=3
```

would specify a null file with resolution 640x480 and 3 channels. Token/value pairs accepted are:

<table>
<thead>
<tr>
<th>Token</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RES=1024x1024</td>
<td>Set resolution (3D example: 256x256x100)</td>
</tr>
<tr>
<td>CHANNELS=4</td>
<td>Set number of channels</td>
</tr>
<tr>
<td>TILES=64x64</td>
<td>Makes it look like a tiled image with tile size</td>
</tr>
<tr>
<td>TYPE=uint8</td>
<td>Set the pixel data type</td>
</tr>
<tr>
<td>PIXEL=r,g,b,...</td>
<td>Set pixel values (comma separates channel values)</td>
</tr>
<tr>
<td>TEX=1</td>
<td>Make it look like a full MIP-mapped texture</td>
</tr>
<tr>
<td>attrib=value</td>
<td>Anything else will set metadata</td>
</tr>
</tbody>
</table>
### 6.16 OpenEXR

OpenEXR is an image file format developed by Industrial Light & Magic, and subsequently open-sourced. OpenEXR’s strengths include support of high dynamic range imagery (half and float pixels), tiled images, explicit support of MIPmaps and cubic environment maps, arbitrary metadata, and arbitrary numbers of color channels. OpenEXR files use the file extension `.exr`. The official OpenEXR site is [http://www.openexr.com/](http://www.openexr.com/).

#### Attributes

<table>
<thead>
<tr>
<th>ImageSpec Attribute</th>
<th>Type</th>
<th>OpeneEXR header data or explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>width, height, x, y</td>
<td>int</td>
<td>dataWindow</td>
</tr>
<tr>
<td>full_width, full_height, full_x, full_y</td>
<td>int</td>
<td>displayWindow</td>
</tr>
<tr>
<td>worldtocamera</td>
<td>matrix</td>
<td>worldToCamera</td>
</tr>
<tr>
<td>worldtoscreen</td>
<td>matrix</td>
<td>worldToScreen</td>

<tr>
<td>ExposureTime</td>
<td>float</td>
<td>expTime</td>
</tr>
<tr>
<td>FNumber</td>
<td>int[2]</td>
<td>Frames per second playback rate (vecsemantics will be marked as RATIONAL)</td>
</tr>
<tr>
<td>captureRate</td>
<td>int[2]</td>
<td>Frames per second capture rate (vecsemantics will be marked as RATIONAL)</td>
</tr>
<tr>
<td>smpte:TimeCode</td>
<td>int[2]</td>
<td>SMPTE time code (vecsemantics will be marked as TIMECODE)</td>
</tr>
<tr>
<td>smpte:KeyCode</td>
<td>int[7]</td>
<td>SMPTE key code (vecsemantics will be marked as KEYCODE)</td>
</tr>
<tr>
<td>openexr:lineOrder</td>
<td>string</td>
<td>OpenEXR lineOrder attribute: &quot;increasingY&quot;, &quot;randomY&quot;, or &quot;decreasingY&quot;.</td>
</tr>
<tr>
<td>openexr:roundingmode</td>
<td>int</td>
<td>the MIPmap rounding mode of the file.</td>
</tr>
<tr>
<td>openexr:dwaCompressionLevel</td>
<td>float</td>
<td>compression level for dwaa or dwab compression (default: 45.0).</td>
</tr>
<tr>
<td>other</td>
<td></td>
<td>All other attributes will be added to the ImageSpec by their name and apparent type.</td>
</tr>
</tbody>
</table>

#### Configuration settings for OpenEXR input
When opening an OpenEXR ImageInput with a *configuration* (see Section *Opening for input with configuration settings/hints*), the following special configuration attributes are supported:

<table>
<thead>
<tr>
<th>Input Configuration Attribute</th>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>oiio:ioproxy</td>
<td>ptr</td>
<td>Pointer to a Filesystem::IOProxy that will handle the I/O, for example by reading from memory rather than the file system.</td>
</tr>
<tr>
<td>oiio:missingcolor</td>
<td>float or string</td>
<td>Either an array of float values or a string holding a comma-separated list of values, if present this is a request to use this color for pixels of any missing tiles or scanlines, rather than considering a tile/scanline read failure to be an error. This can be helpful when intentionally reading partially-written or incomplete files (such as an in-progress render).</td>
</tr>
</tbody>
</table>

**Configuration settings for OpenEXR output**

When opening an OpenEXR ImageOutput, the following special metadata tokens control aspects of the writing itself:

<table>
<thead>
<tr>
<th>Output Configuration Attribute</th>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>oiio:RawColor</td>
<td>int</td>
<td>If nonzero, writing images with non-RGB color models (such as YCbCr) will keep unaltered pixel values (versus the default OIIO behavior of automatically converting from RGB to the designated color space as the pixels are written).</td>
</tr>
<tr>
<td>oiio:ioproxy</td>
<td>ptr</td>
<td>Pointer to a Filesystem::IOProxy that will handle the I/O, for example by writing to a memory buffer.</td>
</tr>
</tbody>
</table>

**Custom I/O Overrides**

OpenEXR input and output both support the “custom I/O” feature via the special "oiio:ioproxy" attributes (see Sections *Custom I/O proxies (and writing the file to a memory buffer)* and *Custom I/O proxies (and reading the file from a memory buffer)*) as well as the set_ioproxy() methods.

**A note on channel names**

The underlying OpenEXR library (libIlmImf) always saves channels into lexicographic order, so the channel order on disk (and thus when read!) will NOT match the order when the image was created.

But in order to adhere to OIIO’s convention that RGBA/Z will always be the first channels (if they exist), OIIO’s OpenEXR reader will automatically reorder just those channels to appear at the front and in that order. All other channel names will remain in their relative order as presented to OIIO by libIlmImf.

**Limitations**

- The OpenEXR format only supports HALF, FLOAT, and UINT32 pixel data. OpenImageIO’s OpenEXR writer will silently convert data in formats (including the common UINT8 and UINT16 cases) to HALF data for output.
6.17 OpenVDB

OpenVDB is an open-source volume data file format. OpenVDB files commonly use the extension `.vdb`. The official OpenVDB site is: [http://www.openvdb.org/](http://www.openvdb.org/) Currently, OpenImageIO only reads OpenVDB files, and does not write them.

Volumes are comprised of multiple *layers* (which appear to OpenImageIO as subimages). Each layer/subimage may have a different name, resolution, and coordinate mapping. Layers may be scalar (1 channel) or vector (3 channel) fields, and the voxel data are always float. OpenVDB files always report as tiled, using the leaf dimension size.

<table>
<thead>
<tr>
<th>ImageSpec Attribute</th>
<th>Type</th>
<th>OpenVDB header data or explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>ImageDescription</td>
<td>string</td>
<td>Description of image element</td>
</tr>
<tr>
<td>oiio:subimagename</td>
<td>string</td>
<td>unique layer name</td>
</tr>
<tr>
<td>openvdb:indexToWorld</td>
<td>matrix of doubles</td>
<td>conversion of voxel index to world space coordinates.</td>
</tr>
<tr>
<td>openvdb:worldToIndex</td>
<td>matrix of doubles</td>
<td>conversion of world space coordinates to voxel index.</td>
</tr>
<tr>
<td>worldToCamera</td>
<td>matrix</td>
<td>World-to-local coordinate mapping.</td>
</tr>
</tbody>
</table>

6.18 PNG

PNG (Portable Network Graphics) is an image file format developed by the open source community as an alternative to the GIF, after Unisys started enforcing patents allegedly covering techniques necessary to use GIF. PNG files use the file extension `.png`.

Attributes

<table>
<thead>
<tr>
<th>ImageSpec Attribute</th>
<th>Type</th>
<th>PNG header data or explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>ImageDescription</td>
<td>string</td>

</tbody>
</table>

Configuration settings for PNG input

When opening an PNG ImageInput with a *configuration* (see Section *Opening for input with configuration settings/hints*), the following special configuration attributes are supported:
Input Configuration Attribute | Type | Meaning
--- | --- | ---
oiio:UnassociatedAlpha | int | If nonzero, will leave alpha unassociated (versus the default of premultiplying color channels by alpha if the alpha channel is unassociated).
oiio:ioproxy | ptr | Pointer to a Filesystem::IOProxy that will handle the I/O, for example by reading from memory rather than the file system.

Configuration settings for PNG output

When opening an PNG ImageOutput, the following special metadata tokens control aspects of the writing itself:

Output Configuration Attribute | Type | Meaning
--- | --- | ---
oiio:dither | int | If nonzero and outputting UINT8 values in the file from a source of higher bit depth, will add a small amount of random dither to combat the appearance of banding.
oiio:ioproxy | ptr | Pointer to a Filesystem::IOProxy that will handle the I/O, for example by writing to a memory buffer.
png:compressionLevel | int | Compression level for zip/deflate compression, on a scale from 0 (fastest, minimal compression) to 9 (slowest, maximal compression). The default is 6. PNG compression is always lossless.
png:filter | int | Controls the “row filters” that prepare the image for optimal compression. The default is 0 (PNG_NO_FILTERS), but other values (which may be “or-ed” or summed to combine their effects) are 8 (PNG_FILTER_NONE), 16 (PNG_FILTER_SUB), 32 (PNG_FILTER_UP), 64 (PNG_FILTER_AVG), or 128 (PNG_FILTER_PAETH).

Custom I/O Overrides

PNG input and output both support the “custom I/O” feature via the special "oiio:ioproxy" attributes (see Sections Custom I/O proxies (and writing the file to a memory buffer) and Custom I/O proxies (and reading the file from a memory buffer)) as well as the set_ioproxy() methods.

Limitations

- PNG stupidly specifies that any alpha channel is “unassociated” (i.e., that the color channels are not “premultiplied” by alpha). This is a disaster, since it results in bad loss of precision for alpha image compositing, and even makes it impossible to properly represent certain additive glows and other desirable pixel values. OpenImageIO automatically associates alpha (i.e., multiplies colors by alpha) upon input and deassociates alpha (divides colors by alpha) upon output in order to properly conform to the OIIO convention (and common sense) that all pixel values passed through the OIIO APIs should use associated alpha.
- PNG only supports UINT8 and UINT16 output; other requested formats will be automatically converted to one of these.

6.18. PNG
6.19 PNM / Netpbm

The Netpbm project, a.k.a. PNM (portable “any” map) defines PBM, PGM, and PPM (portable bitmap, portable grayscale, portable pixmap) files. Without loss of generality, we will refer to these all collectively as “PNM.” These files have extensions .pbm, .pgm, and .ppm and customarily correspond to bi-level bitmaps, 1-channel grayscale, and 3-channel RGB files, respectively, or .pnm for those who reject the nonsense about naming the files depending on the number of channels and bitdepth.

PNM files are not much good for anything, but because of their historical significance and extreme simplicity (that causes many “amateur” programs to write images in these formats), OpenImageIO supports them. PNM files do not support floating point images, anything other than 1 or 3 channels, no tiles, no multi-image, no MIPmapping. It’s not a smart choice unless you are sending your images back to the 1980’s via a time machine.

Attributes

<table>
<thead>
<tr>
<th>ImageSpec Attribute</th>
<th>Type</th>
<th>PNM header data or explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>oiio:BitsPerSample</td>
<td>int</td>
<td>The true bits per sample of the file (1 for true PBM files, even though OIIO will report the format as UINT8).</td>
</tr>
<tr>
<td>pnm:binary</td>
<td>int</td>
<td>nonzero if the file itself used the PNM binary format, 0 if it used ASCII. The PNM writer honors this attribute in the ImageSpec to determine whether to write an ASCII or binary file.</td>
</tr>
</tbody>
</table>

Configuration settings for PNM input

When opening a PNM ImageInput with a configuration (see Section Opening for input with configuration settings/hints), the following special configuration attributes are supported:

<table>
<thead>
<tr>
<th>Input Attribute</th>
<th>Configuration Attribute</th>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>oiio:ioproxy</td>
<td>ptr</td>
<td>Pointer to a Filesystem::IOProxy that will handle the I/O, for example by reading from memory rather than the file system.</td>
</tr>
</tbody>
</table>

Configuration settings for PNM output

When opening a PNM ImageOutput, the following special metadata tokens control aspects of the writing itself:

<table>
<thead>
<tr>
<th>Output Attribute</th>
<th>Configuration Attribute</th>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>oiio:dither</td>
<td>int</td>
<td>If nonzero and outputting UINT8 values in the file from a source of higher bit depth, will add a small amount of random dither to combat the appearance of banding.</td>
</tr>
<tr>
<td></td>
<td>oiio:ioproxy</td>
<td>ptr</td>
<td>Pointer to a Filesystem::IOProxy that will handle the I/O, for example by writing to a memory buffer.</td>
</tr>
</tbody>
</table>

Custom I/O Overrides

PNM input and output both support the “custom I/O” feature via the special "oiio:ioproxy" attributes (see Sections Custom I/O proxies (and writing the file to a memory buffer) and Custom I/O proxies (and reading the file from a memory buffer)) as well as the set_ioproxy() methods.
6.20 PSD

PSD is the file format used for storing Adobe PhotoShop images. OpenImageIO provides limited read abilities for PSD, but not currently the ability to write PSD files.

Configuration settings for PSD input

When opening an ImageInput with a configuration (see Section Opening for input with configuration settings/hints), the following special configuration options are supported:

<table>
<thead>
<tr>
<th>Input Attribute</th>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>oiio:RawColor</td>
<td>int</td>
<td>If nonzero, reading images with non-RGB color models (such as YCbCr or CMYK) will return unaltered pixel values (versus the default OIIO behavior of automatically converting to RGB).</td>
</tr>
<tr>
<td>oiio:ioproxy</td>
<td>ptr</td>
<td>Pointer to a Filesystem:IOProxy that will handle the I/O, for example by reading from memory rather than the file system.</td>
</tr>
</tbody>
</table>

Currently, the PSD format reader supports color modes RGB, CMYK, multichannel, grayscale, indexed, and bitmap. It does NOT currently support Lab or duotone modes.

Custom I/O Overrides

PSD supports the “custom I/O” feature via the special "oiio:ioproxy" attributes (see Sections Custom I/O proxies (and writing the file to a memory buffer) and Custom I/O proxies (and reading the file from a memory buffer)) as well as the set_ioproxy() methods.

6.21 Ptex

Ptex is a special per-face texture format developed by Walt Disney Feature Animation. The format and software to read/write it are open source, and available from http://ptex.us/. Ptex files commonly use the file extension .ptex.

OpenImageIO’s support of Ptex is still incomplete. We can read pixels from Ptex files, but the TextureSystem doesn’t properly filter across face boundaries when using it as a texture. OpenImageIO currently does not write Ptex files at all.

<table>
<thead>
<tr>
<th>ImageSpec Attribute</th>
<th>Type</th>
<th>Ptex header data or explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>ptex:meshType</td>
<td>string</td>
<td>the mesh type, either &quot;triangle&quot; or &quot;quad&quot;.</td>
</tr>
<tr>
<td>ptex:hasEdits</td>
<td>int</td>
<td>nonzero if the Ptex file has edits.</td>
</tr>
<tr>
<td>wrapmode</td>
<td>string</td>
<td>the wrap mode as specified by the Ptex file.</td>
</tr>
<tr>
<td>other</td>
<td></td>
<td>Any other arbitrary metadata in the Ptex file will be stored directly as attributes in the ImageSpec.</td>
</tr>
</tbody>
</table>
6.22 RAW digital camera files

A variety of digital camera “raw” formats are supported via this plugin that is based on the LibRaw library (http://www.libraw.org/).

**Configuration settings for RAW input**

When opening an ImageInput with a *configuration* (see Section *Opening for input with configuration settings/hints*), the following special configuration options are supported:
<table>
<thead>
<tr>
<th>Input Configuration Attribute</th>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>raw:auto_bright</td>
<td>int</td>
<td>If nonzero, will use libraw’s exposure correction. (Default: 0)</td>
</tr>
<tr>
<td>raw:use_camera_wb</td>
<td>int</td>
<td>If 1, use libraw’s camera white balance adjustment. (Default: 1)</td>
</tr>
<tr>
<td>raw:use_camera_matrix</td>
<td>int</td>
<td>Whether to use the embedded color profile, if it’s present: 0 = never, 1 (default) = only for DNG files, 3 = always.</td>
</tr>
<tr>
<td>raw:adjust_maximum_thr</td>
<td>float</td>
<td>If nonzero, auto-adjusting maximum value. (Default: 0.0)</td>
</tr>
<tr>
<td>raw:user_sat</td>
<td>int</td>
<td>If nonzero, sets the camera maximum value that will be normalized to appear saturated. (Default: 0)</td>
</tr>
<tr>
<td>raw:aber</td>
<td>float[2]</td>
<td>Red and blue scale factors for chromatic aberration correction when decoding the raw image. The default (1,1) means to perform no correction. This is an overall spatial scale, sensible values will be very close to 1.0.</td>
</tr>
<tr>
<td>raw:half_size</td>
<td>int</td>
<td>If nonzero, outputs the image in half size. (Default: 0)</td>
</tr>
<tr>
<td>raw:user_mul</td>
<td>float[4]</td>
<td>Sets user white balance coefficients. Only applies if raw:use_camera_wb is not equal to 0.</td>
</tr>
<tr>
<td>raw:ColorSpace</td>
<td>string</td>
<td>Which color primaries to use for the returned pixel values: raw, sRGB, sRGB-linear (sRGB primaries, but a linear transfer function), Adobe, Wide, ProPhoto, ProPhoto-linear, XYZ, ACES (only supported by LibRaw &gt;= 0.18), DCI-P3 (LibRaw &gt;= 0.21), Rec2020 (LibRaw &gt;= 0.2). (Default: sRGB)</td>
</tr>
<tr>
<td>raw:Exposure</td>
<td>float</td>
<td>Amount of exposure before de-mosaicing, from 0.25 (2 stop darken) to 8 (3 stop brighter). (Default: 0, meaning no correction.)</td>
</tr>
<tr>
<td>raw:Demosaic</td>
<td>string</td>
<td>Force a demosaicing algorithm: linear, VNG, PPG, AHD (default), DCB, AHD-Mod, AFD, VCD, Mixed, LMMSE, AMAZE, DHT, AAHD, none.</td>
</tr>
<tr>
<td>raw:HighlightMode</td>
<td>int</td>
<td>Set libraw highlight mode processing: 0 = clip, 1 = unclip, 2 = blend, 3+ = rebuild. (Default: 0.)</td>
</tr>
<tr>
<td>raw:balance_clamped</td>
<td>int</td>
<td>If nonzero, balance any clamped highlight values in the image. Resolves issues where highlights take on an undesired hue shift due to incongruous channel sensor saturation. Enabling this option will change the output datatype to HALF. (Default: 0)</td>
</tr>
<tr>
<td>raw:apply_scene_linear_scale</td>
<td>int</td>
<td>If nonzero, applies an additional multiplication to the pixel values returned by libraw. See raw:camera_to_scene_linear_scale for more details. Enabling this option will change the output datatype to HALF. (Default: 0)</td>
</tr>
<tr>
<td>raw:camera_to_scene_linear_scale</td>
<td>float</td>
<td>Whilst the libraw pixel values are linear, they are normalized based on the whitepoint / sensor / ISO and shooting conditions. An additional multiplication is needed to bring exposure levels up so that a correctly photographed 18% grey card has pixel values at 0.18. Setting this metadata key implies raw:apply_scene_linear_scale. Enabling this option will change the output datatype to HALF. (Default: 0)</td>
</tr>
<tr>
<td>raw:user_flip</td>
<td>int</td>
<td>Set libraw user flip value : -1 ignored, other values are between [0; 8] with the same definition than the Exif orientation code.</td>
</tr>
</tbody>
</table>
6.23 RLA

RLA (Run-Length encoded, version A) is an early CGI renderer output format, originating from Wavefront Advanced Visualizer and used primarily by software developed at Wavefront. RLA files commonly use the file extension .rla.

Attributes

<table>
<thead>
<tr>
<th>ImageSpec Attribute</th>
<th>Type</th>
<th>RLA header data or explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>width, height, x, y</td>
<td>int</td>
<td>RLA “active/viewable” window.</td>
</tr>
<tr>
<td>full_width, full_height,</td>
<td>int</td>
<td>RLA “full” window.</td>
</tr>
<tr>
<td>full_x, full_y</td>
<td></td>
<td></td>
</tr>
<tr>
<td>rla:FrameNumber</td>
<td>int</td>
<td>frame sequence number.</td>
</tr>
<tr>
<td>rla:Revision</td>
<td>int</td>
<td>file format revision number, currently 0xFFFE.</td>
</tr>
<tr>
<td>rla:JobNumber</td>
<td>int</td>
<td>job number ID of the file.</td>
</tr>
<tr>
<td>rla:FieldRendered</td>
<td>int</td>
<td>whether the image is a field-rendered (interlaced) 0 for false, non-</td>
</tr>
<tr>
<td></td>
<td></td>
<td>zero for true.</td>
</tr>
<tr>
<td>rla:FileName</td>
<td>string</td>
<td>name under which the file was originally saved.</td>
</tr>
<tr>
<td>ImageDescription</td>
<td>string</td>
<td>RLA “Description” of the image.</td>
</tr>
<tr>
<td>Software</td>
<td>string</td>
<td>name of software used to save the image.</td>
</tr>
<tr>
<td>HostComputer</td>
<td>string</td>
<td>name of machine used to save the image.</td>
</tr>
<tr>
<td>Artist</td>
<td>string</td>
<td>RLA “UserName”: logon name of user who saved the image.</td>
</tr>
<tr>
<td>rla:Aspect</td>
<td>string</td>
<td>textual description format description string.</td>
</tr>
<tr>
<td>rla:ColorChannel</td>
<td>string</td>
<td>textual description of color channel data format (usually rgb).</td>
</tr>
<tr>
<td>rla:Time</td>
<td>string</td>
<td>description (format not standardized) of amount of time spent on cre-</td>
</tr>
<tr>
<td></td>
<td></td>
<td>ating the image.</td>
</tr>
<tr>
<td>rla:Filter</td>
<td>string</td>
<td>name of post-processing filter applied to the image.</td>
</tr>
<tr>
<td>rla:AuxData</td>
<td>string</td>
<td>textual description of auxiliary channel data format.</td>
</tr>
<tr>
<td>rla:AspectRatio</td>
<td>float</td>
<td>image aspect ratio.</td>
</tr>
<tr>
<td>rla:RedChroma</td>
<td>vec2 or vec3 of floats</td>
<td>red point XY (vec2) or XYZ (vec3) coordinates.</td>
</tr>
<tr>
<td>rla:GreenChroma</td>
<td>vec2 or vec3 of floats</td>
<td>green point XY (vec2) or XYZ (vec3) coordinates.</td>
</tr>
<tr>
<td>rla:BlueChroma</td>
<td>vec2 or vec3 of floats</td>
<td>blue point XY (vec2) or XYZ (vec3) coordinates.</td>
</tr>
<tr>
<td>rla:WhitePoint</td>
<td>vec2 or vec3 of floats</td>
<td>white point XY (vec2) or XYZ (vec3) coordinates.</td>
</tr>
<tr>
<td>oiio:ColorSpace</td>
<td>string</td>
<td>Color space (see Section Color information).</td>
</tr>
<tr>
<td>oiio:Gamma</td>
<td>float</td>
<td>the gamma correction value (if specified).</td>
</tr>
</tbody>
</table>

Configuration settings for RLA output

When opening a RLA ImageOutput, the following special metadata tokens control aspects of the writing itself:

<table>
<thead>
<tr>
<th>Output Configuration Attribute</th>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>oiio:dither</td>
<td>int</td>
<td>If nonzero and outputting UINT8 values in the file from a source of</td>
</tr>
<tr>
<td></td>
<td></td>
<td>higher bit depth, will add a small amount of random dither to combat</td>
</tr>
<tr>
<td></td>
<td></td>
<td>the appearance of banding.</td>
</tr>
</tbody>
</table>
Limitations

- OpenImageIO will only write a single image to each file, multiple subimages are not supported by the writer (but are supported by the reader).

6.24 SGI

The SGI image format was a simple raster format used long ago on SGI machines. SGI files use the file extensions sgi, rgb, rgba, bw, int, and inta.

The SGI format is sometimes used for legacy apps, but has little merit otherwise: no support for tiles, no MIPmaps, no multi-subimage, only 8- and 16-bit integer pixels (no floating point), only 1-4 channels.

Attributes

<table>
<thead>
<tr>
<th>ImageSpec Attribute</th>
<th>Type</th>
<th>SGI header data or explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>compression</td>
<td>string</td>
<td>The compression of the SGI file (rle, if RLE compression is used).</td>
</tr>
<tr>
<td>ImageDescription</td>
<td>string</td>
<td>Image name.</td>
</tr>
</tbody>
</table>

Configuration settings for SGI output

When opening an SGI ImageOutput, the following special metadata tokens control aspects of the writing itself:

<table>
<thead>
<tr>
<th>Output Configuration Attribute</th>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>oiiio:dither</td>
<td>int</td>
<td>If nonzero and outputting UINT8 values in the file from a source of higher bit depth, will add a small amount of random dither to combat the appearance of banding.</td>
</tr>
</tbody>
</table>

6.25 Softimage PIC

Softimage PIC is an image file format used by the SoftImage 3D application, and some other programs that needed to be compatible with it. Softimage files use the file extension .pic.

The Softimage PIC format is sometimes used for legacy apps, but has little merit otherwise, so currently OpenImageIO only reads Softimage files and is unable to write them.

<table>
<thead>
<tr>
<th>ImageSpec Attribute</th>
<th>Type</th>
<th>PIC header data or explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>compression</td>
<td>string</td>
<td>The compression of the SGI file (rle, if RLE compression is used).</td>
</tr>
<tr>
<td>ImageDescription</td>
<td>string</td>
<td>Comment</td>
</tr>
<tr>
<td>oiiio:BitsPerSample</td>
<td>int</td>
<td>the true bits per sample of the PIC file.</td>
</tr>
</tbody>
</table>
6.26 Targa

Targa (a.k.a. Truevision TGA) is an image file format with little merit except that it is very simple and is used by many legacy applications. Targa files use the file extension .tga, or, much more rarely, .tpic. The official Targa format specification may be found at: http://www.dca.fee.unicamp.br/~martino/disciplinas/ea978/tgaffs.pdf

Attributes

<table>
<thead>
<tr>
<th>ImageSpec Attribute</th>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>ImageDescription</td>
<td>string</td>
<td>TGA header data or explanation</td>
</tr>
<tr>
<td>Artist</td>
<td>string</td>
<td>author</td>
</tr>
<tr>
<td>DocumentName</td>
<td>string</td>
<td>job name/ID</td>
</tr>
<tr>
<td>Software</td>
<td>string</td>
<td>software name</td>
</tr>
<tr>
<td>DateTime</td>
<td>string</td>
<td>TGA time stamp</td>
</tr>
<tr>
<td>targa:JobTime</td>
<td>string</td>
<td>TGA “job time.”</td>
</tr>
<tr>
<td>compression</td>
<td>string</td>
<td>values of none and rle are supported. The writer will use RLE compression if any unknown compression methods are requested.</td>
</tr>
<tr>
<td>targa:alpha_type</td>
<td>int</td>
<td>Meaning of any alpha channel (0 = none; 1 = undefined, ignore; 2 = undefined, preserve; 3 = useful unassociated alpha; 4 = useful associated alpha / premultiplied color).</td>
</tr>
<tr>
<td>targa:ImageID</td>
<td>string</td>
<td>Image ID</td>
</tr>
<tr>
<td>targa:JobTime</td>
<td>string</td>
<td>Job time</td>
</tr>
<tr>
<td>targa:version</td>
<td>int</td>
<td>TGA file format version (1 or 2)</td>
</tr>
<tr>
<td>PixelAspectRatio</td>
<td>float</td>
<td>pixel aspect ratio</td>
</tr>
<tr>
<td>oiio:BitsPerSample</td>
<td>int</td>
<td>the true bits per sample of the PIC file.</td>
</tr>
<tr>
<td>oiio:ColorSpace</td>
<td>string</td>
<td>Color space (see Section Color information).</td>
</tr>
<tr>
<td>oiio:Gamma</td>
<td>float</td>
<td>the gamma correction value (if specified).</td>
</tr>
</tbody>
</table>

If the TGA file contains a thumbnail, its dimensions will be stored in the attributes "thumbnail_width", "thumbnail_height", and "thumbnail_nchannels", and the thumbnail pixels themselves will be retrievable via ImageInput::get_thumbnail() or ImageBuf::thumbnail() or ImageCache::get_thumbnail().

Configuration settings for Targa input

When opening an Targa ImageInput with a configuration (see Section Opening for input with configuration settings/hints), the following special configuration attributes are supported:

<table>
<thead>
<tr>
<th>Input Attribute</th>
<th>Configuration Attribute</th>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>oiio:ioproxy</td>
<td>ptr</td>
<td></td>
<td>Pointer to a Filesystem::IOProxy that will handle the I/O, for example by reading from memory rather than the file system.</td>
</tr>
<tr>
<td>oiio:UnassociatedAlpha</td>
<td>int</td>
<td></td>
<td>If nonzero, and the file contains unassociated alpha, this will cause the reader to leave alpha unassociated (versus the default of premultiplying color channels by alpha if the alpha channel is unassociated).</td>
</tr>
</tbody>
</table>

Configuration settings for Targa output

When opening a Targa ImageOutput, the following special metadata tokens control aspects of the writing itself:
Output Configuration Attribute | Type | Meaning
--- | --- | ---
oiio:dither | int | If nonzero and outputting UINT8 values in the file from a source of higher bit depth, will add a small amount of random dither to combat the appearance of banding.
oiio:ioproxy | ptr | Pointer to a Filesystem::IOProxy that will handle the I/O, for example by writing to a memory buffer.

Custom I/O Overrides

DDS supports the “custom I/O” feature via the special "oiio:ioproxy" attributes (see Sections Custom I/O proxies (and writing the file to a memory buffer) and Custom I/O proxies (and reading the file from a memory buffer)) as well as the set_ioproxy() methods.

Limitations

- The Targa reader reserves enough memory for the entire image. Therefore it is not a good choice for high-performance image use such as would be used for ImageCache or TextureSystem.
- Targa files only support 8- and 16-bit unsigned integers (no signed, floating point, or HDR capabilities); the OpenImageIO TGA writer will silently convert all output images to UINT8 (except if UINT16 is explicitly requested).
- Targa only supports grayscale, RGB, and RGBA; the OpenImageIO TGA writer will fail its call to open() if it is asked create a file with more than 4 color channels.

6.27 Term (Terminal)

This experimental output-only “format” is actually a procedural output that writes a low-res representation of the image to the console output. It requires a terminal application that supports Unicode and 24 bit color extensions.

The term ImageOutput supports the following special metadata tokens to control aspects of the writing itself:

Output Configuration Attribute | Type | Meaning
--- | --- | ---
term:method | string | May be one of iterm2, 24bit (default), 24bit-space, 256color, or dither.
term:fit | int | If 1 (the default), the image will be resized to fit on the console window.

The iterm2 mode is the best quality and is the default mode when actually running on a Mac and launching using iTerm2 as the terminal. This mode uses iTerm2’s nonstandard extension to directly output an pixel array to be visible in the terminal.

The default in other circumstances is the 24bit mode, which displays two approximately square pixels vertically in each character cell, by outputting the Unicode “upper half block” glyph (\u2508) with the foreground color set to the top pixel’s color and the background color set to the bottom pixel’s color.

If this doesn’t look right, or your terminal doesn’t support Unicode, the 24bit-space is an alternate mode that displays one elongated pixel in each character cell, writing a space character with the correct color.
There’s also a 256color method that just uses the 6x6x6 color space in the 256 color palette – which looks horrible – and an experimental dither which does a half-assed Floyd-Steinberg dithering, horizontally only, and frankly is not an improvement unless you squint really hard. These may change or be eliminated in the future.

In all cases, the image will automatically be resized to fit in the terminal and keep approximately the correct aspect ratio, as well as converted to sRGB so it looks kinda ok.

6.28 TIFF

TIFF (Tagged Image File Format) is a flexible file format created by Aldus, now controlled by Adobe. TIFF supports nearly everything anybody could want in an image format (and has exactly the complexity you would expect from such a requirement). TIFF files commonly use the file extensions .tif or .tiff. Additionally, OpenImageIO associates the following extensions with TIFF files by default: .tx, .env, .sm, .vsm.

The official TIFF format specification may be found here: http://partners.adobe.com/public/developer/tiff/index.html

The most popular library for reading TIFF directly is libtiff, available here: http://www.remotesensing.org/libtiff/

OpenImageIO uses libtiff for its TIFF reading/writing.

We like TIFF a lot, especially since its complexity can be nicely hidden behind OIIO’s simple APIs. It supports a wide variety of data formats (though unfortunately not half), an arbitrary number of channels, tiles and multiple subimages (which makes it our preferred texture format), and a rich set of metadata.

OpenImageIO supports the vast majority of TIFF features, including: tiled images (tiled) as well as scanline images; multiple subimages per file (multiimage); MIPmapping (using multi-subimage; that means you can’t use multiimage and MIPmaps simultaneously); data formats 8-16, and 32 bit integer (both signed and unsigned), and 32- and 64-bit floating point; palette images (will convert to RGB); “miniswhite” photometric mode (will convert to “minisblack”).

The TIFF plugin attempts to support all the standard Exif, IPTC, and XMP metadata if present.

Configuration settings for TIFF input

When opening an ImageInput with a configuration (see Section Opening for input with configuration settings/hints), the following special configuration options are supported:

<table>
<thead>
<tr>
<th>Input Configuration Attribute</th>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>oiio:UnassociatedAlpha</td>
<td>int</td>
<td>If nonzero, and the file contains unassociated alpha, this will cause the reader to leave alpha unassociated (versus the default of premultiplying color channels by alpha if the alpha channel is unassociated).</td>
</tr>
<tr>
<td>oiio:RawColor</td>
<td>int</td>
<td>If nonzero, reading images with non-RGB color models (such as YCbCr) will return unaltered pixel values (versus the default OIIO behavior of automatically converting to RGB).</td>
</tr>
<tr>
<td>oiio:ioproxy</td>
<td>ptr</td>
<td>Pointer to a Filesystem::IOProxy that will handle the I/O, for example by reading from memory rather than the file system.</td>
</tr>
</tbody>
</table>

Configuration settings for TIFF output

When opening an ImageOutput, the following special metadata tokens control aspects of the writing itself:
### Output Configuration Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>oiio:BitsPerSample</code></td>
<td>int</td>
<td>Requests a rescaling to a specific bits per sample (such as writing 12-bit TIFFs).</td>
</tr>
<tr>
<td><code>oiio:dither</code></td>
<td>int</td>
<td>If nonzero and outputting UINT8 values in the file from a source of higher bit depth, will add a small amount of random dither to combat the appearance of banding.</td>
</tr>
<tr>
<td><code>oiio:ioproxy</code></td>
<td>ptr</td>
<td>Pointer to a <code>Filesystem::IOProxy</code> that will handle the I/O, for example by writing to memory rather than the file system.</td>
</tr>
<tr>
<td><code>oiio:UnassociatedAlpha</code></td>
<td>int</td>
<td>If nonzero, any alpha channel is understood to be unassociated, and the EXTRASAMPLES tag in the TIFF file will be set to reflect this.</td>
</tr>
<tr>
<td><code>tiff:write_exif</code></td>
<td>int</td>
<td>If zero, will not write any Exif data to the TIFF file. (The default is 1.)</td>
</tr>
<tr>
<td><code>tiff:half</code></td>
<td>int</td>
<td>If nonzero, allow writing TIFF files with half (16 bit float) pixels. The default of 0 will automatically translate to float pixels, since most non-OIIO applications will not properly read half TIFF files despite their being legal.</td>
</tr>
<tr>
<td><code>tiff:ColorSpace</code></td>
<td>string</td>
<td>Requests that the file be saved with a non-RGB color spaces. Choices are RGB, CMYK. (YCbCr, CIELAB, ICCLAB, ITULAB are not yet supported.)</td>
</tr>
<tr>
<td><code>tiff:zipquality</code></td>
<td>int</td>
<td>A time-vs-space knob for zip compression, ranging from 1-9 (default is 6). Higher means compress to less space, but taking longer to do so. It is strictly a time vs space tradeoff, the visual image quality is identical (lossless) no matter what the setting.</td>
</tr>
<tr>
<td><code>tiff:RowsPerStrip</code></td>

<td>Overrides TIFF scanline rows per strip with a specific request (if not supplied, OIIO will choose a reasonable default).</td>
</tr>
<tr>
<td><code>tiff:bigtiff</code></td>
<td>int</td>
<td>If nonzero, forces use of “bigtiff,” a nonstandard extension that allows files to be more than 4 GB (default: 0).</td>
</tr>
<tr>
<td><code>tiff:write_extrasamples</code></td>
<td>int</td>
<td>If zero, do NOT write the “EXTRASAMPLES” tag to the TIFF header. (The default is 1, which means write the tag.)</td>
</tr>
<tr>
<td><code>tiff:write_iptc</code></td>
<td>int</td>
<td>If nonzero, write an IPTC data block to the TIFF file. (The default is 0, which means not to write an IPTC block.)</td>
</tr>
</tbody>
</table>

### TIFF compression modes

The full list of possible TIFF compression mode values are as follows ($ ^*$ indicates that OpenImageIO can write that format, and is not part of the format name):

```
none $ ^*$ lzw $ ^*$ zip $ ^*$ ccitt_t4 ccitt_t6 ccittfax3 ccittfax4 ccittrle2 ccittrle $ ^*$ dcs isojbig IT8BL IT8CTPAD IT8LW IT8MP jp2000 jpeg $ ^*$ lzma next ojpeg packbits $ ^*$ pixarfilm pixarlog sgilog24 sgilog T43 T85 thunderscan
```

### Custom I/O Overrides

TIFF input and output support the “custom I/O” feature via the `ImageInput::set_ioproxy()` method and the special "`oiio:ioproxy" attributes (see Section Custom I/O proxies (and reading the file from a memory buffer)).

### Limitations

OpenImageIO’s TIFF reader and writer have some limitations you should be aware of:

- No separate per-channel data formats (not supported by `libtiff`).
- Only multiples of 8 bits per pixel may be passed through OpenImageIO’s APIs, e.g., 1-, 2-, and 4-bits per pixel will be passed by OIIO as 8 bit images; 12 bits per pixel will be passed as 16, etc. But the `oiio:BitsPerSample` attribute in the ImageSpec will correctly report the original bit depth of the file. Similarly for output, you must pass 8 or 16 bit output, but `oiio:BitsPerSample` gives a hint about how
you want it to be when written to the file, and it will try to accommodate the request (for signed integers, TIFF output can accommodate 2, 4, 8, 10, 12, and 16 bits).

- JPEG compression is limited to 8-bit per channel, 3-channel files.

</table>
6.29 Webp

WebP is an image file format developed by Google that is intended to be an open standard for lossy-compressed images for use on the web.

Attributes

<table>
<thead>
<tr>
<th>ImageSpec Attribute</th>
<th>Type</th>
<th>WebP header data or explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>oiio:Movie</td>
<td>int</td>
<td>If nonzero, indicates that it’s a multi-subimage file intended to represent an animation.</td>
</tr>
<tr>
<td>oiio:LoopCount</td>
<td>int</td>
<td>Number of times the animation should be played (0-65535, 0 stands for infinity).</td>
</tr>
<tr>
<td>webp:LoopCount</td>
<td>int</td>
<td>Deprecated synonym for oiio:LoopCount.</td>
</tr>
</tbody>
</table>

Configuration settings for WebP input

When opening an WebP ImageInput with a configuration (see Section Opening for input with configuration settings/hints), the following special configuration attributes are supported:

<table>
<thead>
<tr>
<th>Input Configuration Attribute</th>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>oiio:ioproxy</td>
<td>ptr</td>
<td>Pointer to a Filesystem::IOProxy that will handle the I/O, for example by reading from memory rather than the file system.</td>
</tr>
</tbody>
</table>

Configuration settings for WebP output

When opening a WebP ImageOutput, the following special metadata tokens control aspects of the writing itself:

<table>
<thead>
<tr>
<th>Output Configuration Attribute</th>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>oiio:dither</td>
<td>int</td>
<td>If nonzero and outputting UINT8 values in the file from a source of higher bit depth, will add a small amount of random dither to combat the appearance of banding.</td>
</tr>
<tr>
<td>oiio:ioproxy</td>
<td>ptr</td>
<td>Pointer to a Filesystem::IOProxy that will handle the I/O, for example by writing to a memory buffer.</td>
</tr>
</tbody>
</table>

Custom I/O Overrides

WebP input and output both support the “custom I/O” feature via the special "oiio:ioproxy" attributes (see Sections Custom I/O proxies (and writing the file to a memory buffer) and Custom I/O proxies (and reading the file from a memory buffer)) as well as the set_ioproxy() methods.

Limitations

- WebP only supports 3-channel (RGB) or 4-channel (RGBA) images and must be 8-bit unsigned integer pixel values (uint8).
6.30 Zfile

Zfile is a very simple format for writing a depth (z) image, originally from Pixar’s PhotoRealistic RenderMan but now supported by many other renderers. It’s extremely minimal, holding only a width, height, world-to-screen and camera-to-screen matrices, and uncompressed float pixels of the z-buffer. Zfile files use the file extension .zfile.

CHAPTER
SEVEN

CACHED IMAGES

7.1 Image Cache Introduction and Theory of Operation

ImageCache is a utility class that allows an application to read pixels from a large number of image files while using a remarkably small amount of memory and other resources. Of course it is possible for an application to do this directly using ImageInput objects. But ImageCache offers the following advantages:

- ImageCache presents an even simpler user interface than ImageInput — the only supported operations are asking for an ImageSpec describing a subimage in the file, retrieving for a block of pixels, and locking/reading/releasing individual tiles. You refer to images by filename only; you don’t need to keep track of individual file handles or ImageInput objects. You don’t need to explicitly open or close files.

- The ImageCache is completely thread-safe; if multiple threads are accessing the same file, the ImageCache internals will handle all the locking and resource sharing.

- No matter how many image files you are accessing, the ImageCache will maintain a reasonable number of simultaneously-open files, automatically closing files that have not been needed recently.

- No matter how large the total pixels in all the image files you are dealing with are, the ImageCache will use only a small amount of memory. It does this by loading only the individual tiles requested, and as memory allotments are approached, automatically releasing the memory from tiles that have not been used recently.

In short, if you have an application that will need to read pixels from many large image files, you can rely on ImageCache to manage all the resources for you. It is reasonable to access thousands of image files totalling hundreds of GB of pixels, efficiently and using a memory footprint on the order of 50 MB.

Below are some simple code fragments that shows ImageCache in action:

```cpp
#include <OpenImageIO/imagecache.h>
using namespace OIIO;

// Create an image cache and set some options
ImageCache *cache = ImageCache::create();
cache->attribute ("max_memory_MB", 500.0f);
cache->attribute ("autotile", 64);

// Get a block of pixels from a file.
// (for brevity of this example, let's assume that 'size' is the
// number of channels times the number of pixels in the requested region)
float pixels[size];
cache->get_pixels ("file1.jpg", 0, 0, xbegin, xend, ybegin, yend,
                   zbegin, zend, TypeDesc::FLOAT, pixels);

// Get information about a file
ImageSpec spec;
```
bool ok = cache->get_imagespec ("file2.exr", spec);
if (ok)
    std::cout << "resolution is " << spec.width << "x"
    << spec.height << "\n";

// Request and hold a tile, do some work with its pixels, then release
ImageCache::Tile *tile;
tile = cache->get_tile ("file2.exr", 0, 0, x, y, z);
// The tile won’t be freed until we release it, so this is safe:
TypeDesc format;
void *p = cache->tile_pixels (tile, format);
// Now p points to the raw pixels of the tile, whose data format
// is given by 'format'.
cache->release_tile (tile);
// Now cache is permitted to free the tile when needed

// Note that all files were referenced by name, we never had to open
// or close any files, and all the resource and memory management
// was automatic.
ImageCache::destroy (cache);

7.2 ImageCache API

class OIIO::ImageCache
Define an API to an abstract class that manages image files, caches of open file handles as well as tiles of pixels
so that truly huge amounts of image data may be accessed by an application with low memory footprint.

Creating and destroying an image cache

ImageCache is an abstract API described as a pure virtual class. The actual internal implementation is not
exposed through the external API of OpenImageIO. Because of this, you cannot construct or destroy the concrete
implementation, so two static methods of ImageCache are provided:

static ImageCache *create (bool shared = true)
    Create a ImageCache and return a raw pointer to it. This should only be freed by passing it to
    ImageCache::destroy()!

    Return A raw pointer to an ImageCache, which can only be freed with ImageCache::destroy().
    See ImageCache::destroy

Parameters

- shared: If true, the pointer returned will be a shared ImageCache (so that multiple parts of an
  application that request an ImageCache will all end up with the same one). If shared is false,
  a completely unique ImageCache will be created and returned.

static void destroy (ImageCache *cache, bool teardown = false)
    Destroy an allocated ImageCache, including freeing all system resources that it holds.

    It is safe to destroy even a shared ImageCache, as the implementation of destroy() will recognize a
    shared one and only truly release its resources if it has been requested to be destroyed as many times as
    shared ImageCache’s were created.
Parameters

- **cache**: Raw pointer to the `ImageCache` to destroy.
- **teardown**: For a shared `ImageCache`, if the `teardown` parameter is `true`, it will try to truly destroy the shared cache if nobody else is still holding a reference (otherwise, it will leave it intact). This parameter has no effect if `cache` was not the single globally shared `ImageCache`.

Setting options and limits for the image cache

These are the list of attributes that can be set or queried by `attribute/getattribute`:

- **int max_open_files**: The maximum number of file handles that the image cache will hold open simultaneously. (Default = 100)
- **float max_memory_MB**: The maximum amount of memory (measured in MB) used for the internal "tile cache." (Default: 256.0 MB)
- **string searchpath**: The search path for images: a colon-separated list of directories that will be searched in order for any image filename that is not specified as an absolute path. (Default: "")
- **string plugin_searchpath**: The search path for plugins: a colon-separated list of directories that will be searched in order for any OIIO plugins, if not found in OIIO’s `lib` directory. (Default: "")
- **int autotile, int autoscanline**: These attributes control how the image cache deals with images that are not “tiled” (i.e., are stored as scanlines).

  If `autotile` is set to 0 (the default), an untiled image will be treated as if it were a single tile of the resolution of the whole image. This is simple and fast, but can lead to poor cache behavior if you are simultaneously accessing many large untiled images.

  If `autotile` is nonzero (e.g., 64 is a good recommended value), any untiled images will be read and cached as if they were constructed in tiles of size:

  - `autotile * autotile` if `autoscanline` is 0
  - `width * autotile` if `autoscanline` is nonzero.

  In both cases, this should lead more efficient caching. The `autoscanline` determines whether the “virtual tiles” in the cache are square (if `autoscanline` is 0, the default) or if they will be as wide as the image but only `autotile` scanlines high. You should try in your application to see which leads to higher performance.

- **int autoscanline**: autotile using full width tiles
- **int automip**: If 0 (the default), an untiled single-subimage file will only be able to utilize that single subimage. If nonzero, any untiled, single-subimage (un-MIP-mapped) images will have lower-resolution MIP-map levels generated on-demand if pixels are requested from the lower-res subimages (that don’t really exist). Essentially this makes the `ImageCache` pretend that the file is MIP-mapped even if it isn’t.
- **int accept_untiled**: When nonzero, `ImageCache` accepts untiled images as usual. When zero, `ImageCache` will reject untiled images with an error condition, as if the file could not be properly read. This is sometimes helpful for applications that want to enforce use of tiled images only. (default=1)
- **int accept_unmipped**: When nonzero, `ImageCache` accepts un-MIPmapped images as usual. When set to zero, `ImageCache` will reject un-MIPmapped images with an error condition, as if the file
could not be properly read. This is sometimes helpful for applications that want to enforce use of MIP-mapped images only. (Default: 1)

- **int statistics:level**: verbosity of statistics auto-printed.

- **int forcefloat**: If set to nonzero, all image tiles will be converted to *float* type when stored in the image cache. This can be helpful especially for users of ImageBuf who want to simplify their image manipulations to only need to consider *float* data. The default is zero, meaning that image pixels are not forced to be *float* when in cache.

- **int failure_retries**: When an image file is opened or a tile/scanline is read but a file error occurs, if this attribute is nonzero, it will try the operation again up to this many times before giving up and reporting a failure. Setting this to a small nonzero number (like 3) may help make an application more robust to occasional spurious networking or other glitches that would otherwise cause the entire long-running application to fail upon a single transient error. (Default: 0)

- **int deduplicate**: When nonzero, the *ImageCache* will notice duplicate images under different names if their headers contain a SHA-1 fingerprint (as is done with maketx-produced textures) and handle them more efficiently by avoiding redundant reads. The default is 1 (de-duplication turned on). The only reason to set it to 0 is if you specifically want to disable the de-duplication optimization.

- **string substitute_image**: When set to anything other than the empty string, the *ImageCache* will use the named image in place of all other images. This allows you to run an app using OIIO and (if you can manage to get this option set) automagically substitute a grid, zone plate, or other special debugging image for all image/texture use.

- **int unassociatedalpha**: When nonzero, will request that image format readers try to leave input images with unassociated alpha as they are, rather than automatically converting to associated alpha upon reading the pixels. The default is 0, meaning that the automatic conversion will take place.

- **int max_errors_per_file**: The maximum number of errors that will be printed for each file. The default is 100. If your output is cluttered with error messages and after the first few for each file you aren’t getting any helpful additional information, this can cut down on the clutter and the runtime. (default: 100)

- **int trust_file_extensions**: When nonzero, assume that the file extensions of any texture requests correctly indicates the file format (when enabled, this reduces the number of file opens, at the expense of not being able to open files if their format do not actually match their filename extension). Default: 0

- **string options** This catch-all is simply a comma-separated list of *name=value* settings of named options, which will be parsed and individually set. Example:

  ```
  ic->attribute ("options", "max_memory_Mb=512.0,autotile=1");
  ```

  Note that if an option takes a string value that must itself contain a comma, it is permissible to enclose the value in either single (’ ’) or double (””) quotes.

**Read-only attributes**

Additionally, there are some read-only attributes that can be queried with *getattr* (*getattribute*)() even though they cannot be set via *attribute*():

- **int total_files**: The total number of unique file names referenced by calls to the *ImageCache*.

- **string[] all_filenames**: An array that will be filled with the list of the names of all files referenced by calls to the *ImageCache*. (The array is of *cstring* or *char*.)

- **int64 stats:cache_memory_used**: Total bytes used by tile cache.
• int stat::tiles_created, int stat::tiles_current, int stat::tiles_peak: Total times created, still allocated (at the time of the query), and the peak number of tiles in memory at any time.

• int stat::open_files_created , int stat::open_files_current , int stat::open_files_peak : Total number of times a file was opened, number still opened (at the time of the query), and the peak number of files opened at any time.

• int stat::find_tile_calls: Number of times a filename was looked up in the file cache.

• int64 stat::image_size: Total size (uncompressed bytes of pixel data) of all images referenced by the ImageCache. (Note: Prior to 1.7, this was called stat::files_totalsize.)

• int64 stat::file_size : Total size of all files (as on disk, possibly compressed) of all images referenced by the ImageCache.

• int64 stat::bytes_read: Total size (uncompressed bytes of pixel data) read.

• int stat::unique_files: Number of unique files opened.

• float stat::fileio_time: Total I/O-related time (seconds).

• float stat::fileopen_time: I/O time related to opening and reading headers (but not pixel I/O).

• float stat::file_locking_time: Total time (across all threads) that threads blocked waiting for access to the file data structures.

• float stat::tile_locking_time: Total time (across all threads) that threads blocked waiting for access to the tile cache data structures.

• float stat::find_file_time: Total time (across all threads) that threads spent looking up files by name.

• float stat::find_tile_time: Total time (across all threads) that threads spent looking up individual tiles.

The following member functions of ImageCache allow you to set (and in some cases retrieve) options that control the overall behavior of the image cache:

virtual bool attribute(string_view name, TypeDesc type, const void *val) = 0

Set a named attribute (i.e., a property or option) of the ImageCache.

Example:

```cpp
ImageCache *ic;
...
int maxfiles = 50;
ic->attribute ("max_open_files", TypeDesc::INT, &maxfiles);

const char *path = "/my/path";
ic->attribute ("searchpath", TypeDesc::STRING, &path);

// There are specialized versions for setting a single int, // float, or string without needing types or pointers:
ic->attribute ("max_open_files", 50);
ic->attribute ("max_memory_MB", 4000.0f);
ic->attribute ("searchpath", "/my/path");
```

Note: When passing a string, you need to pass a pointer to the char*, not a pointer to the first character. (Rationale: for an int attribute, you pass the address of the int. So for a string, which is a char*, you need to pass the address of the string, i.e., a char**).
Return `true` if the name and type were recognized and the attribute was set, or `false` upon failure (including it being an unrecognized attribute or not of the correct type).

Parameters

- **name**: Name of the attribute to set.
- **type**: `TypeDesc` describing the type of the attribute.
- **val**: Pointer to the value data.

```
virtual bool attribute(string_view name, int val) = 0
    Specialized `attribute()` for setting a single `int` value.
virtual bool attribute(string_view name, float val) = 0
    Specialized `attribute()` for setting a single `float` value.
virtual bool attribute(string_view name, string_view val) = 0
    Specialized `attribute()` for setting a single string value.
```

```
virtual bool getattribute(string_view name, TypeDesc type, void *val) const = 0
    Get the named attribute, store it in `*val`. All of the attributes that may be set with the `attribute()` call may also be queried with `getattribute()`.
```

Examples:

```cpp
ImageCache *ic;
...
int maxfiles;
ic->getattribute("max_open_files", TypeDesc::INT, &maxfiles);

const char *path;
ic->getattribute("searchpath", TypeDesc::STRING, &path);

// There are specialized versions for retrieving a single int, // float, or string without needing types or pointers:
int maxfiles;
ic->getattribute("max_open_files", maxfiles);
const char *path;
ic->getattribute("searchpath", &path);
```

Note: When retrieving a string, you need to pass a pointer to the `char*`, not a pointer to the first character. Also, the `char*` will end up pointing to characters owned by the `ImageCache`; the caller does not need to ever free the memory that contains the characters.

Return `true` if the name and type were recognized and the attribute was retrieved, or `false` upon failure (including it being an unrecognized attribute or not of the correct type).

Parameters

- **name**: Name of the attribute to retrieve.
- **type**: `TypeDesc` describing the type of the attribute.
- **val**: Pointer where the attribute value should be stored.

```
virtual bool getattribute(string_view name, int &val) const = 0
    Specialized `attribute()` for retrieving a single `int` value.
virtual bool getattribute(string_view name, float &val) const = 0
    Specialized `attribute()` for retrieving a single `float` value.
```
virtual bool getattribute (string_view name, char **val) const = 0
Specialized attribute() for retrieving a single string value as a char*.

virtual bool getattribute (string_view name, std::string &val) const = 0
Specialized attribute() for retrieving a single string value as a std::string.

Opaque data for performance lookups

The ImageCache implementation needs to maintain certain per-thread state, and some methods take an opaque Perthread pointer to this record. There are three options for how to deal with it:

a. Don’t worry about it at all: don’t use the methods that want Perthread pointers, or always pass nullptr for any *Perthread* arguments, and ImageCache will do thread-specific-pointer retrieval as necessary (though at some small cost).

b. If your app already stores per-thread information of its own, you may call get_perthread_info(nullptr) to retrieve it for that thread, and then pass it into the functions that allow it (thus sparing them the need and expense of retrieving the thread-specific pointer). However, it is crucial that this pointer not be shared between multiple threads. In this case, the ImageCache manages the storage, which will automatically be released when the thread terminates.

c. If your app also wants to manage the storage of the Perthread, it can explicitly create one with create_perthread_info(), pass it around, and eventually be responsible for destroying it with destroy_perthread_info(). When managing the storage, the app may reuse the Perthread for another thread after the first is terminated, but still may not use the same Perthread for two threads running concurrently.

typedef pvt::ImageCachePerThreadInfo Perthread
Define an opaque data type that allows us to have a pointer to certain per-thread information that the ImageCache maintains. Any given one of these should NEVER be shared between running threads.

typedef pvt::ImageCacheFile ImageHandle
Define an opaque data type that allows us to have a handle to an image (already having its name resolved) but without exposing any internals.

virtual Perthread *get_perthread_info (Perthread *thread_info = NULL) = 0
Retrieve a Perthread, unique to the calling thread. This is a thread-specific pointer that will always return the Perthread for a thread, which will also be automatically destroyed when the thread terminates.

Applications that want to manage their own Perthread pointers (with create_thread_info and destroy_thread_info) should still call this, but passing in their managed pointer. If the passed-in thread_info is not NULL, it won’t create a new one or retrieve a TSP, but it will do other necessary housekeeping on the Perthread information.

virtual Perthread *create_thread_info () = 0
Create a new Perthread. It is the caller’s responsibility to eventually destroy it using destroy_thread_info().

virtual void destroy_thread_info (Perthread *thread_info) = 0
Destroy a Perthread that was allocated by create_thread_info().

virtual ImageHandle *get_image_handle (ustring filename, Perthread *thread_info = NULL) = 0
Retrieve an opaque handle for fast image lookups. The filename is presumed to be UTF-8 encoded. The opaque pointer thread_info is thread-specific information returned by get_perthread_info(). Return NULL if something has gone horribly wrong.
inline ImageHandle *get_image_handle (const std::wstring &filename, Perthread *thread_info = NULL)

Get an ImageHandle using a UTF-16 encoded wstring filename.

virtual bool good (ImageHandle *file) = 0

Return true if the image handle (previously returned by get_image_handle()) is a valid image that can be subsequently read.

virtual ustring filename_from_handle (ImageHandle *handle) = 0

Given a handle, return the filename for that image.

This method was added in OpenImageIO 2.3.

Getting information about images

virtual std::string resolve_filename (const std::string &filename) const = 0

Given possibly-relative filename (UTF-8 encoded), resolve it and use the true path to the file, with searchpath logic applied.

virtual bool get_image_info (ustring filename, int subimage, int mipmap, ustring dataname, TypeDesc datatype, void *data) = 0

Get information or metadata about the named image and store it in *data.

Data names may include any of the following:

- "exists": Stores the value 1 (as an int) if the file exists and is an image format that OpenImageIO can read, or 0 if the file does not exist, or could not be properly read as an image. Note that unlike all other queries, this query will “succeed” (return true) even if the file does not exist.
- "udim": Stores the value 1 (as an int) if the file is a “virtual UDIM” or texture atlas file (as described in :ref:sec-texturesys-udim) or 0 otherwise.
- "subimages": The number of subimages in the file, as an int.
- "resolution": The resolution of the image file, which is an array of 2 integers (described as TypeDesc(INT,2)).
- "miplevels": The number of MIPmap levels for the specified subimage (an integer).
- "texturetype": A string describing the type of texture of the given file, which describes how the texture may be used (also which texture API call is probably the right one for it). This currently may return one of: "unknown", "Plain Texture", "Volume Texture", "Shadow", or "Environment".
- "textureformat": A string describing the format of the given file, which describes the kind of texture stored in the file. This currently may return one of: "unknown", "Plain Texture", "Volume Texture","Shadow","CubeFace Shadow","Volume Shadow","LatLong Environment", or "CubeFace Environment". Note that there are several kinds of shadows and environment maps, all accessible through the same API calls.
- "channels": The number of color channels in the file (an int).
- "format": The native data format of the pixels in the file (an integer, giving the TypeDesc::BASETYPE of the data). Note that this is not necessarily the same as the data format stored in the image cache.
- "cachedformat": The native data format of the pixels as stored in the image cache (an integer, giving the TypeDesc::BASETYPE of the data). Note that this is not necessarily the same as the native data format of the file.
• "datawindow" : Returns the pixel data window of the image, which is either an array of 4 integers (returning xmin, ymin, xmax, ymax) or an array of 6 integers (returning xmin, ymin, zmin, xmax, ymax, zmax). The z values may be useful for 3D/volumetric images; for 2D images they will be 0).

• "displaywindow" : Returns the display (a.k.a. “full”) window of the image, which is either an array of 4 integers (returning xmin, ymin, xmax, ymax) or an array of 6 integers (returning xmin, ymin, zmin, xmax, ymax, zmax). The z values may be useful for 3D/volumetric images; for 2D images they will be 0).

• "worldtocamera" : The viewing matrix, which is a 4x4 matrix (an Imath::M44f, described as TypeDesc(FLOAT,MATRIX)), giving the world-to-camera 3D transformation matrix that was used when the image was created. Generally, only rendered images will have this.

• "worldtoscreen" : The projection matrix, which is a 4x4 matrix (an Imath::M44f, described as TypeDesc(FLOAT,MATRIX)), giving the matrix that projected points from world space into a 2D screen coordinate system where $x$ and $y$ range from -1 to +1. Generally, only rendered images will have this.

• "worldtoNDC" : The projection matrix, which is a 4x4 matrix (an Imath::M44f, described as TypeDesc(FLOAT,MATRIX)), giving the matrix that projected points from world space into a 2D NDC coordinate system where $x$ and $y$ range from 0 to +1. Generally, only rendered images will have this.

• "averagecolor" : If available in the metadata (generally only for files that have been processed by maketx), this will return the average color of the texture (into an array of float).

• "averagealpha" : If available in the metadata (generally only for files that have been processed by maketx), this will return the average alpha value of the texture (into a float).

• "constantcolor" : If the metadata (generally only for files that have been processed by maketx) indicates that the texture has the same values for all pixels in the texture, this will retrieve the constant color of the texture (into an array of floats). A non-constant image (or one that does not have the special metadata tag identifying it as a constant texture) will fail this query (return false).

• "constantalpha" : If the metadata indicates that the texture has the same values for all pixels in the texture, this will retrieve the constant alpha value of the texture (into a float). A non-constant image (or one that does not have the special metadata tag identifying it as a constant texture) will fail this query (return false).

• "stat:tilesread" : Number of tiles read from this file (int64).

• "stat:bytesread" : Number of bytes of uncompressed pixel data read from this file (int64).

• "stat:redundant_tiles" : Number of times a tile was read, where the same tile had been read before. (int64).

• "stat:redundant_bytesread" : Number of bytes (of uncompressed pixel data) in tiles that were read redundantly. (int64).

• "stat:redundant_bytesread" : Number of tiles read from this file (int).

• "stat:image_size" : Size of the uncompressed image pixel data of this image, in bytes (int64).

• "stat:file_size" : Size of the disk file (possibly compressed) for this image, in bytes (int64).

• "stat:timesopened" : Number of times this file was opened (int).

• "stat:iotime" : Time (in seconds) spent on all I/O for this file (float).

• "stat:mipsused" : Stores 1 if any MIP levels beyond the highest resolution were accessed, otherwise 0. (int)
• "stat:is_duplicate": Stores 1 if this file was a duplicate of another image, otherwise 0.  
  (int)
• Anything else: For all other data names, the the metadata of the image file will be searched for an 
  item that matches both the name and data type.

Return true if get_image_info() is able to find the requested dataname for the image and it 
matched the requested datatype. If the requested data was not found or was not of the right data 
type, return false. Except for the "exists" query, a file that does not exist or could not be read 
properly as an image also constitutes a query failure that will return false.

Parameters

• filename: The name of the image, as a UTF-8 encoded ustring.
• subimage/miplevel: The subimage and MIP level to query.
• dataname: The name of the metadata to retrieve.
• datatype: TypeDesc describing the data type.
• data: Pointer to the caller-owned memory where the values should be stored. It is the caller’s 
  responsibility to ensure that data points to a large enough storage area to accommodate the 
  datatype requested.

virtual bool get_image_info(ImageHandle *file, Perthread *thread_info, int subimage, int miplevel, 
  ustring dataname, TypeDesc datatype, void *data) = 0
A more efficient variety of get_image_info() for cases where you can use an ImageHandle* to 
specify the image and optionally have a Perthread* for the calling thread.

virtual bool get_imagespec(ustring filename, ImageSpec &spec, int subimage = 0, int miplevel = 
  0, bool native = false) = 0
Copy the ImageSpec associated with the named image (the first subimage & miplevel by default, or as set 
by subimage and miplevel).

Return true upon success, false upon failure failure (such as being unable to find, open, or read the 
file, or if it does not contain the designated subimage or MIP level).

Parameters

• filename: The name of the image, as a UTF-8 encoded ustring.
• spec: ImageSpec into which will be copied the spec for the requested image.
• subimage/miplevel: The subimage and MIP level to query.
• native: If false (the default), then the spec retrieved will accurately describe the image 
  stored internally in the cache, whereas if native is true, the spec retrieved will reflect the 
  contents of the original file. These may differ due to use of certain ImageCache settings such as 
  "forcefloat" or "autotile".

virtual bool get_imagespec(ImageHandle *file, Perthread *thread_info, ImageSpec &spec, int 
  subimage = 0, int miplevel = 0, bool native = false) = 0
A more efficient variety of get_imagespec() for cases where you can use an ImageHandle* to 
specify the image and optionally have a Perthread* for the calling thread.

virtual const ImageSpec *imagespec(ustring filename, int subimage = 0, int miplevel = 0, bool 
  native = false) = 0
Return a pointer to an ImageSpec associated with the named image (the first subimage & MIP level by 
default, or as set by subimage and miplevel) if the file is found and is an image format that can be 
read, otherwise return nullptr.
This method is much more efficient than `get_imagespec()`, since it just returns a pointer to the spec held internally by the ImageCache (rather than copying the spec to the user’s memory). However, the caller must beware that the pointer is only valid as long as nobody (even other threads) calls `invalidate()` on the file, or `invalidate_all()`, or destroys the ImageCache.

**Return** A pointer to the spec, if the image is found and able to be opened and read by an available image format plugin, and the designated subimage and MIP level exists.

**Parameters**
- `filename`: The name of the image, as a UTF-8 encoded ustring.
- `subimage/miplevel`: The subimage and MIP level to query.
- `native`: If false (the default), then the spec retrieved will accurately describe the image stored internally in the cache, whereas if `native` is true, the spec retrieved will reflect the contents of the original file. These may differ due to use of certain ImageCache settings such as "forcefloat" or "autotile".

```cpp
virtual const ImageSpec *imagespec(ImageHandle *file, Perthread *thread_info, int subimage = 0, int miplevel = 0, bool native = false) = 0
```

A more efficient variety of `imagespec()` for cases where you can use an ImageHandle* to specify the image and optionally have a Perthread* for the calling thread.

```cpp
virtual bool get_thumbnail(ustring filename, ImageBuf &thumbnail, int subimage = 0) = 0
```

Copy into `thumbnail` any associated thumbnail associated with this image (for the first subimage by default, or as set by `subimage`).

**Return** true upon success, false upon failure (such as being unable to find, open, or read the file, or if it does not contain a thumbnail).

**Parameters**
- `filename`: The name of the image, as a UTF-8 encoded ustring.
- `thumbnail`: ImageBuf into which will be copied the thumbnail, if it exists. If no thumbnail can be retrieved, `thumb` will be reset to an uninitialized (empty) ImageBuf.
- `subimage`: The subimage to query.

```cpp
virtual bool get_thumbnail(ImageHandle *file, Perthread *thread_info, ImageBuf &thumbnail, int subimage = 0) = 0
```

A more efficient variety of `get_thumbnail()` for cases where you can use an ImageHandle* to specify the image and optionally have a Perthread* for the calling thread.

### Getting Pixels

```cpp
virtual bool get_pixels(ustring filename, int subimage, int miplevel, int xbegin, int xend, int ybegin, int yend, int zbegin, int zend, int chbegin, int chend, TypeDesc format, void *result, stride_t xstride = AutoStride, stride_t ystride = AutoStride, stride_t zstride = AutoStride, int cache_chbegin = 0, int cache_chend = -1) = 0
```

For an image specified by name, retrieve the rectangle of pixels from the designated subimage and MIP level, storing the pixel values beginning at the address specified by `result` and with the given strides. The pixel values will be converted to the data type specified by `format`. The rectangular region to be retrieved includes `begin` but does not include `end` (much like STL begin/end usage). Requested pixels that are not part of the valid pixel data region of the image file will be filled with zero values.
Return  

true for success, false for failure.

Parameters

- *filename*: The name of the image, as a UTF-8 encoded ustring.
- *subimage/miplevel*: The subimage and MIP level to retrieve pixels from.
- *xbegin/xend/ybegin/yend/zbegin/zend*: The range of pixels to retrieve. The pixels retrieved include the begin value but not the end value (much like STL begin/end usage).
- *chbegin/chend*: Channel range to retrieve. To retrieve all channels, use chbegin = 0, chend = nchannels.
- *format*: **TypeDesc** describing the data type of the values you want to retrieve into result. The pixel values will be converted to this type regardless of how they were stored in the file.
- *result*: Pointer to the memory where the pixel values should be stored. It is up to the caller to ensure that result points to an area of memory big enough to accommodate the requested rectangle (taking into consideration its dimensions, number of channels, and data format).
- *xstride/ystride/zstride*: The number of bytes between the beginning of successive pixels, scanlines, and image planes, respectively. Any stride values set to AutoStride will be assumed to indicate a contiguous data layout in that dimension.
- *cache_chbegin/cache_chend*: These parameters can be used to tell the ImageCache to read and cache a subset of channels (if not specified or if they denote a non-positive range, all the channels of the file will be stored in the cached tile).

```cpp
virtual bool get_pixels(ImageHandle *file, Perthread *thread_info, int subimage, int miplevel, int xbegin, int xend, int ybegin, int yend, int zbegin, int zend, int chbegin, int chend, TypeDesc format, void *result, stride_t xstride = AutoStride, stride_t ystride = AutoStride, stride_t zstride = AutoStride, int cache_chbegin = 0, int cache_chend = -1) = 0
```

A more efficient variety of get_pixels() for cases where you can use an ImageHandle* to specify the image and optionally have a Perthread* for the calling thread.

```cpp
virtual bool get_pixels(ustring filename, int subimage, int miplevel, int xbegin, int xend, int ybegin, int yend, int zbegin, int zend, TypeDesc format, void *result) = 0
```

A simplified get_pixels() where all channels are retrieved, strides are assumed to be contiguous.

```cpp
virtual bool get_pixels(ImageHandle *file, Perthread *thread_info, int subimage, int miplevel, int xbegin, int xend, int ybegin, int yend, int zbegin, int zend, TypeDesc format, void *result) = 0
```

A more efficient variety of get_pixels() for cases where you can use an ImageHandle* to specify the image and optionally have a Perthread* for the calling thread.

Controlling the cache

```cpp
typedef pvt::ImageCacheTile Tile
```

An opaque data type that allows us to have a pointer to a tile but without exposing any internals.

```cpp
virtual void invalidate(ustring filename, bool force = true) = 0
```

Invalidates any loaded tiles or open file handles associated with the filename (UTF-8 encoded), so that any subsequent queries will be forced to re-open the file or re-load any tiles (even those that were previously loaded and would ordinarily be reused). A client might do this if, for example, they are aware that an image being held in the cache has been updated on disk. This is safe to do even if other procedures are currently holding reference-counted tile pointers from the named image, but those procedures will not get updated pixels until they release the tiles they are holding.
If `force` is true, this invalidation will happen unconditionally; if false, the file will only be invalidated if it has been changed since it was first opened by the `ImageCache`.

```cpp
virtual void invalidate (ImageHandle *file, bool force = true) = 0
```

A more efficient variety of `invalidate()` for cases where you already have an `ImageHandle*` for the file you want to invalidate.

```cpp
virtual void invalidate_all (bool force = false) = 0
```

Invalidate all loaded tiles and close open file handles. This is safe to do even if other procedures are currently holding reference-counted tile pointers from the named image, but those procedures will not get updated pixels (if the images change) until they release the tiles they are holding.

If `force` is true, everything will be invalidated, no matter how wasteful it is, but if `force` is false, in actuality files will only be invalidated if their modification times have been changed since they were first opened.

```cpp
virtual void close (ustring filename) = 0
```

Close any open file handles associated with a named file (UTF-8 encoded), but do not invalidate any image spec information or pixels associated with the files. A client might do this in order to release OS file handle resources, or to make it safe for other processes to modify image files on disk.

```cpp
virtual void close_all () = 0
close() all files known to the cache.
```

```cpp
virtual Tile* get_tile (ustring filename, int subimage, int mplevel, int x, int y, int z, int chbegin = 0, int chend = -1) = 0
```

Find the tile specified by an image filename (UTF-8 encoded), subimage & mplevel, the coordinates of a pixel, and optionally a channel range. An opaque pointer to the tile will be returned, or `nullptr` if no such file (or tile within the file) exists or can be read. The tile will not be purged from the cache until after `release_tile()` is called on the tile pointer the same number of times that `get_tile()` was called (reference counting). This is thread-safe! If `chend < chbegin`, it will retrieve a tile containing all channels in the file.

```cpp
virtual Tile* get_tile (ImageHandle *file, Perthread *thread_info, int subimage, int mplevel, int x, int y, int z, int chbegin = 0, int chend = -1) = 0
```

A slightly more efficient variety of `get_tile()` for cases where you can use an `ImageHandle*` to specify the image and optionally have a `Perthread*` for the calling thread.

See `get_pixels()`

```cpp
virtual void release_tile (Tile* tile) const = 0
```

After finishing with a tile, `release_tile` will allow it to once again be purged from the tile cache if required.

```cpp
virtual TypeDesc tile_format (const Tile* tile) const = 0
```

Retrieve the data type of the pixels stored in the tile, which may be different than the type of the pixels in the disk file.

```cpp
virtual ROI tile_roi (const Tile* tile) const = 0
```

Retrieve the ROI describing the pixels and channels stored in the tile.

```cpp
virtual const void *tile_pixels (Tile* tile, TypeDesc &format) const = 0
```

For a tile retrieved by `get_tile()`, return a pointer to the pixel data itself, and also store in `format` the data type that the pixels are internally stored in (which may be different than the data type of the pixels in the disk file). This method should only be called on a tile that has been requested by `get_tile()` but has not yet been released with `release_tile()`.

```cpp
virtual bool add_file (ustring filename, ImageInput::Creator creator = nullptr, const ImageSpec *config = nullptr, bool replace = false) = 0
```

The `add_file()` call causes a file to be opened or added to the cache. There is no reason to use this method...
unless you are supplying a custom creator, or configuration, or both.

If creator is not NULL, it points to an `ImageInput::Creator` that will be used rather than the default `ImageInput::create()`, thus instead of reading from disk, creates and uses a custom `ImageInput` to generate the image. The ‘creator’ is a factory that creates the custom `ImageInput` and will be called like this:

```cpp
std::unique_ptr<ImageInput> in (creator());
```

Once created, the `ImageCache` owns the `ImageInput` and is responsible for destroying it when done. Custom `ImageInputs` allow “procedural” images, among other things. Also, this is the method you use to set up a “writable” `ImageCache` images (perhaps with a type of `ImageInput` that’s just a stub that does as little as possible).

If `config` is not NULL, it points to an `ImageSpec` with configuration options/hints that will be passed to the underlying `ImageInput::open()` call. Thus, this can be used to ensure that the `ImageCache` opens a call with special configuration options.

This call (including any custom creator or configuration hints) will have no effect if there’s already an image by the same name in the cache. Custom creators or configurations only “work” the FIRST time a particular filename is referenced in the lifetime of the `ImageCache`. But if replace is true, any existing entry will be invalidated, closed and overwritten. So any subsequent access will see the new file. Existing texture handles will still be valid.

```cpp
virtual bool add_tile (ustring filename, int subimage, int mipmaplevel, int x, int y, int z, int chbegin, int chend, TypeDesc format, const void *buffer, stride_t xstride = AutoStride, stride_t ystride = AutoStride, stride_t zstride = AutoStride, bool copy = true)
= 0
```

Preemptively add a tile corresponding to the named image, at the given subimage, MIP level, and channel range. The tile added is the one whose corner is (x,y,z), and buffer points to the pixels (in the given format, with supplied strides) which will be copied and inserted into the cache and made available for future lookups. If chend < chbegin, it will add a tile containing the full set of channels for the image. Note that if the ‘copy’ flag is false, the data is assumed to be in some kind of persistent storage and will not be copied, nor will its pixels take up additional memory in the cache.

**Errors and statistics**

```cpp
virtual bool has_error () const = 0
Is there a pending error message waiting to be retrieved?

virtual std::string geterror (bool clear = true) const = 0
Return the text of all pending error messages issued against this `ImageCache`, and clear the pending error message unless clear is false. If no error message is pending, it will return an empty string.

virtual std::string getstats (int level = 1) const = 0
Returns a big string containing useful statistics about the `ImageCache` operations, suitable for saving to a file or outputting to the terminal. The level indicates the amount of detail in the statistics, with higher numbers (up to a maximum of 5) yielding more and more esoteric information.

virtual void reset_stats () = 0
Reset most statistics to be as they were with a fresh `ImageCache`. Caveat emptor: this does not flush the cache itself, so the resulting statistics from the next set of texture requests will not match the number of tile reads, etc., that would have resulted from a new `ImageCache`.  

---

174 Chapter 7. Cached Images
TEXTURE ACCESS: TEXTURESYSTEM

8.1 Texture System Introduction and Theory of Operation

Coming soon. FIXME

8.2 Helper Classes

8.2.1 Imath

The texture functionality of OpenImageIO uses the excellent open source Imath types when it requires 3D vectors and transformation matrices. Specifically, we use Imath::V3f for 3D positions and directions, and Imath::M44f for 4x4 transformation matrices. To use these yourself, we recommend that you:

```cpp
// If using Imath 3.x:
#include <Imath/ImathVec.h>
#include <Imath/ImathMatrix.h>

// OR, if using OpenEXR 2.x, before Imath split off:
#include <OpenEXR/ImathVec.h>
#include <OpenEXR/ImathMatrix.h>
```

Please refer to the Imath documentation and header files for more complete information about use of these types in your own application. However, note that you are not strictly required to use these classes in your application — Imath::V3f has a memory layout identical to float[3] and Imath::M44f has a memory layout identical to float[16], so as long as your own internal vectors and matrices have the same memory layout, it’s ok to just cast pointers to them when passing as arguments to TextureSystem methods.

8.2.2 TextureOpt

TextureOpt is a structure that holds many options controlling single-point texture lookups. Because each texture lookup API call takes a reference to a TextureOpt, the call signatures remain uncluttered rather than having an ever-growing list of parameters, most of which will never vary from their defaults. Here is a brief description of the data members of a TextureOpt structure:

- **int firstchannel**: The beginning channel for the lookup. For example, to retrieve just the blue channel, you should have firstchannel = 2 while passing nchannels = 1 to the appropriate texture function.

- **int subimage, ustring subimagename**: Specifies the subimage or face within the file to use for the texture lookup. If subimagename is set (it defaults to the empty string), it will try to use the subimage that had a matching metadata "oiio:subimagename", otherwise the integer subimage will be used (which
defaults to 0, i.e., the first/default subimage). Nonzero subimage indices only make sense for a texture file that supports subimages (like TIFF or multi-part OpenEXR) or separate images per face (such as Ptex). This will be ignored if the file does not have multiple subimages or separate per-face textures.

- **Wrap swrap, twrap**: Specify the wrap mode for 2D texture lookups (and 3D volume texture lookups, using the additional rwrap field). These fields are ignored for shadow and environment lookups. These specify what happens when texture coordinates are found to be outside the usual [0,1] range over which the texture is defined. Wrap is an enumerated type that may take on any of the following values:
  - **WrapBlack**: The texture is black outside the [0,1] range.
  - **WrapClamp**: The texture coordinates will be clamped to [0,1], i.e., the value outside [0,1] will be the same as the color at the nearest point on the border.
  - **WrapPeriodic**: The texture is periodic, i.e., wraps back to 0 after going past 1.
  - **WrapMirror**: The texture presents a mirror image at the edges, i.e., the coordinates go from 0 to 1, then back down to 0, then back up to 1, etc.
  - **WrapDefault**: Use whatever wrap might be specified in the texture file itself, or some other suitable default (caveat emptor).

The wrap mode does not need to be identical in the s and t directions.

- **float swidth, twidth**: For each direction, gives a multiplier for the derivatives. Note that a width of 0 indicates a point sampled lookup (assuming that blur is also zero). The default width is 1, indicating that the derivatives should guide the amount of blur applied to the texture filtering (not counting any additional blur specified).

- **float sblur, tblur**: For each direction, specifies an additional amount of pre-blur to apply to the texture (after derivatives are taken into account), expressed as a portion of the width of the texture. In other words, blur = 0.1 means that the texture lookup should act as if the texture was pre-blurred with a filter kernel with a width 1/10 the size of the full image. The default blur amount is 0, indicating a sharp texture lookup.

- **float fill**: Specifies the value that will be used for any color channels that are requested but not found in the file. For example, if you perform a 4-channel lookup on a 3-channel texture, the last channel will get the fill value. (Note: this behavior is affected by the "gray_to_rgb" attribute described in the Section about TextureSystem attributes.

- **const float* missingcolor**: If not NULL, indicates that a missing or broken texture should not be treated as an error, but rather will simply return the supplied color as the texture lookup color and texture() will return true. If the missingcolor field is left at its default (a NULL pointer), a missing or broken texture will be treated as an error and texture() will return false. Note: When not NULL, the data must point to nchannels contiguous floats.

- **Wrap rwrap, float rblur, rwidth**: Specifies wrap, blur, and width for the third component of 3D volume texture lookups. These are not used for 2D texture or environment lookups.

- **MipMode mipmode**: Determines if/how MIP-maps are used:
  - **MipModeDefault**: The default high-quality lookup (same as Aniso).
  - **MipModeNoMIP**: Just use highest-res image, no MIP mapping
  - **MipModeOneLevel**: Use just one mipmap level
  - **MipModeTrilinear**: Use two MIPmap levels (trilinear)
  - **MipModeAniso**: Use two MIPmap levels w/ anisotropic

- **InterpMode interpmode**: Determines how we sample within a mipmap level:
  - **InterpClosest**: Force closest texel.
- InterpBilinear: Force bilinear lookup within a mip level.
- InterpBicubic: Force cubic lookup within a mip level.
- InterpSmartBicubic: Bicubic when maxifying, else bilinear (default).

- int anisotropic: Maximum anisotropic ratio (default: 32).
- bool conservative_filter: When true (the default), filters conservatively in a way that chooses to sometimes over-blur rather than alias.

8.3 TextureSystem API

class OIIIO::TextureSystem
Define an API to an abstract class that manages texture files, caches of open file handles as well as tiles of texels so that truly huge amounts of texture may be accessed by an application with low memory footprint, and ways to perform antialiased texture, shadow map, and environment map lookups.

Creating and destroying a texture system

TextureSystem is an abstract API described as a pure virtual class. The actual internal implementation is not exposed through the external API of OpenImageIO. Because of this, you cannot construct or destroy the concrete implementation, so two static methods of TextureSystem are provided:

static TextureSystem *create (bool shared = true, ImageCache *imagecache = nullptr)
Create a TextureSystem and return a pointer to it. This should only be freed by passing it to TextureSystem::destroy()!

Return A raw pointer to a TextureSystem, which can only be freed with TextureSystem::destroy().

See TextureSystem::destroy

Parameters

- shared: If shared is true, the pointer returned will be a shared TextureSystem, (so that multiple parts of an application that request a TextureSystem will all end up with the same one, and the same underlying ImageCache). If shared is false, a completely unique TextureCache will be created and returned.

- imagecache: If shared is false and imagecache is not nullptr, the TextureSystem will use this as its underlying ImageCache. In that case, it is the caller who is responsible for eventually freeing the ImageCache after the TextureSystem is destroyed. If shared is false and imagecache is nullptr, then a custom ImageCache will be created, owned by the TextureSystem, and automatically freed when the TS destroys.

static void destroy (TextureSystem *ts, bool teardown_imagecache = false)
Destroy an allocated TextureSystem, including freeing all system resources that it holds.

It is safe to destroy even a shared TextureSystem, as the implementation of destroy() will recognize a shared one and only truly release its resources if it has been requested to be destroyed as many times as shared TextureSystem’s were created.

Parameters

- ts: Raw pointer to the TextureSystem to destroy.
• teardown_imagecache: For a shared TextureSystem, if the teardown_imagecache parameter is true, it will try to truly destroy the shared cache if nobody else is still holding a reference (otherwise, it will leave it intact). This parameter has no effect if ts was not the single globally shared TextureSystem.

Setting options and limits for the texture system

These are the list of attributes that can be set or queried by attribute/getattribute:

All attributes ordinarily recognized by ImageCache are accepted and passed through to the underlying ImageCache. These include:

• int max_open_files: Maximum number of file handles held open.
• float max_memory_MB: Maximum tile cache size, in MB.
• string searchpath: Colon-separated search path for texture files.
• string plugin_searchpath: Colon-separated search path for plugins.
• int autotile: If >0, tile size to emulate for non-tiled images.
• int autoscanline: If nonzero, autotile using full width tiles.
• int automip: If nonzero, emulate mipmap on the fly.
• int accept_untiled: If nonzero, accept untiled images.
• int accept_unmipped: If nonzero, accept unmipped images.
• int failure_retries: How many times to retry a read failure.
• int deduplicate: If nonzero, detect duplicate textures (default=1).
• string substitute_image: If supplied, an image to substitute for all texture references.
• int max_errors_per_file: Limits how many errors to issue for each file. (default: 100)

Texture-specific settings:

• matrix44 worldtocommon / matrix44 commontoworld: The 4x4 matrices that provide the spatial transformation from “world” to a “common” coordinate system and back. This is mainly used for shadow map lookups, in which the shadow map itself encodes the world coordinate system, but positions passed to shadow() are expressed in “common” coordinates. You do not need to set commontoworld and worldtocommon separately; just setting either one will implicitly set the other, since each is the inverse of the other.

• int gray_to_rgb: If set to nonzero, texture lookups of single-channel (grayscale) images will replicate the sole channel’s values into the next two channels, making it behave like an RGB image that happens to have all three channels with identical pixel values. (Channels beyond the third will get the “fill” value.) The default value of zero means that all missing channels will get the “fill” color.

• int max_tile_channels: The maximum number of color channels in a texture file for which all channels will be loaded as a single cached tile. Files with more than this number of color channels will have only the requested subset loaded, in order to save cache space (but at the possible wasted expense of separate tiles that overlap their channel ranges). The default is 5.

• int max_mip_res: NEW 2.1 Sets the maximum MIP-map resolution for filtered texture lookups. The MIP levels used will be clamped to those having fewer than this number of pixels in each dimension. This can be helpful as a way to limit disk I/O when doing fast preview renders (with the tradeoff that you may see some texture more blurry than they would ideally be). The default is \(1 << 30\), a value so large that no such clamping will be performed.
• string latlong_up: The default “up” direction for latlong environment maps (only applies if the map itself doesn’t specify a format or is in a format that explicitly requires a particular orientation). The default is "y". (Currently any other value will result in z being “up.”)

• int flip_t: If nonzero, t coordinates will be flipped 1 - t for all texture lookups. The default is 0.

• string options This catch-all is simply a comma-separated list of name=value settings of named options, which will be parsed and individually set.

Note that if an option takes a string value that must itself contain a comma, it is permissible to enclose the value in either single ‘ ‘ or double “ ” quotes.

Read-only attributes
Additionally, there are some read-only attributes that can be queried with `getattribute()` even though they cannot be set via `attribute()`:

The following member functions of `TextureSystem` allow you to set (and in some cases retrieve) options that control the overall behavior of the texture system:

```cpp
virtual bool attribute(string_view name, TypeDesc type, const void *val) = 0
```  
Set a named attribute (i.e., a property or option) of the `TextureSystem`.

Example:

```cpp
TextureSystem *ts;
...
int maxfiles = 50;
ts->attribute ("max_open_files", TypeDesc::INT, &maxfiles);

const char *path = "/my/path";
ts->attribute ("searchpath", TypeDesc::STRING, &path);
```

// There are specialized versions for retrieving a single int, float, or string without needing types or pointers:
```cpp
ts->getattribute ("max_open_files", 50);
ic->attribute ("max_memory_MB", 4000.0f);
ic->attribute ("searchpath", "/my/path");
```

Note: When passing a string, you need to pass a pointer to the char*, not a pointer to the first character. (Rationale: for an int attribute, you pass the address of the int. So for a string, which is a char*, you need to pass the address of the string, i.e., a char**).
virtual bool attribute (string_view name, string_view val) = 0
    Specialized attribute() for setting a single string value.

virtual bool getattribute (string_view name, TypeDesc type, void *val) const = 0
    Get the named attribute of the texture system, store it in *val. All of the attributes that may be set with
    the attribute() call may also be queried with getattribute().

Examples:

    TextureSystem *ic;
    ...
    int maxfiles;
    ts->getattribute ("max_open_files", TypeDesc::INT, &maxfiles);
    const char *path;
    ts->getattribute ("searchpath", TypeDesc::STRING, &path);

    // There are specialized versions for retrieving a single int,
    // float, or string without needing types or pointers:
    int maxfiles;
    ts->getattribute ("max_open_files", maxfiles);
    const char *path;
    ts->getattribute ("searchpath", &path);

Note: When retrieving a string, you need to pass a pointer to the char*, not a pointer to the first character.
Also, the char* will end up pointing to characters owned by the ImageCache; the caller does not need to
ever free the memory that contains the characters.

Return true if the name and type were recognized and the attribute was retrieved, or false upon
failure (including it being an unrecognized attribute or not of the correct type).

Parameters
    • name: Name of the attribute to retrieve.
    • type: TypeDesc describing the type of the attribute.
    • val: Pointer where the attribute value should be stored.

virtual bool getattribute (string_view name, int &val) const = 0
    Specialized attribute() for retrieving a single int value.

virtual bool getattribute (string_view name, float &val) const = 0
    Specialized attribute() for retrieving a single float value.

virtual bool getattribute (string_view name, char **val) const = 0
    Specialized attribute() for retrieving a single string value as a char*.

virtual bool getattribute (string_view name, std::string &val) const = 0
    Specialized attribute() for retrieving a single string value as a std::string.
Opaque data for performance lookups

The TextureSystem implementation needs to maintain certain per-thread state, and some methods take an opaque Perthread pointer to this record. There are three options for how to deal with it:

a. Don’t worry about it at all: don’t use the methods that want Perthread pointers, or always pass nullptr for any 'Perthread*' arguments, and ImageCache will do thread-specific-pointer retrieval as necessary (though at some small cost).

b. If your app already stores per-thread information of its own, you may call get_perthread_info(nullptr) to retrieve it for that thread, and then pass it into the functions that allow it (thus sparing them the need and expense of retrieving the thread-specific pointer). However, it is crucial that this pointer not be shared between multiple threads. In this case, the ImageCache manages the storage, which will automatically be released when the thread terminates.

c. If your app also wants to manage the storage of the Perthread, it can explicitly create one with create_perthread_info(), pass it around, and eventually be responsible for destroying it with destroy_perthread_info(). When managing the storage, the app may reuse the Perthread for another thread after the first is terminated, but still may not use the same Perthread for two threads running concurrently.

```
virtual Perthread *get_perthread_info (Perthread *thread_info = nullptr) = 0
```
Retrieve a Perthread, unique to the calling thread. This is a thread-specific pointer that will always return the Perthread for a thread, which will also be automatically destroyed when the thread terminates.

Applications that want to manage their own Perthread pointers (with create_thread_info and destroy_thread_info) should still call this, but passing in their managed pointer. If the passed-in thread_info is not nullptr, it won’t create a new one or retrieve a TSP, but it will do other necessary housekeeping on the Perthread information.

```
virtual Perthread *create_thread_info () = 0
```
Create a new Perthread. It is the caller’s responsibility to eventually destroy it using destroy_thread_info().

```
virtual void destroy_thread_info (Perthread *thread_info) = 0
```
Destroy a Perthread that was allocated by create_thread_info().

```
virtual TextureHandle *get_texture_handle (ustring filename, Perthread *thread_info = nullptr) = 0
```
Retrieve an opaque handle for fast texture lookups. The filename is presumed to be UTF-8 encoded. The opaque pointer thread_info is thread-specific information returned by get_perthread_info(). Return nullptr if something has gone horribly wrong.

```
inline TextureHandle *get_texture_handle (const std::wstring &filename, Perthread *thread_info = nullptr)
```
Get a TextureHandle using a UTF-16 encoded wstring filename.

```
virtual bool good (TextureHandle *texture_handle) = 0
```
Return true if the texture handle (previously returned by get_image_handle()) is a valid texture that can be subsequently read.

```
virtual ustring filename_from_handle (TextureHandle *handle) = 0
```
Given a handle, return the UTF-8 encoded filename for that texture.

This method was added in OpenImageIO 2.3.
Texture lookups

```cpp
virtual bool texture(ustring filename, TextureOpt &options, float s, float t, float dsdx, float dtedx, float dsdy, float dtedy, int nchannels, float *result, float *dresultds = nullptr, float *dresultdt = nullptr) = 0
```

Perform a filtered 2D texture lookup on a position centered at 2D coordinates \((s, t)\) from the texture identified by `filename`, and using relevant texture options. The `nchannels` parameter determines the number of channels to retrieve (e.g., 1 for a single value, 3 for an RGB triple, etc.). The filtered results will be stored in `result[0..nchannels-1]`.

We assume that this lookup will be part of an image that has pixel coordinates \(x\) and \(y\). By knowing how \(s\) and \(t\) change from pixel to pixel in the final image, we can properly filter or antialias the texture lookups. This information is given via derivatives \(dsdx\) and \(dtedx\) that define the change in \(s\) and \(t\) per unit of \(x\), and \(dsdy\) and \(dtedy\) that define the change in \(s\) and \(t\) per unit of \(y\). If it is impossible to know the derivatives, you may pass 0 for them, but in that case you will not receive an antialiased texture lookup.

Return `true` upon success, or `false` if the file was not found or could not be opened by any available ImageIO plugin.

Parameters

- `filename`: The name of the texture, as a UTF-8 encoded ustring.
- `options`: Fields within `options` that are honored for 2D texture lookups include the following:
  - `int firstchannel`: The index of the first channel to look up from the texture.
  - `int subimage / ustring subimagename`: The subimage or face within the file, specified by either by name (if non-empty) or index. This will be ignored if the file does not have multiple subimages or separate per-face textures.
  - `Wrap swrap, twrap`: Specify the wrap mode for each direction, one of: `WrapBlack`, `WrapClamp`, `WrapPeriodic`, `WrapMirror`, or `WrapDefault`.
  - `float swidth, twidth`: For each direction, gives a multiplier for the derivatives.
  - `float sblur, tblur`: For each direction, specifies an additional amount of pre-blur to apply to the texture (after derivatives are taken into account), expressed as a portion of the width of the texture.
  - `float fill`: Specifies the value that will be used for any color channels that are requested but not found in the file. For example, if you perform a 4-channel lookup on a 3-channel texture, the last channel will get the fill value. (Note: this behavior is affected by the "gray_to_rgb" `TextureSystem` attribute.

- `const float *missingcolor`: If not nullptr, specifies the color that will be returned for missing or broken textures (rather than being an error).
- `s/t`: The 2D texture coordinates.
- `dsdx, dtedx, dsdy, dtedy`: The differentials of \(s\) and \(t\) relative to canonical directions \(x\) and \(y\). The choice of \(x\) and \(y\) are not important to the implementation; it can be any imposed 2D coordinates, such as pixels in screen space, adjacent samples in parameter space on a surface, etc. The \(st\) derivatives determine the size and shape of the ellipsoid over which the texture lookup is filtered.
- `nchannels`: The number of channels of data to retrieve into `result` (e.g., 1 for a single value, 3 for an RGB triple, etc.).
- `result[]`: The result of the filtered texture lookup will be placed into `result[0..nchannels-1]`. 

182 Chapter 8. Texture Access: TextureSystem
• \texttt{dresultds/dresultdt}: If non-null, these designate storage locations for the derivatives of \texttt{result}, i.e., the rate of change per unit \textit{s} and \textit{t}, respectively, of the filtered texture. If supplied, they must allow for \texttt{ncannels} of storage.

\texttt{virtual bool texture(TextureHandle *texture	handle, Perthread *thread_info, TextureOpt &options, float \textit{s}, float \textit{t}, float \textit{dsdx}, float \textit{dsdy}, float \textit{dtdx}, float \textit{dtdy}, int \texttt{ncannels}, float *result, float *dresultds = nullptr, float *dresultdt = nullptr)} = 0

Slightly faster version of \texttt{texture()} lookup if the app already has a texture handle and per-thread info.

\texttt{virtual bool texture3d(ustring filename, TextureOpt &options, V3fParam \textit{P}, V3fParam \textit{dPdx}, V3fParam \textit{dPdy}, V3fParam \textit{dPdz}, int \texttt{ncannels}, float *result, float *dresultds = nullptr, float *dresultdt = nullptr, float *dresultdr = nullptr)} = 0

Perform a filtered 3D volumetric texture lookup on a position centered at 3D position \texttt{P} (with given differentials) from the texture identified by \texttt{filename}, and using relevant texture \texttt{options}. The filtered results will be stored in \texttt{result[0..ncannels-1]}.

The \texttt{P} coordinate and \texttt{dPdx}, \texttt{dPdy}, and \texttt{dPdz} derivatives are assumed to be in some kind of common global coordinate system (usually “world” space) and will be automatically transformed into volume local coordinates, if such a transformation is specified in the volume file itself.

\textbf{Return} true upon success, or false if the file was not found or could not be opened by any available ImageIO plugin.

\textbf{Parameters}

• \texttt{filename}: The name of the texture, as a UTF-8 encoded ustring.

• \texttt{options}: Fields within \texttt{options} that are honored for 3D texture lookups include the following:

  – int \texttt{firstchannel}: The index of the first channel to look up from the texture.

  – int \texttt{subimage} / ustring \texttt{subimagename}: The subimage or field within the volume, specified by either by name (if non-empty) or index. This will be ignored if the file does not have multiple subimages or separate per-face textures.

  – Wrap \texttt{swrap}, \texttt{twrap}, \texttt{rwrap}: Specify the \texttt{wrap mode} for each direction, one of: \texttt{WrapBlack}, \texttt{WrapClamp}, \texttt{WrapPeriodic}, \texttt{WrapMirror}, or \texttt{WrapDefault}.

  – float \texttt{swidth}, \texttt{twidth}, \texttt{rwidth}: For each direction, gives a multiplier for the derivatives.

  – float \texttt{sblur}, \texttt{tblur}, \texttt{rblur}: For each direction, specifies an additional amount of pre-blur to apply to the texture (after derivatives are taken into account), expressed as a portion of the width of the texture.

  – float \texttt{fill}: Specifies the value that will be used for any color channels that are requested but not found in the file. For example, if you perform a 4-channel lookup on a 3-channel texture, the last channel will get the fill value. (Note: this behavior is affected by the "gray_to_rgb" \texttt{TextureSystem} attribute.

  – const float *\texttt{missingcolor}: If not nullptr, specifies the color that will be returned for missing or broken textures (rather than being an error).

  – float \texttt{time}: A time value to use if the volume texture specifies a time-varying local transformation (default: 0).

• \texttt{P}: The 2D texture coordinates.
OpenImageIO, Release 2.4.1

- \( \frac{dP}{dx} / \frac{dP}{dy} / \frac{dP}{dz} \): The differentials of \( P \). We assume that this lookup will be part of an image that has pixel coordinates \( x \) and \( y \) and depth \( z \). By knowing how \( P \) changes from pixel to pixel in the final image, and as we step in \( z \) depth, we can properly filter or antialias the texture lookups. This information is given via derivatives \( \frac{dP}{dx} \), \( \frac{dP}{dy} \), and \( \frac{dP}{dz} \) that define the changes in \( P \) per unit of \( x \), \( y \), and \( z \), respectively. If it is impossible to know the derivatives, you may pass 0 for them, but in that case you will not receive an antialiased texture lookup.

- \( nchannels \): The number of channels of data to retrieve into \( result \) (e.g., 1 for a single value, 3 for an RGB triple, etc.).

- \( \text{result[]} \): The result of the filtered texture lookup will be placed into \( \text{result}[0..nchannels-1] \).

- \( \text{dresult}ds / \text{dresult}dt / \text{dresult}dr \): If non-null, these designate storage locations for the derivatives of \( \text{result} \), i.e., the rate of change per unit \( s \), \( t \), and \( r \), respectively, of the filtered texture. If supplied, they must allow for \( nchannels \) of storage.

```
virtual bool texture3d(TextureHandle *texture_handle, Perthread *thread_info, TextureOpt &options, V3fParam P, V3fParam dPdx, V3fParam dPdy, V3fParam dPdz, int nchannels, float *result, float *dresultds = nullptr, float *dresultdt = nullptr, float *dresultdr = nullptr) = 0
```

Slightly faster version of \( \text{texture3d}() \) lookup if the app already has a texture handle and per-thread info.

```
virtual bool environment(ustring filename, TextureOpt &options, V3fParam R, V3fParam dRdx, V3fParam dRdy, int nchannels, float *result, float *dresultds = nullptr, float *dresultdt = nullptr, float *dresultdr = nullptr) = 0
```

Perform a filtered directional environment map lookup in the direction of vector \( R \), from the texture identified by \( \text{filename} \), and using relevant texture \( \text{options} \). The filtered results will be stored in \( \text{result}[] \).

Return \( \text{true} \) upon success, or \( \text{false} \) if the file was not found or could not be opened by any available ImageIO plugin.

Parameters

- \( \text{filename} \): The name of the texture, as a UTF-8 encode \( \text{ustring} \).

- \( \text{options} \): Fields within \( \text{options} \) that are honored for environment lookups include the following:
  
  - \( \text{int firstchannel} \): The index of the first channel to look up from the texture.
  
  - \( \text{int subimage / ustring subimagemename} \): The subimage or face within the file, specified by either by name (if non-empty) or index. This will be ignored if the file does not have multiple subimages or separate per-face textures.
  
  - \( \text{float swidth, twidth} \): For each direction, gives a multiplier for the derivatives.
  
  - \( \text{float sblur, tblur} \): For each direction, specifies an additional amount of pre-blur to apply to the texture (after derivatives are taken into account), expressed as a portion of the width of the texture.
  
  - \( \text{float fill} \): Specifies the value that will be used for any color channels that are requested but not found in the file. For example, if you perform a 4-channel lookup on a 3-channel texture, the last channel will get the fill value. (Note: this behavior is affected by the "gray_to_rgb" \( \text{TextureSystem} \) attribute.
  
  - \( \text{const float *missingcolor} \): If not \( \text{nullptr} \), specifies the color that will be returned for missing or broken textures (rather than being an error).

- \( \text{R} \): The direction vector to look up.
• \(dRdx/dRdy\): The differentials of \(R\) with respect to image coordinates \(x\) and \(y\).

• \(nchannels\): The number of channels of data to retrieve into \(result\) (e.g., 1 for a single value, 3 for an RGB triple, etc.).

• \(result[]\): The result of the filtered texture lookup will be placed into \(result[0..nchannels-1]\).

• \(dresultds/dresultdt\): If non-null, these designate storage locations for the derivatives of \(result\), i.e., the rate of change per unit \(s\) and \(t\), respectively, of the filtered texture. If supplied, they must allow for \(nchannels\) of storage.

\[
\text{virtual bool } \text{environment} \left( \text{TextureHandle } *\text{texture_handle}, \text{ Perthread } *\text{thread_info}, \text{ TextureOpt &options}, \text{ V3fParam } R, \text{ V3fParam } dRdx, \text{ V3fParam } dRdy, \text{ int } nchannels, \text{ float } *\text{result}, \text{ float } *\text{dresultds} = \text{nullptr}, \text{ float } *\text{dresultdt} = \text{nullptr} \right) = 0
\]

Slightly faster version of \(\text{environment()}\) if the app already has a texture handle and per-thread info.

**Batched texture lookups**

\[
\text{virtual bool } \text{texture} \left( \text{ustring } filename, \text{ TextureOptBatch &options, Tex::RunMask mask, const float } *s, \text{ const float } *t, \text{ const float } *dsdx, \text{ const float } *dtdx, \text{ const float } *dsdy, \text{ const float } *dtdy, \text{ int } nchannels, \text{ float } *\text{result}, \text{ float } *\text{dresultds} = \text{nullptr}, \text{ float } *\text{dresultdt} = \text{nullptr} \right) = 0
\]

Perform filtered 2D texture lookups on a batch of positions from the same texture, all at once. The parameters \(s, t, dsdx, dttx, dsdy, dtty\) are each a pointer to \([\text{BatchWidth}]\) values. The \(mask\) determines which of those array elements to actually compute.

The float* results act like float\([\text{nchannels}] [\text{BatchWidth}]\), so that effectively \(result[0..\text{BatchWidth}-1]\) are the “red” result for each lane, \(result[\text{BatchWidth}..2\times\text{BatchWidth}-1]\) are the “green” results, etc. The \(dresultds\) and \(dresultdt\) should either both be provided, or else both be nullptr (meaning no derivative results are required).

Return \(true\) upon success, or \(false\) if the file was not found or could not be opened by any available ImageIO plugin.

**Parameters**

- \(filename\): The name of the texture, as a UTF-8 encode ustring.
- \(options\): A TextureOptBatch containing texture lookup options. This is conceptually the same as a TextureOpt, but the following fields are arrays of \([\text{BatchWidth}]\) elements: sblur, tblur, swidth, twidth. The other fields are, as with TextureOpt, ordinary scalar values.
- \(mask\): A bit-field designating which “lanes” should be computed: if \(\text{mask} & (1<<i)\) is nonzero, then results should be computed and stored for \(result[...][i]\).
- \(s/t\): Pointers to the 2D texture coordinates, each as a float\([\text{BatchWidth}]\).
- \(dsdx/dtdx/dsdy/dtdy\): The differentials of \(s\) and \(t\) relative to canonical directions \(x\) and \(y\), each as a float\([\text{BatchWidth}]\).
- \(nchannels\): The number of channels of data to retrieve into \(result\) (e.g., 1 for a single value, 3 for an RGB triple, etc.).
- \(result[]\): The result of the filtered texture lookup will be placed here, as float\([\text{nchannels}] [\text{BatchWidth}]\). (Note the “SOA” data layout.)
- \(dresultds/dresultdt\): If non-null, these designate storage locations for the derivatives of \(result\), and like \(result\) are in SOA layout: float\([\text{nchannels}] [\text{BatchWidth}]\).
virtual bool texture(TextureHandle *texture_handle, Perthread *thread_info, TextureOptBatch &options, Tex::RunMask mask, const float *s, const float *t, const float *dsdx, const float *dtdx, const float *dsdy, const float *dt.dy, int nchannels, float *result, float *dresultds = nullptr, float *dresultdt = nullptr) = 0

Slightly faster version of texture() lookup if the app already has a texture handle and per-thread info.

virtual bool texture3d(ustring filename, TextureOptBatch &options, Tex::RunMask mask, float *P, const float *dPdx, const float *dPdy, const float *dPdz, int nchannels, float *result, float *dresultds = nullptr, float *dresultdt = nullptr, float *dresultdr = nullptr) = 0

Slightly faster version of texture3d() lookup if the app already has a texture handle and per-thread info.

Perform filtered 3D volumetric texture lookups on a batch of positions from the same texture, all at once. The “point-like” parameters P, dPdx, dPdy, and dPdz are each a pointers to arrays of float value[3][BatchWidth] (or alternately like Imath::Vec3<FloatWide>). That is, each one points to all the x values for the batch, immediately followed by all the y values, followed by the z values. The mask determines which of those array elements to actually compute.

The various results arrays are also arranged as arrays that behave as if they were declared float result[channels][BatchWidth], where all the batch values for channel 0 are adjacent, followed by all the batch values for channel 1, etc.

Return true upon success, or false if the file was not found or could not be opened by any available ImageIO plugin.

Parameters

- filename: The name of the texture, as a UTF-8 encode ustring.
- options: A TextureOptBatch containing texture lookup options. This is conceptually the same as a TextureOpt, but the following fields are arrays of [BatchWidth] elements: sblur, tblur, swidth, twidth. The other fields are, as with TextureOpt, ordinary scalar values.
- mask: A bit-field designating which “lanes” should be computed: if mask & (1<<i) is nonzero, then results should be computed and stored for result[...][i].
- P: Pointers to the 3D texture coordinates, each as a float[3][BatchWidth].
- dPdx/dPdy/dPdz: The differentials of P relative to canonical directions x, y, and z, each as a float[3][BatchWidth].
- nchannels: The number of channels of data to retrieve into result (e.g., 1 for a single value, 3 for an RGB triple, etc.).
- result[]: The result of the filtered texture lookup will be placed here, as float [nchannels][BatchWidth]. (Note the “SOA” data layout.)
- dresultds/dresultdt/dresultdr: If non-null, these designate storage locations for the derivatives of result, and like result are in SOA layout: float [nchannels][BatchWidth].
Perform filtered directional environment map lookups on a batch of directions from the same texture, all at once. The “point-like” parameters $R$, $dRdx$, and $dRdy$ are each a pointer to arrays of float value[3][BatchWidth] (or alternately like Imath::Vec3<FloatWide>). That is, each one points to all the $x$ values for the batch, immediately followed by all the $y$ values, followed by the $z$ values. The mask determines which of those array elements to actually compute.

The various results arrays are also arranged as arrays that behave as if they were declared float result[channels][BatchWidth], where all the batch values for channel 0 are adjacent, followed by all the batch values for channel 1, etc.

Return true upon success, or false if the file was not found or could not be opened by any available ImageIO plugin.

Parameters

- filename: The name of the texture, as a UTF-8 encode ustring.
- options: A TextureOptBatch containing texture lookup options. This is conceptually the same as a TextureOpt, but the following fields are arrays of [BatchWidth] elements: sblur, tblur, swidth, twidth. The other fields are, as with TextureOpt, ordinary scalar values.
- mask: A bit-field designating which “lanes” should be computed: if mask & (1<<i) is nonzero, then results should be computed and stored for result[...][i].
- $R$: Pointers to the 3D texture coordinates, each as a float[3][BatchWidth].
- $dRdx$/dRdy: The differentials of $R$ relative to canonical directions $x$ and $y$, each as a float[3][BatchWidth].
- nchannels: The number of channels of data to retrieve into result (e.g., 1 for a single value, 3 for an RGB triple, etc.).
- result[ ]: The result of the filtered texture lookup will be placed here, as float [nchannels][BatchWidth]. (Note the “SOA” data layout.)
- dresultds/dresultdt: If non-null, these designate storage locations for the derivatives of result, and like result are in SOA layout: float [nchannels][BatchWidth]

virtual bool environment (TextureHandle *texture_handle, Perthread *thread_info, TextureOpt-Batch &options, Tex::RunMask mask, const float *R, const float *dRdx, const float *dRdy, int nchannels, float *result, float *dresultds = nullptr, float *dresultdt = nullptr) = 0

Slightly faster version of environment() if the app already has a texture handle and per-thread info.

Texture metadata and raw texels

virtual std::string resolve_filename (const std::string &filename) const = 0

Given possibly-relative ‘filename’ (UTF-8 encoded), resolve it using the search path rules and return the full resolved filename.

virtual bool get_texture_info (ustring filename, int subimage, ustring dataname, TypeDesc datatype, void *data) = 0

Get information or metadata about the named texture and store it in *data.

Data names may include any of the following:
exists (int): Stores the value 1 if the file exists and is an image format that OpenImageIO can read, or 0 if the file does not exist, or could not be properly read as a texture. Note that unlike all other queries, this query will “succeed” (return true) even if the file does not exist.

udim (int): Stores the value 1 if the file is a “virtual UDIM” or texture atlas file (as described in Section :ref:sec-texturesys-udim) or 0 otherwise.

subimages (int): The number of subimages/faces in the file, as an integer.

resolution (int[2] or int[3]): The resolution of the texture file, if an array of 2 integers (described as TypeDesc(INT, 2)), or the 3D resolution of the texture file, which is an array of 3 integers (described as TypeDesc(INT, 3)) The third value will be 1 unless it’s a volumetric (3D) image.

mplevels (int): The number of MIPmap levels for the specified subimage (an integer).

texturetype (string): A string describing the type of texture of the given file, which describes how the texture may be used (also which texture API call is probably the right one for it). This currently may return one of: “unknown”, “Plain Texture”, “Volume Texture”, “Shadow”, or “Environment”.

textureformat (string): A string describing the format of the given file, which describes the kind of texture stored in the file. This currently may return one of: “unknown”, “Plain Texture”, “Volume Texture”, “Shadow”, “CubeFace Shadow”, “Volume Shadow”, “LatLong Environment”, or “CubeFace Environment”. Note that there are several kinds of shadows and environment maps, all accessible through the same API calls.

channels (int): The number of color channels in the file.

format (int): The native data format of the pixels in the file (an integer, giving the TypeDesc::BASETYPE of the data). Note that this is not necessarily the same as the data format stored in the image cache.

cachedformat (int): The native data format of the pixels as stored in the image cache (an integer, giving the TypeDesc::BASETYPE of the data). Note that this is not necessarily the same as the native data format of the file.

datawindow (int[4] or int[6]): Returns the pixel data window of the image, which is either an array of 4 integers (returning xmin, ymin, xmax, ymax) or an array of 6 integers (returning xmin, ymin, zmin, xmax, ymax, zmax). The z values may be useful for 3D/volumetric images; for 2D images they will be 0).

displaywindow (matrix): Returns the display (a.k.a. full) window of the image, which is either an array of 4 integers (returning xmin, ymin, xmax, ymax) or an array of 6 integers (returning xmin, ymin, zmin, xmax, ymax, zmax). The z values may be useful for 3D/volumetric images; for 2D images they will be 0).

worldtocamera (matrix): The viewing matrix, which is a 4x4 matrix (an Imath::M44f, described as TypeMatrix44) giving the world-to-camera 3D transformation matrix that was used when the image was created. Generally, only rendered images will have this.

worldtoscreen (matrix): The projection matrix, which is a 4x4 matrix (an Imath::M44f, described as TypeMatrix44) giving the matrix that projected points from world space into a 2D screen coordinate system where x and y range from -1 to +1. Generally, only rendered images will have this.

worldtoNDC (matrix): The projection matrix, which is a 4x4 matrix (an Imath::M44f, described as TypeMatrix44) giving the matrix that projected points from world space into a 2D screen coordinate system where x and y range from 0 to +1. Generally, only rendered images will have this.

averagecolor (float[nchannels]): If available in the metadata (generally only for files that have been processed by maketx), this will return the average color of the texture (into an array of floats).
• **averagealpha** (float): If available in the metadata (generally only for files that have been processed by `maketx`), this will return the average alpha value of the texture (into a float).

• **constantcolor** (float[nchannels]): If the metadata (generally only for files that have been processed by `maketx`) indicates that the texture has the same values for all pixels in the texture, this will retrieve the constant color of the texture (into an array of floats). A non-constant image (or one that does not have the special metadata tag identifying it as a constant texture) will fail this query (return false).

• **constantalpha** (float): If the metadata indicates that the texture has the same values for all pixels in the texture, this will retrieve the constant alpha value of the texture. A non-constant image (or one that does not have the special metadata tag identifying it as a constant texture) will fail this query (return false).

• **stat:tilesread** (int64): Number of tiles read from this file.

• **stat:bytesread** (int64): Number of bytes of uncompressed pixel data read.

• **stat:redundant_tiles** (int64): Number of times a tile was read, where the same tile had been read before.

• **stat:redundant_bytesread** (int64): Number of bytes (of uncompressed pixel data) in tiles that were read redundantly.

• **stat:redundant_bytesread** (int): Number of tiles read from this file.

• **stat:timesopened** (int): Number of times this file was opened.

• **stat:iotime** (float): Time (in seconds) spent on all I/O for this file.

• **stat:mipsused** (int): Stores 1 if any MIP levels beyond the highest resolution were accessed, otherwise 0.

• **stat:is_duplicate** (int): Stores 1 if this file was a duplicate of another image, otherwise 0.

• **Anything else**: For all other data names, the metadata of the image file will be searched for an item that matches both the name and data type.

Return true if `get_texture_info()` is able to find the requested dataname for the texture and it matched the requested datatype. If the requested data was not found or was not of the right data type, return false. Except for the "exists" query, a file that does not exist or could not be read properly as an image also constitutes a query failure that will return false.

**Parameters**

- **filename**: The name of the texture, as a UTF-8 encode ustring.

- **subimage**: The subimage to query. (The metadata retrieved is for the highest-resolution MIP level of that subimage.)

- **dataname**: The name of the metadata to retrieve.

- **datatype**: `TypeDesc` describing the data type.

- **data**: Pointer to the caller-owned memory where the values should be stored. It is the caller’s responsibility to ensure that `data` points to a large enough storage area to accommodate the datatype requested.

```cpp
virtual bool get_texture_info(TextureHandle *texture_handle, Perthread *thread_info, int subimage, ustring dataname, TypeDesc datatype, void *data)
```

A more efficient variety of `get_texture_info()` for cases where you can use a `TextureHandle*` to specify the image and optionally have a `Perthread*` for the calling thread.
virtual bool get_imagespec(ustring filename, int subimage, ImageSpec &spec) = 0

Copy the ImageSpec associated with the named texture (the first subimage by default, or as set by subimage).

Return true upon success, false upon failure (such as being unable to find, open, or read the file, or if it does not contain the designated subimage or MIP level).

Parameters

- *filename*: The name of the texture, as a UTF-8 encode ustring.
- *subimage*: The subimage to query. (The spec retrieved is for the highest-resolution MIP level of that subimage.)
- *spec*: ImageSpec into which will be copied the spec for the requested image.

virtual bool get_imagespec(TextureHandle *texture_handle, Perthread *thread_info, int subimage, ImageSpec &spec) = 0

A more efficient variety of get_imagespec() for cases where you can use a TextureHandle* to specify the image and optionally have a Perthread* for the calling thread.

virtual const ImageSpec *imagespec(ustring filename, int subimage = 0) = 0

Return a pointer to an ImageSpec associated with the named texture if the file is found and is an image format that can be read, otherwise return nullptr.

This method is much more efficient than get_imagespec(), since it just returns a pointer to the spec held internally by the TextureSystem (rather than copying the spec to the user’s memory). However, the caller must beware that the pointer is only valid as long as nobody (even other threads) calls invalidate() on the file, or invalidate_all(), or destroys the TextureSystem and its underlying ImageCache.

Return A pointer to the spec, if the image is found and able to be opened and read by an available image format plugin, and the designated subimage exists.

Parameters

- *filename*: The name of the texture, as a UTF-8 encode ustring.
- *subimage*: The subimage to query. (The spec retrieved is for the highest-resolution MIP level of that subimage.)

virtual const ImageSpec *imagespec(TextureHandle *texture_handle, Perthread *thread_info = nullptr, int subimage = 0) = 0

A more efficient variety of imagespec() for cases where you can use a TextureHandle* to specify the image and optionally have a Perthread* for the calling thread.

virtual bool get_texels(ustring filename, TextureOpt &options, int mplevel, int xbegin, int xend, int ybegin, int yend, int zbegin, int zend, int chbegin, int chend, TypeDesc format, void *result) = 0

For a texture specified by name, retrieve the rectangle of raw unfiltered texels from the subimage specified in options and at the designated mplevel, storing the pixel values beginning at the address specified by result. The pixel values will be converted to the data type specified by format. The rectangular region to be retrieved includes begin but does not include end (much like STL begin/end usage). Requested pixels that are not part of the valid pixel data region of the image file will be filled with zero values. Channels requested but not present in the file will get the options.fill value.

Return true for success, false for failure.
Parameters

- **filename**: The name of the texture, as a UTF-8 encode ustring.
- **options**: A TextureOpt describing access options, including wrap modes, fill value, and sub-image, that will be used when retrieving pixels.
- **miplevel**: The MIP level to retrieve pixels from (0 is the highest resolution level).
- **xbegin/xend/ybegin/yend/zbegin/zend**: The range of pixels to retrieve. The pixels retrieved include the begin value but not the end value (much like STL begin/end usage).
- **chbegin/chend**: Channel range to retrieve. To retrieve all channels, use chbegin = 0, chend = nchannels.
- **format**: TypeDesc describing the data type of the values you want to retrieve into result. The pixel values will be converted to this type regardless of how they were stored in the file or in the cache.
- **result**: Pointer to the memory where the pixel values should be stored. It is up to the caller to ensure that result points to an area of memory big enough to accommodate the requested rectangle (taking into consideration its dimensions, number of channels, and data format).

```cpp
virtual bool get_texels(TextureHandle *texture_handle, Perthread *thread_info, TextureOpt &options, int miplevel, int xbegin, int xend, int ybegin, int yend, int zbegin, int zend, int chbegin, int chend, TypeDesc format, void *result) = 0
```

A more efficient variety of `get_texels()` for cases where you can use a TextureHandle* to specify the image and optionally have a Perthread* for the calling thread.

Methods for UDIM patterns

```cpp
virtual bool is_udim(ustring filename) = 0
Is the UTF-8 encoded filename a UDIM pattern?
```

This method was added in OpenImageIO 2.3.

```cpp
virtual bool is_udim(TextureHandle *udimfile) = 0
Does the handle refer to a file that's a UDIM pattern?
```

This method was added in OpenImageIO 2.3.

```cpp
virtual TextureHandle *resolve_udim(ustring udimpattern, float s, float t) = 0
For a UDIM filename pattern (UTF-8 encoded) and texture coordinates, return the TextureHandle pointer for the concrete tile file it refers to, or nullptr if there is no corresponding tile (udim sets are allowed to be sparse).
```

This method was added in OpenImageIO 2.3.

```cpp
virtual TextureHandle *resolve_udim(TextureHandle *udimfile, Perthread *thread_info, float s, float t) = 0
A more efficient variety of `resolve_udim()` for cases where you have the TextureHandle* that corresponds to the “virtual” UDIM file and optionally have a Perthread* for the calling thread.
```

This method was added in OpenImageIO 2.3.

```cpp
virtual void inventory_udim(ustring udimpattern, std::vector<ustring> &filenames, int &nutiles, int &nvtiles) = 0
Produce a full inventory of the set of concrete files comprising the UDIM set specified by UTF-8 encoded udimpattern. The apparent number of texture atlas tiles in the u and v directions will be written to nutiles and nvtiles, respectively. The vector filenames will be sized to ntiles * nvtiles and filled with the the names of the concrete files comprising the atlas, with an empty ustring corresponding
to any unpopulated tiles (the UDIM set is allowed to be sparse). The filename list is indexed as \texttt{utile + vtile}

This method was added in OpenImageIO 2.3.

\texttt{virtual void inventory_udim(TextureHandle *udimfile, Perthread *thread_info, std::vector<ustring> &filenames, int &nutiles, int &nvtiles) = 0}

A more efficient variety of \texttt{inventory_udim()} for cases where you have the TextureHandle* that corresponds to the "virtual" UDIM file and optionally have a Perthread* for the calling thread.

This method was added in OpenImageIO 2.3.

\section*{Controlling the cache}

\texttt{virtual void invalidate(ustring filename, bool force = true) = 0}

Invalidate any cached information about the named file (UTF-8 encoded), including loaded texture tiles from that texture, and close any open file handle associated with the file. This calls \texttt{ImageCache::invalidate(filename,force)} on the underlying \texttt{ImageCache}.

\texttt{virtual void invalidate_all(bool force = false) = 0}

Invalidate all cached data for all textures. This calls \texttt{ImageCache::invalidate_all(force)} on the underlying \texttt{ImageCache}.

\texttt{virtual void close(ustring filename) = 0}

Close any open file handles associated with a UTF-8 encoded filename, but do not invalidate any image spec information or pixels associated with the files. A client might do this in order to release OS file handle resources, or to make it safe for other processes to modify textures on disk. This calls \texttt{ImageCache::close(force)} on the underlying \texttt{ImageCache}.

\texttt{virtual void close_all() = 0}

close() all files known to the cache.

\section*{Errors and statistics}

\texttt{virtual bool has_error() const = 0}

Is there a pending error message waiting to be retrieved?

\texttt{virtual std::string geterror(bool clear = true) const = 0}

Return the text of all pending error messages issued against this \texttt{TextureSystem}, and clear the pending error message unless \texttt{clear} is false. If no error message is pending, it will return an empty string.

\texttt{virtual std::string getstats(int level = 1, bool icstats = true) const = 0}

Returns a big string containing useful statistics about the \texttt{TextureSystem} operations, suitable for saving to a file or outputting to the terminal. The \texttt{level} indicates the amount of detail in the statistics, with higher numbers (up to a maximum of 5) yielding more and more esoteric information. If \texttt{icstats} is true, the returned string will also contain all the statistics of the underlying \texttt{ImageCache}, but if false will only contain texture-specific statistics.

\texttt{virtual void reset_stats() = 0}

Reset most statistics to be as they were with a fresh \texttt{TextureSystem}. Caveat emptor: this does not flush the cache itself, so the resulting statistics from the next set of texture requests will not match the number of tile reads, etc., that would have resulted from a new \texttt{TextureSystem}. 

192 Chapter 8. Texture Access: TextureSystem
Public Functions

virtual ImageCache *imagecache() const = 0

Return an opaque, non-owning pointer to the underlying ImageCache (if there is one).

8.4 UDIM texture atlases

8.4.1 Texture lookups

The texture() call supports virtual filenames that expand per lookup for UDIM tiled texture atlases. The substitutions will occur if the texture filename initially passed to texture() does not exist as a concrete file and contains one or more of the following substrings:

<table>
<thead>
<tr>
<th>Pattern</th>
<th>Numbering scheme</th>
<th>Example expansion if u=0.5, v=2.5</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;UDIM&gt;</td>
<td>1001 + utile + vtile*10</td>
<td>1021</td>
</tr>
<tr>
<td>&lt;u&gt;</td>
<td>utile</td>
<td>u0</td>
</tr>
<tr>
<td>&lt;v&gt;</td>
<td>vtile</td>
<td>v2</td>
</tr>
<tr>
<td>&lt;U&gt;</td>
<td>utile + 1</td>
<td>u1</td>
</tr>
<tr>
<td>&lt;V&gt;</td>
<td>vtile + 1</td>
<td>v3</td>
</tr>
<tr>
<td>&lt;uvtile&gt;</td>
<td>equivalent to &lt;u&gt;_&lt;v&gt;</td>
<td>u0_v2</td>
</tr>
<tr>
<td>&lt;UVTILE&gt;</td>
<td>equivalent to &lt;U&gt;_&lt;V&gt;</td>
<td>u1_v3</td>
</tr>
<tr>
<td>_u##v##</td>
<td>utile, vtile</td>
<td>_u00v02</td>
</tr>
<tr>
<td>%(UDIM)d</td>
<td>synonym for &lt;UDIM&gt;</td>
<td>1021</td>
</tr>
</tbody>
</table>

where the tile numbers are derived from the input u,v texture coordinates as follows:

```cpp
// Each unit square of texture is a different tile
utile = max (0, int(u));
vtile = max (0, int(v));
// Re-adjust the texture coordinates to the offsets within the tile
u = u - utile;
v = v - vtile;
```

Example:

```cpp
ustring filename ("paint.<UDIM>.tif");
float s = 1.4, t = 3.8;
texsys->texture (filename, s, t, ...);
```

will retrieve from file `paint.1032.tif` at coordinates (0.4,0.8).

8.4.2 Handles of udim files

Calls to get_texture_handle(), when passing a UDIM pattern filename, will always succeed. But withing knowing a specific u and v, it has no way to know that the concrete file you will eventually ask for would not succeed, so this handle is for the overall “virtual” texture atlas.

You can retrieve the handle of a specific “tile” of the UDIM set by using

TextureHandle *resolve_udim (ustring udimpattern, float s, float t)
TextureHandle *resolve_udim (TextureHandle *udimfile, Perthread *thread_info, float s, float t)

Note: these will return nullptr if the UDIM tile for those coordinates is unpopulated.
Note also that the \texttt{is_udim()} method can be used to ask whether a filename or handle corresponds to a UDIM pattern (the whole set of atlas tiles):

```cpp
bool is_udim (ustring filename)
bool is_udim (TextureHandle *udimfile)
```

### 8.4.3 Retrieving metadata from UDIM sets and tiles

Calls to \texttt{get_texture_info()} on UDIM file pattern will succeed if the metadata is found and has the same value in all of the populated “tiles” of a UDIM. If not all populated tile files have the same value for that attribute, the call will fail.

If you want to know the metadata at a specific texture coordinate, you can use a combination of \texttt{resolve_udim()} to find the handle for the corresponding concrete texture file for that “tile,” and then \texttt{get_texture_info()} to retrieve the metadata for the concrete file.

### 8.4.4 Full inventory of a UDIM set

You can get the range in u and v of the UDIM texture atlas, and the list of all of the concrete filenames of the corresponding tiles with this method:

```cpp
void inventory_udim (ustring udimpattern, std::vector<ustring> &filenames, int &nutiles, int &nvtiles)
void inventory_udim (TextureHandle *udimfile, Perthread *thread_info, std::vector<ustring> &filenames, int &nutiles, int &nvtiles)
```

The indexing scheme is that \texttt{filenames[u + v * nvtiles]} is the name of the tile with integer indices \((u,v)\), where 0 is the first index of each row or column.

The combination of \texttt{inventory_udim()} and \texttt{get_texture_handle()} of the listed filenames can be used to generate the corresponding handles for each UDIM tile.

### 8.5 Batched Texture Lookups

On CPU architectures with SIMD processing, texturing entire batches of samples at once may provide a large speedup compared to texturing each sample point individually. The batch size is fixed (for any build of OpenImageIO) and may be accessed with the following constant:

```cpp
constexpr int OIIO::Tex::BatchWidth = OIIO_TEXTURE_SIMD_BATCH_WIDTH
```

The SIMD width for batched texturing operations. This is fixed within any release of OpenImageIO, but may change from release to release and also may be overridden at build time. A typical batch size is 16.

```cpp
typedef simd::VecType<float, OIIO_TEXTURE_SIMD_BATCH_WIDTH>::type OIIO::Tex::FloatWide
```

A type alias for a SIMD vector of floats with the batch width.

```cpp
typedef simd::VecType<int, OIIO_TEXTURE_SIMD_BATCH_WIDTH>::type OIIO::Tex::IntWide
```

A type alias for a SIMD vector of ints with the batch width.

All of the batched calls take a \texttt{run mask}, which describes which subset of “lanes” should be computed by the batched lookup:

```cpp
typedef uint64_t OIIO::Tex::RunMask
```

\texttt{RunMask} is defined to be an integer large enough to hold at least \texttt{BatchWidth} bits. The least significant bit corresponds to the first (i.e., [0]) position of all batch arrays. For each position \(i\) in the batch, the bit identified by \((1 \ll i)\) controls whether that position will be computed.
enumerator RunMaskOn

The defined constant RunMaskOn contains the value with all bits 0..BatchWidth-1 set to 1.

8.5.1 Batched Options

TextureOptBatch is a structure that holds the options for doing an entire batch of lookups from the same texture at once. The members of TextureOptBatch correspond to the similarly named members of the single-point TextureOpt, so we refer you to Section TextureOpt for detailed explanations, and this section will only explain the differences between batched and single-point options. Members include:

- int firstchannel:
- int subimage, ustring subimagename:
- Wrap swrap, twrap, rwrap:
- float fill:
- const float* missingcolor:
- MipMode mipmode:
- InterpMode interpmode:
- int anisotropic:
- bool conservative_filter:

These fields are all scalars — a single value for each TextureOptBatch — which means that the value of these options must be the same for every texture sample point within a batch. If you have a number of texture lookups to perform for the same texture, but they have (for example) differing wrap modes or subimages from point to point, then you must split them into separate batch calls.

- float sblur[Tex::BatchWidth]:
- float tblur[Tex::BatchWidth]:
- float rblur[Tex::BatchWidth]:

These arrays hold the s, and t blur amounts, for each sample in the batch, respectively. (And the r blur amount, used only for volumetric texture3d() lookups.)

- float swidth[Tex::BatchWidth]:
- float twidth[Tex::BatchWidth]:
- float rwidth[Tex::BatchWidth]:

These arrays hold the s, and t filtering width multiplier for derivatives, for each sample in the batch, respectively. (And the r multiplier, used only for volumetric texture3d() lookups.)

8.5.2 Batched Texture Lookup Calls

bool TextureSystem::texture(ustring filename, TextureOptBatch &options, Tex::RunMask mask,
const float *s, const float *t, const float *dsdx, const float *dtdx,
const float *dsdy, const float *dtdy, int nchannels, float *result, float *
dresultds = nullptr, float *dresultdt = nullptr)
bool TextureSystem::texture (TextureHandle *texture_handle, Perthread *thread_info, TextureOptBatch &options, Tex::RunMask mask, const float *s, const float *t, const float *dsdx, const float *dsdy, const float *dtdx, const float *dtdy, int nchannels, float *result, float *dresultds = nullptr, float *dresultdt = nullptr, float *dresultdr = nullptr)

Perform filtered 2D texture lookups on a batch of positions from the same texture, all at once. The parameters s, t, dsdx, dt dx, and dsdy, dt dy are each a pointer to [BatchWidth] values. The mask determines which of those array elements to actually compute.

The various results are arranged as arrays that behave as if they were declared:

```
float result[nchannels][BatchWidth]
```

In other words, all the batch values for channel 0 are adjacent, followed by all the batch values for channel 1, etc. (This is “SOA” order.)

This function returns true upon success, or false if the file was not found or could not be opened by any available ImageIO plugin.

bool texture3d (ustring filename, TextureOptBatch &options, Tex::RunMask mask, const float *P, const float *dPdx, const float *dPdy, const float *dPdz, int nchannels, float *result, float *dresultds = nullptr, float *dresultdt = nullptr, float *dresultdr = nullptr)

bool texture3d (TextureHandle *texture_handle, Perthread *thread_info, TextureOptBatch &options, Tex::RunMask mask, const float *P, const float *dPdx, const float *dPdy, const float *dPdz, int nchannels, float *result, float *dresultds = nullptr, float *dresultdt = nullptr, float *dresultdr = nullptr)

Perform filtered 3D volumetric texture lookups on a batch of positions from the same texture, all at once. The "point-like" parameters P, dPdx, dPdy, and dPdz are each a pointers to arrays of float value[3][BatchWidth]. That is, each one points to all the x values for the batch, immediately followed by all the y values, followed by the z values.

The various results arrays are also arranged as arrays that behave as if they were declared float result[nchannels][BatchWidth], where all the batch values for channel 0 are adjacent, followed by all the batch values for channel 1, etc.

This function returns true upon success, or false if the file was not found or could not be opened by any available ImageIO plugin.

bool environment (ustring filename, TextureOptBatch &options, Tex::RunMask mask, const float *R, const float *dRdx, const float *dRdy, int nchannels, float *result, float *dresultds = nullptr, float *dresultdt = nullptr, float *dresultdr = nullptr)

bool environment (TextureHandle *texture_handle, Perthread *thread_info, TextureOptBatch &options, Tex::RunMask mask, const float *R, const float *dRdx, const float *dRdy, int nchannels, float *result, float *dresultds = nullptr, float *dresultdt = nullptr, float *dresultdr = nullptr)

Perform filtered directional environment map lookups on a batch of positions from the same texture, all at once. The “point-like” parameters R, dRdx, and dRdy are each a pointers to arrays of float value[3][BatchWidth]. That is, each one points to all the x values for the batch, immediately followed by all the y values, followed by the z values.

Perform filtered directional environment map lookups on a collection of directions all at once, which may be much more efficient than repeatedly calling the single-point version of environment(). The parameters R, dRdx, and dRdy are now VaryingRef’s that may refer to either a single or an array of values, as are many the fields in the options.

The various results arrays are also arranged as arrays that behave as if they were declared float result[nchannels][BatchWidth], where all the batch values for channel 0 are adjacent, followed by all the batch values for channel 1, etc.
This function returns true upon success, or false if the file was not found or could not be opened by any available ImageIO plugin.
9.1 ImageBuf Introduction and Theory of Operation

ImageBuf is a utility class that stores an entire image. It provides a nice API for reading, writing, and manipulating images as a single unit, without needing to worry about any of the details of storage or I/O.

All I/O involving ImageBuf (that is, calls to read or write) are implemented underneath in terms of ImageCache, ImageInput, and ImageOutput, and so support all of the image file formats supported by OIIO.

The ImageBuf class definition requires that you:

```
#include <OpenImageIO/imagebuf.h>
```

```c
enum OIIO::ImageBuf::IBStorage

An ImageBuf can store its pixels in one of several ways (each identified by an IBStorage enumerated value):

Values:

enumerator UNINITIALIZED

An ImageBuf that doesn’t represent any image at all (either because it is newly constructed with the default constructor, or had an error during construction).

enumerator LOCALBUFFER

“Local storage” is allocated to hold the image pixels internal to the ImageBuf. This memory will be freed when the ImageBuf is destroyed.

enumerator APPBUFFER

The ImageBuf “wraps” pixel memory already allocated and owned by the calling application. The caller will continue to own that memory and be responsible for freeing it after the ImageBuf is destroyed.

enumerator IMAGECACHE

The ImageBuf is “backed” by an ImageCache, which will automatically be used to retrieve pixels when requested, but the ImageBuf will not allocate separate storage for it. This brings all the advantages of the ImageCache, but can only be used for read-only ImageBuf’s that reference a stored image file.
9.2 Constructing, destructing, resetting an ImageBuf

There are several ways to construct an ImageBuf. Each constructor has a corresponding reset method that takes the same arguments. Calling reset on an existing ImageBuf is equivalent to constructing a new ImageBuf from scratch (even if the ImageBuf, prior to reset, previously held an image).

9.2.1 Making an empty or uninitialized ImageBuf

OIIO::ImageBuf::ImageBuf()

Default constructor makes an empty/uninitialized ImageBuf. There isn’t much you can do with an uninitialized buffer until you call reset(). The storage type of a default-constructed ImageBuf is IBStorage::UNINITIALIZED.

inline void OIIO::ImageBuf::reset()

Destroy any previous contents of the ImageBuf and re-initialize it to resemble a freshly constructed ImageBuf using the default constructor (holding no image, with storage IBStorage::UNINITIALIZED).

9.2.2 Constructing a readable ImageBuf

explicit OIIO::ImageBuf::ImageBuf (string_view name, int subimage = 0, int miplevel = 0, ImageCache *imagecache = nullptr, const ImageSpec *config = nullptr, Filesystem::IOProxy *ioproxy = nullptr)

Construct a read-only ImageBuf that will be used to read the named file (at the given subimage and MIP-level, defaulting to the first subimage of the file, highest-res MIP level). But don’t read it yet! The image will actually be read lazily, only when other methods need to access the spec and/or pixels, or when an explicit call to init_spec() or read() is made, whichever comes first.

The implementation may end up either reading the entire image internally owned memory (if so, the storage will be LOCALBUFFER), or it may rely on being backed by an ImageCache (in this case, the storage will be IMAGECACHE) depending on the image size and other factors.

Parameters

- **name**: The image to read.
- **subimage/miplevel**: The subimage and MIP level to read (defaults to the first subimage of the file, highest-res MIP level).
- **imagecache**: Optionally, a particular ImageCache to use. If nullptr, the default global/shared image cache will be used. If a custom ImageCache (not the global/shared one), it is important that the IC should not be destroyed while the ImageBuf is still alive.
- **config**: Optionally, a pointer to an ImageSpec whose metadata contains configuration hints that set options related to the opening and reading of the file.
- **ioproxy**: Optional pointer to an IOPProxy to use when reading from the file. The caller retains ownership of the proxy.

void OIIO::ImageBuf::reset (string_view name, int subimage = 0, int miplevel = 0, ImageCache *imagecache = nullptr, const ImageSpec *config = nullptr, Filesystem::IOProxy *ioproxy = nullptr)

Destroy any previous contents of the ImageBuf and re-initialize it as if newly constructed with the same arguments, as a read-only representation of an existing image file.
9.2.3 Constructing a writable ImageBuf

```cpp
explicit OIIIO::ImageBuf::ImageBuf(const ImageSpec &spec, InitializePixels zero = InitializePixels::Yes)

Construct a writable ImageBuf with the given specification (including resolution, data type, metadata, etc.). The ImageBuf will allocate and own its own pixel memory and will free that memory automatically upon destruction, clear(), or reset(). Upon successful initialization, the storage will be reported as LOCALBUFFER.
```

Parameters

- **spec**: An `ImageSpec` describing the image and its metadata. If not enough information is given to know how much memory to allocate (width, height, depth, channels, and data format), the ImageBuf will remain in an UNINITIALIZED state and will have no local pixel storage.
- **zero**: After a successful allocation of the local pixel storage, this parameter controls whether the pixels will be initialized to hold zero (black) values (`InitializePixels::Yes`) or if the pixel memory will remain uninitialized (`InitializePixels::No`) and thus may hold nonsensical values. Choosing `No` may save the time of writing to the pixel memory if you know for sure that you are about to overwrite it completely before you will need to read any pixel values.

```cpp
void OIIIO::ImageBuf::reset(const ImageSpec &spec, InitializePixels zero = InitializePixels::Yes)

Destroy any previous contents of the ImageBuf and re-initialize it as if newly constructed with the same arguments, as a read/write image with locally allocated storage that can hold an image as described by `spec`. The optional `zero` parameter controls whether the pixel values are filled with black/empty, or are left uninitialized after being allocated.

Note that if the `ImageSpec` does not contain enough information to specify how much memory to allocate (width, height, channels, and data format), the ImageBuf will remain uninitialized (regardless of how `zero` is set).
```

```cpp
bool OIIIO::ImageBuf::make_writable(bool keep_cache_type = false)

Make the ImageBuf be writable. That means that if it was previously backed by an ImageCache (storage was IMAGECACHE), it will force a full read so that the whole image is in local memory. This will invalidate any current iterators on the image. It has no effect if the image storage is not IMAGECACHE.

Return True if it works (including if no read was necessary), false if something went horribly wrong.

Parameters

- **keep_cache_type**: If true, preserve any ImageCache-forced data types (you might want to do this if it is critical that the apparent data type doesn’t change, for example if you are calling `make_writable()` from within a type-specialized function).
```

9.2.4 Constructing an ImageBuf that “wraps” an application buffer

```cpp
OIIO::ImageBuf::ImageBuf(const ImageSpec &spec, void *buffer, stride_t xstride = AutoStride, stride_t ystride = AutoStride, stride_t zstride = AutoStride)

Construct a writable ImageBuf that “wraps” existing pixel memory owned by the calling application. The ImageBuf does not own the pixel storage and will not free/delete that memory, even when the ImageBuf is destroyed. Upon successful initialization, the storage will be reported as APPBUFFER.
```

Parameters
**OpenImageIO, Release 2.4.1**

- **spec**: An *ImageSpec* describing the image and its metadata. If not enough information is given to know the “shape” of the image (width, height, depth, channels, and data format), the ImageBuf will remain in an UNINITIALIZED state.

- **buffer**: A pointer to the caller-owned memory containing the storage for the pixels. It must be already allocated with enough space to hold a full image as described by spec.

- **xstride/ystride/zstride**: The distance in bytes between successive pixels, scanlines, and image planes in the buffer (or *AutoStride* to indicate “contiguous” data in any of those dimensions).

```cpp
void OIIIO::ImageBuf::reset (const ImageSpec &spec, void *buffer, stride_t xstride = AutoStride, stride_t ystride = AutoStride, stride_t zstride = AutoStride)
```

Destroy any previous contents of the ImageBuf and re-initialize it as if newly constructed with the same arguments, to “wrap” existing pixel memory owned by the calling application.

### 9.2.5 Reading and Writing disk images

```cpp
bool OIIIO::ImageBuf::read (int subimage = 0, int mipmaplevel = 0, bool force = false, TypeDesc convert = TypeDesc::UNKNOWN, ProgressCallback progress_callback = nullptr, void *progress_callback_data = nullptr)
```

Read the particular subimage and MIP level of the image. Generally, this will skip the expensive read if the file has already been read into the ImageBuf (at the specified subimage and MIP level). It will clear and re-allocate memory if the previously allocated space was not appropriate for the size or data type of the image being read.

In general, `read()` will try not to do any I/O at the time of the `read()` call, but rather to have the ImageBuf “backed” by an *ImageCache*, which will do the file I/O on demand, as pixel values are needed, and in that case the ImageBuf doesn’t actually allocate memory for the pixels (the data lives in the ImageCache). However, there are several conditions for which the *ImageCache* will be bypassed, the ImageBuf will allocate “local” memory, and the disk file will be read directly into allocated buffer at the time of the `read()` call: (a) if the force parameter is true; (b) if the convert parameter requests a data format conversion to a type that is not the native file type and also is not one of the internal types supported by the *ImageCache* (specifically, float and UINT8); (c) if the ImageBuf already has local pixel memory allocated, or “wraps” an application buffer.

Note that `read()` is not strictly necessary. If you are happy with the filename, subimage and MIP level specified by the ImageBuf constructor (or the last call to `reset()`), and you want the storage to be backed by the *ImageCache* (including storing the pixels in whatever data format that implies), then the file contents will be automatically read the first time you make any other ImageBuf API call that requires the spec or pixel values. The only reason to call `read()` yourself is if you are changing the filename, subimage, or MIP level, or if you want to use `force = true` or a specific convert value to force data format conversion.

**Return** true upon success, or false if the read failed (in which case, you should be able to retrieve an error message via `geterror()`).

**Parameters**

- **subimage/mipmaplevel**: The subimage and MIP level to read.
- **force**: If true, will force an immediate full read into ImageBuf-owned local pixel memory (yielding a LOCALPIXELS storage buffer). Otherwise, it is up to the implementation whether to immediately read or have the image backed by an *ImageCache* (storage IMAGECACHE.)
- **convert**: If set to a specific type (not UNKNOWN), the ImageBuf memory will be allocated for that type specifically and converted upon read.
- **progress_callback/progress_callback_data**: If progress_callback is non-NULL, the underlyng read, if expensive, may make several calls to
progress_callback(portion_done) which allows you to implement some sort of progress meter. Note that if the ImageBuf is backed by an ImageCache, the progress callback will never be called, since no actual file I/O will occur at this time (ImageCache will load tiles or scanlines on demand, as individual pixel values are needed).

bool OIIIO::ImageBuf::read(int subimage, int mipmap, int chbegin, int chend, bool force, TypeDesc convert, ProgressCallback progress_callback = nullptr, void *progress_callback_data = nullptr)

Read the file, if possible only allocating and reading a subset of channels, [chbegin..chend-1]. This can be a performance and memory improvement for some image file formats, if you know that any use of the ImageBuf will only access a subset of channels from a many-channel file.

Additional parameters:

Parameters

• chbegin/chend: The subset (a range with “exclusive end”) of channels to read, if the implementation is able to read only a subset of channels and have a performance advantage by doing so. If chbegin is 0 and chend is either negative or greater than the number of channels in the file, all channels will be read. Please note that it is “advisory” and not guaranteed to be honored by the underlying implementation.

bool OIIIO::ImageBuf::init_spec(string_view filename, int subimage, int mipmap)

Read the ImageSpec for the given file, subimage, and MIP level into the ImageBuf, but will not read the pixels or allocate any local storage (until a subsequent call to read()). This is helpful if you have an ImageBuf and you need to know information about the image, but don’t want to do a full read yet, and maybe won’t need to do the full read, depending on what’s found in the spec.

Note that init_spec() is not strictly necessary. If you are happy with the filename, subimage and MIP level specified by the ImageBuf constructor (or the last call to reset()), then the spec will be automatically read the first time you make any other ImageBuf API call that requires it. The only reason to call read() yourself is if you are changing the filename, subimage, or MIP level, or if you want to use force=true or a specific convert value to force data format conversion.

Return true upon success, or false if the read failed (in which case, you should be able to retrieve an error message via geterror()).

Parameters

• filename: The filename to read from (should be the same as the filename used when the ImageBuf was constructed or reset.)

• subimage/mipmap: The subimage and MIP level to read.

bool OIIIO::ImageBuf::write(string_view filename, TypeDesc dtype = TypeUnknown, string_view fileformat = string_view(), ProgressCallback progress_callback = nullptr, void *progress_callback_data = nullptr) const

Write the image to the named file, converted to the specified pixel data type dtype (TypeUnknown signifies to use the data type of the buffer), and file format (an empty fileformat means to infer the type from the filename extension).

By default, it will always try to write a scanline-oriented file, unless the set_write_tiles() method has been used to override this.

Return true upon success, or false if the write failed (in which case, you should be able to retrieve an error message via geterror()).
Parameters

- **filename**: The filename to write to.
- **dtype**: Optional override of the pixel data format to use in the file being written. The default (UNKNOWN) means to try writing the same data format that as pixels are stored within the ImageBuf memory (or whatever type was specified by a prior call to `set_write_format()`). In either case, if the file format does not support that data type, another will be automatically chosen that is supported by the file type and loses as little precision as possible.
- **fileformat**: Optional override of the file format to write. The default (empty string) means to infer the file format from the extension of the `filename` (for example, “foo.tif” will write a TIFF file).
- **progress_callback/progress_callback_data**: If `progress_callback` is non-NULL, the underlying write, if expensive, may make several calls to `progress_callback(progress_callback_data, portion_done)` which allows you to implement some sort of progress meter.

```cpp
bool OIIO::ImageBuf::write (ImageOutput *out, ProgressCallback progress_callback = nullptr, void *progress_callback_data = nullptr) const
```

Write the pixels of the ImageBuf to an open `ImageOutput`. The `ImageOutput` must have already been opened with a spec that indicates a resolution identical to that of this ImageBuf (but it may have specified a different pixel data type, in which case data conversions will happen automatically). This method does NOT close the file when it’s done (and so may be called in a loop to write a multi-image file).

Note that since this uses an already-opened `ImageOutput`, which is too late to change how it was opened, it does not honor any prior calls to `set_write_format` or `set_write_tiles`.

The main application of this method is to allow an ImageBuf (which by design may hold only a single image) to be used for the output of one image of a multi-subimage and/or MIP-mapped image file.

Return true if all went ok, false if there were errors writing.

Parameters

- **out**: A pointer to an already-opened `ImageOutput` to which the pixels of the ImageBuf will be written.
- **progress_callback/progress_callback_data**: If `progress_callback` is non-NULL, the underlying write, if expensive, may make several calls to `progress_callback(progress_callback_data, portion_done)` which allows you to implement some sort of progress meter.

```cpp
void OIIO::ImageBuf::set_write_format (TypeDesc format)
```

Set the pixel data format that will be used for subsequent `write()` calls that do not themselves request a specific data type request.

Note that this does not affect the variety of `write()` that takes an open `ImageOutput*` as a parameter.

Parameters

- **format**: The data type to be used for all channels.

```cpp
void OIIO::ImageBuf::set_write_format (cspan<TypeDesc> format)
```

Set the per-channel pixel data format that will be used for subsequent `write()` calls that do not themselves request a specific data type request.
Parameters

- **format**: The type of each channel (in order). Any channel’s format specified as `TypeUnknown` will default to be whatever type is described in the `ImageSpec` of the buffer.

```cpp
void OIIO::ImageBuf::set_write_tiles (int width = 0, int height = 0, int depth = 0)
```

Override the tile sizing for subsequent calls to the `write()` method (the variety that does not take an open `ImageOutput*`). Setting all three dimensions to 0 indicates that the output should be a scanline-oriented file.

This lets you write a tiled file from an ImageBuf that may have been read originally from a scanline file, or change the dimensions of a tiled file, or to force the file written to be scanline even if it was originally read from a tiled file.

In all cases, if the file format ultimately written does not support tiling, or the tile dimensions requested, a suitable supported tiling choice will be made automatically.

```cpp
void OIIO::ImageBuf::set_write_ioproxy (Filesystem::IOProxy *ioproxy)
```

Supply an IOProxy to use for a subsequent call to `write()`.

If a proxy is set but it later turns out that the file format selected does not support write proxies, then `write()` will fail with an error.

### 9.3 Getting and setting information about an ImageBuf

```cpp
bool OIIO::ImageBuf::initialized () const
```

Returns `true` if the ImageBuf is initialized, `false` if not yet initialized.

```cpp
IBStorage OIIO::ImageBuf::storage () const
```

Which type of storage is being used for the pixels? Returns an enumerated type describing the type of storage currently employed by the ImageBuf: `UNINITIALIZED` (no storage), `LOCALBUFFER` (the ImageBuf has allocated and owns the pixel memory), `APPBUFFER` (the ImageBuf “wraps” memory owned by the calling application), or `IMAGECACHE` (the image is backed by an `ImageCache`).

```cpp
const ImageSpec &OIIO::ImageBuf::spec () const
```

Return a read-only (const) reference to the image spec that describes the buffer.

```cpp
const ImageSpec &OIIO::ImageBuf::nativespec () const
```

Return a read-only (const) reference to the “native” image spec (that describes the file, which may be slightly different than the spec of the ImageBuf, particularly if the IB is backed by an `ImageCache` that is imposing some particular data format or tile size).

This may differ from `spec()` for example, if a data format conversion was requested, if the buffer is backed by an `ImageCache` which stores the pixels internally in a different data format than that of the file, or if the file had differing per-channel data formats (ImageBuf must contain a single data format for all channels).

```cpp
ImageSpec &OIIO::ImageBuf::specmod ()
```

Return a writable reference to the `ImageSpec` that describes the buffer. It’s ok to modify most of the metadata, but if you modify the spec’s `format`, `width`, `height`, or `depth` fields, you get the pain you deserve, as the ImageBuf will no longer have correct knowledge of its pixel memory layout. USE WITH EXTREME CAUTION.

```cpp
string_view OIIO::ImageBuf::name (void) const
```

Returns the name of the buffer (name of the file, for an ImageBuf read from disk).

```cpp
string_view OIIO::ImageBuf::file_format_name (void) const
```

Return the name of the image file format of the file this ImageBuf refers to (for example "openexr"). Returns an empty string for an ImageBuf that was not constructed as a direct reference to a file.
int OIIIO::ImageBuf::subimage() const
Return the index of the subimage within the file that the ImageBuf refers to. This will always be 0 for an ImageBuf that was not constructed as a direct reference to a file, or if the file contained only one image.

int OIIIO::ImageBuf::nsubimages() const
Return the number of subimages in the file this ImageBuf refers to. This will always be 1 for an ImageBuf that was not constructed as a direct reference to a file.

int OIIIO::ImageBuf::miplevel() const
Return the index of the miplevel with a file’s subimage that the ImageBuf is currently holding. This will always be 0 for an ImageBuf that was not constructed as a direct reference to a file, or if the subimage within that file was not MIP-mapped.

int OIIIO::ImageBuf::nmiplevels() const
Return the number of MIP levels of the current subimage within the file this ImageBuf refers to. This will always be 1 for an ImageBuf that was not constructed as a direct reference to a file, or if this subimage within the file was not MIP-mapped.

int OIIIO::ImageBuf::nchannels() const
Return the number of color channels in the image. This is equivalent to spec().nchannels.

int xbegin() const
int xend() const
int ybegin() const
int yend() const
int zbegin() const
int zend() const
Returns the [begin,end) range of the pixel data window of the buffer. These are equivalent to spec().x, spec().x+spec().width, spec().y, spec().y+spec().height, spec().z, and spec().z+spec().depth, respectively.

int OIIIO::ImageBuf::orientation() const
Return the current "Orientation" metadata for the image, per the table in sec-metadata-orientation_

void OIIIO::ImageBuf::set_orientation(int orient)
Set the "Orientation" metadata for the image.

int oriented_width() const
int oriented_height() const
int oriented_x() const
int oriented_y() const
int oriented_full_width() const
int oriented_full_height() const
int oriented_full_x() const
int oriented_full_y() const
The oriented width, height, x, and y describe the pixel data window after taking the display orientation into consideration. The full versions the “full” (a.k.a. display) window after taking the display orientation into consideration.

ROI OIIIO::ImageBuf::roi() const
Return pixel data window for this ImageBuf as a ROI.

ROI OIIIO::ImageBuf::roi_full() const
Return full/display window for this ImageBuf as a ROI.
void OIIO::ImageBuf::set_origin(int x, int y, int z = 0)

Alters the metadata of the spec in the ImageBuf to reset the “origin” of the pixel data window to be the specified coordinates. This does not affect the size of the pixel data window, only its position.

void OIIO::ImageBuf::set_full(int xbegin, int xend, int ybegin, int yend, int zbegin, int zend)

Set the “full” (a.k.a. display) window to

\[(xbegin, xend) \times (ybegin, yend) \times (zbegin, zend)\]

This does not affect the size of the pixel data window.

void OIIO::ImageBuf::set_roi_full(const ROI &newroi)

Set full/display window for this ImageBuf to a ROI. Does NOT change the channels of the spec, regardless of newroi.

bool OIIO::ImageBuf::contains_roi(ROI roi) const

Is the specified roi completely contained in the data window of this ImageBuf?

TypeDesc OIIO::ImageBuf::pixeltype() const

The data type of the pixels stored in the buffer (equivalent to spec().format).

int OIIO::ImageBuf::threads() const

Retrieve the current thread-spawning policy of this ImageBuf.

void OIIO::ImageBuf::threads(int n) const

Set the threading policy for this ImageBuf, controlling the maximum amount of parallelizing thread “fan-out” that might occur during expensive operations. The default of 0 means that the global attribute("threads") value should be used (which itself defaults to using as many threads as cores).

The main reason to change this value is to set it to 1 to indicate that the calling thread should do all the work rather than spawning new threads. That is probably the desired behavior in situations where the calling application has already spawned multiple worker threads.

### 9.4 Copying ImageBuf’s and blocks of pixels

const ImageBuf &OIIO::ImageBuf::operator=(const ImageBuf &src)

Copy assignment.

const ImageBuf &OIIO::ImageBuf::operator=(ImageBuf &&src)

Move assignment.

bool OIIO::ImageBuf::copy(const ImageBuf &src, TypeDesc format = TypeUnknown)

Try to copy the pixels and metadata from src to *this (optionally with an explicit data format conversion).

If the previous state of *this was uninitialized, owning its own local pixel memory, or referring to a read-only image backed by ImageCache, then local pixel memory will be allocated to hold the new pixels and the call always succeeds unless the memory cannot be allocated. In this case, the format parameter may request a pixel data type that is different from that of the source buffer.

If *this previously referred to an app-owned memory buffer, the memory cannot be re-allocated, so the call will only succeed if the app-owned buffer is already the correct resolution and number of channels. The data type of the pixels will be converted automatically to the data type of the app buffer.

Return true upon success or false upon error/failure.

Parameters
• src: Another ImageBuf from which to copy the pixels and metadata.

• format: Optionally request the pixel data type to be used. The default of TypeUnknown means to use whatever data type is used by the src. If *this is already initialized and has APPBUFFER storage ("wrapping" an application buffer), this parameter is ignored.

ImageBuf OIIIO::ImageBuf::copy (TypeDesc format) const
Return a full copy of this ImageBuf (optionally with an explicit data format conversion).

void OIIIO::ImageBuf::copy_metadata (const ImageBuf &src)
Copy all the metadata from src to *this (except for pixel data resolution, channel types and names, and data format).

bool OIIIO::ImageBuf::copy_pixels (const ImageBuf &src)
Copy the pixel data from src to *this, automatically converting to the existing data format of *this. It only copies pixels in the overlap regions (and channels) of the two images; pixel data in *this that do exist in src will be set to 0, and pixel data in src that do not exist in *this will not be copied.

inline void OIIIO::ImageBuf::swap (ImageBuf &other)
Swap the entire contents with another ImageBuf.

9.5 Getting and setting pixel values

Getting and setting individual pixels – slow

float OIIIO::ImageBuf::getchannel (int x, int y, int z, int c, WrapMode wrap = WrapBlack) const
Retrieve a single channel of one pixel.

Return The data value, converted to a float.

Parameters
• x/y/z: The pixel coordinates.
• c: The channel index to retrieve.
• wrap: WrapMode that determines the behavior if the pixel coordinates are outside the data window: WrapBlack, WrapClamp, WrapPeriodic, WrapMirror.

void OIIIO::ImageBuf::getpixel (int x, int y, int z, float *pixel, int maxchannels = 1000, WrapMode wrap = WrapBlack) const
Retrieve the pixel value by x, y, z pixel indices, placing its contents in pixel[0..n-1] where n is the smaller of maxchannels the actual number of channels stored in the buffer.

Parameters
• x/y/z: The pixel coordinates.
• pixel: The results are stored in pixel[0..nchannels-1]. It is up to the caller to ensure that pixel points to enough memory to hold the required number of channels.
• maxchannels: Optional clamp to the number of channels retrieved.
• wrap: WrapMode that determines the behavior if the pixel coordinates are outside the data window: WrapBlack, WrapClamp, WrapPeriodic, WrapMirror.
void OIIIO::ImageBuf::interppixel(float x, float y, float *pixel, WrapMode wrap = WrapBlack) const

Sample the image plane at pixel coordinates (x,y), using linear interpolation between pixels, placing the result in pixel[].

Parameters

- **x/y**: The pixel coordinates. Note that pixel data values themselves are at the pixel centers, so pixel (i,j) is at image plane coordinate (i+0.5, j+0.5).
- **pixel**: The results are stored in pixel[0..nchannels-1]. It is up to the caller to ensure that pixel points to enough memory to hold the number of channels in the image.
- **wrap**: WrapMode that determines the behavior if the pixel coordinates are outside the data window: WrapBlack, WrapClamp, WrapPeriodic, WrapMirror.

void OIIIO::ImageBuf::interppixel_bicubic(float x, float y, float *pixel, WrapMode wrap = WrapBlack) const

Bicubic interpolation at pixel coordinates (x,y).

void OIIIO::ImageBuf::interppixel_NDC(float s, float t, float *pixel, WrapMode wrap = WrapBlack) const

Linearly interpolate at NDC coordinates (s,t), where (0,0) is the upper left corner of the display window, (1,1) the lower right corner of the display window.

Note **interppixel()** uses pixel coordinates (ranging 0..resolution) whereas **interppixel_NDC()** uses NDC coordinates (ranging 0..1).

void OIIIO::ImageBuf::interppixel_bicubic_NDC(float s, float t, float *pixel, WrapMode wrap = WrapBlack) const

Bicubic interpolation at NDC space coordinates (s,t), where (0,0) is the upper left corner of the display (a.k.a. “full”) window, (1,1) the lower right corner of the display window.

inline void OIIIO::ImageBuf::setpixel(int x, int y, int z, cspan<float> pixel)

Set the pixel with coordinates (x,y,z) to have the values in span pixel[]. The number of channels copied is the minimum of the span length and the actual number of channels in the image.

inline void OIIIO::ImageBuf::setpixel(int i, cspan<float> pixel)

Set the i-th pixel value of the image (out of width*height*depth), from floating-point values in span pixel[]. The number of channels copied is the minimum of the span length and the actual number of channels in the image.

Getting and setting regions of pixels – fast

bool OIIIO::ImageBuf::get_pixels(ROI roi, TypeDesc format, void *result, stride_t xstride = AutoStride, stride_t ystride = AutoStride, stride_t zstride = AutoStride) const

Retrieve the rectangle of pixels spanning the ROI (including channels) at the current subimage and MIP-map level, storing the pixel values beginning at the address specified by result and with the given strides (by default, AutoStride means the usual contiguous packing of pixels) and converting into the data type described by format. It is up to the caller to ensure that result points to an area of memory big enough to accommodate the requested rectangle. Return true if the operation could be completed, otherwise return false.
bool OIIIO::ImageBuf::set_pixels(ROI roi, TypeDesc format, const void *data, stride_t xstride = AutoStride, stride_t ystride = AutoStride, stride_t zstride = AutoStride)

Copy the data into the given ROI of the ImageBuf. The data points to values specified by format, with layout detailed by the stride values (in bytes, with AutoStride indicating “contiguous” layout). It is up to the caller to ensure that data points to an area of memory big enough to account for the ROI. If roi is set to ROI::all(), the data buffer is assumed to have the same resolution as the ImageBuf itself. Return true if the operation could be completed, otherwise return false.

9.6 Deep data in an ImageBuf

bool OIIIO::ImageBuf::deep() const

Does this ImageBuf store deep data? Returns true if the ImageBuf holds a “deep” image, false if the ImageBuf holds an ordinary pixel-based image.

int OIIIO::ImageBuf::deep_samples(int x, int y, int z = 0) const

Retrieve the number of deep data samples corresponding to pixel (x,y,z). Return 0 if not a deep image, or if the pixel is outside of the data window, or if the designated pixel has no deep samples.

void OIIIO::ImageBuf::set_deep_samples(int x, int y, int z, int nsamples)

Set the number of deep samples for pixel (x,y,z). If data has already been allocated, this is equivalent to inserting or erasing samples.

void OIIIO::ImageBuf::deep_insert_samples(int x, int y, int z, int samplepos, int nsamples)

Insert nsamples new samples, starting at position samplepos of pixel (x,y,z).

void OIIIO::ImageBuf::deep_erase_samples(int x, int y, int z, int samplepos, int nsamples)

Remove nsamples samples, starting at position samplepos of pixel (x,y,z).

float OIIIO::ImageBuf::deep_value(int x, int y, int z, int c, int s) const

Return the value (as a float) of sample s of channel c of pixel (x,y,z). Return 0 if not a deep image or if the pixel coordinates or channel number are out of range or if that pixel has no deep samples.

uint32_t OIIIO::ImageBuf::deep_value_uint(int x, int y, int z, int c, int s) const

Return the value (as a uint32_t) of sample s of channel c of pixel (x,y,z). Return 0 if not a deep image or if the pixel coordinates or channel number are out of range or if that pixel has no deep samples.

void OIIIO::ImageBuf::set_deep_value(int x, int y, int z, int c, int s, float value)

Set the value of sample s of channel c of pixel (x,y,z) to a float value (it is expected that channel c is a floating point type).

void OIIIO::ImageBuf::set_deep_value(int x, int y, int z, int c, int s, uint32_t value)

Set the value of sample s of channel c of pixel (x,y,z) to a uint32_t value (it is expected that channel c is an integer type).

const void *OIIIO::ImageBuf::deep_pixel_ptr(int x, int y, int z, int c, int s = 0) const

Return a pointer to the raw data of pixel (x,y,z), channel c, sample s. Return nullptr if the pixel coordinates or channel number are out of range, if the pixel/channel has no deep samples, or if the image is not deep. Use with caution these pointers may be invalidated by calls that adjust the number of samples in any pixel.

DeepData &OIIIO::ImageBuf::deepdata()

const DeepData &OIIIO::ImageBuf::deepdata() const

Returns a reference to the underlying DeepData for a deep image.
9.7 Error Handling

```cpp
template<typename ...Args>
inline void OIIO::ImageBuf:::errorf (const char *fmt, const Args&... args) const
    Error reporting for ImageBuf: call this with printf-like arguments to report an error. It is not necessary to have the error message contain a trailing newline.

bool OIIO::ImageBuf:::has_error (void) const
    Returns true if the ImageBuf has had an error and has an error message ready to retrieve via geterror().

std::string OIIO::ImageBuf:::geterror (bool clear = true) const
    Return the text of all pending error messages issued against this ImageBuf, and clear the pending error message unless clear is false. If no error message is pending, it will return an empty string.
```

9.8 Miscellaneous

```cpp
void *localpixels ()
const void *localpixels () const
    Return a raw pointer to the “local” pixel memory, if they are fully in RAM and not backed by an ImageCache, or nullptr otherwise. You can also test it like a bool to find out if pixels are local.

void *pixeladdr (int x, int y, int z = 0, int ch = 0)
const void *pixeladdr (int x, int y, int z = 0, int ch = 0) const
    Return the address where pixel \((x,y,z)\), channel \(ch\), is stored in the image buffer. Use with extreme caution! Will return nullptr if the pixel values aren’t local in RAM.

int OIIO::ImageBuf:::pixelindex (int x, int y, int z, bool check_range = false) const
    Return the index of pixel \((x,y,z)\). If check_range is true, return -1 for an invalid coordinate that is not within the data window.

static WrapMode OIIO::ImageBuf:::WrapMode_from_string (string_view name)
    Return the WrapMode corresponding to the name ("default", "black", "clamp", "periodic", "mirror"). For an unknown name, this will return WrapDefault.
```

9.9 Iterators – the fast way of accessing individual pixels

Sometimes you need to visit every pixel in an ImageBuf (or at least, every pixel in a large region). Using the getpixel() and setpixel() for this purpose is simple but very slow. But ImageBuf provides templated Iterator and ConstIterator types that are very inexpensive and hide all the details of local versus cached storage.

**Note:** ImageBuf::ConstIterator is identical to the Iterator, except that ConstIterator may be used on a const ImageBuf and may not be used to alter the contents of the ImageBuf. For simplicity, the remainder of this section will only discuss the Iterator.

An Iterator is associated with a particular ImageBuf. The Iterator has a current pixel coordinate that it is visiting, and an iteration range that describes a rectangular region of pixels that it will visit as it advances. It always starts at the upper left corner of the iteration region. We say that the iterator is done after it has visited every pixel in its iteration range. We say that a pixel coordinate exists if it is within the pixel data window of the ImageBuf. We say that a pixel coordinate is valid if it is within the iteration range of the iterator.
The `Iterator<BUFT, USERT>` is templated based on two types: `BUFT` the type of the data stored in the `ImageBuf`, and `USERT` type of the data that you want to manipulate with your code. `USERT` defaults to `float`, since usually you will want to do all your pixel math with `float`. We will thus use `Iterator<T>` synonymously with `Iterator<T, float>`.

For the remainder of this section, we will assume that you have a `float`-based `ImageBuf`, for example, if it were set up like this:

```cpp
ImageBuf buf("myfile.exr");
buf.read(0, 0, true, TypeDesc::FLOAT);
```

```cpp
template<>
Iterator<BUFT> (ImageBuf &buf, WrapMode wrap = WrapDefault)
    Initialize an iterator that will visit every pixel in the data window of `buf`, and start it out pointing to the upper left corner of the data window. The `wrap` describes what values will be retrieved if the iterator is positioned outside the data window of the buffer.

template<>
Iterator<BUFT> (ImageBuf &buf, const ROI &roi, WrapMode wrap = WrapDefault)
    Initialize an iterator that will visit every pixel of `buf` within the region described by `roi`, and start it out pointing to pixel `(roi.xbegin, roi.ybegin, roi.zbegin)`. The `wrap` describes what values will be retrieved if the iterator is positioned outside the data window of the buffer.

template<>
Iterator<BUFT> (ImageBuf &buf, int x, int y, int z, WrapMode wrap = WrapDefault)
    Initialize an iterator that will visit every pixel in the data window of `buf`, and start it out pointing to pixel `(x, y, z)`. The `wrap` describes what values will be retrieved if the iterator is positioned outside the data window of the buffer.

`Iterator::operator++()`
    The `++` operator advances the iterator to the next pixel in its iteration range. (Both prefix and postfix increment operator are supported.)

`bool Iterator::done()` const
    Returns `true` if the iterator has completed its visit of all pixels in its iteration range.

`ROI Iterator::range()` const
    Returns the iteration range of the iterator, expressed as an ROI.

`int Iterator::x()` const
`int Iterator::y()` const
`int Iterator::z()` const
    Returns the x, y, and z pixel coordinates, respectively, of the pixel that the iterator is currently visiting.

`bool Iterator::valid()` const
    Returns `true` if the iterator’s current pixel coordinates are within its iteration range.

`bool Iterator::valid(int x, int y, int z = 0)` const
    Returns `true` if pixel coordinate `(x, y, z)` are within the iterator’s iteration range (regardless of where the iterator itself is currently pointing).

`bool Iterator::exists()` const
    Returns `true` if the iterator’s current pixel coordinates are within the data window of the `ImageBuf`.

`bool Iterator::exists(int x, int y, int z = 0)` const
    Returns `true` if pixel coordinate `(x, y, z)` are within the pixel data window of the `ImageBuf` (regardless of where the iterator itself is currently pointing).
USERT &Iterator::operator[](int i)
    The value of channel i of the current pixel. (The wrap mode, set up when the iterator was constructed, determines what value is returned if the iterator points outside the pixel data window of its buffer.)

int Iterator::deep_samples() const
    For deep images only, retrieves the number of deep samples for the current pixel.

void Iterator::set_deep_samples()
    For deep images only (and non-const ImageBuf), set the number of deep samples for the current pixel. This only is useful if the ImageBuf has not yet had the deep_alloc() method called.

USERT Iterator::deep_value(int c, int s) const
    For deep images only, returns the value of channel c, sample number s, at the current pixel.

void Iterator::set_deep_value(int c, int s, float value)
void Iterator::set_deep_value(int c, int s, uint32_t value)
    For deep images only (and non-cconst ImageBuf, sets the value of channel c, sample number s, at the current pixel. This only is useful if the ImageBuf has already had the deep_alloc() method called.

9.9.1 Example: Visiting all pixels to compute an average color

```cpp
void print_channel_averages (const std::string &filename)
{
    // Set up the ImageBuf and read the file
    ImageBuf buf (filename);
    bool ok = buf.read (0, 0, true, TypeDesc::FLOAT); // Force a float buffer
    if (! ok)
        return;

    // Initialize a vector to contain the running total
    int nc = buf.nchannels();
    std::vector<float> total (n, 0.0);

    // Iterate over all pixels of the image, summing channels separately
    for (ImageBuf::ConstIterator<float> it (buf); ! it.done(); ++it)
        for (int c = 0; c < nc; ++c)
            total[c] += it[c];

    // Print the averages
    imagesize_t npixels = buf.spec().image_pixels();
    for (int c = 0; c < nc; ++c)
        std::cout << "Channel " << c << " avg = " (total[c] / npixels) << "\n";
}
```

9.9.2 Example: Set all pixels in a region to black

```cpp
bool make_black (ImageBuf &buf, ROI region)
{
    if (buf.spec().format != TypeDesc::FLOAT)
        return false; // Assume it's a float buffer

    // Clamp the region's channel range to the channels in the image
    roi.chend = std::min (roi.chend, buf.nchannels);

    // (continues on next page)
}
```
// Iterate over all pixels in the region...
for (ImageBuf::Iterator<float> it (buf, region); !it.done(); ++it) {
    if (!it.exists()) // Make sure the iterator is pointing
        continue; // to a pixel in the data window
    for (int c = roi.chbegin; c < roi.chend; ++c)
        it[c] = 0.0f; // clear the value
}
return true;

9.10 Dealing with buffer data types

The previous section on iterators presented examples and discussion based on the assumption that the ImageBuf was
guaranteed to store float data and that you wanted all math to also be done as float computations. Here we will
explain how to deal with buffers and files that contain different data types.

9.10.1 Strategy 1: Only have float data in your ImageBuf

When creating your own buffers, make sure they are float:

ImageSpec spec (640, 480, 3, TypeDesc::FLOAT); // <-- float buffer
ImageBuf buf ("mybuf", spec);

When using ImageCache-backed buffers, force the ImageCache to convert everything to float:

// Just do this once, to set up the cache:
ImageCache *cache = ImageCache::create (true /* shared cache */);
cache->attribute ("forcefloat", 1);
...
ImageBuf buf ("myfile.exr"); // Backed by the shared cache

Or force the read to convert to float in the buffer if it’s not a native type that would automatically stored as a float
internally to the ImageCache:\footnote{ImageCache only supports a limited set of types internally, currently float, half, uint8, uint16, and all other data types are converted to these automatically as they are read into the cache.}

ImageBuf buf ("myfile.exr"); // Backed by the shared cache
buf.read (0, 0, false /* don't force read to local mem */,
        TypeDesc::FLOAT /* but do force conversion to float*/);

Or force a read into local memory unconditionally (rather than relying on the ImageCache), and convert to float:

ImageBuf buf ("myfile.exr");
buf.read (0, 0, true /*force read*/,
        TypeDesc::FLOAT /* force conversion */);
9.10.2 Strategy 2: Template your iterating functions based on buffer type

Consider the following alternate version of the `make_black` function from Section *Example: Set all pixels in a region to black*:

```
template<typename BUFT>
static bool make_black_impl (ImageBuf &buf, ROI region)
{
    // Clamp the region's channel range to the channels in the image
    roi.chend = std::min (roi.chend, buf.nchannels);

    // Iterate over all pixels in the region...
    for (ImageBuf::Iterator<BUFT> it (buf, region); ! it.done(); ++it) {
        if (! it.exists()) // Make sure the iterator is pointing
            continue; // to a pixel in the data window
        for (int c = roi.chbegin; c < roi.chend; ++c)
            it[c] = 0.0f; // clear the value
    }
    return true;
}
```

```
bool make_black (ImageBuf &buf, ROI region)
{
    if (buf.spec().format == TypeDesc::FLOAT)
        return make_black_impl<float> (buf, region);
    else if (buf.spec().format == TypeDesc::HALF)
        return make_black_impl<half> (buf, region);
    else if (buf.spec().format == TypeDesc::UINT8)
        return make_black_impl<unsigned char> (buf, region);
    else if (buf.spec().format == TypeDesc::UINT16)
        return make_black_impl<unsigned short> (buf, region);
    else {
        buf.error ("Unsupported pixel data format %s", buf.spec().format);
        return false;
    }
}
```

In this example, we make an implementation that is templated on the buffer type, and then a wrapper that calls the appropriate template specialization for each of 4 common types (and logs an error in the buffer for any other types it encounters).

In fact, `imagebufalgo_util.h` provides a macro to do this (and several variants, which will be discussed in more detail in the next chapter). You could rewrite the example even more simply:

```
#include <OpenImageIO/imagebufalgo_util.h>

template<typename BUFT>
static bool make_black_impl (ImageBuf &buf, ROI region)
{
    ... same as before ...
}
```

```
bool make_black (ImageBuf &buf, ROI region)
{
    bool ok;
    OIIOT_DISPATCH_COMMON_TYPES (ok, "make_black", make_black_impl,
                                  buf.spec().format, buf, region);
    return ok;
}
```

9.10. Dealing with buffer data types
This other type-dispatching helper macros will be discussed in more detail in Chapter *ImageBufAlgo: Image Processing*.
ImageBufAlgo is a set of image processing functions that operate on ImageBuf’s. The functions are declared in the header file OpenImageIO/imagebufalgo.h and are declared in the namespace ImageBufAlgo.

10.1 ImageBufAlgo common principles

This section explains the general rules common to all ImageBufAlgo functions. Only exceptions to these rules will be explained in the subsequent listings of all the individual ImageBufAlgo functions.

10.1.1 Return values and error messages

Most ImageBufAlgo functions that produce image data come in two forms:

1. Return an ImageBuf.

   The return value is a new ImageBuf containing the result image. In this case, an entirely new image will be created to hold the result. In case of error, the result image returned can have any error conditions checked with has_error() and geterror().

   C++

   ```
   // Method 1: Return an image result
   ImageBuf dst = ImageBufAlgo::over (fg, bg);
   if (dst.has_error())
       std::cout << "error: " << dst.geterror() << "\n";
   ```

   Python

   ```
   # Method 1: Return an image result
   fg = ImageBuf("fg.exr")
   bg = ImageBuf("bg.exr")
   dst = ImageBufAlgo.over (fg, bg)
   if dst.has_error() :
       print("error:", dst.geterror())
   ```

2. Pass a destination ImageBuf reference as the first parameter.

   The function is passed a destination ImageBuf where the results will be stored, and the return value is a bool that is true if the function succeeds or false if the function fails. Upon failure, the destination ImageBuf (the one that is being altered) will have an error message set.

   C++

   ```
   ```
// Method 2: Write into an existing image
ImageBuf fg ("fg.exr"), bg ("bg.exr");
ImageBuf dst; // will be the output image
bool ok = ImageBufAlgo::over (dst, fg, bg);
if (! ok)
    std::cout << "error: " << dst.geterror() << ":";

Python

# Method 2: Write into an existing image
fg = ImageBuf("fg.exr")
bg = ImageBuf("bg.exr")
dst = ImageBuf() # will be the output image
ok = ImageBufAlgo.over (dst, fg, bg)
if not ok :
    print("error:", dst.geterror())

The first option (return an ImageBuf directly) is a more compact and intuitive notation that is natural for most simple uses. But the second option (pass an ImageBuf& referring to an existing destination) offers additional flexibility, including more careful control over allocations, the ability to partially overwrite regions of an existing image, and the ability for the destination image to also be one of the input images (for example, add(A,A,B) adds B into existing image A, with no third image allocated at all).

For a small minority of ImageBufAlgo functions, there are only input images, and no image outputs (e.g., isMonochrome()). In such cases, the error message should be retrieved from the first input image.

10.1.2 Region of interest

Most ImageBufAlgo functions take an optional ROI parameter that restricts the operation to a range in x, y, z, and channels. The default-constructed ROI (also known as ROI::All()) means no region restriction – the whole image will be copied or altered.

For ImageBufAlgo functions that write into a destination ImageBuf parameter and it is already initialized (i.e. allocated with a particular size and data type), the operation will be performed on the pixels in the destination that overlap the ROI, leaving pixels in the destination which are outside the ROI unaltered.

For ImageBufAlgo functions that return an ImageBuf directly, or if their dst parameter is an uninitialized ImageBuf, the ROI (if set) determines the size of the result image. If the ROI is the default All, the result image size will be the union of the pixel data windows of the input images and have a data type determined by the data types of the input images.

Most ImageBufAlgo functions also respect the chbegin and chend members of the ROI, thus restricting the channel range on which the operation is performed. The default ROI constructor sets up the ROI to specify that the operation should be performed on all channels of the input image(s).

10.1.3 Constant and per-channel values

Many ImageBufAlgo functions take per-channel constant-valued arguments (for example, a fill color). These parameters are passed as cspan<float>. These are generally expected to have length equal to the number of channels. But you may also pass a single float which will be used as the value for all channels. (More generally, what is happening is that the last value supplied is replicated for any missing channel.)

Some ImageBufAlgo functions have parameters of type Image_or_Const, which may take either an ImageBuf reference, or a per-channel constant, or a single constant to be used for all channels.
10.1.4 Multithreading

All ImageBufAlgo functions take an optional \texttt{nthreads} parameter that signifies the maximum number of threads to use to parallelize the operation. The default value for \texttt{nthreads} is 0, which signifies that the number of thread should be the OIIIO global default set by \texttt{OIIIO::attribute()} (see Section \textit{Global Attributes}), which itself defaults to be the detected level of hardware concurrency (number of cores available).

Generally you can ignore this parameter (or pass 0), meaning to use all the cores available in order to perform the computation as quickly as possible. The main reason to explicitly pass a different number (generally 1) is if the application is multithreaded at a high level, and the thread calling the ImageBufAlgo function just wants to continue doing the computation without spawning additional threads, which might tend to crowd out the other application threads.

10.2 Pattern generation

For the ImageBufAlgo functions in this section, there is no “source” image. Therefore, either an initialized \texttt{dst} must be supplied (to give a pre-allocated size and data type of the image), or else it is strictly necessary to supply an ROI parameter to specify the size of the new image (the data type in this case will always be \texttt{float}). It is an error if one of the pattern generation ImageBufAlgo functions is neither supplied a pre-allocated \texttt{dst} nor a non-default ROI.

10.2.1 zero() – create a black image

\texttt{ImageBuf OIIIO::ImageBufAlgo::zero (ROI roi, int nthreads = 0)}

Create an all-black \texttt{float} image of size and channels as described by the \texttt{ROI}.

Result-as-parameter version:

\texttt{bool OIIIO::ImageBufAlgo::zero (ImageBuf &dst, ROI roi = {}, int nthreads = 0)}

Write to an existing image \texttt{dst} (allocating if it is uninitialized).

Examples:

\texttt{C++}

// Create a new 3-channel, 512x512 float image filled with 0.0 values.
ImageBuf zero = ImageBufAlgo::zero (ROI(0,512,0,512,0,1,0,3));

// Zero out an existing buffer, keeping it the same size and data type
ImageBuf A = ...;
...
ImageBufAlgo::zero (A);

// Zero out just the green channel, leave everything else the same
ROI roi = A.roi ();
roi.chbegin = 1; // green
roi.chend = 2; // one past the end of the channel region
ImageBufAlgo::zero (A, roi);

// Zero out a rectangular region of an existing buffer
ImageBufAlgo::zero (A, ROI (0, 100, 0, 100));

\texttt{Python}
# Create a new 3-channel, 512x512 float image filled with 0.0 values.
zero = ImageBufAlgo.zero (ROI(0,512,0,512,0,1,0,3))

# Zero out an existing buffer, keeping it the same size and data type
A = ImageBuf(...)
...
ImageBufAlgo.zero (A)

# Zero out just the green channel, leave everything else the same
roi = A.roi
roi.chbegin = 1  # green
roi.chend = 2    # one past the end of the channel region
ImageBufAlgo.zero (A, roi)

# Zero out a rectangular region of an existing buffer
ImageBufAlgo.zero (A, ROI (0, 100, 0, 100))

# Create a new 3-channel, 512x512 float image filled with 0.0 values.
oiiotool --create 512x512 3 -d float -o out.exr

# Zero out an existing image, keeping it the same size and data type.
# For simplicity, just scale all values by 0.0
oiiotool in.exr --mulc 0.0 -o out.exr

# Zero out just the green channel, leave everything else the same.
# Again, rely on --mulc to scale the channels
oiiotool in.exr --mulc 1,0,1 -o out.exr

# Zero out a rectangular region of an existing image
oiiotool in.exr --fill:color=0,0,0 100x100+0+0 -o out.exr

10.2.2 fill() – fill a region with a solid color or gradient

group fill

Fill an image region with given channel values, either returning a new image or altering the existing dst image within the ROI. Note that the values arrays start with channel 0, even if the ROI indicates that a later channel is the first to be changed.

Three varieties of fill() exist: (a) a single set of channel values that will apply to the whole ROI, (b) two sets of values that will create a linearly interpolated gradient from top to bottom of the ROI, (c) four sets of values that will be bilinearly interpolated across all four corners of the ROI.
## Functions

**ImageBuf** `fill (cspan<float> values, ROI roi, int nthreads = 0)`

**ImageBuf** `fill (cspan<float> top, cspan<float> bottom, ROI roi, int nthreads = 0)`

**ImageBuf** `fill (cspan<float> topleft, cspan<float> topright, cspan<float> bottomleft, cspan<float> bottomright, ROI roi, int nthreads = 0)`

**bool** `fill (ImageBuf & dst, cspan<float> values, ROI roi = {}, int nthreads = 0)`

**bool** `fill (ImageBuf & dst, cspan<float> top, cspan<float> bottom, ROI roi = {}, int nthreads = 0)`

**bool** `fill (ImageBuf & dst, cspan<float> topleft, cspan<float> topright, cspan<float> bottomleft, cspan<float> bottomright, ROI roi = {}, int nthreads = 0)`

### Examples:

#### C++

```cpp
// Create a new 640x480 RGB image, with a top-to-bottom gradient
// from red to pink
float pink[3] = { 1, 0.7, 0.7 };  
float red[3] = { 1, 0, 0 };  
ImageBuf A = ImageBufAlgo::fill (red, pink, ROI(0, 640, 0, 480, 0, 1, 0, 3));

// Draw a filled red rectangle overtop existing image A.
ImageBufAlgo::fill (A, red, ROI(50, 100, 75, 175));
```

#### Python

```python
# Create a new 640x480 RGB image, with a top-to-bottom gradient
# from red to pink
pink = (1, 0.7, 0.7)
red = (1, 0, 0)
A = ImageBufAlgo.fill (top=red, bottom=pink,
                        ROI(0, 640, 0, 480, 0, 1, 0, 3))

# Draw a filled red rectangle overtop existing image A.
ImageBufAlgo.fill (A, red, ROI(50, 100, 75, 175))
```

#### oiiotool

```bash
# Create a new 640x480 RGB image, with a top-to-bottom gradient
# from red to pink
oiiotool --pattern fill:top=1,0.7,0.7:bottom=1,0,0 640x480 3 -o A.exr

# Draw a filled red rectangle overtop existing image A.exr
oiiotool A.exr --pattern fill:color=1,0,0 25x75 3 --paste +50+100 -o
     --> A.exr
```
10.2.3 checker() – make a checker pattern

`OIIO::ImageBufAlgo::checker(int width, int height, int depth, float color1, float color2, int xoffset, int yoffset, int zoffset, ROI roi, int nthreads = 0)`

Create a checkerboard pattern of size given by `roi`, with origin given by the `offset` values, checker size given by the `width`, `height`, `depth` values, and alternating between `color1[]` and `color2[]`. The pattern is defined in abstract “image space” independently of the pixel data window of `dst` or the `ROI`.

Result-as-parameter version:

```cpp
bool OIIO::ImageBufAlgo::checker(ImageBuf &dst, int width, int height, int depth, float color1, float color2, int xoffset = 0, int yoffset = 0, int zoffset = 0, ROI roi = {}, int nthreads = 0)
```

Write to an existing image `dst` (allocating if it is uninitialized).

Examples:

**C++**

```cpp
// Create a new 640x480 RGB image, fill it with a two-toned gray checkerboard, the checkers being 64x64 pixels each.
ImageBuf A (ImageSpec(640, 480, 3, TypeDesc::FLOAT);
float dark[3] = { 0.1, 0.1, 0.1 };
float light[3] = { 0.4, 0.4, 0.4 };
ImageBufAlgo::checker(A, 64, 64, 1, dark, light, 0, 0, 0);
```

**Python**

```python
# Create a new 640x480 RGB image, fill it with a two-toned gray checkerboard, the checkers being 64x64 pixels each.
A = ImageBuf (ImageSpec(640, 480, 3, "float")
dark = (0.1, 0.1, 0.1)
light = (0.4, 0.4, 0.4)
A = ImageBufAlgo.checker (64, 64, 1, dark, light,
                        roi=ROI(0, 640, 0, 480, 0, 1, 0, 3))
```

**oiiotool**

```bash
# Create a new 640x480 RGB image, fill it with a two-toned gray checkerboard, the checkers being 64x64 pixels each.
oiiotool --pattern checker:width=64:color1=0.1,0.1,0.1:color2=0.4,0.4 640x480 3 -o A.exr
```
10.2.4 Noise patterns

ImageBuf OIIO::ImageBufAlgo::noise (string_view noisetype, float A = 0.0f, float B = 0.1f, bool mono = false, int seed = 0, ROI roi = {}, int nthreads = 0)

Return an image of “noise” in every pixel and channel specified by the roi. There are several noise types to choose from, and each behaves differently and has a different interpretation of the A and B parameters:

- “gaussian” adds Gaussian (normal distribution) noise values with mean value A and standard deviation B.
- “white” adds independent uniformly distributed values on range [A,B).
- “uniform” (synonym for “white”)
- "blue” adds “blue noise” uniformly distributed on range [A,B) but not independent; rather, they are chosen for good spectral properties for sampling and dither.
- ”salt” changes to value A a portion of pixels given by B.

If the mono flag is true, a single noise value will be applied to all channels specified by roi, but if mono is false, a separate noise value will be computed for each channel in the region.

The random number generator is actually driven by a hash on the “image space” coordinates and channel, independently of the pixel data window of dst or the ROI. Choosing different seed values will result in a different pattern, but for the same seed value, the noise at a given pixel coordinate (x,y,z) channel c will is completely deterministic and repeatable.

Result-as-parameter version:

bool OIIO::ImageBufAlgo::noise (ImageBuf &dst, string_view noisetype, float A = 0.0f, float B = 0.1f, bool mono = false, int seed = 0, ROI roi = {}, int nthreads = 0)

Write to an existing image dst (allocating if it is uninitialized).

Examples:

C++
// Create a new 256x256 field of grayscale white noise on [0,1)
ImageBuf A = ImageBufAlgo::noise ("uniform", 0.0f /*min*/, 1.0f /*max*/,
true /*mono*/, 1 /*seed*/, ROI(0,256,0,256,0,1,0,3));

// Create a new 256x256 field of grayscale blue noise on [0,1)
ImageBuf B = ImageBufAlgo::noise ("blue", 0.0f /*min*/, 1.0f /*max*/,
true /*mono*/, 1 /*seed*/, ROI(0,256,0,256,0,1,0,3));

// Add color Gaussian noise to an existing image
ImageBuf C ("tahoe.jpg");
ImageBufAlgo::noise (C, "gaussian", 0.0f /*mean*/, 0.1f /*stddev*/,
false /*mono*/, 1 /*seed*/);

// Use salt and pepper noise to make occasional random dropouts
ImageBuf D ("tahoe.jpg");
ImageBufAlgo::noise (D, "salt", 0.0f /*value*/, 0.01f /*portion*/,
true /*mono*/, 1 /*seed*/);

Python

```python
# Create a new 256x256 field of grayscale white noise on [0,1)
A = ImageBufAlgo.noise ("uniform", min=0.0, max=1.0, mono=True,
seed=1,
roi = ROI(0,256,0,256,0,1,0,3))

# Create a new 256x256 field of grayscale blue noise on [0,1)
B = ImageBufAlgo.noise ("blue", min=0.0, max=1.0, mono=True, seed=1,
roi = ROI(0,256,0,256,0,1,0,3))

# Add color Gaussian noise to an existing image
C = ImageBuf ("tahoe.jpg")
ImageBufAlgo::noise (C, "gaussian", A=0.0, B=0.1, mono=False, seed=1)

# Use salt and pepper noise to make occasional random dropouts
D = ImageBuf ("tahoe.jpg")
ImageBufAlgo::noise (D, "salt", A=0.0, B=0.01, mono=True, seed=1)
```
oiiotool

```bash
# Create a new 256x256 field of grayscale white noise on [0,1)
oiiotool --pattern noise:type=uniform:mono=1:seed=1 256x256 3 -o A.exr

# Create a new 256x256 field of grayscale blue noise on [0,1)
oiiotool --pattern noise:type=blue:mono=1:seed=1 256x256 3 -o B.exr

# Add color Gaussian noise to an existing image
oiiotool tahoe.jpg --noise:type=gaussian:stddev=0.1 -o C.exr

# Use salt and pepper noise to make occasional random dropouts
oiiotool tahoe.jpg --noise:type=salt:value=0:portion=0.01:mono=1 -o D.exr
```
**const ImageBuf &OIIO::ImageBufAlgo::bluenoise_image()**

Return a const reference to a periodic bluenoise texture with float data in 4 channels that are uncorrelated to each other. Note that unlike most other ImageBufAlgo functions, it does not return an ImageBuf by value, but by const reference.

Example:

**C++**

```cpp
const ImageBuf& A = ImageBufAlgo::bluenoise_image();
```

**Python**

```python
A = ImageBufAlgo.bluenoise_image()
```

### 10.2.5 Drawing shapes: points, lines, boxes

**bool OIIO::ImageBufAlgo::render_point** (ImageBuf &dst, int x, int y, cspan<float> color = 1.0f, ``ROI roi = {}, int nthreads = 0``)

Render a single point at (x,y) of the given color “over” the existing image dst. If there is no alpha channel, the color will be written unconditionally (as if the alpha is 1.0).

Examples:

**C++**

```cpp
ImageBuf A (ImageSpec (640, 480, 4, TypeDesc::FLOAT));
float red[4] = { 1, 0, 0, 1 }
ImageBufAlgo::render_point (A, 50, 100, red);
```

**Python**

```python
A = ImageBuf(ImageSpec(640, 480, 4, "float"))
red = (1, 0, 0, 1)
ImageBufAlgo.render_point (A, 50, 100, red)
```

**oiiotool**

```bash
oiiotool A.exr -point:color=1,0,0,1 50,100 -o out.exr
```

---

**10.2. Pattern generation**
bool OIIIO::ImageBufAlgo::render_line(ImageBuf &dst, int x1, int y1, int x2, int y2, cspan<"float"> color = 1.0f, bool skip_first_point = false, ROI roi = {}, int nthreads = 0)

Render a line from pixel (x1,y1) to (x2,y2) into dst, doing an “over” of the color (if it includes an alpha channel) onto the existing data in dst. The color should include as many values as roi.chend-1. The ROI can be used to limit the pixel area or channels that are modified, and default to the entirety of dst. If skip_first_point is true, the first point (x1, y1) will not be drawn (this can be helpful when drawing poly-lines, to avoid double-rendering of the vertex positions).

Examples:

**C++**

```cpp
ImageBuf A (ImageSpec (640, 480, 4, TypeDesc::FLOAT));
float red[4] = { 1, 0, 0, 1 };
ImageBufAlgo::render_line (A, 10, 60, 250, 20, red);
ImageBufAlgo::render_line (A, 250, 20, 100, 190, red, true);
```

**Python**

```python
A = ImageBuf(ImageSpec(640, 480, 4, "float"))
red = (1, 0, 0, 1)
ImageBufAlgo.render_line (A, 10, 60, 250, 20, red);
ImageBufAlgo.render_line (A, 250, 20, 100, 190, red, True)
```

**oiiotool**

```bash
oiiotool A.exr -line:color=1,0,0,1 10,60,20,100 -o out.exr
```

bool OIIIO::ImageBufAlgo::render_box(ImageBuf &dst, int x1, int y1, int x2, int y2, cspan<"float"> color = 1.0f, bool fill = false, ROI roi = {}, int nthreads = 0)

Render a filled or unfilled box with corners at pixels (x1,y1) and (x2,y2) into dst, doing an “over” of the color (if it includes an alpha channel) onto the existing data in dst. The color must include as many values as roi.chend-1. The ROI can be used to limit the pixel area or channels that are modified, and default to the entirety of dst. If fill is true, the box will be completely filled in, otherwise only its outline will be drawn.

Examples:

**C++**

```cpp
ImageBuf A (ImageSpec (640, 480, 4, TypeDesc::FLOAT));
float cyan[4] = { 0, 1, 1, 1 };
```
10.2.6 Drawing text

```cpp
float yellow_transparent[4] = { 0.5, 0.5, 0, 0.5 };
ImageBufAlgo::render_box (A, 150, 100, 240, 180, cyan);
ImageBufAlgo::render_box (A, 100, 50, 180, 140, yellow_transparent, true);
```

```python
A = ImageBuf(ImageSpec(640, 480, 4, "float"))
cyanc = (0, 1, 1, 1)
yellow_transparent = (0.5, 0.5, 0, 0.5)
ImageBufAlgo.render_box (A, 150, 100, 240, 180, cyan)
ImageBufAlgo.render_box (A, 100, 50, 180, 140, yellow_transparent, fill=True)
```

```
oiiotool A.exr -box:color=0,1,1,1 150,100,240,180 \
    -box:color=0.5,0.5,0,0.5 100,50,180,140 -o out.exr
```

Render a text string (encoded as UTF-8) into image dst. If the dst image is not yet initialized, it will be initialized to be a black background exactly large enough to contain the rasterized text. If dst is already initialized, the text will be rendered into the existing image by essentially doing an “over” of the character into the existing pixel data.

Note that any named fonts (if not a full pathname) will search for the fonts in the following places: (a) any directories named in the global “font_searchpath” attribute or the $OPENIMAGEIO_FONTS environment variable; (b) any font-related subdirectories (fonts, Fonts, share/fonts, or Library/Fonts) underneath the directories in environment variables $HOME, $SystemRoot, $OpenImageIO_ROOT; (c) a number of common system font areas, including /usr/share/fonts, /Library/fonts, and C:/Windows/fonts; (d) in fonts directories one level up from the place where the currently running binary lives.

**Parameters**
• **dst:** Destination ImageBuf text is rendered into this image.

• **x/y:** The position to place the text.

• **text:** The text to draw. Linefeed (\n) characters are respected as indications that the text spans multiple rows.

• **fontsize/fontname:** Size and name of the font. If the name is not a full pathname to a font file, it will search for a matching font, defaulting to some reasonable system font if not supplied at all, and with a nominal height of fontsize (in pixels).

• **textcolor:** Color for drawing the text, defaulting to opaque white (1.0,1.0,...) in all channels if not supplied. If provided, it is expected to point to a float array of length at least equal to Rspec(). nchannels, or defaults will be chosen for you).

• **alignx/aligny:** The default behavior is to align the left edge of the character baseline to (x,y). Optionally, alignx and aligny can override the alignment behavior, with horizontal alignment choices of TextAlignX::Left, Right, and Center, and vertical alignment choices of Baseline, Top, Bottom, or Center.

• **shadow:** If nonzero, a “drop shadow” of this radius will be used to make the text look more clear by dilating the alpha channel of the composite (makes a black halo around the characters).

Examples:

C++

```cpp
ImageBufAlgo::render_text (ImgA, 50, 100, "Hello, world");
float red[] = { 1, 0, 0, 1 }; ImageBufAlgo::render_text (ImgA, 100, 200, "Go Big Red!",
60, "Arial Bold", red);
float white[] = { 1, 1, 1, 1 }; ImageBufAlgo::render_text (ImgB, 320, 240, "Centered",
60, "Arial Bold", white,
TextAlignX::Center, TextAlignY::Center);
```

Python

```python
ImageBufAlgo.render_text (ImgA, 50, 100, "Hello, world")
red = (1, 0, 0, 1)
ImageBufAlgo.render_text (ImgA, 100, 200, "Go Big Red!",
60, "Arial Bold", red)
white = (1, 1, 1, 1)
ImageBufAlgo.render_text (ImgB, 320, 240, "Centered",
fontsize=60, fontname="Arial Bold",
color=white, alignx="center", aligny=
˓→"center")
```

oiiotool

```bash
oiiotool ImgA.exr --text:x=50:y=100 "Hello, world" \ --text:x=100:y=200:fontsize=60:fontname="Arial Bold":color=1,0,0,1 \ "Go Big Red!" \ -o out.exr
```

(continues on next page)
ROI OIIIO::ImageBufAlgo::text_size(string_view text, int fontsize = 16, string_view fontname = "")

The helper function text_size() merely computes the dimensions of the text, returning it as an ROI relative to the left side of the baseline of the first character. Only the x and y dimensions of the ROI will be used. The x dimension runs from left to right, and y runs from top to bottom (image coordinates). For a failure (such as an invalid font name), the ROI will return false if you call its defined() method. The text may contain linefeed characters to designate multiple lines of text.

Examples:

C++

```cpp
// Render text centered in the image, using text_size to find out // the size we will need and adjusting the coordinates.
ImageBuf A (ImageSpec (640, 480, 4, TypeDesc::FLOAT));
ROI Aroi = A.roi();
ROI size = ImageBufAlgo::text_size ("Centered", 48, "Courier New");
if (size.defined()) {
    int x = Aroi.xbegin + Aroi.width()/2 - (size.xbegin + size.
    width()/2);
    int y = Aroi.ybegin + Aroi.height()/2 - (size.ybegin + size.
    height()/2);
    ImageBufAlgo::render_text (A, x, y, "Centered", 48, "Courier New
    ");
}
```

Python

```python
# Render text centered in the image, using text_size to find out # the size we will need and adjusting the coordinates.
A = ImageBuf (ImageSpec (640, 480, 4, "float"))
Aroi = A.roi
size = ImageBufAlgo.text_size ("Centered", 48, "Courier New")
if size.defined() :
    x = Aroi.xbegin + Aroi.width//2 - (size.xbegin + size.width//2)
```

(continues on next page)
10.3 Image transformations and data movement

10.3.1 Shuffling channels

ImageBufAlgo::channels (const ImageBuf &: src, int nchannels, cspan<int> channelorder, cspan<float> channelvalues = {}, cspan<std::string> newchannelnames = {}, bool shuffle_channel_names = false, int nthreads = 0)

Generic channel shuffling: return (or store in dst) a copy of src, but with channels in the order channelorder[0..nchannels-1] (or set to a constant value, designated by channelorder[i] = -1 and having the fill value in channelvalues[i]). In-place operation is allowed (i.e., dst and src the same image, but an extra copy will occur).

Parameters

- nchannels: The total number of channels that will be set up in the dst image.
- channelorder: For each channel in dst, the index of he src channel from which to copy. Any channelorder[i] < 0 indicates that the channel i should be filled with constant value channelvalues[i] rather than copy any channel from src. If channelorder itself is empty, the implied channel order will be {0, 1, ..., nchannels-1}, meaning that it’s only renaming, truncating, or extending channels, not reordering the channels that are already present.
- channelvalues: Fill values for color channels in which channelorder[i] < 0. This can be empty if no channels are to be filled with constant values.
- newchannelnames: An array of new channel names. Channels for which this specifies an empty string will have their name taken from the src channel that was copied. If newchannelnames is entirely empty, all channel names will simply be copied from src.
- shuffle_channel_names: If true, the channel names will be taken from the corresponding channels of the source image be careful with this, shuffling both channel ordering and their names could result in no semantic change at all, if you catch the drift. If false (the default), the resulting dst image will have default channel names in the usual order (“R”, “G”, etc.).

Result-as-parameter version:

bool ImageBufAlgo::channels (ImageBuf &dst, const ImageBuf &: src, int nchannels, cspan<int> channelorder, cspan<float> channelvalues = {}, cspan<std::string> newchannelnames = {}, bool shuffle_channel_names = false, int nthreads = 0)

Write to an existing image dst (allocating if it is uninitialized).

Examples:

C++
// Copy the first 3 channels of an RGBA, drop the alpha
ImageBuf RGBA (...,) // assume it's initialized, 4 chans
ImageBuf RGB = ImageBufAlgo::channels (RGBA, 3, {} /*default ordering*/);

// Copy just the alpha channel, making a 1-channel image
ImageBuf Alpha = ImageBufAlgo::channels (RGBA, 1, 3 /*alpha_channel*/);

// Swap the R and B channels
int channelorder[] = { 2 /*B*/, 1 /*G*/, 0 /*R*/, 3 /*A*/ };
ImageBuf BRGA = ImageBufAlgo::channels (BRGA, RGBA, 4, channelorder);

// Add an alpha channel with value 1.0 everywhere to an RGB image,
// keep the other channels with their old ordering, values, and names.
int channelorder[] = { 0, 1, 2, -1 /*use a float value*/ };
float channelvalues[] = { 0 /*ignore*/, 0 /*ignore*/, 0 /*ignore*/, 1.0 };
std::string channelnames[] = { "", "", "", "A" };
ImageBuf RGBA = ImageBufAlgo::channels (RGB, 4, channelorder, channelvalues, channelnames);

Python

# Copy the first 3 channels of an RGBA, drop the alpha
RGBA = ImageBuf(...) # assume it's initialized, 4 chans
RGB = ImageBufAlgo.channels (RGBA, (0, 1, 2))

# Copy just the alpha channel, making a 1-channel image
Alpha = ImageBufAlgo.channels (RGBA, ("A",))

# Swap the R and B channels
BRGA = ImageBufAlgo.channels (BRGA, RGBA, (2, 1, 0, 3))

# Add an alpha channel with value 1.0 everywhere to an RGB image,
# keep the other channels with their old ordering, values, and names.
RGBA = ImageBufAlgo.channels (RGB, (0, 1, 2, 1.0),
        newchannelnames=("", "", "", "A"))

oiiootool

# Copy the first 3 channels of an RGBA, drop the alpha
oiiootool RGBA.exr -ch R,G,B -o RGB.exr

# Copy just the alpha channel, making a 1-channel image
oiiootool RGBA.exr -ch A -o A.exr

# Swap the R and B channels
oiiootool RGBA.exr -ch R=B,G,B=R,A -o BGRA.exr

# Add an alpha channel with value 1.0 everywhere to an RGB image,
# keep the other channels with their old ordering, values, and names.
oiiootool RGB.exr -ch 0,1,2,1.0 -o RGBA.exr

10.3. Image transformations and data movement 231
ImageBuf OIIIO::ImageBufAlgo::channel_append(const ImageBuf &A, const ImageBuf &B, ROI roi = {}, int nthreads = 0)

Append the channels of A and B together into dst over the region of interest. If the region passed is uninitialized (the default), it will be interpreted as being the union of the pixel windows of A and B (and all channels of both images). If dst is not already initialized, it will be resized to be big enough for the region.

Result-as-parameter version:

bool OIIIO::ImageBufAlgo::channel_append(ImageBuf &dst, const ImageBuf &A, const ImageBuf &B, ROI roi = {}, int nthreads = 0)

Write to an existing image dst (allocating if it is uninitialized).

Examples:

C++

```cpp
ImageBuf RGBA ("rgba.exr");
ImageBuf Z ("z.exr");
ImageBuf RGBAZ = ImageBufAlgo::channel_append (RGBA, Z);
```

Python

```python
RGBA = ImageBuf("rgba.exr")
Z = ImageBuf("z.exr")
RGBAZ = ImageBufAlgo.channel_append (RGBA, Z)
```

oiiotool

```bash
oiiotool rgba.exr z.exr --chappend -o rgbaz.exr
```

ImageBuf OIIIO::ImageBufAlgo::copy(const ImageBuf &src, TypeDesc convert = TypeUnknown, ROI roi = {}, int nthreads = 0)

Return the specified region of pixels of src as specified by roi (which will default to the whole of src, optionally with the pixel type overridden by convert (if it is not TypeUnknown)).

Result-as-parameter version:

bool OIIIO::ImageBufAlgo::copy(ImageBuf &dst, const ImageBuf &src, TypeDesc convert = TypeUnknown, ROI roi = {}, int nthreads = 0)

Write to an existing image dst (allocating if it is uninitialized). If dst is not already initialized, it will be set to the same size as roi (defaulting to all of src).

Examples:

C++

```cpp
// Set B to be a copy of A, but converted to float
ImageBuf A ("A.exr");
ImageBuf B = ImageBufAlgo::copy (A, TypeDesc::FLOAT);
```

Python
# Set B to be a copy of A, but converted to float
A = ImageBuf("A.exr")
B = ImageBufAlgo.copy (A, convert="float")

# Convert A to float pixels
oiiotool A.exr -d float -o B.exr

ImageBuf OIIIO::ImageBufAlgo::crop(const ImageBuf &src, ROI roi = {}, int nthreads = 0)
Return the specified region of src as an image, without altering its position in the image plane.

Pixels from src which are outside roi will not be copied, and new black pixels will be added for regions of roi which were outside the data window of src.

Note that the crop operation does not actually move the pixels on the image plane or adjust the full/display window; it merely restricts which pixels are copied from src to dst. (Note the difference compared to cut ()).

Result-as-parameter version:

bool OIIIO::ImageBufAlgo::crop(ImageBuf &dst, const ImageBuf &src, ROI roi = {}, int nthreads = 0)
Write to an existing image dst (allocating if it is uninitialized).

Examples:

C++

// Set B to be a 200x100 region of A starting at (50,50), trimming // the exterior away but leaving that region in its original position.
ImageBuf A("A.exr");
ImageBuf B = ImageBufAlgo::crop(A, ROI(50,250,50,150));

Python

# Set B to be a 200x100 region of A starting at (50,50), trimming # the exterior away but leaving that region in its original position.
A = ImageBuf("A.exr")
B = ImageBufAlgo.crop(A, ROI(50,250,50,150));

# Set B to be a 200x100 region of A starting at (50,50), trimming # the exterior away but leaving that region in its original position.
oiiotool A.exr --crop 200x100+50+50 -o B.exr

ImageBuf OIIIO::ImageBufAlgo::cut(const ImageBuf &src, ROI roi = {}, int nthreads = 0)
Return the designated region of src, but repositioned to the image origin and with the full/display window set to exactly cover the new pixel data window. (Note the difference compared to crop ()).
Result-as-parameter version:

```cpp
bool OIIIO::ImageBufAlgo::cut (ImageBuf &dst, const ImageBuf &src, ROI roi = {}, int nthreads = 0)
```

Write to an existing image `dst` (allocating if it is uninitialized).

Examples:

**C++**

```cpp
// Set B to be a 200x100 region of A starting at (50,50), but
// moved to the upper left corner so its new origin is (0,0).
ImageBuf A ("A.exr");
ImageBuf B = ImageBufAlgo::cut (A, ROI(50,250,50,150));
```

**Python**

```python
# Set B to be a 200x100 region of A starting at (50,50), but
# moved to the upper left corner so its new origin is (0,0).
A = ImageBuf("A.exr")
B = ImageBufAlgo.cut (A, ROI(50,250,50,150))
```

**oiiotool**

```bash
# Set B to be a 200x100 region of A starting at (50,50), but
# moved to the upper left corner so its new origin is (0,0).
oiiotool A.exr --cut 200x100+50+50 -o B.exr
```

```cpp
bool OIIIO::ImageBufAlgo::paste (ImageBuf &dst, int xbegin, int ybegin, int zbegin, int chbegin,
                                    const ImageBuf &src, ROI srcroi = {}, int nthreads = 0)
```

Copy `src` pixels within `srcroi` into the `dst` image, offset so that source location (0,0,0) will be copied to destination location (xbegin,ybegin,zbegin). If the `srcroi` is `ROI::All()`, the entirety of the data window of `src` will be used. It will copy into channels[chbegin...], as many channels as are described by `srcroi`. Pixels or channels of `src` inside `srcroi` will replace the corresponding destination pixels entirely, whereas `src` pixels outside of `srcroi` will not be copied and the corresponding offset pixels of `dst` will not be altered.

Examples:

**C++**

```cpp
// Paste fg.exr on top of bg.exr, offset by (100,100)
ImageBuf Bg ("bg.exr");
ImageBuf Fg ("fg.exr");
ImageBufAlgo::paste (Bg, 100, 100, 0, 0, Fg);
```

**Python**

```python
# Paste fg.exr on top of bg.exr, offset by (100,100)
Bg ImageBuf("bg.exr")
Fg ImageBuf("fg.exr")
ImageBufAlgo.paste (Bg, 100, 100, 0, 0, Fg)
```

**oiiotool**

```bash
# Paste fg.exr on top of bg.exr, offset by (100,100)
bg.exr --paste 100x100+0+0 -o fg.exr
```

```bash
# Paste fg.exr on top of bg.exr, offset by (100,100)
oiiotool bg.exr fg.exr --paste +100+100 -o bg.exr
```

group **rotateN**

Return (or copy into `dst`) a rotated copy of the image pixels of `src`, in 90 degree increments. Pictorially:

<table>
<thead>
<tr>
<th>rotate90</th>
<th>rotate180</th>
<th>rotate270</th>
</tr>
</thead>
<tbody>
<tr>
<td>AB --&gt; CA</td>
<td>AB --&gt; DC</td>
<td>AB --&gt; BD</td>
</tr>
<tr>
<td>CD</td>
<td>DB</td>
<td>CD</td>
</tr>
<tr>
<td></td>
<td></td>
<td>AC</td>
</tr>
</tbody>
</table>

**Functions**

ImageBuf `rotate90` (const ImageBuf & `src`, ROI `roi = {}`, int `nthreads = 0`)

ImageBuf `rotate180` (const ImageBuf & `src`, ROI `roi = {}`, int `nthreads = 0`)

ImageBuf `rotate270` (const ImageBuf & `src`, ROI `roi = {}`, int `nthreads = 0`)

bool `rotate90` (ImageBuf & `dst`, const ImageBuf & `src`, ROI `roi = {}`, int `nthreads = 0`)

bool `rotate180` (ImageBuf & `dst`, const ImageBuf & `src`, ROI `roi = {}`, int `nthreads = 0`)

bool `rotate270` (ImageBuf & `dst`, const ImageBuf & `src`, ROI `roi = {}`, int `nthreads = 0`)

**Examples:**

C++

```cpp
ImageBuf A ("grid.jpg");
ImageBuf R90 = ImageBufAlgo::rotate90 (A);
ImageBuf R180 = ImageBufAlgo::rotate180 (A);
ImageBuf R270 = ImageBufAlgo::rotate270 (A);
```

Python

```python
A = ImageBuf("grid.jpg")
R90 = ImageBufAlgo.rotate90 (A)
R180 = ImageBufAlgo.rotate180 (A)
R270 = ImageBufAlgo.rotate270 (A)
```

```
oiiotool grid.jpg -rotate 90 -o R90.jpg
oiiotool grid.jpg -rotate 180 -o R180.jpg
oiiotool grid.jpg -rotate 270 -o R270.jpg
```

10.3. Image transformations and data movement 235
**group flip-flop-transpose**

Return (or copy into dst) a subregion of src, but with the scanlines exchanged vertically (flip), or columns exchanged horizontally (flop), or transposed across the diagonal by swapping rows for columns (transpose) within the display/full window. In other words,

<table>
<thead>
<tr>
<th>flip</th>
<th>flop</th>
<th>transpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>AB --&gt; CD</td>
<td>AB --&gt; BA</td>
<td>AB --&gt; AC</td>
</tr>
<tr>
<td>CD</td>
<td>AB</td>
<td>CD</td>
</tr>
<tr>
<td></td>
<td></td>
<td>BD</td>
</tr>
</tbody>
</table>

**Functions**

ImageBuf flip (const ImageBuf & src, ROI roi = {}, int nthreads = 0)

ImageBuf flop (const ImageBuf & src, ROI roi = {}, int nthreads = 0)

ImageBuf transpose (const ImageBuf & src, ROI roi = {}, int nthreads = 0)

bool flip (ImageBuf & dst, const ImageBuf & src, ROI roi = {}, int nthreads = 0)

bool flop (ImageBuf & dst, const ImageBuf & src, ROI roi = {}, int nthreads = 0)

bool transpose (ImageBuf & dst, const ImageBuf & src, ROI roi = {}, int nthreads = 0)

Examples:

**C++**

```cpp
ImageBuf A ("grid.jpg");
ImageBuf B;
B = ImageBufAlgo::flip (A);
B = ImageBufAlgo::flop (A);
B = ImageBufAlgo::transpose (A);
```

**Python**

```python
A = ImageBuf("grid.jpg")
B = ImageBufAlgo.flip (A)
B = ImageBufAlgo.flop (A)
B = ImageBufAlgo.transpose (A)
```

**oiiotool**

```bash
oiiotool grid.jpg --flip -o flip.jpg
oiiotool grid.jpg --flop -o flop.jpg
oiiotool grid.jpg --transpose -o transpose.jpg
```

![Images of original, flip, flop, transpose](image-url)
ImageBuf OIIIO::ImageBufAlgo::reorient (const ImageBuf & src, int nthreads = 0)
Return (or store into dst) a copy of src, but with whatever set of rotations, flips, or flops are necessary to transform the pixels into the configuration suggested by the “Orientation” metadata of the image (and the “Orientation” metadata is then set to 1, ordinary orientation).

Result-as-parameter version:

bool OIIIO::ImageBufAlgo::reorient (ImageBuf & dst, const ImageBuf & src, int nthreads = 0)
Write to an existing image dst (allocating if it is uninitialized).

Examples:

C++

ImageButton A ("tahoe.jpg");
A = ImageBufAlgo::reorient (A);

Python

A = ImageBuf("tahoe.jpg")
A = ImageBufAlgo.reorient (A)

oiiotool

oiiotool Tahoe.jpg --reorient -o out.jpg

ImageButton OIIIO::ImageBufAlgo::circular_shift (const ImageBuf & src, int xshift, int yshift, int zshift = 0, ROI roi = {}, int nthreads = 0)
Return a subregion of src, but circularly shifting by the given amount. To clarify, the circular shift of [0,1,2,3,4,5] by +2 is [4,5,0,1,2,3].

Result-as-parameter version:

bool OIIIO::ImageBufAlgo::circular_shift (ImageBuf & dst, const ImageBuf & src, int xshift, int yshift, int zshift = 0, ROI roi = {}, int nthreads = 0)
Write to an existing image dst (allocating if it is uninitialized).

Examples:

C++

ImageButton A ("grid.jpg");
ImageButton B = ImageBufAlgo::circular_shift (A, 70, 30);

Python

A = ImageBuf("tahoe.jpg")
A = ImageBufAlgo.circular_shift (A, 70, 30)

oiiotool

oiiotool Tahoe.jpg --cshift +70+30 -o out.jpg
group rotate

Rotate the src image by the angle (in radians, with positive angles clockwise). When center_x and center_y are supplied, they denote the center of rotation; in their absence, the rotation will be about the center of the image’s display window.

Only the pixels (and channels) of dst that are specified by roi will be copied from the rotated src; the default roi is to alter all the pixels in dst. If dst is uninitialized, it will be resized to be an ImageBuf large enough to hold the rotated image if recompute_roi is true, or will have the same ROI as src if recompute_roi is false. It is an error to pass both an uninitialized dst and an undefined roi.

The filter is used to weight the src pixels falling underneath it for each dst pixel. The caller may specify a reconstruction filter by name and width (expressed in pixels units of the dst image), or rotate() will choose a reasonable default high-quality default filter (lanczos3) if the empty string is passed, and a reasonable filter width if filterwidth is 0. (Note that some filter choices only make sense with particular width, in which case this filterwidth parameter may be ignored.)

Functions

ImageBuf rotate(const ImageBuf &src, float angle, string_view filtername = string_view(), float filterwidth = 0.0f, bool recompute_roi = false, ROI roi = {}, int nthreads = 0)

ImageBuf rotate(const ImageBuf &src, float angle, Filter2D *filter, bool recompute_roi = false, ROI roi = {}, int nthreads = 0)

ImageBuf rotate(const ImageBuf &src, float angle, float center_x, float center_y, string_view filtername = string_view(), float filterwidth = 0.0f, bool recompute_roi = false, ROI roi = {}, int nthreads = 0)

ImageBuf rotate(const ImageBuf &src, float angle, float center_x, float center_y, Filter2D *filter, bool recompute_roi = false, ROI roi = {}, int nthreads = 0)

bool rotate(ImageBuf &dst, const ImageBuf &src, float angle, string_view filtername = string_view(), float filterwidth = 0.0f, bool recompute_roi = false, ROI roi = {}, int nthreads = 0)

bool rotate(ImageBuf &dst, const ImageBuf &src, float angle, Filter2D *filter, bool recompute_roi = false, ROI roi = {}, int nthreads = 0)

bool rotate(ImageBuf &dst, const ImageBuf &src, float angle, float center_x, float center_y, string_view filtername = string_view(), float filterwidth = 0.0f, bool recompute_roi = false, ROI roi = {}, int nthreads = 0)
bool rotate(ImageBuf &dst, const ImageBuf &src, float angle, float center_x, float center_y, Filter2D *filter, bool recompute_roi = false, ROI roi = {}, int nthreads = 0)

Examples:

C++

```cpp
ImageBuf Src("tahoe.exr");
ImageBuf Dst = ImageBufAlgo::rotate(Src, 45.0);
```

Python

```python
Src = ImageBuf("tahoe.exr")
Dst = ImageBufAlgo.rotate(Src, 45.0)
```

oiiotool

```bash
oiiotool tahoe.exr --rotate 45.0 -o out.exr
```

group resize

Set dst, over the region of interest, to be a resized version of the corresponding portion of src (mapping such that the “full” image window of each correspond to each other, regardless of resolution). If dst is not yet initialized, it will be sized according to roi.

The caller may either (a) explicitly pass a reconstruction filter, or (b) specify one by filtername and filterwidth. If filter is nullptr or if filtername is the empty string resize() will choose a reasonable high-quality default (blackman-harris when upsizing, lanczos3 when downsizing). The filter is used to weight the src pixels falling underneath it for each dst pixel; the filter’s size is expressed in pixel units of the dst image.

10.3. Image transformations and data movement 239
Functions

ImageBuf `resize (const ImageBuf &src, string_view filtername = "", float filterwidth = 0.0f, ROI roi = {}, int nthreads = 0)`

ImageBuf `resize (const ImageBuf &src, Filter2D *filter, ROI roi = {}, int nthreads = 0)`

bool `resize (ImageBuf &dst, const ImageBuf &src, string_view filtername = "", float filterwidth = 0.0f, ROI roi = {}, int nthreads = 0)`

bool `resize (ImageBuf &dst, const ImageBuf &src, Filter2D *filter, ROI roi = {}, int nthreads = 0)`

Examples:

Examples:

C++

```cpp
// Resize the image to 640x480, using the default filter
ImageBuf Src ("tahoe.exr");
ROI roi (0, 640, 0, 480, 0, 1, /*chans=*/ 0, Src.nchannels());
ImageBuf Dst = ImageBufAlgo::resize (Src, ",", 0, roi);
```

Python

```python
# Resize the image to 640x480, using the default filter
Src = ImageBuf("tahoe.exr")
roi = ROI(0, 640, 0, 480, 0, 1, 0, Src.nchannels)
Dst = ImageBufAlgo.resize (Src, roi=roi)
```

oiiotool

```bash
# Resize the image to 640x480, using the default filter
oiiotool tahoe.exr --resize 640x480 -o out.exr
```

ImageBuf OIIIO::ImageBufAlgo::resample (const ImageBuf &src, bool interpolate = true, ROI roi = {}, int nthreads = 0)

Set dst, over the region of interest, to be a resized version of the corresponding portion of src (mapping such that the “full” image window of each correspond to each other, regardless of resolution). If dst is not yet initialized, it will be sized according to roi.

Unlike `ImageBufAlgo::resize()`, `resample()` does not take a filter; it just samples either with a bilinear interpolation (if `interpolate` is true, the default) or uses the single “closest” pixel (if `interpolate` is false). This makes it a lot faster than a proper `resize()`, though obviously with lower quality (aliasing when downsizing, pixel replication when upsizing).

For “deep” images, this function returns copies the closest source pixel needed, rather than attempting to interpolate deep pixels (regardless of the value of `interpolate`).

Result-as-parameter version:

bool OIIIO::ImageBufAlgo::resample (ImageBuf &dst, const ImageBuf &src, bool interpolate = true, ROI roi = {}, int nthreads = 0)

Write to an existing image dst (allocating if it is uninitialized).

Examples:

C++

```cpp```
// Resample quickly to 320x240, with default interpolation
ImageBuf Src ("tahoe.exr");
ROI roi (0, 320, 0, 240, 0, 1, /*chans=*/ 0, Src.nchannels());
ImageBuf Dst = ImageBufAlgo::resiresampleze (Src, true, roi);

Python

# Resample quickly to 320x240, with default interpolation
Src = ImageBuf("tahoe.exr")
roi = ROI(0, 320, 0, 240, 0, 1, 0, Src.nchannels)
Dst = ImageBufAlgo.resample (Src, roi=roi)

oiiootool

# Resample quickly to 320x240, with default interpolation
oiiootool tahoe.exr --resample 320x240 -o out.exr

**group fit**

Fit src into dst (to a size specified by roi, if dst is not initialized), resizing but preserving its original aspect ratio. Thus, it will resize to be the largest size with the same aspect ratio that can fit inside the region, but will not stretch to completely fill it in both dimensions.

The *fillmode* determines which of several methods will be used to determine how the image will fill the new frame, if its aspect ratio does not precisely match the original source aspect ratio:

- "width" exactly fills the width of the new frame, either cropping or letterboxing the height if it isn’t precisely the right size to preserve the original aspect ratio.
- "height" exactly fills the height of the new frame, either cropping or letterboxing the width if it isn’t precisely the right size to preserve the original aspect ratio.
- "letterbox" (the default) chooses whichever of “width” or “height” will maximally fill the new frame with no image data lost (it will only letterbox, never crop).

If *exact* is true, will result in an exact match on aspect ratio and centering (partial pixel shift if necessary), whereas *exact=false* will only preserve aspect ratio and centering to the precision of a whole pixel.

The filter is used to weight the src pixels falling underneath it for each dst pixel. The caller may specify a reconstruction filter by name and width (expressed in pixels units of the dst image), or *rotate()* will choose a reasonable default high-quality default filter (lanczos3) if the empty string is passed, and a reasonable filter width if *filterwidth* is 0. (Note that some filter choices only make sense with particular width, in which case this *filterwidth* parameter may be ignored.)

**Functions**

ImageBuf fit (const ImageBuf &src, string_view filtername = ", float filterwidth = 0.0f, string_view fillmode = "letterbox", bool exact = false, ROI roi = {}, int nthreads = 0)

ImageBuf fit (const ImageBuf &src, Filter2D *filter, string_view fillmode = "letterbox", bool exact = false, ROI roi = {}, int nthreads = 0)

bool fit (ImageBuf &dst, const ImageBuf &src, string_view filtername = ", float filterwidth = 0.0f, string_view fillmode = "letterbox", bool exact = false, ROI roi = {}, int nthreads = 0)
bool \textbf{fit} (ImageBuf \&\textit{dst}, \textit{const} ImageBuf \&\textit{src}, Filter2D *\textit{filter}, string\_view \textit{fillmode} = "letterbox", bool \textit{exact} = false, ROI \textit{roi} = {}, int \textit{nthreads} = 0)

Examples:

\textbf{C++}

```cpp
// Resize to fit into a max of 640x480, preserving the aspect ratio
ImageBuf Src ("tahoe.exr");
ROI roi (0, 640, 0, 480, 0, 1, /*chans*/0, Src.nchannels());
ImageBuf Dst = ImageBufAlgo::fit (Src, ",", 0, true, roi);
```

\textbf{Python}

```python
# Resize to fit into a max of 640x480, preserving the aspect ratio
Src = ImageBuf("tahoe.exr")
roi = ROI(0, 640, 0, 480, 0, 0, Src.nchannels)
Dst = ImageBufAlgo.fit (Src, ",", 0, True, roi)
```

\textbf{oiiotool}

```bash
# Resize to fit into a max of 640x480, preserving the aspect ratio
oiiotool tahoe.exr --fit 640x480 -o out.exr
```

group \textbf{warp}

Warp the \textit{src} image using the supplied 3x3 transformation matrix.

Only the pixels (and channels) of \textit{dst} that are specified by \textit{roi} will be copied from the warped \textit{src}; the default \textit{roi} is to alter all the pixels in \textit{dst}. If \textit{dst} is uninitialized, it will be sized to be an ImageBuf large enough to hold the warped image if \textit{recompute\_roi} is true, or will have the same \textit{ROI} as \textit{src} if \textit{recompute\_roi} is false. It is an error to pass both an uninitialized \textit{dst} and an undefined \textit{roi}.

The caller may explicitly pass a reconstruction filter, or specify one by name and size, or if the name is the empty string \textit{resize()} will choose a reasonable high-quality default if \textit{nullptr} is passed. The filter is used to weight the \textit{src} pixels falling underneath it for each \textit{dst} pixel; the filter’s size is expressed in pixel units of the \textit{dst} image.

\textbf{Functions}

ImageBuf \textbf{warp} (\textit{const} ImageBuf &\textit{src}, M33fParam \textit{M}, string\_view \textit{filtername} = string\_view(), float \textit{filterwidth} = 0.0f, bool \textit{recompute\_roi} = false, ImageBuf::WrapMode \textit{wrap} = ImageBuf::WrapDefault, ROI \textit{roi} = {}, int \textit{nthreads} = 0)

ImageBuf \textbf{warp} (\textit{const} ImageBuf &\textit{src}, M33fParam \textit{M}, \textit{const} Filter2D *\textit{filter}, bool \textit{recompute\_roi} = false, ImageBuf::WrapMode \textit{wrap} = ImageBuf::WrapDefault, ROI \textit{roi} = {}, int \textit{nthreads} = 0)

bool \textbf{warp} (ImageBuf &\textit{dst}, \textit{const} ImageBuf &\textit{src}, M33fParam \textit{M}, string\_view \textit{filtername} = string\_view(), float \textit{filterwidth} = 0.0f, bool \textit{recompute\_roi} = false, ImageBuf::WrapMode \textit{wrap} = ImageBuf::WrapDefault, ROI \textit{roi} = {}, int \textit{nthreads} = 0)

bool \textbf{warp} (ImageBuf &\textit{dst}, \textit{const} ImageBuf &\textit{src}, M33fParam \textit{M}, \textit{const} Filter2D *\textit{filter}, bool \textit{recompute\_roi} = false, ImageBuf::WrapMode \textit{wrap} = ImageBuf::WrapDefault, ROI \textit{roi} = {}, int \textit{nthreads} = 0)

Examples:
C++

Imath::M33f M ( 0.7071068, 0.7071068, 0,
-0.7071068, 0.7071068, 0,
20, -8.284271, 1);
ImageBuf Src ("tahoe.exr");
ImageBuf Dst = ImageBufAlgo::warp (dst, src, M, "lanczos3");

Python

M = ( 0.7071068, 0.7071068, 0,
-0.7071068, 0.7071068, 0,
20, -8.284271, 1)
Src = ImageBuf("tahoe.exr")
Dst = ImageBufAlgo.warp (dst, src, M, "lanczos3");

oiiotool

oiiotool Tahoe.exr --warp 0.7071068,0.7071068,0,-0.7071068,0.7071068,
→0,20,-8.284271,1 -o out.exr

10.4 Image arithmetic

ImageBuf OIIO::ImageBufAlgo::add(Image_or_Const A, Image_or_Const B, ROI roi = {}, int
nthreads = 0)
Compute per-pixel sum A + B, returning the result image.
A and B may each either be an ImageBuf&, or a cspan<float> giving a per-channel constant, or a single
constant used for all channels. (But at least one must be an image.)
Result-as-parameter version:

bool OIIO::ImageBufAlgo::add(ImageBuf &dst, Image_or_Const A, Image_or_Const B, ROI roi = {}, int nthreads =
0)
Write to an existing image dst (allocating if it is uninitialized).
Examples:

C++

// Add images A and B
ImageBuf A ("a.exr");
ImageBuf B ("b.exr");
ImageBuf Sum = ImageBufAlgo::add (A, B);

// Add 0.2 to channels 0-2, but not to channel 3
ImageBuf Sum = ImageBufAlgo::add (A, { 0.2f, 0.2f, 0.2f, 0.0f });

Python

# Add images A and B
A = ImageBuf("a.exr")
B = ImageBuf("b.exr")
sum = ImageBufAlgo.add (A, B)

# Add 0.2 to channels 0-2, but not to channel 3
Sum = ImageBufAlgo.add (A, (0.2, 0.2, 0.2, 0.0))

oiiotool

# Add images A and B
oiiotool a.exr b.exr --add -o sum.exr

# Add 0.2 to channels 0-2, but not to channel 3
oiiotool a.exr --addc 0.2,0.2,0.2,0.0 -o sum.exr

ImageBuf OIIIO::ImageBufAlgo::sub (Image_or_Const A, Image_or_Const B, ROI roi = {}, int nthreads = 0)

Compute per-pixel signed difference A - B, returning the result image.

A and B may each either be an ImageBuf, or a cspan<float> giving a per-channel constant, or a single constant used for all channels. (But at least one must be an image.)

Result-as-parameter version:

bool OIIIO::ImageBufAlgo::sub (ImageBuf &dst, Image_or_Const A, Image_or_Const B, ROI roi = {}, int nthreads = 0)

Write to an existing image dst (allocating if it is uninitialized).

Examples:

C++

ImageBuf A ("a.exr");
ImageBuf B ("b.exr");
ImageBuf Diff = ImageBufAlgo::sub (A, B);

Python

A = ImageBuf("a.exr")
B = ImageBuf("b.exr")
Diff = ImageBufAlgo.sub (A, B)

oiiotool

oiiotool a.exr b.exr --sub -o diff.exr

ImageBuf OIIIO::ImageBufAlgo::absdiff (Image_or_Const A, Image_or_Const B, ROI roi = {}, int nthreads = 0)

Compute per-pixel absolute difference abs (A - B), returning the result image.
A and B may each either be an `ImageBuf&`, or a `cspan<float>` giving a per-channel constant, or a single constant used for all channels. (But at least one must be an image.)

Result-as-parameter version:

```cpp
bool OIIO::ImageBufAlgo::absdiff (ImageBuf &dst, Image_or_Const A, Image_or_Const B, ROI roi = {}, int nthreads = 0)
```

Write to an existing image `dst` (allocating if it is uninitialized).

Examples:

**C++**

```cpp
ImageBuf A ("a.exr");
ImageBuf B ("b.exr");
ImageBuf Diff = ImageBufAlgo::absdiff (A, B);
```

**Python**

```python
A = ImageBuf("a.exr")
B = ImageBuf("b.exr")
Diff = ImageBufAlgo.absdiff (A, B)
```

`oiiotool`

```bash
oiiotool a.exr b.exr --absdiff -o diff.exr
```

ImageBuf `OIIO::ImageBufAlgo::abs (const ImageBuf &A, ROI roi = {}, int nthreads = 0)`

Compute per-pixel absolute value `abs(A)`, returning the result image.

Result-as-parameter version:

```cpp
bool OIIO::ImageBufAlgo::abs (ImageBuf &dst, const ImageBuf &A, ROI roi = {}, int nthreads = 0)
```

Write to an existing image `dst` (allocating if it is uninitialized).

Examples:

**C++**

```cpp
ImageBuf A ("a.exr");
ImageBuf Abs = ImageBufAlgo::abs (A);
```

**Python**

```python
A = ImageBuf("a.exr")
Abs = ImageBufAlgo.abs (A)
```

`oiiotool`

```bash
oiiotool a.exr --abs -o abs.exr
```
ImageBuf OIIO::ImageBufAlgo::mul (Image_or_Const A, Image_or_Const B, ROI roi = {}, int nthreads = 0)
    
Compute per-pixel product A * B, returning the result image.

Either both A and B are images, or one is an image and the other is a cspan<float> giving a per-channel constant or a single constant used for all channels.

Result-as-parameter version:

    bool OIIO::ImageBufAlgo::mul (ImageBuf & dst, Image_or_Const A, Image_or_Const B, ROI roi = {}, int nthreads = 0)

Write to an existing image dst (allocating if it is uninitialized).

Examples:

C++

```cpp
// Pixel-by-pixel, channel-by-channel multiplication of A and B
ImageBuf A ("a.exr");
ImageBuf B ("b.exr");
ImageBuf Product = ImageBufAlgo::mul (A, B);

// In-place reduce intensity of A's channels 0-2 by 50%
ImageBufAlgo::mul (A, A, (0.5f, 0.5f, 0.5f, 1.0f));
```

Python

```python
# Pixel-by-pixel, channel-by-channel multiplication of A and B
A = ImageBuf("a.exr")
B = ImageBuf("b.exr")
Product = ImageBufAlgo.mul (A, B)

# In-place reduce intensity of A's channels 0-2 by 50%
ImageBufAlgo.mul (A, A, (0.5, 0.5, 0.5, 1.0))
```

oiiotool

```bash
# Pixel-by-pixel, channel-by-channel multiplication of A and B
oiiotool a.exr b.exr --mul -o product.exr

# In-place reduce intensity of A's channels 0-2 by 50%
oiiotool a.exr --mulc 0.5,0.5,0.5,1.0 -o a.exr
```

ImageBuf OIIO::ImageBufAlgo::div (Image_or_Const A, Image_or_Const B, ROI roi = {}, int nthreads = 0)
    
Compute per-pixel division A / B, returning the result image. Division by zero is defined to result in zero.

A is always an image, and B is either an image or a cspan<float> giving a per-channel constant or a single constant used for all channels.

Result-as-parameter version:

    bool OIIO::ImageBufAlgo::div (ImageBuf & dst, Image_or_Const A, Image_or_Const B, ROI roi = {}, int nthreads = 0)

Write to an existing image dst (allocating if it is uninitialized).
Examples:

C++

```cpp
// Pixel-by-pixel, channel-by-channel division of A by B
ImageBuf A ("a.exr");
ImageBuf B ("b.exr");
ImageBuf Ratio = ImageBufAlgo::div (A, B);

// In-place reduce intensity of A's channels 0-2 by 50%
ImageBufAlgo::div (A, A, { 2.0f, 2.0f, 2.0f, 1.0f });
```

Python

```python
# Pixel-by-pixel, channel-by-channel division of A by B
A = ImageBuf("a.exr")
B = ImageBuf("b.exr")
Ratio = ImageBufAlgo.div (A, B)

# In-place reduce intensity of A's channels 0-2 by 50%
ImageBufAlgo.div (A, A, (2.0, 2.0, 2.0, 1.0))
```

oiiotool

```bash
# Pixel-by-pixel, channel-by-channel division of A by B
oiiotool a.exr b.exr --div -o ratio.exr

# In-place reduce intensity of A's channels 0-2 by 50%
oiiotool a.exr --divc 2,2,2,1 -o a.exr
```

ImageBuf \( \text{OIIO}::\text{ImageBufAlgo}::\text{mad} \) (Image or Const A, Image or Const B, Image or Const C, ROI roi = {}, int nthreads = 0)

Compute per-pixel multiply-and-add \( A \ast B + C \), returning the result image.

A, B, and C are each either an image, or a cspan<float> giving a per-channel constant or a single constant used for all channels. (Note: at least one must be an image.)

Result-as-parameter version:

```cpp
bool OIIO::ImageBufAlgo::mad (ImageBuf &dst, Image_or_Const A, Image_or_Const B, Image_or_Const C, ROI roi = {}, int nthreads = 0)

Write to an existing image \( \text{dst} \) (allocating if it is uninitialized).
```

Examples:

C++

```cpp
// Pixel-by-pixel, channel-by-channel A \ast B + C
ImageBuf A ("a.exr");
ImageBuf B ("b.exr");
ImageBuf C ("c.exr");
ImageBuf Result = ImageBufAlgo::mad (A, B, C);

// Compute the "inverse" A, which is 1.0-A, as A*(-1) + 1
```

(continues on next page)
// Do this in-place, and only for the first 3 channels (leave any
// alpha channel, if present, as it is).
ImageBuf Ainv = ImageBufAlgo::mad (A, { -1.0, -1.0, -1.0, 1.0 },
        { 1.0, 1.0, 1.0, 0.0 });

Python

# Pixel-by-pixel, channel-by-channel A * B + C
A = ImageBuf("a.exr")
B = ImageBuf("b.exr")
C = ImageBuf("c.exr")
Result = ImageBufAlgo.mad (A, B, C)

# Compute the "inverse" A, which is 1.0-A, as A*(-1) + 1
# Do this in-place, and only for the first 3 channels (leave any
# alpha channel, if present, as it is).
Ainv = ImageBufAlgo.mad (A, (-1.0, -1.0, -1.0, 1.0), (1.0, 1.0, 1.0, 0.0))

oiiootool

# Pixel-by-pixel, channel-by-channel A * B + C
oiiootool a.exr b.exr c.exr --mad -o result.exr

ImageBuf::ImageBufAlgo::over (const ImageBuf &A, const ImageBuf &B, ROI roi = {}, int nthreads = 0)

Return the composite of A over B using the Porter/Duff definition of “over”, returning true upon success and false for any of a variety of failures (as described below).

A and B (and dst, if already defined/allocated) must have valid alpha channels identified by their ImageSpec alpha_channel field. If A or B do not have alpha channels (as determined by those rules) or if the number of non-alpha channels do not match between A and B, over() will fail, returning false.

If dst is not already an initialized ImageBuf, it will be sized to encompass the minimal rectangular pixel region containing the union of the defined pixels of A and B, and with a number of channels equal to the number of non-alpha channels of A and B, plus an alpha channel. However, if dst is already initialized, it will not be resized, and the “over” operation will apply to its existing pixel data window. In this case, dst must have an alpha channel designated and must have the same number of non-alpha channels as A and B, otherwise it will fail, returning false.

A, B, and dst need not perfectly overlap in their pixel data windows; pixel values of A or B that are outside their respective pixel data window will be treated as having “zero” (0,0,0...) value.

Result-as-parameter version:

bool OIIIO::ImageBufAlgo::over (ImageBuf &dst, const ImageBuf &A, const ImageBuf &B, ROI roi = {}, int nthreads = 0)

Write to an existing image dst (allocating if it is uninitialized).

Examples:

C++
ImageBuf A("a.exr");
ImageBuf B("b.exr");
ImageBuf Composite = ImageBufAlgo::over (A, B);

C++

A = ImageBuf("a.exr")
B = ImageBuf("b.exr")
Composite = ImageBufAlgo.over (A, B)

oiiootool

oiiootool a.exr b.exr --over -o composite.exr

ImageBuf OIIO::ImageBufAlgo::zover(const ImageBuf &A, const ImageBuf &B, bool z_zeroisinf = false, ROI roi = {}, int nthreads = 0)

Just like ImageBufAlgo::over(), but inputs A and B must have designated 'z' channels, and on a pixel-by-pixel basis, the z values will determine which of A or B will be considered the foreground or background (lower z is foreground). If z_zeroisinf is true, then z=0 values will be treated as if they are infinitely far away.

Result-as-parameter version:

bool OIIO::ImageBufAlgo::zover(ImageBuf &dst, const ImageBuf &A, const ImageBuf &B, bool z_zeroisinf = false, ROI roi = {}, int nthreads = 0)

Write to an existing image dst (allocating if it is uninitialized).

Examples:

C++

ImageBuf A("a.exr");
ImageBuf B("b.exr");
ImageBuf Composite = ImageBufAlgo::zover (A, B);

C++

A = ImageBuf("a.exr")
B = ImageBuf("b.exr")
Composite = ImageBufAlgo.zover (A, B)

oiiootool

oiiootool a.exr b.exr --zover -o composite.exr

ImageBuf OIIO::ImageBufAlgo::invert(const ImageBuf &A, ROI roi = {}, int nthreads = 0)

Compute per-pixel value inverse 1.0 - A (which you can think of as roughly meaning switching white and black), returning the result image.

10.4. Image arithmetic
Tips for callers: (1) You probably want to set roi to restrict the operation to only the color channels, and not accidentally include alpha, z, or others. (2) There may be situations where you want to unpremult() before the invert, then premult() the result, so that you are computing the inverse of the unmasked color.

Result-as-parameter version:

```c++
bool OIIO::ImageBufAlgo::invert (ImageBuf &dst, const ImageBuf &A, ROI roi = {}, int nthreads = 0)
```

Write to an existing image dst (allocating if it is uninitialized).

Examples:

**C++**

```c++
// Invert all channels of A
ImageBuf A("a.exr");
ImageBuf Inverse = ImageBufAlgo::invert (Inverse, A);

// In this example, we are careful to deal with alpha in an RGBA image.
// First we copy A to Inverse, un-premultiply the color values by alpha,
// invert just the color channels in-place, and then re-premultiply the colors by alpha.
// colors by alpha.
roi = A.roi();
roi.chend = 3;     // Restrict roi to only R,G,B
ImageBuf Inverse = ImageBufAlgo::unpremult (A);
ImageBufAlgo::invert (Inverse, Inverse, roi);
ImageBufAlgo::repremult (Inverse, Inverse);
```

**Python**

```python
# Invert all channels of A
A = ImageBuf("a.exr")
Inverse = ImageBufAlgo.invert (Inverse, A)

# In this example, we are careful to deal with alpha in an RGBA image.
# First we copy A to Inverse, un-premultiply the color values by alpha,
# invert just the color channels in-place, and then re-premultiply the colors by alpha.
# colors by alpha.
roi = A.roi.copy()
roi.chend = 3  # Restrict roi to only R,G,B
Inverse = ImageBufAlgo.unpremult (A)
ImageBufAlgo.invert (Inverse, Inverse, roi)
ImageBufAlgo.repremult (Inverse, Inverse)
```

**ooiotool**

```bash
# Invert all channels of A, including alpha.
# Because oiiotool --invert by default includes only the first 3 channels, we have to use optional modifiers to include alpha.
oiiotool a.exr --invert:chbegin=0:chend=3 -o inverse.exr

# In this example, invert only the RGB channels (which is the default behavior of oiiotool --invert) and also we un-premultiply the color
```

(continues on next page)
# values by alpha, invert, and then re-premultiply the colors by alpha.

oiio tool a.exr --unpremult --invert --repremult -o inverse.exr

```cpp
OIIO::ImageBufAlgo::pow(const ImageBuf &A, cspan<float> B, ROI roi = {}, int nthreads = 0)
```

Compute per-pixel raise-to-power $A^B$ returning the result image. It is permitted for $\text{dst}$ and $A$ to be the same image.

$A$ is always an image, and $B$ is either an image or a `cspan<float>` giving a per-channel constant or a single constant used for all channels.

Result-as-parameter version:

```cpp
bool OIIO::ImageBufAlgo::pow(ImageBuf &dst, const ImageBuf &A, cspan<float> B, ROI roi = {}, int nthreads = 0)
```

Write to an existing image $\text{dst}$ (allocating if it is uninitialized).

Examples:

**C++**

```cpp
// Gamma-correct by 2.2 channels 0-2 of the image, in-place
ImageBuf A ("a.exr");
const float g = 1.0f / 2.2f;
ImageBufAlgo::pow (A, A, { g, g, g, 1.0f });
```

**Python**

```python
```

10.4. Image arithmetic 251
# Gamma-correct by 2.2 channels 0-2 of the image, in-place
A = ImageBuf("a.exr")
g = 1.0 / 2.2
ImageBufAlgo.pow (A, A, (g, g, g, 1))

oiiootool

# Gamma-correct by 2.2 channels 0-2 of the image, in-place
oiiootool a.exr --powc 0.4545,0.4545,0.4545,1.0 -o a.exr

ImageBuf::ImageBufAlgo::channel_sum(const ImageBuf &src, cspan<float> weights = 1.0f, ROI roi = {}, int nthreads = 0)
Converts a multi-channel image into a one-channel image via a weighted sum of channels:

(channel[0]*weight[0] + channel[1]*weight[1] + ...)

returning the resulting one-channel image. The weights, if not supplied, default to \(1, 1, 1, \ldots\)

Result-as-parameter version:

bool OIIIO::ImageBufAlgo::channel_sum(ImageBuf &dst, const ImageBuf &src, cspan<float> weights = 1.0f, ROI roi = {}, int nthreads = 0)

Write to an existing image dst (allocating if it is uninitialized).

Examples:
Compute luminance via a weighted sum of R,G,B (assuming Rec709 primaries and a linear scale):

C++

// Compute luminance via a weighted sum of R,G,B
// (assuming Rec709 primaries and a linear scale)
float luma_weights[3] = { .2126, .7152, .0722, 0.0 }; ImageBuf A ("a.exr");
ImageBuf lum = ImageBufAlgo::channel_sum (A, luma_weights);

Python

# Compute luminance via a weighted sum of R,G,B
# (assuming Rec709 primaries and a linear scale)
A = ImageBuf("a.exr")
lum = ImageBufAlgo.channel_sum (A, (.2126, .7152, .0722, 0.0))

oiiootool

# Compute luminance via a weighted sum of R,G,B
# (assuming Rec709 primaries and a linear scale)
oiiootool a.exr --chsum 0.2126,0.7152,0.0722,0.0 -o lum.exr
Max, min, clamp

*group maxminclamp*

`max()` and `min()` take the pixel-by-pixel, channel-by-channel maximum and minimum of two images, or of an image and a constant.

`clamp()` restricts values of an image to the range between per-channel minimum and maximum constant values.

**Functions**

`ImageBuf max (Image_or_Const A, Image_or_Const B, ROI roi = {}, int nthreads = 0)`

Compute per-pixel $\max(A, B)$, returning the result image.

Either both $A$ and $B$ are images, or one is an image and the other is a `cspan<float>` giving a per-channel constant or a single constant used for all channels.

`bool max (ImageBuf &dst, Image_or_Const A, Image_or_Const B, ROI roi = {}, int nthreads = 0)`

Write to an existing image `dst` (allocating if it is uninitialized).

`ImageBuf min (Image_or_Const A, Image_or_Const B, ROI roi = {}, int nthreads = 0)`

Compute per-pixel $\min(A, B)$, returning the result image.

Either both $A$ and $B$ are images, or one is an image and the other is a `cspan<float>` giving a per-channel constant or a single constant used for all channels.

`bool min (ImageBuf &dst, Image_or_Const A, Image_or_Const B, ROI roi = {}, int nthreads = 0)`

Write to an existing image `dst` (allocating if it is uninitialized).

`ImageBuf clamp(const ImageBuf &src, cspan<float> min = -std::numeric_limits<float>::max(), cspan<float> max = std::numeric_limits<float>::max(), bool clampalpha01 = false, ROI roi = {}, int nthreads = 0)`

Return pixels of `src` with pixel values clamped as follows:

**Parameters**

- `min`: The minimum clamp value for each channel. If `min` is empty, no minimum clamping is performed.
- `max`: The maximum clamp value for each channel. If `max` is empty, no maximum clamping is performed.
- `clampalpha01`: If true, then additionally any alpha channel is clamped to the 0-1 range.

`bool clamp (ImageBuf &dst, const ImageBuf &src, cspan<float> min = -std::numeric_limits<float>::max(), cspan<float> max = std::numeric_limits<float>::max(), bool clampalpha01 = false, ROI roi = {}, int nthreads = 0)`

Write to an existing image `dst` (allocating if it is uninitialized).

**Examples:**

C++

```cpp
// min of images A and B, assign to MinImage
ImageBuf A ("a.exr");
ImageBuf B ("b.exr");
ImageBuf MinImage = ImageBufAlgo::min (Sum, A, B);

// Squash negative values in A by taking max(A, 0.0) for all channels
ImageBuf A ("a.exr");
ImageBufAlgo::max (A, A, 0.0f);```

(continues on next page)
// Clamp image buffer A in-place to the \([0,1]\) range for all pixels.
ImageBufAlgo::clamp (A, A, 0.0f, 1.0f);

// Just clamp alpha to \([0,1]\) in-place
ImageBufAlgo::clamp (A, A, -std::numeric_limits<float>::max(),
                      std::numeric_limits<float>::max(), true);

// Clamp R & G to \([0,0.5]\), leave other channels alone
std::vector<float> min (A.nchannels(), -std::numeric_limits<float>::max());
std::vector<float> max (A.nchannels(), std::numeric_limits<float>::max());
min[0] = 0.0f; max[0] = 0.5f;
min[1] = 0.0f; max[1] = 0.5f;
ImageBufAlgo::clamp (A, A, &min[0], &max[0], false);

Python

# min of images A and B, assign to MinImage
A = ImageBuf("a.exr")
B = ImageBuf("b.exr")
MinImage = ImageBufAlgo.min (Sum, A, B)

# Squash negative values in A by taking max(A, 0.0) for all channels
A = ImageBuf("a.exr")
ImageBufAlgo.max (A, A, 0.0)

# Clamp image buffer A in-place to the \([0,1]\) range for all pixels.
ImageBufAlgo.clamp (A, A, 0.0, 1.0)

# Just clamp alpha to \([0,1]\) in-place
ImageBufAlgo.clamp (A, A, -1.0e30, 1.0e30, True)

# Clamp R & G to \([0,0.5]\), leave other channels alone
ImageBufAlgo.clamp (A, A, (0, 0, -1.0e30, -1.0e30),
                     (0.5, 0.5, 1.0e30, 1.0e30), False)

oiiootool

# min of images A and B, assign to MinImage
oiiootool a.exr b.exr --min -o minimage.exr

# Squash negative values in A by taking max(A, 0.0) for all channels
oiiootool.exr a.exr --maxc 0 -o a.exr

# Clamp image buffer A in-place to the \([0,1]\) range for all pixels.
oiiootool.exr a.exr --clamp:min=0:max=1 -o a.exr

# Just clamp alpha to \([0,1]\) in-place
oiiootool.exr a.exr --clamp:min=,,,0:max=,,,1 -o a.exr

# Clamp R & G to \([0,0.5]\), leave other channels alone
oiiootool.exr a.exr --clamp:min=0,,,max=1,,, -o a.exr
group maxminchan

maxchan() computes a one-channel image that for each pixel, contains the maximum value of all channels of corresponding pixel of the source image. minchan() similarly computes the minimum value of all channels.

Version 2.3.10

Functions

ImageBuf maxchan (const ImageBuf &A, ROI roi = {}, int nthreads = 0)
bool maxchan (ImageBuf &dst, const ImageBuf &A, ROI roi = {}, int nthreads = 0)
ImageBuf minchan (const ImageBuf &src, ROI roi = {}, int nthreads = 0)
bool minchan (ImageBuf &dst, const ImageBuf &src, ROI roi = {}, int nthreads = 0)

Examples:

C++

```cpp
// Computes the maximum of R, G, B.
ImageBuf A ("rgb.exr");
ImageBuf B = ImageBufAlgo::maxchan (A);
```

Python

```python
# Computes the maximum of R, G, B.
A = ImageBuf("a.exr")
B = ImageBufAlgo.maxchan (A)
```

oiiotool

```bash
# Computes the maximum of R, G, B.
oiiotool a.exr -maxchan -o b.exr
```

ImageBuf OIIO::ImageBufAlgo::contrast_remap (const ImageBuf &src, cspan<float> black = 0.0f, cspan<float> white = 1.0f, cspan<float> min = 0.0f, cspan<float> max = 1.0f, cspan<float> scontrast = 1.0f, cspan<float> sthresh = 0.5f, ROI roi = {}, int nthreads = 0)

Return pixel values that are a contrast-remap of the corresponding values of the src image, transforming pixel value domain [black, white] to range [min, max], either linearly or with optional application of a smooth sigmoidal remapping (if scontrast != 1.0).

The following steps are performed, in order:

a. Linearly rescale values [black, white] to [0, 1].

b. If scontrast != 1, apply a sigmoidal remapping where a larger scontrast value makes a steeper slope, and the steepest part is at value sthresh (relative to the new remapped value after steps 1 & 2; the default is 0.5).
c. Rescale the range of that result: 0.0 -> min and 1.0 -> max.

Values outside of the [black,white] range will be extrapolated to outside [min,max], so it may be prudent to apply a `clamp()` to the results.

The black, white, min, max, scontrast, sthresh parameters may each either be a single float value for all channels, or a span giving per-channel values.

You can use this function for a simple linear contrast remapping of [black, white] to [min, max] if you use the default values for sthresh. Or just a simple sigmoidal contrast stretch within the [0,1] range if you leave all other parameters at their defaults, or a combination of these effects. Note that if black == white, the result will be a simple binary thresholding where values < black map to min and values >= black map to max.

Result-as-parameter version:

```cpp
bool OIIO::ImageBufAlgo::contrast_remap(ImageBuf &dst, const ImageBuf &src, cspan<float> black = 0.0f, cspan<float> white = 1.0f, cspan<float> min = 0.0f, cspan<float> max = 1.0f, cspan<float> scontrast = 1.0f, cspan<float> sthresh = 0.5f, ROI = {}, int nthreads = 0)
```

Write to an existing image `dst` (allocating if it is uninitialized).

Examples:

C++

```cpp
ImageBuf A ("tahoe.tif");
// Simple linear remap that stretches input 0.1 to black, and input // 0.75 to white.
ImageBuf linstretch = ImageBufAlgo::contrast_remap (A, 0.1f, 0.75f);

// Remapping 0->1 and 1->0 inverts the colors of the image, // equivalent to ImageBufAlgo::invert().
ImageBuf inverse = ImageBufAlgo::contrast_remap (A, 1.0f, 0.0f);

// Use a sigmoid curve to add contrast but without any hard cutoffs. // Use a contrast parameter of 5.0.
ImageBuf sigmoid = ImageBufAlgo::contrast_remap (A, 0.0f, 1.0f, 0.0f, 1.0f, 5.0f);
```

Python

```python
A = ImageBuf("tahoe.tif")
# Simple linear remap that stretches input 0.1 to black, and input # 0.75 to white.
linstretch = ImageBufAlgo.contrast_remap (A, 0.1, 0.75)

# Remapping 0->1 and 1->0 inverts the colors of the image, # equivalent to ImageBufAlgo:invert().
inverse = ImageBufAlgo.contrast_remap (A, 1.0, 0.0)

# Use a sigmoid curve to add contrast but without any hard cutoffs. # Use a contrast parameter of 5.0.
sigmoid = ImageBufAlgo.contrast_remap (A, 0.0, 1.0, 0.0, 1.0, 5.0)
```
oiiootool

```plaintext
# Simple linear remap that stretches input 0.1 to black, and input
# 0.75 to white.
oiiotool tahoe.exr --contrast:black=0.1:white=0.75 -o linstretch.exr

# Remapping 0->1 and 1->0 inverts the colors of the image,
# equivalent to ImageBufAlgo::invert().
oiiotool tahoe.tif --contrast:black=1.0:white=0.0:clamp=0 -o inverse.tif

# Use a sigmoid curve to add contrast but without any hard cutoffs.
# Use a contrast parameter of 5.0.
oiiotool tahoe.tif --contrast:scontrast=5 -o sigmoid.tif
```

![original linstretch inverse sigmoid](https://via.placeholder.com/150)

| original | linstretch | inverse | sigmoid |

**group saturate**

Increase or decrease color saturation of the image.

The saturate operation returns (or copies into dst) the pixels of src within the ROI, and in the process adjusts the color saturation of the three consecutive channels starting with firstchannel based on the scale parameter: 0.0 fully desaturates to a greyscale image of perceptually equivalent luminance, 1.0 leaves the colors unchanged, scale values inside this range interpolate between them, and scale > 1 would increase apparent color saturation.

Channels that are within the range of roi.chbegin to roi.chend-1, but outside the range of firstchannel to firstchannel+2 are simply copied unaltered. Only three channels at a time can be desaturated, by default the first three channels, though firstchannel may be used to specify a different subset of channels. It is allowed for src and dst to be the same image.

**Version** 2.4+

**Functions**

ImageBuf saturate (const ImageBuf &src, float scale = 0.0f, int firstchannel = 0, ROI roi = {}, int nthreads = 0)

bool saturate (ImageBuf &dst, const ImageBuf &src, float scale = 0.0f, int firstchannel = 0, ROI roi = {}, int nthreads = 0)

Examples:

C++
ImageBuf img("tahoe.exr");
ImageBuf grey = ImageBufAlgo::saturate (img, 0.0f);
ImageBuf colorful = ImageBufAlgo::saturate (img, 2.0f);

Python

img = ImageBuf("tahoe.exr")
grey = ImageBufAlgo.saturate (img, 0.0)
colorful = ImageBufAlgo.saturate (img, 2.0)

oiiotool

oiiotool tahoe.exr -saturate 0.0 -o grey.exr
oiiotool tahoe.exr -saturate 2.0 -o colorful.exr

group color_map

Remap value range by spline or name

Return (or copy into dst) pixel values determined by looking up a color map using values of the source image, using either the channel specified by srcchannel, or the luminance of src’s RGB if srcchannel is -1. This happens for all pixels within the ROI (which defaults to all of src), and if dst is not already initialized, it will be initialized to the ROI and with color channels equal to channels.

In the variant that takes a knots parameter, this specifies the values of a linearly-interpolated color map given by knots[nknots*channels]. An input value of 0.0 is mapped to knots[0..channels-1] (one value for each color channel), and an input value of 1.0 is mapped to knots[(nknots-1)*channels..knots.size()-1].

In the variant that takes a mapname parameter, this is the name of a color map. Recognized map names include: “inferno”, “viridis”, “magma”, “plasma”, all of which are perceptually uniform, strictly increasing in luminance, look good when converted to grayscale, and work for people with all types of colorblindness. Also “turbo” has most of these properties (except for being strictly increasing in luminance) and is a nice rainbow-like pattern. Also supported are the following color maps that do not have those desirable qualities (and are thus not recommended, but are present for back-compatibility or for use by clueless people): “blue-red”, “spectrum”, and “heat”. In all cases, the implied channels is 3.
Functions

ImageBuf color_map(const ImageBuf &src, int srcchannel, int nknots, int channels, cspan<float> knots, ROI roi = {}, int nthreads = 0)

ImageBuf color_map(const ImageBuf &src, int srcchannel, string_view mapname, ROI roi = {}, int nthreads = 0)

bool color_map(ImageBuf &dst, const ImageBuf &src, int srcchannel, int nknots, int channels, cspan<float> knots, ROI roi = {}, int nthreads = 0)

bool color_map(ImageBuf &dst, const ImageBuf &src, int srcchannel, string_view mapname, ROI roi = {}, int nthreads = 0)

Examples:

C++

```cpp
// Use luminance of a.exr (assuming Rec709 primaries and a linear scale) and map to a spectrum-like palette:
ImageBuf A ("a.exr");
ImageBuf B = ImageBufAlgo::color_map (A, -1, "turbo");
```

Python

```python
# Use luminance of a.exr (assuming Rec709 primaries and a linear scale) and map to a spectrum-like palette:
A = ImageBuf("a.exr")
B = ImageBufAlgo.color_map (A, -1, "turbo")
```

oiiotool

```bash
# Use luminance of a.exr (assuming Rec709 primaries and a linear scale) and map to a spectrum-like palette:
oiiotool a.exr --colormap turbo -o b.exr
```

```
original inferno viridis turbo custom values
```

*group range*

Nonlinear range remapping for contrast preservation
**rangecompress()** returns (or copy into dst) all pixels and color channels of src within region roi (defaulting to all the defined pixels of dst), rescaling their range with a logarithmic transformation. Alpha and z channels are not transformed.

**rangeexpand()** performs the inverse transformation (logarithmic back into linear).

If useluma is true, the luma of channels [roi.chbegin..roi.chbegin+2] (presumed to be R, G, and B) are used to compute a single scale factor for all color channels, rather than scaling all channels individually (which could result in a color shift).

The purpose of these function is as follows: Some image operations (such as resizing with a “good” filter that contains negative lobes) can have objectionable artifacts when applied to images with very high-contrast regions involving extra bright pixels (such as highlights in HDR captured or rendered images). By compressing the range pixel values, then performing the operation, then expanding the range of the result again, the result can be much more pleasing (even if not exactly correct).

**Functions**

ImageBuf **rangecompress** (const ImageBuf & src, bool useluma = false, ROI roi = {}, int nthreads = 0)

ImageBuf **rangeexpand** (const ImageBuf & src, bool useluma = false, ROI roi = {}, int nthreads = 0)

bool **rangecompress** (ImageBuf & dst, const ImageBuf & src, bool useluma = false, ROI roi = {}, int nthreads = 0)

bool **rangeexpand** (ImageBuf & dst, const ImageBuf & src, bool useluma = false, ROI roi = {}, int nthreads = 0)

**Examples:**

In this example, we resize the image to 640x480, using a Lanczos3 filter, which has negative lobes. To prevent those negative lobes from producing ringing or negative pixel values for HDR data, do range compression, then resize, then re-expand the range.

**C++**

```cpp
// 1. Read the original image
ImageBuf Src ("tahoeHDR.exr");

// 2. Range compress to a logarithmic scale
ImageBuf Compressed = ImageBufAlgo::rangecompress (Src);

// 3. Now do the resize
ImageBuf Dst = ImageBufAlgo::resize (Compressed, "lanczos3", 6.0f, ROI(0, 640, 0, 480));

// 4. Expand range to be linear again (operate in-place)
ImageBufAlgo::rangeexpand (Dst, Dst);
```

**Python**

```python
# 1. Read the original image
Src = ImageBuf("tahoeHDR.exr")

# 2. Range compress to a logarithmic scale
Compressed = ImageBufAlgo.rangecompress (Src)

# 3. Now do the resize

### (continues on next page)
Dst = ImageBufAlgo.resize (Compressed, "lanczos3", 6.0, ROI(0, 640, \rightarrow 0, 480))

# 4. Expand range to be linear again (operate in-place)
ImageBufAlgo.rangeexpand (Dst, Dst)

oiio
tahoeHDR.exr --rangecompress --resize 640x480 --rangeexpand
\rightarrow -o out.exr

# Alternately, the --resize command has an option to do the
# range compression/expansion on its own:
oiio
tahoeHDR.exr --resize:highlightcomp=1 640x480 -o out.exr

10.5 Image comparison and statistics

PixelStats OIIO::ImageBufAlgo::computePixelStats (const ImageBuf &src, ROI roi = {}, int nthreads = 0)
Compute statistics about the ROI of the src image, returning a PixelStats structure. Upon success, the returned vectors in the result structure will have size == src.nchannels(). If there is a failure, the vector sizes will be 0 and an error will be set in src.

The PixelStats structure is defined as follows in C++:

```cpp
struct PixelStats {
    std::vector<float> min;
    std::vector<float> max;
    std::vector<float> avg;
    std::vector<float> stddev;
    std::vector<imagesize_t> nancount;
    std::vector<imagesize_t> infcount;
    std::vector<imagesize_t> finitecount;
};
```

Examples:

C++

```cpp
ImageBuf A ("a.exr");
auto stats = ImageBufAlgo::computePixelStats(A);
if (stats.min.size() == 0) return; // empty vectors means we could not get the stats
for (int c = 0; c < A.nchannels(); ++c) {
    std::cout << "Channel " << c << ":
    std::cout << " min = " << stats.min[c] << "\n";
    std::cout << " max = " << stats.max[c] << "\n";
    std::cout << " average = " << stats.avg[c] << "\n";
    std::cout << " standard deviation = " << stats.stddev[c] << "\n";
    std::cout << " NaN values = " << stats.nancount[c] << "\n";
    std::cout << " Inf values = " << stats.infcount[c] << "\n";
    std::cout << " finite values = " << stats.finitecount[c] << "\n";
}
```

(continues on next page)
Python

```python
A = ImageBuf("a.exr")
stats = ImageBufAlgo.computePixelStats(A)
if stats is None:
    return
for c in A.channels:
    print("Channel", c, ":")
    print(" min =", stats.min[c])
    print(" max =", stats.max[c])
    print(" average =", stats.avg[c])
    print(" standard deviation =", stats.stddev[c])
    print(" # NaN values =", stats.nancount[c])
    print(" # Inf values =", stats.infcount[c])
    print(" # finite values =", stats.finitecount[c])
```

-oiiotool

```bash
oiiotool -stats -v a.exr
```

**CompareResults**

```cpp
OIIO::ImageBufAlgo::compare (const ImageBuf &A, const ImageBuf &B, float failthresh, float warnthresh, ROI roi = {}, int nthreads = 0)
```

Numerically compare two images. The difference threshold (for any individual color channel in any pixel) for a “failure” is failthresh, and for a “warning” is warnthresh. The results are stored in result. If roi is defined, pixels will be compared for the pixel and channel range that is specified. If roi is not defined, the comparison will be for all channels, on the union of the defined pixel windows of the two images (for either image, undefined pixels will be assumed to be black).

The CompareResults structure is defined in C++ as follows:

```cpp
struct CompareResults {
    double meanerror, rms_error, PSNR, maxerror;
    int maxx, maxy, maxz, maxc;
    imagesize_t nwarn, nfail;
    bool error;
};
```

Examples:

```cpp
ImageBuf A ("a.exr");
ImageBuf B ("b.exr");
auto comp = ImageBufAlgo::compare(A, B, 1.0f/255.0f, 0.0f);
if (comp.nwarn == 0 && comp.nfail == 0) {
    std::cout << "Images match within tolerance\n"
} else {
    std::cout << "Image differed: " << comp.nfail << " failures, "
```

(continues on next page)
<< comp.nwarn << " warnings.
std::cout << "Average error was " << comp.meanerror << "\n";
std::cout << "RMS error was " << comp.rms_error << "\n";
std::cout << "PSNR was " << comp.PSNR << "\n";
std::cout << "largest error was " << comp.maxerror
<< " on pixel (" << comp maxx << "," << comp.maxy
<< "," << comp.maxz << ")", channel " << comp.maxc << "\n";
}

Python

A = ImageBuf("a.exr")
B = ImageBuf("b.exr")
comp = ImageBufAlgo.compare(A, B, 1.0f/255.0f, 0.0f)
if comp.nwarn == 0 and comp.nfail == 0 :
  print("Images match within tolerance")
else :
  print("Image differed:", comp.nfail, "failures,", comp.nwarn, "warnings.
    ")
  print("Average error was", comp.meanerror)
  print("RMS error was", comp.rms_error)
  print("PSNR was", comp.PSNR)
  print("largest error was", comp.maxerror, "on pixel (",
    comp.maxx, ",", comp.maxy, ",", comp.maxz, ")", channel", comp.
    
    maxc)

oiiotool

oiiotool a.exr b.exr --diff

int OIIIO::ImageBufAlgo::compare_Yee(const ImageBuf &A, const ImageBuf &B, CompareResults &result, float luminance = 100, float fov = 45, ROI roi = {}, int nthreads = 0)

Compare two images using Hector Yee’s perceptual metric, returning the number of pixels that fail the comparison. Only the first three channels (or first three channels specified by roi) are compared. Free parameters are the ambient luminance in the room and the field of view of the image display; our defaults are probably reasonable guesses for an office environment. The ‘result’ structure will store the maxerror, and the maxx, maxy, maxz of the pixel that failed most severely. (The other fields of the CompareResults are not used for Yee comparison.)

Works for all pixel types. But it’s basically meaningless if the first three channels aren’t RGB in a linear color space that sort of resembles AdobeRGB.

Return true on success, false on error.

bool OIIIO::ImageBufAlgo::isConstantColor(const ImageBuf &src, float threshold = 0.0f, span<float> color = {}, ROI roi = {}, int nthreads = 0)

Do all pixels within the ROI have the same values for channels [roi.chbegin..roi.chend-1], within
a tolerance of +/- threshold? If so, return true and store that color in color[chbegin...chend-1] (if color is not empty); otherwise return false. If roi is not defined (the default), it will be understood to be all of the defined pixels and channels of source.

Examples:

C++

```cpp
ImageBuf A ("a.exr");
std::vector<float> color (A.nchannels());
if (ImageBufAlgo::isConstantColor (A, color)) {
    std::cout << "The image has the same value in all pixels: ";
    for (int c = 0; c < A.nchannels(); ++c)
        std::cout << (c ? " " : "") << color[c];
    std::cout << "\n";
} else {
    std::cout << "The image is not a solid color.\n";
}
```

Python

```python
A = ImageBuf ("a.exr")
color = ImageBufAlgo.isConstantColor (A, color)
if color is not None :
    print ("The image has the same value in all pixels: ", color)
else :
    print ("The image is not a solid color.")
```

bool OIIIO::ImageBufAlgo::isConstantChannel(const ImageBuf &src, int channel, float val, float threshold = 0.0f, ROI roi = {}, int nthreads = 0)

Does the requested channel have a given value (within a tolerance of +/- threshold) for every channel within the ROI? (For this function, the ROI’s chbegin/chend are ignored.) Return true if so, otherwise return false. If roi is not defined (the default), it will be understood to be all of the defined pixels and channels of source.

Examples:

C++

```cpp
ImageBuf A ("a.exr");
int alpha = A.spec().alpha_channel;
if (alpha < 0)
    std::cout << "The image does not have an alpha channel\n";
else if (ImageBufAlgo::isConstantChannel (A, alpha, 1.0f))
    std::cout << "The image has alpha = 1.0 everywhere\n";
else
    std::cout << "The image has alpha != 1 in at least one pixel\n";
```

Python

```python
A = ImageBuf ("a.exr")
alpha = A.spec.alpha_channel
if alpha < 0 :
    print ("The image does not have an alpha channel")
```

(continues on next page)
else if ImageBufAlgo.isConstantChannel (A, alpha, 1.0f) :
    print ("The image has alpha = 1.0 everywhere")
else
    print ("The image has alpha != 1 in at least one pixel")

bool OIIIO::ImageBufAlgo::isMonochrome (const ImageBuf &src, float threshold = 0.0f, ROI roi =
{} , int nthreads = 0)
Is the image monochrome within the ROI, i.e., for every pixel within the region, do all channels [roi.chbegin,
roi.chend) have the same value (within a tolerance of +/- threshold)? If roi is not defined (the default), it will be
understood to be all of the defined pixels and channels of source.

Examples:
C++

ImageBuf A ("a.exr");
ROI roi = get_roi (A.spec());
roi.chend = std::min (3, roi.chend); // only test RGB, not alpha
if (ImageBufAlgo::isMonochrome (A, roi))
    std::cout << "a.exr is really grayscale\n";

Python

A = ImageBuf("a.exr")
roi = A.roi.copy()
roi.chend = min(3, roi.chend)
if ImageBufAlgo.isMonochrome(A, roi) :
    print("a.exr is really grayscale")

bool OIIIO::ImageBufAlgo::color_count (const ImageBuf &src, imagesize_t *count, int ncolors,
cspan<float> color, cspan<float> eps = 0.001f, ROI roi =
{} , int nthreads = 0)
Count how many pixels in the ROI match a list of colors. The colors to match are in:

colors[0 ... nchans-1]
colors[nchans ... 2*nchans-1]
...
colors[(ncolors-1)*nchans ... (ncolors*nchans)-1]

and so on, a total of ncolors consecutively stored colors of nchans channels each (nchans is the number
of channels in the image, itself, it is not passed as a parameter).

eps[0..nchans-1] are the error tolerances for a match, for each channel. Setting eps[c] =
numeric_limits<float> max() will effectively make it ignore the channel. The default eps is 0.001
for all channels (this value is chosen because it requires exact matches for 8 bit images, but allows a wee bit of
imprecision for float images.

10.5. Image comparison and statistics
Upon success, return `true` and store the number of pixels that matched each color `count[0..ncolors-1]`. If there is an error, returns `false` and sets an appropriate error message set in `src`.

Examples:

**C++**

```cpp
ImageBuf A ("a.exr");
int n = A.nchannels();

// Try to match two colors: pure red and green
std::vector<float> colors (2*n, numeric_limits<float>::max());
colors[0] = 1.0f; colors[1] = 0.0f; colors[2] = 0.0f;
colors[n+0] = 0.0f; colors[n+1] = 1.0f; colors[n+2] = 0.0f;
const int ncolors = 2;
imagesize_t count[ncolors];
ImageBufAlgo::color_count (A, count, ncolors);
std::cout << "Number of red pixels : " << count[0] << "\n";
std::cout << "Number of green pixels : " << count[1] << "\n";
```

**oiiotool**

```
oiiotool a.exr --colorcount "1,0,0;0,1,0"
```

```cpp
bool OIIIO::ImageBufAlgo::color_range_check (const ImageBuf &src, imagesize_t *lowcount, imagesize_t *highcount, imagesize_t *inrangeCount, cspan<float> low, cspan<float> high, ROI roi = {}, int nthreads = 0)

Count how many pixels in the image (within the `ROI`) are outside the value range described by `low[roi.chbegin..roi.chend-1]` and `high[roi.chbegin..roi.chend-1]` as the low and high acceptable values for each color channel.

The number of pixels containing values that fall below the lower bound will be stored in `*lowcount`, the number of pixels containing values that fall above the upper bound will be stored in `*highcount`, and the number of pixels for which all channels fell within the bounds will be stored in `*inrangeCount`. Any of these may be NULL, which simply means that the counts need not be collected or stored.

**C++**

```cpp
ImageBuf A ("a.exr");
ROI roi = get_roi (A.spec());
roi.chend = std::min (roi.chend, 4); // only compare RGBA
float low[] = {0, 0, 0, 0};
float high[] = {1, 1, 1, 1};
imagesize_t lowcount, highcount, inrangeCount;
ImageBufAlgo::color_range_check (A, &lowcount, &highcount, &inrangeCount, low, high, roi);
std::cout << lowcount << " pixels had components < 0\n";
std::cout << highcount << " pixels had components > 1\n";
std::cout << inrangeCount << " pixels were fully within [0,1] range\n";
```

Python
A = ImageBuf("a.exr")
roi = A.roi.copy()
roi.chend = min (roi.chend, 4)  # only compare RGBA

low = (0, 0, 0, 0)
high = (1, 1, 1, 1)

lowcount, highcount, inrangecount = ImageBufAlgo.color_range_check (A, low, high, roi)
print(lowcount, "pixels had components < 0")
print(highcount, "pixels had components > 1")
print(inrangecount, "pixels were fully within [0,1] range")

oiio
oiio tool a.exr --rangecheck "0,0,0,0;1,1,1,1"

ROI OIIIO::ImageBufAlgo::nonzero_region (const ImageBuf &src, ROI roi = {}, int nthreads = 0)
Find the minimal rectangular region within roi (which defaults to the entire pixel data window of src) that consists of nonzero pixel values. In other words, gives the region that is a “shrink-wraps” of src to exclude black border pixels. Note that if the entire image was black, the ROI returned will contain no pixels.

For “deep” images, this function returns the smallest ROI that contains all pixels that contain depth samples, and excludes the border pixels that contain no depth samples at all.

Examples:
C++

ImageBuf A ("a.exr");
ROI shrunk = ImageBufAlgo::nonzero_region (A);
if (shrunk.undefined())
    std::cout << "All pixels were empty\n"
else
    std::cout << "Non-empty region was " << shrunk << "\n";

Python

A = ImageBuf("a.exr")
shrunk = ImageBufAlgo.nonzero_region (A)
if not shrunk.defined:
    print ("All pixels were empty")
else:
    print ("Non-empty region was", shrunk)

std::string OIIIO::ImageBufAlgo::computePixelHashSHA1 (const ImageBuf &src, string_view extrainfo = "", ROI roi = {}, int block-size = 0, int nthreads = 0)
Compute the SHA-1 byte hash for all the pixels in the specified region of the image. If blocksize > 0, the function will compute separate SHA-1 hashes of each blocksize batch of scanlines, then return a hash of the individual hashes. This is just as strong a hash, but will NOT match a single hash of the entire image (blocksize==0). But by breaking up the hash into independent blocks, we can parallelize across multiple threads, given by nthreads (if nthreads is 0, it will use the global OIIO thread count). The extrainfo provides additional text that will be incorporated into the hash.

Examples:

C++

```cpp
ImageBuf A ("a.exr");
std::string hash;
hash = ImageBufAlgo::computePixelHashSHA1 (A, "", ROI::All(), 64);
```

Python

```python
A = ImageBuf("a.exr")
hash = ImageBufAlgo.computePixelHashSHA1 (A, blocksize=64)
```

std::vector<imagesize_t> OIIO::ImageBufAlgo::histogram(const ImageBuf &src, int channel = 0, int bins = 256, float min = 0.0f, float max = 1.0f, bool ignore_empty = false, ROI roi = {}, int nthreads = 0)

Compute a histogram of src, for the given channel and ROI. Return a vector of length bins that contains the counts of how many pixel values were in each of bins equally spaced bins covering the range of values [min,max]. Values < min count for bin 0, values > max count for bin nbins-1. If ignore_empty is true, no counts will be incremented for any pixels whose value is 0 in all channels.

If there was an error, the returned vector will be empty, and an error message will be retrievable from src.geterror().

Examples:

C++

```cpp
ImageBuf Src ("tahoe.exr");
const int bins = 4;
auto hist = ImageBufAlgo::histogram (Src, 0, bins, 0.0f, 1.0f);
std::cout << "Channel 0 of the image had:
";
float binsize = (max-min)/nbins;
for (int i = 0; i < nbins; ++i)
    hist[i] << " pixels that are >= " << (min+i*binsize) << " and "
    << (i == nbins-1 ? " <= " : " < ")
    << (min+(i+1)*binsize) << "\n";
```

Python

```python
Src = ImageBuf("tahoe.exr")
bins = 4
hist = ImageBufAlgo.histogram (Src, channel=0, bins=4, min=0.0, max=1.0)
print ("Channel 0 of the image had:")
binsize = (max-min)/nbins
for i in range(nbins) :
    pass
```

(continues on next page)
print (hist[i], "pixels that are \( \geq \)", (min+i*binsize), "and",
("\leq" if i == nbins-1 else ")", (min+(i+1)*binsize))

10.6 Convolutions and frequency-space algorithms

ImageBuf OIIIO::ImageBufAlgo::make_kernel(string_view name, float width, float height, float depth = 1.0f, bool normalize = true)

Make a 1-channel float image of the named kernel. The size of the image will be big enough to contain the kernel given its size (width x height) and rounded up to odd resolution so that the center of the kernel can be at the center of the middle pixel. The kernel image will be offset so that its center is at the (0,0) coordinate. If normalize is true, the values will be normalized so that they sum to 1.0. If depth > 1, a volumetric kernel will be created. Use with caution!

Note that “catmull-rom” and “lanczos3” are fixed-size kernels that don’t scale with the width, and are therefore probably less useful in most cases.

The ImageBuf that is returned indicates if there was an error, in which case return.has_error() will be true and return.geterror() can be used to retrieve an error message.

Examples:

C++

```cpp
ImageBuf K = ImageBufAlgo::make_kernel ("gaussian", 5.0f, 5.0f);
```

Python

```python
K = ImageBufAlgo.make_kernel ("gaussian", 5.0, 5.0)
```

Oiiotool

```bash
oiiotool --makekernel gaussian 5x5 -o kernel.exr
```

ImageBuf OIIIO::ImageBufAlgo::convolve(const ImageBuf &src, const ImageBuf &kernel, bool normalize = true, ROI roi = {}, int nthreads = 0)

Return the convolution of src and a kernel. If roi is not defined, it defaults to the full size src. If normalized is true, the kernel will be normalized for the convolution, otherwise the original values will be used.

Result-as-parameter version:

```cpp
bool OIIIO::ImageBufAlgo::convolve(ImageBuf &dst, const ImageBuf &src, const ImageBuf &kernel, bool normalize = true, ROI roi = {}, int nthreads = 0)
```

Write to an existing image dst (allocating if it is uninitialized). If roi is not defined, it defaults to the full size of dst (or src, if dst was uninitialized). If dst is uninitialized, it will be allocated to be the size specified by roi.
Examples:

C++

```cpp
// Blur an image with a 5x5 Gaussian kernel
ImageBuf Src ("tahoe.exr");
ImageBuf K = ImageBufAlgo::make_kernel ("gaussian", 5.0f, 5.0f);
ImageBuf Blurred = ImageBufAlgo::convolve (Src, K);
```

Python

```python
Src = ImageBuf("tahoe.exr")
K = ImageBufAlgo.make_kernel ("gaussian", 5.0, 5.0)
Blurred = ImageBufAlgo.convolve (Src, K)
```

Oiiotool

```bash
oiiotool tahoe.exr --makekernel gaussian 5x5 --convolve -o blurred.exr
```

ImageBuf `OIIO::ImageBufAlgo::laplacian` (const ImageBuf &src, ROI roi = {}, int nthreads = 0)

Return the Laplacian of the corresponding region of `src`. The Laplacian is the generalized second derivative of the image

$$\frac{\partial^2 s}{\partial x^2} + \frac{\partial^2 s}{\partial y^2}$$

which is approximated by convolving the image with a discrete 3x3 Laplacian kernel,

```
[  0  1  0  ]
[  1 -4  1  ]
[  0  1  0  ]
```

Result-as-parameter version:

```cpp
bool OIIO::ImageBufAlgo::laplacian (ImageBuf &dst, const ImageBuf &src, ROI roi = {}, int nthreads = 0)
```

Write to an existing image `dst` (allocating if it is uninitialized).

Examples:

C++
ImageBuf src "tahoe.exr";
ImageBuf lap = ImageBufAlgo::laplacian (src);

Python

src = ImageBuf("tahoe.exr")
lap = ImageBufAlgo.laplacian (src)

oiio tool

oiio tool tahoe.exr --laplacian -o laplacian.exr

10.6. Convolutions and frequency-space algorithms

**group fft–iff**

Fast Fourier Transform and inverse

Return (or copy into dst) the discrete Fourier transform (DFT), or its inverse, of the section of src denoted by roi. If roi is not defined, it will be all of src’s pixels.

*fft* () takes the discrete Fourier transform (DFT) of the section of src denoted by roi, returning it or storing it in dst. If roi is not defined, it will be all of src’s pixels. Only one channel of src may be transformed at a time, so it will be the first channel described by roi (or, again, channel 0 if roi is undefined). If not already in the correct format, dst will be re-allocated to be a 2-channel float buffer of size roi.width() x roi.height, with channel 0 being the “real” part and channel 1 being the “imaginary” part. The values returned are actually the unitary DFT, meaning that it is scaled by 1/sqrt(npixels).

*ifft* () takes the inverse discrete Fourier transform, transforming a 2-channel complex (real and imaginary) frequency domain image and into a single-channel spatial domain image. src must be a 2-channel float image, and is assumed to be a complex frequency-domain signal with the “real” component in channel 0 and the “imaginary” component in channel 1. dst will end up being a float image of one channel (the real component is kept, the imaginary component of the spatial-domain will be discarded). Just as with *fft* (), the *ifft* () function is dealing with the unitary DFT, so it is scaled by 1/sqrt(npixels).
Functions

ImageBuf `fft` (const ImageBuf &src, ROI roi = {}, int nthreads = 0)
ImageBuf `ifft` (const ImageBuf &src, ROI roi = {}, int nthreads = 0)
bool `fft` (ImageBuf &dst, const ImageBuf &src, ROI roi = {}, int nthreads = 0)
bool `ifft` (ImageBuf &dst, const ImageBuf &src, ROI roi = {}, int nthreads = 0)

Examples:

C++

```cpp
ImageBuf Src ("tahoe.exr");
// Take the DFT of the first channel of Src
ImageBuf Freq = ImageBufAlgo::fft (Src);
// At this point, Freq is a 2-channel float image (real, imag)
// Convert it back from frequency domain to a spatial image
ImageBuf Spatial = ImageBufAlgo::ifft (Freq);
```

Python

```python
src = ImageBuf("tahoe.exr")

# Take the DFT of the first channel of Src
Freq = ImageBufAlgo.fft (Src)
# At this point, Freq is a 2-channel float image (real, imag)
# Convert it back from frequency domain to a spatial image
Spatial = ImageBufAlgo.ifft (Freq)
```

oiiotool

```bash
oiiotool tahoe.exr --fft -o freq.exr
oiiotool freq.exr --ifft -o spatial.exr
```

group complex-polar

Converting complex to polar and back

The `polar_to_complex()` function transforms a 2-channel image whose channels are interpreted as complex values (real and imaginary components) into the equivalent values expressed in polar form of amplitude and phase (with phase between 0 and 2\(\pi\)).

The `complex_to_polar()` function performs the reverse transformation, converting from polar values (amplitude and phase) to complex (real and imaginary).

In either case, the section of `src` denoted by `roi` is transformed, storing the result in `dst`. If `roi` is not defined, it will be all of `src`'s pixels. Only the first two channels of `src` will be transformed.

The transformation between the two representations are:

```
real = amplitude * cos(phase);
imag = amplitude * sin(phase);
```
amplitude = hypot(real, imag);
phase = atan2(imag, real);

Functions

ImageBuf complex_to_polar(const ImageBuf &src, ROI roi = {}, int nthreads = 0)
bool complex_to_polar(ImageBuf &dst, const ImageBuf &src, ROI roi = {}, int nthreads = 0)
ImageBuf polar_to_complex(const ImageBuf &src, ROI roi = {}, int nthreads = 0)
bool polar_to_complex(ImageBuf &dst, const ImageBuf &src, ROI roi = {}, int nthreads = 0)

Examples:
C++

// Suppose we have an FFT in frequency space values expressed as
// complex values (real, imaginary)
ImageBuf fft("fft.exr");

// Convert to polar values (amplitude, phase)
ImageBuf Polar = ImageBufAlgo::complex_to_polar(fft);

// Convert from polar back to (real, imag)
ImageBuf Freq = ImageBufAlgo::polar_to_complex(Polar);

Python

# Suppose we have an FFT in frequency space values expressed as
# complex values (real, imaginary)
fft = ImageBuf("fft.exr")

# Convert to polar values (amplitude, phase)
Polar = ImageBufAlgo.complex_to_polar(fft)

# Convert from polar back to (real, imag)
Freq = ImageBufAlgo.polar_to_complex(Polar)

ioiotool

# Suppose we have an FFT in frequency space values expressed as
# complex values (real, imaginary).
# Convert to polar values (amplitude, phase)
ioiotool fft.exr --polar -o polar.exr

# Convert from polar back to (real, imag)
ioiotool polar.exr --unpolar -o freq.exr
10.7 Image Enhancement / Restoration

ImageBuf OIIO::ImageBufAlgo::fixNonFinite(const ImageBuf &src, NonFiniteFixMode mode = NONFINITE_BOX3, int *pixelsFixed = nullptr, ROI roi = {}, int nthreads = 0)

fixNonFinite() returns in image containing the values of src (within the ROI), while repairing any non-finite (NaN/Inf) pixels. If pixelsFixed is not nullptr, store in it the number of pixels that contained non-finite value. It is permissible to operate in-place (with src and dst referring to the same image).

How the non-finite values are repaired is specified by one of the mode parameter, which is an enum of NonFiniteFixMode.

This function works on all pixel data types, though it’s just a copy for images with pixel data types that cannot represent NaN or Inf values.

Result-as-parameter version:

bool OIIO::ImageBufAlgo::fixNonFinite(ImageBuf &dst, const ImageBuf &src, NonFiniteFixMode mode = NONFINITE_BOX3, int *pixelsFixed = nullptr, ROI roi = {}, int nthreads = 0)

Write to an existing image dst (allocating if it is uninitialized).

Examples:

C++

```
ImageBuf Src ("tahoe.exr");
int pixelsFixed = 0;
ImageBufAlgo::fixNonFinite (Src, Src, ImageBufAlgo::NONFINITE_BOX3, &pixelsFixed);
std::cout << "Repaired " << pixelsFixed << " non-finite pixels\n"
```

Python

```
Src = ImageBuf("tahoe.exr")
ImageBufAlgo.fixNonFinite (Src, Src, "box3", oiiio.NONFINITE_BOX3)
```

**oiiotool**

```
oiiotool tahoe.exr --fixnan box3 -o fixed.exr
```

ImageBuf OIIO::ImageBufAlgo::fillholes_pushpull (const ImageBuf &src, ROI roi = {}, int nthreads = 0)

Copy the specified ROI of src and fill any holes (pixels where alpha < 1) with plausible values using a push-pull technique. The src image must have an alpha channel. The dst image will end up with a copy of src, but will have an alpha of 1.0 everywhere within roi, and any place where the alpha of src was < 1, dst will have a pixel color that is a plausible “filling” of the original alpha hole.

Result-as-parameter version:

bool OIIO::ImageBufAlgo::fillholes_pushpull(ImageBuf &dst, const ImageBuf &src, ROI roi = {}, int nthreads = 0)

Write to an existing image dst (allocating if it is uninitialized).
Examples:

**C++**

```cpp
ImageBuf Src ("holes.exr");
ImageBuf Filled = ImageBufAlgo::fillholes_pushpull (Src);
```

**Python**

```python
Src = ImageBuf("holes.exr")
Filled = ImageBufAlgo.fillholes_pushpull (Src)
```

**oiiotool**

```bash
oiiotool holes.exr --fillholes -o filled.exr
```

```cpp
OIIO::ImageBufAlgo::median_filter(const ImageBuf &src, int width = 3, int height = -1, ROI roi = {}, int nthreads = 0)
```

Return a median-filtered version of the corresponding region of `src`. The median filter replaces each pixel with the median value underneath the `width x height` window surrounding it. If `height <= 0`, it will be set to `width`, making a square window.

Median filters are good for removing high-frequency detail smaller than the window size (including noise), without blurring edges that are larger than the window size.

**Result-as-parameter version:**

```cpp
bool OIIIO::ImageBufAlgo::median_filter(ImageBuf &dst, const ImageBuf &src, int width = 3, int height = -1, ROI roi = {}, int nthreads = 0)
```

Write to an existing image `dst` (allocating if it is uninitialized).

Examples:

**C++**

```cpp
ImageBuf Noisy ("tahoe.exr");
ImageBuf Clean = ImageBufAlgo::median_filter (Noisy, 3, 3);
```

**Python**

```python
Noisy = ImageBuf("tahoe.exr")
Clean = ImageBufAlgo.median_filter (Noisy, 3, 3)
```

**oiiotool**

```bash
oiiotool Tahoe.exr --median 3x3 -o clean.exr
```
ImageBuf OIIIO::ImageBufAlgo::unsharp_mask(const ImageBuf &src, string_view kernel = "gaussian", float width = 3.0f, float contrast = 1.0f, float threshold = 0.0f, ROI roi = {}, int nthreads = 0)

Return a sharpened version of the corresponding region of src using the “unsharp mask” technique. Unsharp masking basically works by first blurring the image (low pass filter), subtracting this from the original image, then adding the residual back to the original to emphasize the edges. Roughly speaking,

\[
dst = src + contrast \times \text{thresh}(src - \text{blur}(src))
\]

The specific blur can be selected by kernel name and width (for example, “gaussian” is typical). As a special case, “median” is also accepted as the kernel name, in which case a median filter is performed rather than a blurring convolution (Gaussian and other blurs sometimes over-sharpen edges, whereas using the median filter will sharpen compact high-frequency details while not over-sharpening long edges).

The contrast is a multiplier on the overall sharpening effect. The thresholding step causes all differences less than threshold to be squashed to zero, which can be useful for suppressing sharpening of low-contrast details (like noise) but allow sharpening of higher-contrast edges.

Result-as-parameter version:

bool OIIIO::ImageBufAlgo::unsharp_mask(ImageBuf &dst, const ImageBuf &src, string_view kernel = "gaussian", float width = 3.0f, float contrast = 1.0f, float threshold = 0.0f, ROI roi = {}, int nthreads = 0)

Write to an existing image dst (allocating if it is uninitialized).

Examples:

C++

ImageBuf Blurry("tahoe.exr");
ImageBuf Sharp = ImageBufAlgo::unsharp_mask(Blurry, "gaussian", 5.0f);

Python

Blurry ImageBuf("tahoe.exr")
Sharp = ImageBufAlgo.unsharp_mask(Blurry, "gaussian", 5.0)

oiiotool
10.8 Morphological filters

ImageBuf OIIO::ImageBufAlgo::dilate(const ImageBuf &src, int width = 3, int height = -1, ROI roi = {}, int nthreads = 0)

Return a dilated version of the corresponding region of src. Dilation is defined as the maximum value of all pixels under nonzero values of the structuring element (which is taken to be a width x height square). If height is not set, it will default to be the same as width. Dilation makes bright features wider and more prominent, dark features thinner, and removes small isolated dark spots.

Result-as-parameter version:

bool OIIO::ImageBufAlgo::dilate(ImageBuf &dst, const ImageBuf &src, int width = 3, int height = -1, ROI roi = {}, int nthreads = 0)

Write to an existing image dst (allocating if it is uninitialized).

ImageBuf OIIO::ImageBufAlgo::erode(const ImageBuf &src, int width = 3, int height = -1, ROI roi = {}, int nthreads = 0)

Return an eroded version of the corresponding region of src. Erosion is defined as the minimum value of all pixels under nonzero values of the structuring element (which is taken to be a width x height square). If height is not set, it will default to be the same as width. Erosion makes dark features wider, bright features thinner, and removes small isolated bright spots.

Result-as-parameter version:

bool OIIO::ImageBufAlgo::erode(ImageBuf &dst, const ImageBuf &src, int width = 3, int height = -1, ROI roi = {}, int nthreads = 0)

Write to an existing image dst (allocating if it is uninitialized).

Dilation and erosion are basic morphological filters, and more complex ones are often constructed from them:

- “open” is erode followed by dilate, and it keeps the overall shape while removing small bright regions;
- “close” is dilate followed by erode, and it keeps the overall shape while removing small dark regions;
- “morphological gradient” is dilate minus erode, which gives a bright perimeter edge;
- “tophat” is the original source minus the “open”, which isolates local peaks;
- “bottomhat” is the “close” minus the original source, which isolates dark holes.

Examples:

C++
ImageBuf Source ("source.tif");

ImageBuf Dilated = ImageBufAlgo::dilate (Source, 3, 3);
ImageBuf Eroded = ImageBufAlgo::erode (Source, 3, 3);

// Morphological "open" is dilate(erase((source))
ImageBuf Opened = ImageBufAlgo::dilate (Eroded, 3, 3);
// Morphological "close" is erase(dilate(source))
ImageBuf Closed = ImageBufAlgo::erode (Dilated, 3, 3);
// Morphological "gradient" is dilate minus erase
ImageBuf Gradient = ImageBufAlgo::sub (Dilated, Eroded);
// Tophat filter is source minus open
ImageBuf Tophat = ImageBufAlgo::sub (Source, Opened);
// Bottomhat filter is close minus source
ImageBuf Bottomhat = ImageBufAlgo::sub (Close, Source);

Python

Source = ImageBuf("source.tif")

Dilated = ImageBufAlgo.dilate (Source, 3, 3)
Eroded = ImageBufAlgo.erode (Source, 3, 3)

# Morphological "open" is dilate(erase((source))
Opened = ImageBufAlgo.dilate (Eroded, 3, 3)
# Morphological "close" is erase(dilate(source))
Closed = ImageBufAlgo.erode (Dilated, 3, 3)
# Morphological "gradient" is dilate minus erase
Gradient = ImageBufAlgo.sub (Dilated, Eroded)
# Tophat filter is source minus open
Tophat = ImageBufAlgo.sub (Source, Opened)
# Bottomhat filter is close minus source
Bottomhat = ImageBufAlgo.sub (Close, Source)

oiiotool

oiiotool source.tif --dilate 3x3 -o dilated.tif
oiiotool source.tif --erode 3x3 -o eroded.tif

# Morphological "open" is dilate(erase((source))
oiiotool source.tif --erode 3x3 --dilate 3x3 -o opened.tif
# Morphological "close" is erase(dilate(source))
oiiotool source.tif --dilate 3x3 --erode 3x3 -o closed.tif
# Morphological "gradient" is dilate minus erase
oiiotool source.tif --dilate 3x3 source.tif --erode 3x3 --sub -o gradient.tif
# Tophat filter is source minus open
oiiotool source.tif source.tif --erode 3x3 --dilate 3x3 --sub -o tophat.tif
# Bottomhat filter is close minus source
oiiotool source.tif --dilate 3x3 --erode 3x3 source.tif --sub -o bottomhat.tif
10.9 Color space conversion

**group** colorconvert

Convert between color spaces

Return (or copy into dst) the pixels of src within the ROI, applying a color space transformation. In-place operations (dst == src) are supported.

The first three channels are presumed to be the color to be transformed, and the fourth channel (if it exists) is presumed to be alpha. Any additional channels will be simply copied unaltered.

If OIIO was built with OpenColorIO support enabled, then the transformation may be between any two spaces supported by the active OCIO configuration, or may be a “look” transformation created by ColorConfig::createLookTransform. If OIIO was not built with OpenColorIO support enabled, then the only transformations available are from “sRGB” to “linear” and vice versa.

**Parameters**

- **fromspace/tospace:** For the varieties of colorconvert() that use named color spaces, these specify the color spaces by name.
- **context_key/context_value:** For the varieties of colorconvert() that use named color spaces, these optionally specify a “key” name/value pair to establish a context (for example, a shot-specific transform).
- **processor:** For the varieties of colorconvert() that have a processor paramater, it is a raw ColorProcessor* object that implements the color transformation. This is a special object created by a ColorConfig (see OpenImageIO/color.h for details).
- **unpremult:** If true, unpremultiply the image (divide the RGB channels by alpha if it exists and is nonzero) before color conversion, then repremult after the after the color conversion. Passing unpremult=false skips this step, which may be desirable if you know that the image is “unassociated alpha” (a.k.a., “not pre-multiplied colors”).
- **colorconfig:** An optional ColorConfig* specifying an OpenColorIO configuration. If not supplied, the default OpenColorIO color configuration found by examining the $OCIO environment variable will be used instead.
Functions

ImageBuf colorconvert (const ImageBuf &src, string_view fromspace, string_view tospace, bool unpremult = true, string_view context_key = "", string_view context_value = ", ColorConfig *colorconfig = nullptr, ROI roi = {}, int nthreads = 0)

Transform between named color spaces, returning an ImageBuf result.

ImageBuf colorconvert (const ImageBuf &src, const ColorProcessor *processor, bool unpremult, ROI roi = {}, int nthreads = 0)

Transform using a ColorProcessor, returning an ImageBuf result.

bool colorconvert (ImageBuf &dst, const ImageBuf &src, string_view fromspace, string_view tospace, bool unpremult = true, string_view context_key = "", string_view context_value = ", ColorConfig *colorconfig = nullptr, ROI roi = {}, int nthreads = 0)

Transform between named color spaces, storing results into an existing ImageBuf.

bool colorconvert (ImageBuf &dst, const ImageBuf &src, const ColorProcessor *processor, bool unpremult, ROI roi = {}, int nthreads = 0)

Transform using a ColorProcessor, storing results into an existing ImageBuf.

bool colorconvert (span<float> color, const ColorProcessor *processor, bool unpremult)

Apply a color transform in-place to just one color: color[0..nchannels-1]. nchannels should either be 3 or 4 (if 4, the last channel is alpha).

inline bool colorconvert (float *color, int nchannels, const ColorProcessor *processor, bool unpremult)

Examples:

C++

ImageBuf Src ("tahoe.jpg");
ImageBuf Dst = ImageBufAlgo::colorconvert (Src, "sRGB", "acescg", true);

Python

Src = ImageBuf("tahoe.jpg")
Dst = ImageBufAlgo.colorconvert (Src, "sRGB", "acescg", True)

oiiotool

oiiotool Tahoe.jpg --colorconvert sRGB acescg -o Tahoe_acescg.exr

- bool colormatrixtransform(ImageBuf &dst, const ImageBuf &src, M44fParam M, bool unpremult = true, ROI roi = {}, int nthreads = 0)

Examples:

C++

ImageBuf Src ("tahoe.exr");
Imath::M44f M (.8047379, .5058794, -.3106172, 0,
    -.3106172, .8047379, .5058794, 0,
    .5058794, -.3106172, .8047379, 0,
    0, 0, 0, 1);
ImageBuf dst = ImageBufAlgo::colormatrixtransform (Src, M);

Python

Src = ImageBuf("tahoe.exr")
M = (.8047379, .5058794, -.3106172, 0,
    -.3106172, .8047379, .5058794, 0,
    .5058794, -.3106172, .8047379, 0,
    0, 0, 0, 1)
dst = ImageBufAlgo.colormatrixtransform (Src, M)

oiiootool

oiiootool tahoe.exr --colormatrixtransform 0.8047379,0.5058794,-0.
    →3106172,0,-0.3106172,0.8047379,0.5058794,0.5058794,-0.3106172,0,0,
    →0,0,1,0 -o tahoe_matrix.exr
Return a copy of the pixels of src within the ROI, applying an OpenColorIO “look” transform to the pixel values. In-place operations (dst == src) are supported.

The first three channels are presumed to be the color to be transformed, and the fourth channel (if it exists) is presumed to be alpha. Any additional channels will be simply copied unaltered.

Parameters

- **looks**: The looks to apply (comma-separated).
- **fromspace/tospace**: For the varieties of colorconvert() that use named color spaces, these specify the color spaces by name.
- **unpremult**: If true, unpremultiply the image (divide the RGB channels by alpha if it exists and is nonzero) before color conversion, then repremult after the after the color conversion. Passing unpremult=false skips this step, which may be desirable if you know that the image is “unassociated alpha” (a.k.a., “not pre-multiplied colors”).
- **inverse**: If true, it will reverse the color transformation and look application.
- **context_key/context_value**: Optional key/value to establish a context (for example, a shot-specific transform).
- **colorconfig**: An optional ColorConfig* specifying an OpenColorIO configuration. If not supplied, the default OpenColorIO color configuration found by examining the $OCIO environment variable will be used instead.

Result-as-parameter version:

```cpp
bool OIIIO::ImageBufAlgo::ociolook (ImageBuf &dst, const ImageBuf &src, string_view looks, string_view fromspace, string_view tospace, bool unpremult = true, bool inverse = false, string_view context_key = "", string_view context_value = "", ColorConfig *colorconfig = nullptr, ROI roi = {}, int nthreads = 0)
```

Write to an existing image dst (allocating if it is uninitialized).

Examples:

C++

```cpp
ImageBuf Src ("tahoe.jpg");
ImageBuf Dst = ImageBufAlgo::ociolook (Src, "look", "vd8", "lnf", true, false, "SHOT", "pe0012 ←");
```

Python

```python
Src = ImageBuf("tahoe.jpg")
Dst = ImageBufAlgo.ociolook (Src, "look", "vd8", "lnf", True, False, "SHOT", "pe0012")
```

oiioctl

```bash
oiiotool tahoe.jpg --
→ociolook:from=vd8:to=lnf:unpremult=1:key=SHOT:value=pe0012 look -o
→out.exr
```
ImageBuf OIIO::ImageBufAlgo::ociodisplay(const ImageBuf &src, string_view display, string_view view, string_view fromspace = "", string_view looks = "", bool unpremult = true, string_view context_key = "", string_view context_value = "", ColorConfig *colorconfig = nullptr, ROI roi = {}, int nthreads = 0)

Return the pixels of src within the ROI, applying an OpenColorIO "display" transform to the pixel values. In-place operations (dst == src) are supported.

The first three channels are presumed to be the color to be transformed, and the fourth channel (if it exists) is presumed to be alpha. Any additional channels will be simply copied unaltered.

Parameters

- **display**: The OCIO “display” to apply. If this is the empty string, the default display will be used.
- **view**: The OCIO “view” to use. If this is the empty string, the default view for this display will be used.
- **fromspace**: If fromspace is not supplied, it will assume that the source color space is whatever is indicated by the source image’s metadata or filename, and if that cannot be deduced, it will be assumed to be scene linear.
- **looks**: The looks to apply (comma-separated). This may be empty, in which case no “look” is used. Note: this parameter value is not used when building against OpenColorIO 2.x.
- **unpremult**: If true, unpremultiply the image (divide the RGB channels by alpha if it exists and is nonzero) before color conversion, then repremult after the after the color conversion. Passing unpremult=false skips this step, which may be desirable if you know that the image is “unassociated alpha” (a.k.a., “not pre-multiplied colors”).
- **inverse**: If true, it will reverse the color transformation and display application.
- **context_key/context_value**: Optional key/value to establish a context (for example, a shot-specific transform).
- **colorconfig**: An optional ColorConfig* specifying an OpenColorIO configuration. If not supplied, the default OpenColorIO color configuration found by examining the $OCIO environment variable will be used instead.

Result-as-parameter version:

bool OIIO::ImageBufAlgo::ociodisplay(ImageBuf &dst, const ImageBuf &src, string_view display, string_view view, string_view fromspace = "", string_view looks = "", bool unpremult = true, string_view context_key = "", string_view context_value = "", ColorConfig *colorconfig = nullptr, ROI roi = {}, int nthreads = 0)

Write to an existing image dst (allocating if it is uninitialized).

Examples:

C++
ImageBuf `Src {"tahoe.exr"};
ImageBuf `Dst = ImageBufAlgo::ociodisplay (`Src, "sRGB", "Film", "1nf", 
   
   
   "", true, "SHOT", "pe0012 
   
   \[\rightarrow\);!

Python

`Src = ImageBuf("tahoe.jpg")
`Dst = ImageBufAlgo.ociodisplay (`Src, "sRGB", "Film", "1nf", 
   
   "", True, "SHOT", "pe0012")

OIIOTool

OIIOTool tahoe.jpg --
   \(-\)ociodisplay:from=1nf:unpremult=1:key=SHOT:value=pe0012 sRGB Film -
   \(-\)o out.exr

ImageBufOII::ImageBufAlgo::ociofiletransform (const ImageBuf &`src, string_view `name, 
   
   bool unpremult = true, bool inverse = false, 
   
   ColorConfig *`colorconfig = nullptr, ROI `roi 
   
   = {}, int `nthreads = 0)

Return the pixels of `src within the `ROI, applying an OpenColorIO “file” transform. In-place operations (`dst 
   
   \[\[= `src) are supported.

The first three channels are presumed to be the color to be transformed, and the fourth channel (if it exists) is 
   
   presumed to be alpha. Any additional channels will be simply copied unaltered.

Parameters

- `name: The name of the file containing the transform information.
- `unpremult: If true, unpremultiply the image (divide the RGB channels by alpha if it exists and 
   
   is nonzero) before color conversion, then repremult after the after the color conversion. Passing 
   
   unpremult=false skips this step, which may be desirable if you know that the image is “unassociated 
   
   alpha” (a.k.a., “not pre-multiplied colors”).
- `inverse: If true, it will reverse the color transformation.
- `colorconfig: An optional ColorConfig* specifying an OpenColorIO configuration. If not 
   
   supplied, the default OpenColorIO color configuration found by examining the SOcio environment 
   
   variable will be used instead.

Result-as-parameter version:

bool OII::ImageBufAlgo::ociofiletransform (ImageBuf &`dst, const Image- 
   
   Buf &`src, string_view `name, 
   
   bool unpremult = true, bool inverse = false, ColorConfig *`color- 
   
   config = nullptr, ROI `roi 
   
   = {}, int `nthreads = 0)

Write to an existing image `dst (allocating if it is uninitialized).

Examples:
C++

```cpp
ImageBuf Src ("tahoe.exr");
ImageBuf Dst = ImageBufAlgo::ociofiletransform (Src, "footransform.csp");
```

Python

```python
Src = ImageBuf("tahoe.exr")
Dst = ImageBufAlgo.ociofiletransform (Src, "footransform.csp")
```

```
oiiotool
doiiotool tahoe.exr --ociofiletransform:unpremult=1 footransform.csp -o out.exr
```

**group premult**

Premultiply or un-premultiply color by alpha

The **unpremult** operation returns (or copies into dst) the pixels of src within the ROI, and in the process divides all color channels (those not alpha or z) by the alpha value, to “un-premultiply” them. This presumes that the image starts of as “associated alpha” a.k.a. “premultiplied,” and you are converting to “unassociated alpha.” For pixels with alpha == 0, the color values are not modified.

The **premult** operation returns (or copies into dst) the pixels of src within the ROI, and in the process multiplies all color channels (those not alpha or z) by the alpha value, to “premultiply” them. This presumes that the image starts of as “unassociated alpha” a.k.a. “non-premultiplied” and converts it to “associated alpha / premultiplied.”

The **repremult** operation is like **premult**, but preserves the color values of pixels whose alpha is 0. This is intended for cases where you unpremult, do an operation (such as color transforms), then want to return to associated/premultiplied alpha in that case, you want to make sure that “glow” pixels (those with alpha=0 but RGB > 0) are preserved for the round trip, and not crushed to black. This use case is distinct from a simple **premult** that is a one-time conversion from unassociated to associated alpha.

All three operations are simply a copy if there is no identified alpha channel (and a no-op if dst and src are the same image).

**Functions**

```cpp
ImageBuf unpremult (const ImageBuf &src, ROI roi = {}, int nthreads = 0)
bool unpremult (ImageBuf &dst, const ImageBuf &src, ROI roi = {}, int nthreads = 0)
ImageBuf premult (const ImageBuf &src, ROI roi = {}, int nthreads = 0)
bool premult (ImageBuf &dst, const ImageBuf &src, ROI roi = {}, int nthreads = 0)
ImageBuf repremult (const ImageBuf &src, ROI roi = {}, int nthreads = 0)
bool repremult (ImageBuf &dst, const ImageBuf &src, ROI roi = {}, int nthreads = 0)
```

Examples:

C++
// Convert from unassociated alpha to associated alpha by
// straightforward multiplication of color by alpha.
ImageBuf Unassoc; // Assume somehow this has unassociated alpha
ImageBuf Assoc = ImageBufAlgo::premult (Unassoc);

// Convert in-place from associated alpha to unassociated alpha,
// preserving the color of alpha==0 pixels.
ImageBuf A;
ImageBufAlgo::unpremult (A, A);

// Finish the round-trip back to associated, still preserving the
// color of alpha==0 pixels. This should result in exactly the same
// pixel values we started with (within precision limits).
ImageBufAlgo::repremult (A, A);

Python

# Convert from unassociated alpha to associated alpha by
# straightforward multiplication of color by alpha.
Unassoc = ImageBuf(...) # Assume somehow this has unassociated alpha
Assoc = ImageBufAlgo.premult (Unassoc)

# Convert in-place from associated alpha to unassociated alpha,
# preserving the color of alpha==0 pixels.
A = ImageBuf(...)  
ImageBufAlgo.unpremult (A, A)

# Finish the round-trip back to associated, still preserving the
# color of alpha==0 pixels. This should result in exactly the same
# pixel values we started with (within precision limits).
ImageBufAlgo.repremult (A, A)
oiiotool

# Convert from unassociated alpha to associated alpha by
# straightforward multiplication of color by alpha.
oiiotool unassoc.tif --premult -o assoc.tif

# Convert in-place from associated alpha to unassociated alpha,
# preserving the color of alpha==0 pixels.
oiiotool A.tif --unpremult -o A.tif

# Finish the round-trip back to associated, still preserving the
# color of alpha==0 pixels. This should result in exactly the same
# pixel values we started with (within precision limits).
oiiotool A.tif --repremult -o A.tif
10.10 Import / export

**group** make_texture

The `make_texture()` function turns an image into a tiled, MIP-mapped, texture file and write it to disk (outputfilename).

The return value is `true` for success, `false` if an error occurred. If there was an error, any error message will be retrievable via the global `OIIO::geterror()` call (since there is no destination `ImageBuf` in which to store it).

Named fields in config:

- `format` : Data format of the texture file (default: `UNKNOWN` = same format as the input)
- `tile_width/tile_height/tile_depth` : Preferred tile size (default: 64x64x1)

Metadata in `config.extra_attribs`

- `compression` (string) : Default: “zip”
- `fovcot` (float) : Default: aspect ratio of the image resolution.
- `planarconfig` (string) : Default: “separate”
- `worldtocamera` (matrix) : World-to-camera matrix of the view.
- `worldtoscreen` (matrix) : World-to-screen space matrix of the view.
- `worldtoNDC` (matrix) : World-to-NDC space matrix of the view.
- `wrapmodes` (string) : Default: “black,black”
- `handed` (string) : “left” or “right” reveals the handedness of the coordinates for normal maps. ("")
- `maketx:verbose` (int) : How much detail should go to outstream (0).
- `maketx:runstats` (int) : If nonzero, print run stats to outstream (0).
- `maketx:resize` (int) : If nonzero, resize to power of 2. (0)
- `maketx:nomipmap` (int) : If nonzero, only output the top MIP level (0).
- `maketx:updatemode` (int) : If nonzero, write new output only if the output file doesn’t already exist, or is older than the input file, or was created with different command-line arguments. (0)
- `maketx:constant_color_detect` (int) : If nonzero, detect images that are entirely one color, and change them to be low resolution (default: 0).
- `maketx:monochrome_detect` (int) : If nonzero, change RGB images which have R==G==B everywhere to single-channel grayscale (default: 0).
- `maketx:opaque_detect` (int) : If nonzero, drop the alpha channel if alpha is 1.0 in all pixels (default: 0).
- `maketx:compute_average` (int) : If nonzero, compute and store the average color of the texture (default: 1).
- `maketx:unpremult` (int) : If nonzero, unpremultiply color by alpha before color conversion, then multiply by alpha after color conversion (default: 0).
- `maketx:incolorspace, maketx:outcolorspace` (string) : These two together will apply a color conversion (with OpenColorIO, if compiled). Default: ""
- **maketx:colorconfig**: Specifies a custom OpenColorIO color config file. Default: ""

- **maketx:checknan**: If nonzero, will consider it an error if the input image has any NaN pixels. (0)

- **maketx:fixnan**: If set to “black” or “box3”, will attempt to repair any NaN pixels found in the input image (default: “none”).

- **maketx:set_full_to_pixels**: If nonzero, doctors the full/display window of the texture to be identical to the pixel/data window and reset the origin to 0,0 (default: 0).

- **maketx:filtername**: If set, will specify the name of a high-quality filter to use when resampling for MIPmap levels. Default: “”, use bilinear resampling.

- **maketx:highlightcomp**: If nonzero, performs highlight compensation range compression and expansion around the resize, plus clamping negative pixel values to zero. This reduces ringing when using filters with negative lobes on HDR images.

- **maketx:sharpen**: If nonzero, sharpens details when creating MIPmap levels. The amount is the contrast metric. The default is 0, meaning no sharpening.

- **maketx:nchannels**: If nonzero, will specify how many channels the output texture should have, padding with 0 values or dropping channels, if it doesn’t the number of channels in the input. (default: 0, meaning keep all input channels)

- **maketx:channelnames**: If set, overrides the channel names of the output image (comma-separated).

- **maketx:fileformatname**: If set, will specify the output file format. (default: “”, meaning infer the format from the output filename)

- **maketx:prman_metadata**: If set, output some metadata that PRMan will need for its textures. (0)

- **maketx:oiio_options**: (Deprecated; all are handled by default)

- **maketx:prman_options**: If nonzero, override a whole bunch of settings as needed to make textures that are compatible with PRMan. (0)

- **maketx:mipimages**: Semicolon-separated list of alternate images to be used for individual MIPmap levels, rather than simply downsizing. (default: “”)

- **maketx:full_command_line**: The command or program used to generate this call, will be embedded in the metadata. (default: “”)

- **maketx:ignore_unassoc**: If nonzero, will disbelieve any evidence that the input image is unassociated alpha. (0)

- **maketx:read_local_MB**: If nonzero, will read the full input file locally if it is smaller than this threshold. Zero causes the system to make a good guess at a reasonable threshold (e.g. 1 GB). (0)

- **maketx:forcefloat**: Forces a conversion through float data for the sake of ImageBuf math. (1)

- **maketx:hash**: Compute the sha1 hash of the file in parallel. (1)

- **maketx:allow_pixel_shift**: Allow up to a half pixel shift per mipmap level. The fastest path may result in a slight shift in the image, accumulated for each mip level with an odd resolution. (0)

- **maketx:bumpformat**: For the MakeTxBumpWithSlopes mode, chooses whether to assume the map is a height map (“height”), a normal map (“normal”), or automatically determine it from the number of channels (“auto”, the default).
• **maketx:uvslopes_scale** (float): If nonzero, when used in MakeTxBumpWithSlopes mode, this computes derivatives for the bumpslopes data in UV space rather than in texel space, and divides them by this scale factor. The default is 0, disabling the feature. If you use this feature, a suggested value is 256.

• **maketx:cdf** (int): If nonzero, will write a Gaussian CDF and Inverse Gaussian CDF as per-channel metadata in the texture, which can be used by shaders to implement Histogram-Preserving Blending. This is only useful when the texture being created is written to an image format that supports arbitrary metadata (e.g. OpenEXR). (See Burley, “On Histogram-Preserving Blending for Randomized Texture Tiling,” JCGT 8(4), 2019, and Heitz/Neyret, “High-Performance By-Example Noise using a Histogram-Preserving Blending Operator,” ACM SIGGRAPH / Eurographics Symposium on High-Performance Graphics 2018.) (default: 0)

• **maketx:cdfsigma** (float): When maketx:cdf is active, determines the CDF sigma (default: 1.0/6).

• **maketx:cdfbits** (int): When maketx:cdf is active, determines the number of bits to use for the size of the CDF table. (default: 8, meaning 256 bins)

**Parameters**

- **mode**: Describes what type of texture file we are creating and may be one of:
  - MakeTxTexture: Ordinary 2D texture.
  - MakeTxEnvLatl: Latitude-longitude environment map
  - MakeTxEnvLatlFromLightProbe: Latitude-longitude environment map constructed from a “light probe” image.
  - MakeTxBumpWithSlopes: Bump/displacement map with extra slope data channels (6 channels total, containing both the height and 1st and 2nd moments of slope distributions) for bump-to-roughness conversion in shaders.

- **outputfilename**: Name of the file in which to save the resulting texture.

- **config**: An ImageSpec that contains all the information and special instructions for making the texture. Anything set in config (format, tile size, or named metadata) will take precedence over whatever is specified by the input file itself. Additionally, named metadata that starts with “maketx:” will not be output to the file itself, but may contain instructions controlling how the texture is created. The full list of supported configuration options is listed below.

- **outstream**: If not `nullptr`, it should point to a stream (for example, `&std::cout`, or a pointer to a local `std::stringstream` to capture output), which is where console output and errors will be deposited. Note that error messages will also be retrievable from OIIO::geterror().

**Functions**

```cpp
bool make_texture(MakeTextureMode mode, const ImageBuf &input, string_view outputfilename,
const ImageSpec &config, std::ostream *outstream = nullptr)
```

Version of `make_texture` that starts with an ImageBuf.

```cpp
bool make_texture(MakeTextureMode mode, string_view filename, string_view outputfilename,
const ImageSpec &config, std::ostream *outstream = nullptr)
```

Version of `make_texture` that starts with a filename and reads the input from that file, rather than being given an ImageBuf directly.

```cpp
bool make_texture(MakeTextureMode mode, const std::vector<std::string> &filenames,
string_view outputfilename, const ImageSpec &config, std::ostream *outstream = nullptr)
```

Version of `make_texture` that takes multiple filenames (reserved for future expansion, such as assembling
several faces into a cube map).

Examples:

C++

```cpp
ImageBuf Input ("in.exr");
ImageSpec config;
config["maketx:highlightcomp"] = 1;
config["maketx:filtername"] = "lanczos3";
config["maketx:opaque_detect"] = 1;

bool ok = ImageBufAlgo::make_texture (ImageBufAlgo::MakeTexTexture,
                                       Input, "texture.exr", config);
if (! ok)
    std::cout << "make_texture error: " << OIIO::geterror() << "\n";
```

Python

```python
Input = ImageBuf("in.exr")
config = ImageSpec()
config["maketx:highlightcomp"] = 1
config["maketx:filtername"] = "lanczos3"
config["maketx:opaque_detect"] = 1

ok = ImageBufAlgo.make_texture (OpenImageIO.MakeTxTexture,
                                Input, "texture.exr", config)
if not ok :
    print("make_texture error:", OpenImageIO.geterror())
```

```
oiiotool
```

```
maketx
```

OpenCV interoperability is performed by the from_OpenCV() and to_OpenCV() functions:

```cpp
bool OIIO::ImageBufAlgo::from_OpenCV (const cv::Mat &mat, TypeDesc convert = TypeUnknown, ROI roi = {}, int nthreads = 0)
Convert an OpenCV cv::Mat into an ImageBuf, copying the pixels (optionally converting to the pixel data type
specified by convert, if not UNKNOWN, which means to preserve the original data type if possible). Return
true if ok, false if it couldn’t figure out how to make the conversion from Mat to ImageBuf. If OpenImageIO
was compiled without OpenCV support, this function will return an empty image with error message set.
```

```cpp
bool OIIO::ImageBufAlgo::to_OpenCV (cv::Mat &dst, const ImageBuf &src, ROI roi = {}, int nthreads = 0)
Construct an OpenCV cv::Mat containing the contents of ImageBuf src, and return true. If it is not possible, or
if OpenImageIO was compiled without OpenCV support, then return false. Note that OpenCV only supports up
to 4 channels, so >4 channel images will be truncated in the conversion.
```
ImageBuf OIIIO::ImageBufAlgo::capture_image (int cameranum = 0, TypeDesc convert = TypeUnknown)
    Capture a still image from a designated camera. If able to do so, store the image in dst and return true. If there
    is no such device, or support for camera capture is not available (such as if OpenCV support was not enabled at
    compile time), return false and do not alter dst.

Examples:

```c++
ImageBuf WebcamImage = ImageBufAlgo::capture_image (0, TypeDesc::UINT8);
WebcamImage.write ("webcam.jpg");
```

10.11 Deep images

A number of ImageBufAlgo functions are designed to work with “deep” images. These are detailed below. In general,
ImageBufAlgo functions not listed in this section should not be expected to work with deep images.

10.11.1 Functions specific to deep images

ImageBuf OIIIO::ImageBufAlgo::deepen (const ImageBuf & src, float zvalue = 1.0f, ROI roi = {}, int nthreads = 0)
    Return the “deep” equivalent of the “flat” input src. Turning a flat image into a deep one means:

    • If the src image has a “Z” channel: if the source pixel’s Z channel value is not infinite, the corresponding
      pixel of dst will get a single depth sample that copies the data from the source pixel; otherwise, dst will
      get an empty pixel. In other words, infinitely far pixels will not turn into deep samples.
    • If the src image lacks a “Z” channel: if any of the source pixel’s channel values are nonzero, the corre-
      sponding pixel of dst will get a single depth sample that copies the data from the source pixel and uses
      the zvalue parameter for the depth; otherwise, if all source channels in that pixel are zero, the destination
      pixel will get no depth samples.

If src is already a deep image, it will just copy pixel values from src.

Result-as-parameter version:

```c++
bool OIIIO::ImageBufAlgo::deepen (ImageBuf & dst, const ImageBuf & src, float zvalue = 1.0f, ROI roi = {}, int nthreads = 0)
```
    Write to an existing image dst (allocating if it is uninitialized).

Examples:

```c++
C++
ImageBuf Flat ("RGBA2.exr");
ImageBuf Deep = ImageBufAlgo::deepen (Flat);
```

Python

```python
Flat = ImageBuf("RGBA2.exr")
Deep = ImageBufAlgo.deepen (Flat)
```
ImageBuf OIIIO::ImageBufAlgo::**flatten** (const ImageBuf &src, ROI roi = {}, int nthreads = 0)

Return the “flattened” composite of deep image src. That is, it converts a deep image to a simple flat image by front-to-back compositing the samples within each pixel. If src is already a non-deep/flat image, it will just copy pixel values from src to dst. If dst is not already an initialized ImageBuf, it will be sized to match src (but made non-deep).

**Result-as-parameter version:**

bool OIIIO::ImageBufAlgo::**flatten** (ImageBuf &dst, const ImageBuf &src, ROI roi = {}, int nthreads = 0)

Write to an existing image dst (allocating if it is uninitialized).

**Examples:**

**C++**

```
ImageBuf Deep ("deepalpha.exr");
ImageBuf Flat = ImageBufAlgo::flatten (Deep);
```

**Python**

```
Deep = ImageBuf("deepalpha.exr")
Flat = ImageBufAlgo.flatten (Deep)
```

```
oiiotool RGBAZ.exr --deepen -o deep.exr
```

ImageBuf OIIIO::ImageBufAlgo::**deep_merge** (const ImageBuf &A, const ImageBuf &B, bool occlusion_cull = true, ROI roi = {}, int nthreads = 0)

Return the deep merge of the samples of deep images A and B, overwriting any existing samples of dst in the ROI. If occlusion_cull is true, any samples occluded by an opaque sample will be deleted.

**Result-as-parameter version:**

bool OIIIO::ImageBufAlgo::**deep_merge** (ImageBuf &dst, const ImageBuf &A, const ImageBuf &B, bool occlusion_cull = true, ROI roi = {}, int nthreads = 0)

Write to an existing image dst (allocating if it is uninitialized).

**Examples:**

**C++**

```
ImageBuf DeepA ("hardsurf.exr");
ImageBuf DeepB ("volume.exr");
ImageBuf Merged = ImageBufAlgo::deep_merge (DeepA, DeepB);
```

**Python**

```
oiiotool deepalpha.exr --flatten -o flat.exr
```
DeepA = ImageBuf("hardsurf.exr")
DeepB = ImageBuf("volume.exr")
Merged = ImageBufAlgo.deep_merge (DeepA, DeepB)

oiiotool

oiiotool hardsurf.exr volume.exr --deep_merge -o merged.exr

ImageBuf OIIIO::ImageBufAlgo::deep_holdout (const ImageBuf & src, const ImageBuf & holdout, ROI roi = {}, int nthreads = 0)

Return the samples of deep image src that are closer than the opaque frontier of deep image holdout, returning true upon success and false for any failures. Samples of src that are farther than the first opaque sample of holdout (for the corresponding pixel) will not be copied to dst. Image holdout is only used as the depth threshold; no sample values from holdout are themselves copied to dst.

Result-as-parameter version:

bool OIIIO::ImageBufAlgo::deep_holdout (ImageBuf & dst, const ImageBuf & src, const ImageBuf & holdout, ROI roi = {}, int nthreads = 0)

Write to an existing image dst (allocating if it is uninitialized).

Examples:

C++

ImageBuf Src ("image.exr");
ImageBuf Holdout ("holdout.exr");
ImageBuf Merged = ImageBufAlgo::deep_holdout (Src, Holdout);

Python

Src = ImageBuf("image.exr")
Holdout = ImageBuf("holdout.exr")
Merged = ImageBufAlgo.deep_holdout (Src, Holdout)

oiiotool

oiiotool image.exr holdout.exr --deep_holdout -o merged.exr
10.11.2 General functions that also work for deep images

ImageBuf `channels` (const ImageBuf &src, int nchannels, cspan<int> channelorder, cspan<float> channelvalues = NULL, cspan<std::string> newchannelnames = {}, bool shuffle_channel_names = false)

bool `channels` (ImageBuf &dst, const ImageBuf &src, int nchannels, cspan<int> channelorder, cspan<float> channelvalues = NULL, cspan<std::string> newchannelnames = {}, bool shuffle_channel_names = false)

Reorder, rename, remove, or add channels to a deep image.

bool `compare` (const ImageBuf &A, const ImageBuf &B, float failthresh, float warnthresh, CompareResults &result, ROI roi = {}, int nthreads = 0)

Numerically compare two images.

bool `computePixelStats` (PixelStats &stats, const ImageBuf &src, ROI roi = {}, int nthreads = 0)

Compute per-channel statistics about the image.

ImageBuf `crop` (const ImageBuf &src, ROI roi = {}, int nthreads = 0)

bool `crop` (ImageBuf &dst, const ImageBuf &src, ROI roi = {}, int nthreads = 0)

Crop the specified region of src, discarding samples outside the ROI.

ROI `nonzero_region` (const ImageBuf &src, ROI roi = {}, int nthreads = 0)

For “deep” images, this function returns the smallest ROI that contains all pixels that contain depth samples, and excludes the border pixels that contain no depth samples at all.

ImageBuf `add` (const ImageBuf &A, cspan<float> B, ROI roi = {}, int nthreads = 0)

bool `add` (ImageBuf &dst, const ImageBuf &A, cspan<float> B, ROI roi = {}, int nthreads = 0)

ImageBuf `sub` (const ImageBuf &A, cspan<float> B, ROI roi = {}, int nthreads = 0)

bool `sub` (ImageBuf &dst, const ImageBuf &A, cspan<float> B, ROI roi = {}, int nthreads = 0)

ImageBuf `mul` (const ImageBuf &A, cspan<float> B, ROI roi = {}, int nthreads = 0)

bool `mul` (ImageBuf &dst, const ImageBuf &A, cspan<float> B, ROI roi = {}, int nthreads = 0)

ImageBuf `div` (const ImageBuf &A, cspan<float> B, ROI roi = {}, int nthreads = 0)

bool `div` (ImageBuf &dst, const ImageBuf &A, cspan<float> B, ROI roi = {}, int nthreads = 0)

Add, subtract, multiply, or divide all the samples in a deep image A by per-channel values B[].

ImageBuf `fixNonFinite` (const ImageBuf &src, NonFiniteFixMode mode = NONFINITE_BOX3, int *pixelsFixed = nullptr, ROI roi = {}, int nthreads = 0)

bool `fixNonFinite` (ImageBuf &dst, const ImageBuf &src, NonFiniteFixMode mode = NONFINITE_BOX3, int *pixelsFixed = nullptr, ROI roi = {}, int nthreads = 0)

Repair nonfinite (NaN or -Inf) values, setting them to 0.0.

ImageBuf `resample` (const ImageBuf &src, bool interpolate = true, ROI roi = {}, int nthreads = 0)

bool `resample` (ImageBuf &dst, const ImageBuf &src, bool interpolate = true, ROI roi = {}, int nthreads = 0)

Compute a resized version of the corresponding portion of src (mapping such that the “full” image window of each correspond to each other, regardless of resolution), for each pixel merely copying the closest deep pixel of the source image (no true interpolation is done for deep images).
11.1 Overview

OpenImageIO provides Python language bindings for much of its functionality.

You must ensure that the environment variable PYTHONPATH includes the python subdirectory of the OpenImageIO installation.

A Python program must import the OpenImageIO package:

```python
import OpenImageIO
```

In most of our examples below, we assume that for the sake of brevity, we will alias the package name as follows:

```python
import OpenImageIO as oiio
from OIIO import ImageInput, ImageOutput
from OIIO import ImageBuf, ImageSpec, ImageBufAlgo
```

11.2 TypeDesc

The TypeDesc class that describes data types of pixels and metadata, described in detail in Section Data Type Descriptions: TypeDesc, is replicated for Python.

```python
class BASETYPE
    The BASETYPE enum corresponds to the C++ TypeDesc::BASETYPE and contains the following values:
    UNKNOWN NONE UINT8 INT8 UINT16 INT16 UINT32 INT32 UINT64 INT64 HALF FLOAT DOUBLE STRING PTR
```

These names are also exported to the OpenImageIO namespace.

```python
class AGGREGATE
    The AGGREGATE enum corresponds to the C++ TypeDesc::AGGREGATE and contains the following values:
    SCALAR VEC2 VEC3 VEC4 MATRIX33 MATRIX44
```

These names are also exported to the OpenImageIO namespace.

```python
class VECSEMANTICS
    The VECSEMANTICS enum corresponds to the C++ TypeDesc::VECSEMANTICS and contains the following values:
```
These names are also exported to the OpenImageIO namespace.

**TypeUnknown**  **TypeString**  **TypeFloat**  **TypeHalf**  
**TypeInt**  **TypeUInt**  **TypeInt16**  **TypeUInt16**  
**TypeColor**  **TypePoint**  **TypeVector**  **TypeNormal**  
**TypeFloat2**  **TypeVector2**  **TypeFloat4**  **TypeVector2i**  
**TypeMatrix**  **TypeMatrix33**  
**TypeTimeCode**  **TypeKeyCode**  **TypeRational**  **TypePointer**

 these are also exported to the OpenImageIO namespace.

Pre-constructed TypeDesc objects for some common types, available in the outer OpenImageIO scope.

Example:

```python
t = TypeFloat
```

**str()** (typedesc)

Returns a string that describes the TypeDesc.

Example:

```python
print (str(TypeDesc(oiio.UINT16)))
> int16
```

**TypeDesc.basetype**

**TypeDesc.aggregate**

**TypeDesc.vecsemantic**

**TypeDesc.arraylen**

Access to the raw fields in the TypeDesc.

Example:

```python
t = TypeDesc(...)  
if t.basetype == oiio.FLOAT :  
    print ("It's made of floats")
```

**int TypeDesc.size ()**

**int TypeDesc.basesize ()**

**TypeDesc TypeDesc.elementtype ()**

**int TypeDesc.numelements ()**

**int TypeDesc.elementssize ()**

The `size()` is the size in bytes, of the type described. The `basesize()` is the size in bytes of the BASETYPE.

The `elementtype()` is the type of each array element, if it is an array, or just the full type if it is not an array. The `elementssize()` is the size, in bytes, of the `elementtype` (thus, returning the same value as `size()` if the type is not an array). The `numelements()` method returns `arraylen` if it is an array, or 1 if it is not an array.

Example:

```python
t = TypeDesc("point[2]")
print "size =", t.size()
print ("elementtype =", t.elementtype())
print ("elementsizes =", t.elementsizes())
```
size = 24
elementtype = point
elementsize = 12

typedesc == typedesc
typedesc != typedesc
TypeDesc.equivvalent(typedesc)
Test for equality or inequality. The equivalent() method is more forgiving than ==, in that it considers POINT, VECTOR, and NORMAL vector semantics to not constitute a difference from one another.

Example:

```python
f = TypeDesc("float")
p = TypeDesc("point")
v = TypeDesc("vector")
print ("float==point?", (f == p))
print ("vector==point?", (v == p))
print ("float.equivalent(point)?", f.equivalent(p))
print ("vector.equivalent(point)?", v.equivalent(p))

> float==point? False
> vector==point? False
> float.equivalent(point)? False
> vector.equivalent(point)? True
```

11.3 ROI

The ROI class that describes an image extent or region of interest, explained in detail in Section Rectangular region of interest: ROI, is replicated for Python.

ROI()
ROI(xbegin, xend, ybegin, yend, zbegin=0, zend=1, chbegin=0, chend=1000)
Construct an ROI with the given bounds. The constructor with no arguments makes an ROI that is “undefined.”

Example:

```python
roi = ROI (0, 640, 0, 480, 0, 1, 0, 4) # video res RGBA
```

roi.xbegin
roi.xend
roi.ybegin
roi.yend
roi.zbegin
roi.zend
roi.chbegin
roi.chend
The basic fields of the ROI (all of type int).

roi.All
A pre-constructed undefined ROI understood to mean unlimited ROI on an image.

roi.defined
True if the ROI is defined, False if the ROI is undefined.

roi.width
The number of pixels in each dimension, and the number of channels, as described by the ROI. (All of type int.)

int ROI.npixels
The total number of pixels in the region described by the ROI (as an int).

ROI.contains(x, y, z=0, ch=0)
Returns True if the ROI contains the coordinate.

ROI.contains(other)
Returns True if the ROI other is entirel contained within this ROI.

ROI get_roi(imagespec)
ROI get_roi_full(imagespec)
Returns an ROI corresponding to the pixel data window of the given ImageSpec, or the display/full window, respectively.

Example:

```python
spec = ImageSpec(...)
roi = oiio.get_roi(spec)
```

set_roi(imagespec, roi)
set_roi_full(imagespec, roi)
Alter the ImageSpec’s resolution and offset to match the passed ROI.

Example:

```python
# spec is an ImageSpec
# The following sets the full (display) window to be equal to the
# pixel data window:
oiio.set_roi_full(spec, oiio.get_roi(spec))
```

## 11.4 ImageSpec

The ImageSpec class that describes an image, explained in detail in Section Image Specification: ImageSpec, is replicated for Python.

ImageSpec()
ImageSpec(typedesc)
ImageSpec(xres, yres, nchannels, typedesc)
ImageSpec(roi, typedesc)
Constructors of an ImageSpec. These correspond directly to the constructors in the C++ bindings.

Example:

```python
import OpenImageIO as oiio
...
# default ctr
```

(continues on next page)
s = ImageSpec()

# construct with known pixel type, unknown resolution
s = ImageSpec(oiio.UINT8)

# construct with known resolution, channels, pixel data type
s = ImageSpec(640, 480, 4, "half")

# construct from an ROI
s = ImageSpec (ROI(0,640,0,480,0,1,0,3), TypeFloat)

ImageSpec.width, ImageSpec.height, ImageSpec.depth
ImageSpec.x, ImageSpec.y, ImageSpec.z

Resolution and offset of the image data (int values).

Example:

s = ImageSpec (...)
print ("Data window is ({},{})-({},{})".format (s.x, s.x+s.width-1,

ImageSpec.full_width, ImageSpec.full_height, ImageSpec.full_depth
ImageSpec.full_x, ImageSpec.full_y, ImageSpec.full_z

Resolution and offset of the “full” display window (int values).

For tiled images, the resolution of the tiles (int values). Will be 0 for untiled images.

ImageSpec.format
A TypeDesc describing the pixel data.

ImageSpec.nchannels
An int giving the number of color channels in the image.

ImageSpec.channelnames
A tuple of strings containing the names of each color channel.

ImageSpec.channelformats
If all color channels have the same format, that will be ImageSpec.format, and channelformats will be None. However, if there are different formats per channel, they will be stored in channelformats as a tuple of TypeDesc objects.

Example:

if spec.channelformats == None:
    print ("All color channels are", str(spec.format))
else:
    print ("Channel formats: ")
    for t in spec.channelformats:
        print ("\t", t)

ImageSpec.alpha_channel
ImageSpec.z_channel

The channel index containing the alpha or depth channel, respectively, or -1 if either one does not exist or cannot be identified.

ImageSpec.deep
True if the image is a deep (multiple samples per pixel) image, of False if it is an ordinary image.
ImageSpec.**extra_attribs**

Direct access to the `extra_attribs` named metadata, appropriate for iterating over the entire list rather than searching for a particular named value.

- `len(extra_attribs)`: Returns the number of extra attributes.
- `extra_attribs[i].name`: The name of the indexed attribute.
- `extra_attribs[i].type`: The type of the indexed attribute, as a `TypeDesc`.
- `extra_attribs[i].value`: The value of the indexed attribute.

Example:

```python
s = ImageSpec(...)
...
print("extra_attribs size is", len(s.extra_attribs))
for i in range(len(s.extra_attribs)) :
    print(i, s.extra_attribs[i].name, str(s.extra_attribs[i].type), " :")
    print ("\t", s.extra_attribs[i].value)
print
```

ImageSpec.**roi**

The ROI describing the pixel data window.

ImageSpec.**roi_full**

The ROI describing the “display window” (or “full size”).

ImageSpec.**set_format**(typedesc)

Given a `TypeDesc`, sets the `format` field and clear any per-channel formats in `channelformats`.

Example:

```python
s = ImageSpec ()
s.set_format (TypeDesc("uint8"))
```

ImageSpec.**default_channel_names**()

Sets `channel_names` to the default names given the value of the `nchannels` field.

ImageSpec.**channelindex**(name)

Return (as an int) the index of the channel with the given name, or -1 if it does not exist.

ImageSpec.**channel_bytes**()

ImageSpec.channel_bytes (channel, native=False) Returns the size of a single channel value, in bytes (as an int). (Analogous to the C++ member functions, see Section Image Specification: ImageSpec for details.)

ImageSpec.**pixel_bytes**()

ImageSpec.pixel_bytes (native=False) ImageSpec.pixel_bytes (chbegin, chend, native=False) Returns the size of a pixel, in bytes (as an int). (Analogous to the C++ member functions, see Section Image Specification: ImageSpec for details.)

ImageSpec.**scanline_bytes**(native=False)

ImageSpec.**tile_bytes**(native=False)

ImageSpec.**image_bytes**(native=False)

Returns the size of a scanline, tile, or the full image, in bytes (as an int). (Analogous to the C++ member functions, see Section Image Specification: ImageSpec for details.)

ImageSpec.**tile_pixels**()

ImageSpec.image_pixels()

Returns the number of pixels in a tile or the full image, respectively (as an int). (Analogous to the C++ member functions, see Section Image Specification: ImageSpec for details.)
OpenImageIO, Release 2.4.1

ImageSpec. **erase_attribute** *(name, searchtype=TypeUnknown, casesensitive=False)*

Remove any specified attributes matching the regular expression `name` from the list of `extra_attribs`.

ImageSpec. **attribute** *(name, int)*
ImageSpec. **attribute** *(name, float)*
ImageSpec. **attribute** *(name, string)*
ImageSpec. **attribute** *(name, typedesc, data)*

Sets a metadata value in the `extra_attribs`. If the metadata item is a single `int`, `float`, or `string`, you can pass it directly. For other types, you must pass the `TypeDesc` and then the data (for aggregate types or arrays, pass multiple values as a tuple).

Example:

```
s = ImageSpec (...)
s.attribute ("foo_str", "blah")
s.attribute ("foo_int", 14)
s.attribute ("foo_float", 3.14)
s.attribute ("foo_vector", TypeDesc.TypeVector, (1, 0, 11))
s.attribute ("foo_matrix", TypeDesc.TypeMatrix,
               (1, 0, 0, 0, 0, 2, 0, 0, 1, 0, 1, 2, 3, 1))
```

ImageSpec. **getattribute** *(name)*
ImageSpec. **getattribute** *(name, typedesc)*

Retrieves a named metadata value from `extra_attribs`. The generic `getattribute()` function returns it regardless of type, or `None` if the attribute does not exist. The typed variety will only succeed if the attribute is actually of that type specified.

Example:

```
foo = s.getattribute ("foo")  # None if not found
foo = s.getattribute ("foo", oiio.FLOAT)  # None if not found AND float
```

ImageSpec. **get_int_attribute** *(name, defaultval=0)*
ImageSpec. **get_float_attribute** *(name, defaultval=0.0)*
ImageSpec. **get_string_attribute** *(name, defaultval="")*

Retrieves a named metadata value from `extra_attribs`, if it is found and is of the given type; returns the default value (or a passed value) if not found.

Example:

```
# If "foo" is not found, or if it's not an int, return 0
foo = s.get_int_attribute ("foo")

# If "foo" is not found, or if it's not a string, return "blah"
foo = s.get_string_attribute ("foo", "blah")
```

**ImageSpec[key]**

ImageSpec provides a Python dict-like interface for metadata, in addition to `attribute()` and `getattribute()`.

The `ImageSpec[key] = value` notation can be used to set an attribute (just like calling `ImageSpec. attribute("key", value)`). Also, `ImageSpec[key]` can retrieve an attribute if it is present, or raise a `KeyError` exception if not found.

Like dictionaries, `key` in `spec` is `True` if the attribute is present, and `del spec['key']` will remove the attribute.

Examples:
# Same as: spec.attribute("Compression", comp)
spec["Compression"] = comp

# Same as: comp = spec.getattribute("Compression")
# if it succeeds, or raises a KeyError if not found.
comp = spec["Compression"]

# Failed spec["key"] will raise a KeyError
try:
    r = spec["unknown"]
except:
    print("'unknown' key was not found")

# "key" in spec is True if the key is present
if "Compression" in spec:
    print("'Compression' metadata is present")

# del spec["key"] removes the key
del key["Compression"]

# ImageSpec.get("key") returns the value, or None if not found
comp = spec.get("Compression")
# and optionally, a default value may be passed
comp = spec.get("Compression", "none")

The basic ["key"] setting and retrieval was added in OpenImageIO in 2.1. The "key" in and del operators, and the get() method, were added in OpenImageIO 2.4.

ImageSpec.metadata_val(paramval, human=False)
For a ParamValue, format its value as a string.

ImageSpec.serialize(format='text', verbose='Detailed')
Return a string containing the serialization of the ImageSpec. The format may be either "text" or "XML". The verbose may be one of "brief", "detailed" or "detailedhuman".

ImageSpec.to_xml()
Equivalent to serialize("xml", "detailedhuman").

ImageSpec.from_xml(xml)
Initializes the ImageSpec from the information in the string xml containing an XML-serialized ImageSpec.

ImageSpec.channel_name(chan)
Returns a string containing the name of the channel with index chan.

ImageSpec.channelindex(name)
Return the integer index of the channel with the given name, or -1 if the name is not a name of one of the channels.

ImageSpec.channelformat(chan)
Returns a TypeDesc of the channel with index chan.

ImageSpec.get_channelformats()
Returns a tuple containing all the channel formats.

ImageSpec.valid_tile_range(xbegin, xend, ybegin, yend, zbegin, zend)
Returns True if the given tile range exactly covers a set of tiles, or False if it isn’t (or if the image is not tiled).

ImageSpec.copy_dimensions(other)
Copies from ImageSpec other only the fields describing the size and data types, but not the arbitrary named
metadata or channel names.

ImageSpec.\texttt{undefined}()

Returns \texttt{True} for a newly initialized (undefined) ImageSpec.

### 11.4.1 Example: Header info

Here is an illustrative example of the use of ImageSpec, a working Python function that opens a file and prints all the relevant header information:

```python
#!/usr/bin/env python
import OpenImageIO as oiio

# Print the contents of an ImageSpec
def print_imagespec (spec, subimage=0, mip=0) :
    if spec.depth <= 1 :
        print (" resolution \$dx\$%dx%+d\$%+d\$%+d\$%+d\$%+d\$ % (spec.width, spec.height, spec.x, spec.y))
    else :
        print (" resolution \$dx\$%dx%+d\$%+d\$%+d\$%+d\$%+d\$ %
                (spec.width, spec.height, spec.depth, spec.x, spec.y, spec.z))
    if (spec.width != spec.full_width or spec.height != spec.full_height
        or spec.depth != spec.full_depth) :
        if spec.full_depth <= 1 :
            print (" full res \$dx\$%dx%+d\$%+d\$%+d\$%+d\$ %
                    (spec.full_width, spec.full_height, spec.full_x, spec.full_y))
        else :
            print (" full res \$dx\$%dx%+d\$%+d\$%+d\$%+d\$ %
                    (spec.full_width, spec.full_height, spec.full_depth,
                     spec.full_x, spec.full_y, spec.full_z))
    if spec.tile_width :
        print (" tile size \$dx\$%dx%+d\$ %
                (spec.tile_width, spec.tile_height, spec.tile_depth))
    else :
        print " untiled"
    if mip >= 1 :
        return
    print (" + str(spec.nchannels), "channels:", spec.channelnames
    print " format = ", str(spec.format)
    if len(spec.channelformats) > 0 :
        print " channelformats = ", spec.channelformats
    print " alpha channel = ", spec.alpha_channel
    print " z channel = ", spec.z_channel
    print " deep = ", spec.deep
    for i in spec.extra_attribs) :
        if type(i.value) == str :
            print " ", i.name, "= \"%s\" + i.value + "\""
        else :
            print " ", i.name, "=", i.value

# poor_mans_iinfo (filename) :
def poor_mans_iinfo (filename) :
    input = ImageInput.open (filename)
    if not input :
        (continues on next page)
print 'Could not open "' + filename + '"
print "\tError: ", oiio.geterror()
return
print 'Opened "' + filename + '" as a ' + input.format_name()
sub = 0
mip = 0
while True :
    if sub > 0 or mip > 0 :
        print "Subimage", sub, "MIP level", mip, ":
        print_imagespec (input.spec(), mip=mip)
        mip = mip + 1
        if input.seek_subimage (sub, mip) :
            continue # proceed to next MIP level
    else :
        sub = sub + 1
        mip = 0
        if input.seek_subimage (sub, mip) :
            continue # proceed to next subimage
        break # no more MIP levels or subimages
input.close ()

11.5 DeepData

The DeepData class describing “deep” image data (multiple depth sample per pixel), which is explained in detail in Section Reading “deep” data, is replicated for Python.

DeepData()

Constructs a DeepData object. It needs to have its init() and alloc() methods called before it can hold any meaningful data.

DeepData.init (npixels, nchannels, channeltypes, channelnames)

Initializes this DeepData to hold npixels total pixels, with nchannels color channels. The data types of the channels are described by channeltypes, a tuple of TypeDesc values (one per channel), and the names are provided in a tuple of strings `channelnames`. After calling init, you still need to set the number of samples for each pixel (using set_nsamples) and then call alloc() to actually allocate the sample memory.

DeepData.initialized()

Returns True if the DeepData is initialized at all.

DeepData.allocated()

Returns True if the DeepData has already had pixel memory allocated.

DeepData.pixels

This int field contains the total number of pixels in this collection of deep data.

DeepData.channels

This int field contains the number of channels.

DeepData.A_channel
DeepData.AR_channel
DeepData.AG_channel
DeepData.AB_channel
DeepData.Z_channel
DeepData.Zback_channel

The channel index of certain named channels, or -1 if they don’t exist. For AR_channel, AG_channel,
AB_channel, if they don’t exist, they will contain the value of A_channel, and Zback_channel will contain the value of z_channel if there is no actual Zback.

DeepData.channelname(c)
Retrieve the name of channel C, as a string.

DeepData.channeltype(c)
Retrieve the data type of channel C, as a TypeDesc.

DeepData.channelsize(c)
Retrieve the size (in bytes) of one datum of channel C.

DeepData.samplesize()
Retrieve the packed size (in bytes) of all channels of one sample.

DeepData.same_channeltypes(other)
Returns True if this DeepData has the same channel types as other.

DeepData.set_samples(pixel, nsamples)
Set the number of samples for a given pixel (specified by integer index).

DeepData.samples(pixel)
Get the number of samples for a given pixel (specified by integer index).

DeepData.insert_samples(pixel, samplepos, n)
Insert n samples starting at the given position of an indexed pixel.

DeepData.erase_samples(pixel, samplepos, n)
Erase n samples starting at the given position of an indexed pixel.

DeepData.set_deep_value(pixel, channel, sample, value)
Set specific float value of a given pixel, channel, and sample index.

DeepData.set_deep_value_uint(pixel, channel, sample, value)
Set specific unsigned int value of a given pixel, channel, and sample index.

DeepData.deep_value(pixel, channel, sample, value)
Retrieve the specific value of a given pixel, channel, and sample index (for float channels).

DeepData.deep_value_uint(pixel, channel, sample)
Retrieve the specific value of a given pixel, channel, and sample index (for uint channels).

DeepData.copy_deep_sample(pixel, sample, src, srcpixel, srcsample)
Copy a deep sample from DeepData src into this DeepData.

DeepData.copy_deep_pixel(pixel, src, srcpixel)
Copy a deep pixel from DeepData src into this DeepData.

DeepData.split(pixel, depth)
Split any samples of the pixel that cross depth. Return True if any splits occurred, False if the pixel was unmodified.

DeepData.sort(pixel)
Sort the samples of the pixel by their Z depth.

DeepData.merge_overlaps(pixel)
Merge any adjacent samples in the pixel that exactly overlap in z range. This is only useful if the pixel has previously been split at all sample starts and ends, and sorted by depth.

DeepData.merge_deep_pixels(pixel, src, srcpixel)
Merge the samples of src’s pixel into this DeepData’s pixel.

DeepData.occlusion_cull(pixel)
Eliminate any samples beyond an opaque sample.
DeepData.\texttt{opaque}_z(pix)le

For the given pixel index, return the z value at which the pixel reaches full opacity.

### 11.6 ImageInput

See Chapter \textit{ImageInput: Reading Images} for detailed explanations of the C++ ImageInput class APIs. The Python APIs are very similar. The biggest difference is that in C++, the various read_* functions write the pixel values into an already-allocated array that belongs to the caller, whereas the Python versions allocate and return an array holding the pixel values (or \textit{None} if the read failed).

\texttt{ImageInput.open(filename[, config_imagespec])}

Creates an ImageInput object and opens the named file. Returns the open ImageInput upon success, or \textit{None} if it failed to open the file (after which, \textit{OpenImageIO.geterror()} will contain an error message). In the second form, the optional ImageSpec argument \textit{config} contains attributes that may set certain options when opening the file.

Example:

```python
input = ImageInput.open("tahoe.jpg")
if input == None:
    print "Error!", oiio.geterror()
    return
```

\texttt{ImageInput.close()}

Closes an open image file, returning \texttt{True} if successful, \texttt{False} otherwise.

Example:

```python
input = ImageInput.open(filename)
...
input.close()
```

\texttt{ImageInput.format_name()}

Returns the format name of the open file, as a string.

Example:

```python
input = ImageInput.open(filename)
if input:
    print filename, "was a", input.format_name(), "file."
    input.close()
```

\texttt{ImageInput.spec()}

Returns an ImageSpec corresponding to the currently open subimage and MIP level of the file.

Example:

```python
input = ImageInput.open(filename)
spec = input.spec()
print "resolution ", spec.width, "x", spec.height
```

\texttt{ImageInput.spec(subimage, miplevel=0)}

Returns a full copy of the ImageSpec corresponding to the designated subimage and MIP level.

\texttt{ImageSpec ImageInput.spec_dimensions(subimage, miplevel=0)}

Returns a partial copy of the ImageSpec corresponding to the designated subimage and MIP level, only copying the dimension fields and not any of the arbitrary named metadata (and is thus much less expensive).
OpenImageIO, Release 2.4.1

ImageInput\texttt{.current\_subimage}()

Returns the current subimage of the file.

ImageInput\texttt{.current\_miplevel}()

Returns the current MIP level of the file.

ImageInput\texttt{.seek\_subimage}(\texttt{subimage}, \texttt{miplevel})

Repositions the file pointer to the given subimage and MIP level within the file (starting with 0). This function returns \texttt{True} upon success, \texttt{False} upon failure (which may include the file not having the specified subimage or MIP level).

Example:

```python
input = ImageInput.open (filename)
mip = 0
while True :
    ok = input.seek_subimage (0, mip)
    if not ok :
        break
    spec = input.spec()
    print "MIP level", mip, "is", spec.width, "x", spec.height
```

ImageInput\texttt{.read\_image}(format='float')

ImageInput\texttt{.read\_image}(chbegin, chend, format='float')

ImageInput\texttt{.read\_image}(subimage, miplevel, chbegin, chend, format='float')

Read the entire image and return the pixels as a NumPy array of values of the given format (described by a TypeDesc or a string, float by default). If the format is unknown, the pixels will be returned in the native format of the file. If an error occurs, None will be returned.

For a normal (2D) image, the array returned will be 3D indexed as \([y][x][\text{channel}]\). For 3D volumetric images, the array returned will be 4D with shape indexed as \([z][y][x][\text{channel}]\).

Example:

```python
input = ImageInput.open (filename)
spec = input.spec ()
pixels = input.read_image ()
print "The first pixel is", pixels[0][0]
print "The second pixel is", pixels[0][1]
input.close ()
```

ImageInput\texttt{.read\_scanline}(y, z, format='float')

Read scanline number \texttt{y} from depth plane \texttt{z} from the open file, returning the pixels as a NumPy array of values of the given type (described by a TypeDesc or a string, float by default). If the type is TypeUnknown, the pixels will be returned in the native format of the file. If an error occurs, None will be returned.

The pixel array returned will be a 2D ndarray, indexed as \([x][\text{channel}]\).

Example:

```python
input = ImageInput.open (filename)
spec = input.spec ()
if spec.tile_width == 0 :
    for y in range(spec.y, spec.y+spec.height) :
        pixels = input.read_scanline (y, spec.z, "float")
        # process the scanline
else :
    print "It's a tiled file"
input.close ()
```
**ImageInput**.read_tile(x, y, z, format='float')

Read the tile whose upper left corner is pixel (x,y,z) from the open file, returning the pixels as a NumPy array of values of the given type (described by a TypeDesc or a string, float by default). If the type is TypeUnknown, the pixels will be returned in the native format of the file. If an error occurs, None will be returned.

For a normal (2D) image, the array of tile pixels returned will be a 3D ndarray indexed as [y][x][channel]. For 3D volumetric images, the array returned will be 4D with shape indexed as [z][y][x][channel].

Example:

```python
input = ImageInput.open (filename)
spec = input.spec ()
if spec.tile_width > 0 :
    for z in range(spec.z, spec.z+spec.depth, spec.tile_depth) :
        for y in range(spec.y, spec.y+spec.height, spec.tile_height) :
            for x in range(spec.x, spec.x+spec.width, spec.tile_width) :
                pixels = input.read_tile (x, y, z, oiiio.FLOAT)
                # process the tile
else :
    print "It's a scanline file"
input.close ()
```

**ImageInput**.read_scanlines(subimage, mipmaplevel, ybegin, yend, z, chbegin, chend, format='float')

**ImageInput**.read_scanlines(ybegin, yend, z, chbegin, chend, format='float')

**ImageInput**.read_tiles(xbegin, xend, ybegin, yend, zbegin, zend, chbegin, chend, format='float')

**ImageInput**.read_tiles(subimage, mipmaplevel, xbegin, xend, ybegin, yend, zbegin, zend, format='float')

Similar to the C++ routines, these functions read multiple scanlines or tiles at once, which in some cases may be more efficient than reading each scanline or tile separately. Additionally, they allow you to read only a subset of channels.

For normal 2D images, both read_scanlines and read_tiles will return a 3D array indexed as [z][y][x][channel].

For 3D volumetric images, both read_scanlines will return a 3D array indexed as [y][x][channel], and read_tiles will return a 4D array indexed as [z][y][x][channel].

Example:

```python
input = ImageInput.open (filename)
spec = input.spec ()

# Read the whole image, the equivalent of
#    pixels = input.read_image (type)
# but do it using read_scanlines or read_tiles:
if spec.tile_width == 0 :
    pixels = input.read_scanlines (spec.y, spec.y+spec.height, 0, 0, spec.nchannels)
else :
    pixels = input.read_tiles (spec.x, spec.x+spec.width, spec.y, spec.y+spec.height, spec.z, spec.z+spec.depth, 0, spec.nchannels)
```

**ImageInput**.read_native_deep_scanlines(subimage, mipmaplevel, ybegin, yend, z, chbegin, chend)

**ImageInput**.read_native_deep_tiles(subimage, mipmaplevel, xbegin, xend, ybegin, yend, zbegin, zend, chbegin, chend)
ImageInput.read_native_deep_image(subimage=0, mipmap=0)
Read a collection of scanlines, tiles, or an entire image of “deep” pixel data from the specified subimage and MIP level. The begin/end coordinates are all integer values. The value returned will be a DeepData if the read succeeds, or None if the read fails.

These methods are guaranteed to be thread-safe against simultaneous calls to any of the other other read_native calls that take an explicit subimage/mipmap.

ImageOutput.get_thumbnail(subimage: int = 0) → ImageBuf
Retrieve an ImageBuf containing reduced-resolution(“thumbnail”) version of the image. If no thumbnail could be retrieved, an empty ImageBuf will be returned.

ImageInput.geterror(clear=True)
Retrieves the error message from the latest failed operation on an ImageInput.

Example:

```python
input = ImageInput.open (filename)
if not input :
    print "Open error:", oiio.geterror()
    # N.B. error on open must be retrieved with the global geterror(),
    # since there is no ImageInput object!
else :
    pixels = input.read_image (oiio.FLOAT)
    if not pixels :
        print "Read_image error:", input.geterror()
    input.close()
```

11.6.1 Example: Reading pixel values from a file to find min/max

```python
#!/usr/bin/env python
import OpenImageIO as oiio

def find_min_max (filename) :
    input = ImageInput.open (filename)
    if not input :
        print 'Could not open "' + filename + '"'
        print '	Error: ", oiio.geterror()
        return
    spec = input.spec()
    nchans = spec.nchannels
    pixels = input.read_image()
    if not pixels :
        print 'Could not read:", input.geterror()
        return
    input.close()  # we're done with the file at this point
    minval = pixels[0][0]  # initialize to the first pixel value
    maxval = pixels[0][0]
    for y in range(spec.height) :
        for x in range(spec.width) :
            p = pixels[y][x]
            for c in range(nchans) :
                if p[c] < minval[c] :
                    minval[c] = p[c]
                if p[c] > maxval[c] :
                    maxval[c] = p[c]
```

(continues on next page)
11.7 ImageOutput

See Chapter *ImageOutput: Writing Images* for detailed explanations of the C++ ImageOutput class APIs. The Python APIs are very similar.

**ImageOutput.create**(name, plugin_searchpath='')

Create a new ImageOutput capable of writing the named file format (which may also be a file name, with the type deduced from the extension). There is an optional parameter giving an colon-separated search path for finding ImageOutput plugins. The function returns an ImageOutput object, or None upon error (in which case, OpenImageIO.geterror() may be used to retrieve the error message).

Example:

```python
import OpenImageIO as oiio
output = ImageOutput.create("myfile.tif")
if not output:
    print "Error:", oiio.geterror()
```

**ImageOutput.format_name()**

The file format name of a created ImageOutput, as a string.

Example:

```python
output = ImageOutput.create(filename)
if output:
    print "Created output" , filename , "as a", output.format_name()
```

**ImageOutput.supports(feature)**

For a created ImageOutput, returns True if the file format supports the named feature (such as “tiles”, “mipmap”, etc., see Section *ImageOutput Class Reference* for the full list), or False if this file format does not support the feature.

Example:

```python
output = ImageOutput.create(filename)
if output:
    print output.format_name() , "supports..."
    print "tiles?", output.supports("tiles")
    print "multi-image?", output.supports("multiimage")
    print "MIP maps?", output.supports("mipmap")
    print "per-channel formats?", output.supports("channelformats")
```

**ImageOutput.open(filename, spec, mode='Create')**

Opens the named output file, with an ImageSpec describing the image to be output. The mode may be one of “Create”, “AppendSubimage”, or “AppendMIPLevel”. See Section *ImageOutput Class Reference* for
details. Returns True upon success, False upon failure (error messages retrieved via ImageOutput.
geterror()).

**Returns** True for success, False for failure.

**Example:**
```python
output = ImageOutput.create (filename)
if not output :
    print "Error:", oiio.geterror()
spec = ImageSpec (640, 480, 3, "uint8")
ok = output.open (filename, spec)
if not ok :
    print "Could not open", filename, ":", output.geterror()
```

**ImageOutput.open(filename, (imagespec, ...))**

This variety of open() is used specifically for multi-subimage files. A tuple of ImageSpec objects is passed, one for each subimage that will be written to the file. After each subimage is written, then a regular call to open(name, newspec, AppendSubimage) moves on to the next subimage.

**Returns** True for success, False for failure.

**ImageOutput.close()**

Closes an open output.

**Returns** True for success, False for failure.

**ImageOutput.spec()**

Returns the ImageSpec of the currently-open output image.

**ImageOutput.write_image(pixels)**

Write the currently opened image all at once. The pixels parameter should be a Numpy ndarray containing data elements indexed as [y][x][channel] for normal 2D images, or for 3D volumetric images, as [z][y][x][channel], or in other words, exactly matching the shape of array returned by ImageInput.read_image(). (It will also work fine if the array is 1D “flattened” version, as long as it contains the correct total number of values.) The data type is deduced from the contents of the array itself. Returns True upon success, False upon failure.

**Example:**
```python
# This example reads a scanline file, then converts it to tiled
# and writes to the same name.
input = ImageInput.open (filename)
spec = input.spec ()
pixels = input.read_image ()
input.close ()

output = ImageOutput.create (filename)
if output.supports("tiles") :
    spec.tile_width = 64
    spec.tile_height = 64
    output.open (filename, spec)
    output.write_image (pixels)
    output.close ()
```

**ImageOutput.write_scanline(y, z, pixels)**

**ImageOutput.write_scanlines(ybegin, yend, z, pixels)**

Write one or many scanlines to the currently open file. Returns True upon success, False upon failure.
The `pixels` parameter should be a Numpy `ndarray` containing data elements indexed as `[x][channel]` for `write_scanline` or as `[y][x][channels]` for `write_scanlines`, exactly matching the shape returned by `ImageInput.read_scanline` or `ImageInput.read_scanlines`. (It will also work fine if the array is 1D “flattened” version, as long as it contains the correct total number of values.)

Example:

```python
# Copy a TIFF image to JPEG by copying scanline by scanline.
input = ImageInput.open("in.tif")
spec = input.spec()
output = ImageOutput.create("out.jpg")
output.open(filename, spec)
for z in range(spec.z, spec.z+spec.depth):
    for y in range(spec.y, spec.y+spec.height):
        pixels = input.read_scanline(y, z)
        output.write_scanline(y, z, pixels)
output.close()
input.close()

# The same example, but copying a whole "plane" of scanlines at a time:
...
for z in range(spec.z, spec.z+spec.depth):
    pixels = input.read_scanlines(spec.y, spec.y+spec.height, z)
    output.write_scanlines(spec.y, spec.y+spec.height, z, pixels)
...
```

ImageOutput.write_tile(x, y, z, pixels)

ImageOutput.write_tiles(xbegin, xend, ybegin, yend, zbegin, zend, pixels)

Write one or many tiles to the currently open file. Returns `True` upon success, `False` upon failure.

The `pixels` parameter should be a Numpy `ndarray` containing data elements indexed as `[y][x][channel]` for normal 2D images, or as `[z][y][x][channels]` 3D volumetric images, exactly matching the shape returned by `ImageInput.read_tile` or `ImageInput.read_tiles`. (It will also work fine if the array is 1D “flattened” version, as long as it contains the correct total number of values.)

Example:

```python
input = ImageInput.open(in_filename)
spec = input.spec()
output = ImageOutput.create(out_filename)
output.open(out_filename, spec)
for z in range(spec.z, spec.z+spec.depth, spec.tile_depth):
    for y in range(spec.y, spec.y+spec.height, spec.tile_height):
        for x in range(spec.x, spec.x+spec.width, spec.tile_width):
            pixels = input.read_tile(x, y, z)
            output.write_tile(x, y, z, pixels)
output.close()
input.close()

# The same example, but copying a whole row of of tiles at a time:
...
for z in range(spec.z, spec.z+spec.depth, spec.tile_depth):
    for y in range(spec.y, spec.y+spec.height, spec.tile_height):
        pixels = input.read_tiles(spec.x, spec.x+spec.width, y, y+tile_width, z, z+tile_width)
        output.write_tiles(spec.x, spec.x+spec.width, y, y+tile_width, z, z+tile_width, pixels)
...
```
ImageOutput.write_deep_scanlinesa(ybegin, yend, z, deepdata)
ImageOutput.write_deep_tiles(xbegin, xend, ybegin, yend, zbegin, zend, deepdata)
ImageOutput.write_deep_image(deepdata)

Write a collection of scanlines, tiles, or an entire image of “deep” pixel data. The begin/end coordinates are all integer values, and deepdata should be a DeepData.

ImageOutput.set_thumbnail(thumb: ImageBuf)

Specify a reduced-resolution (“thumbnail”) version of the image, as an ImageBuf. Note that many image formats may require the thumbnail to be specified prior to writing the pixels. Return True for success, or False if a thumbnail could not be set.

ImageOutput.copy_image(imageinput)

Copy the current image of the open input to the open output. (The reason this may be preferred in some circumstances is that, if input and output were the same kind of input file format, they may have a special efficient technique to copy pixels unaltered, for example by avoiding the decompression/recompression round trip.)

Example:

```python
input = ImageInput.open (in_filename)
spec = input.spec ()
output = ImageOutput.create (out_filename)
output.open (filename, spec)
output.copy_image (input)
output.close ()
input.close ()
```

ImageOutput.geterror(clear=True)

Retrieves the error message from the latest failed operation on an open file.

Example:

```python
output = ImageOutput.create (filename)
if not output :
    print "Create error:", oio.geterror()
    # N.B. error on create must be retrieved with the global geterror(),
    # since there is no ImageOutput object!
else :
    ok = output.open (filename, spec)
    if not ok :
        print "Open error:", output.geterror()
    ok = output.write_image (pixels)
    if not ok :
        print "Write error:", output.geterror()
    output.close ()
```

### 11.8 ImageBuf

See Chapter ImageBuf: Image Buffers for detailed explanations of the C++ ImageBuf class APIs. The Python APIs are very similar.

**ImageBuf()**

Construct a new, empty ImageBuf. The ImageBuf is uninitialized and is awaiting a call to reset() or copy() before it is useful.
ImageBuf(filename[, subimage, mipmap])

Construct a read-only ImageBuf that will read from the named file. Optionally, a specific subimage or MIP level may be specified (defaulting to 0).

Example:

```
import OpenImageIO as oiio
...
buf = ImageBuf("grid.tif")
```

ImageBuf(filename, subimage, mipmap, config)

Construct a read-only ImageBuf that will read from the named file, with an ImageSpec config giving configuration hints.

Example:

```
import OpenImageIO as oiio
...
config = ImageSpec()
config.attribute("oiio:RawColor", 1)
buf = ImageBuf("grid.tif", 0, 0, config)
```

ImageBuf(imagespec, zero=True)

Construct a writable ImageBuf of the dimensions and data format specified by an ImageSpec. The pixels will be initialized to black/empty values if zero is True, otherwise the pixel values will remain uninitialized.

Example:

```
spec = ImageSpec (640, 480, 3, "float")
buf = ImageBuf (spec)
```

ImageBuf(data)

Construct a writable ImageBuf of the dimensions of data, which is a NumPy ndarray of values indexed as [y][x][channel] for normal 2D images, or for 3D volumetric images, as [z][y][x][channel]. The data will be copied into the ImageBuf’s internal storage. The NumPy array may be strided for z, y, or x, but must have “contiguous” channel data within each pixel. The pixel data type is also deduced from the contents of the data array.

Note that this Python ImageBuf will contain its own copy of the data, so further changes to the data array will not affect the ImageBuf. This is different from the C++ ImageBuf constructor from a pointer, which will “wrap” the existing user-provided buffer but not make its own copy.

Example:

```
pixels = numpy.zeros ((640, 480, 3), dtype = numpy.float32)
buf = ImageBuf (pixels)
```

ImageBuf.clear()

Resets the ImageBuf to a pristine state identical to that of a freshly constructed ImageBuf using the default constructor.

Example:

```
buf = ImageBuf (...) 

# The following two commands are equivalent:
buf = ImageBuf ()   # 1 - assign a new blank ImageBuf
buf.clear ()        # 2 - clear the existing ImageBuf
```
ImageBuf.reset (filename, subimage=0, mipmap=0, config=ImageSpec())

Restore the ImageBuf to a newly-constructed state, to read from a filename (optionally specifying a subimage, MIP level, and/or a “configuration” ImageSpec).

ImageBuf.reset (imagespec, zero=True)

Restore the ImageBuf to the newly-constructed state of a writable ImageBuf specified by an ImageSpec. The pixels will be initialized to black/empty if zero is True, otherwise the pixel values will remain uninitialized.

ImageBuf.reset (data)

Reset the ImageBuf to be sized to the dimensions of data, which is a NumPy ndarray of values indexed as [y][x][channel] for normal 2D images, or for 3D volumetric images, as [z][y][x][channel]. The data will be copied into the ImageBuf’s internal storage. The NumPy array may be strided for z, y, or x, but must have “contiguous” channel data within each pixel. The pixel data type is also deduced from the contents of the data array.

Note that this Python ImageBuf will contain its own copy of the data, so further changes to the data array will not affect the ImageBuf. This is different from the C++ ImageBuf constructor from a pointer, which will “wrap” the existing user-provided buffer but not make its own copy.

ImageBuf.read (subimage=0, mipmap=0, force=False, convert=oiio.UNKNOWN)

Explicitly read the image from the file (of a file-reading ImageBuf), optionally specifying a particular subimage, MIP level, and channel range. If force is True, will force an allocation of memory and a full read (versus the default of relying on an underlying ImageCache). If convert is not the default of `UNKNOWN`, it will force the ImageBuf to convert the image to the specified data format (versus keeping it in the native format or relying on the ImageCache to make a data formatting decision).

Note that a call to read() is not necessary — any ImageBuf API call that accesses pixel values will trigger a file read if it has not yet been done. An explicit read() is generally only needed to change the subimage or mipmap, or to force an in-buffer read or format conversion.

The read() method will return True for success, or False if the read could not be performed (in which case, a geterror() call will retrieve the specific error message).

Example:

```python
buf = ImageBuf ("mytexture.exr")
buf.read (0, 2, True)
# That forces an allocation and read of MIP level 2
```

ImageBuf.init_spec (filename, subimage=0, mipmap=0)

Explicitly read just the header from a file-reading ImageBuf (if the header has not yet been read), optionally specifying a particular subimage and MIP level. The init_spec() method will return True for success, or False if the read could not be performed (in which case, a geterror() call will retrieve the specific error message).

Note that a call to init_spec() is not necessary — any ImageBuf API call that accesses the spec will read it automatically it has not yet been done.

ImageBuf.write (filename, dtype='', fileformat='')

Write the contents of the ImageBuf to the named file. Optionally, dtype can override the pixel data type (by default, the pixel data type of the buffer), and fileformat can specify a particular file format to use (by default, it will infer it from the extension of the file name).

Example:

```python
# No-frills conversion of a TIFF file to JPEG
buf = ImageBuf ("in.tif")
buf.write ("out.jpg")
```

(continues on next page)
# Convert to uint16 TIFF
buf = ImageBuf("in.exr")
buf.write("out.tif", "uint16")

ImageBuf.write(imageoutput)
Write the contents of the ImageBuf as the next subimage to an open ImageOutput.

Example:
buf = ImageBuf(...)  # Existing ImageBuf
out = ImageOutput.create("out.exr")
out.open("out.exr", buf.spec())
buf.write(out)
out.close()

ImageBuf.make_writable(keep_cache_type=False)
Force the ImageBuf to be writable. That means that if it was previously backed by an ImageCache (storage was IMAGECACHE), it will force a full read so that the whole image is in local memory.

ImageBuf.set_write_format(format=oiio.UNKNOWN)
ImageBuf.set_write_tiles(width=0, height=0, depth=0)
Override the data format or tile size in a subsequent call to write(). The format argument to set_write_format may be either a single data type description for all channels, or a tuple giving the data type for each channel in order.

Example:
# Conversion to a tiled unsigned 16 bit integer file
buf = ImageBuf("in.tif")
buf.set_write_format("uint16")
buf.set_write_tiles(64, 64)
buf.write("out.tif")

ImageBuf.spec()
ImageBuf.nativespec()
ImageBuf.spec() returns the ImageSpec that describes the contents of the ImageBuf. ImageBuf.nativespec() returns an ImageSpec that describes the contents of the file that the ImageBuf was read from (this may differ from ImageBuf.spec() due to format conversions, or any changes made to the ImageBuf after the file was read, such as adding metadata).

Handy rule of thumb: spec() describes the buffer, nativespec() describes the original file it came from.

Example:
buf = ImageBuf("in.tif")
print "Resolution is", buf.spec().width, "x", buf.spec().height

ImageBuf.specmod()
ImageBuf.specmod() provides a reference to the writable ImageSpec inside the ImageBuf. Be very careful! It is safe to modify certain metadata, but if you change the data format or resolution fields, you will get the chaos you deserve.

Example:
OpenImageIO, Release 2.4.1

```python
# Read an image, add a caption metadata, write it back out in place
buf = ImageBuf("file.tif")
buf.specmod().attribute("ImageDescription", "my photo")
buf.write("file.tif")
```

ImageBuf.has_thumbnail
Contains True if the ImageBuf contains thumbnail data, otherwise False.

ImageBuf.clear_thumbnail()
Remove any associated thumbnail from this buffer.

ImageBuf.set_thumbnail(thumb: ImageBuf)
Set the thumbnail associated with this buffer to thumb.

ImageBuf.thumbnail() → ImageBuf
Return an ImageBuf holding any thumbnail associated with this buffer.

ImageBuf.name
The file name of the image (as a string).

ImageBuf.file_format_name
The file format of the image (as a string).

ImageBuf.subimage
ImageBuf.miplevel
ImageBuf.nsubimages
ImageBuf.nmiplevels
Several fields giving information about the current subimage and MIP level, and the total numbers thereof in the file.

ImageBuf.xbegin
ImageBuf.xend
ImageBuf.ybegin
ImageBuf.yend
ImageBuf.zbegin
ImageBuf.zend
The range of valid pixel data window. Remember that the end is one past the last pixel.

ImageBuf.xmin
ImageBuf.xmax
ImageBuf.ymin
ImageBuf.ymax
ImageBuf.zmin
ImageBuf.zmax
The minimum and maximum (inclusive) coordinates of the pixel data window.

ImageBuf.orientation
ImageBuf.oriented_width
ImageBuf.oriented_height
ImageBuf.oriented_x
ImageBuf.oriented_y
ImageBuf.oriented_full_width
ImageBuf.oriented_full_height
ImageBuf.oriented_full_x
ImageBuf.oriented_full_y
The Orientation field gives the suggested display orientation of the image (see Section Display hints).

The other fields are helpers that give the width, height, and origin (as well as “full” or “display” resolution and origin), taking the intended orientation into consideration.
ImageBuf.

**ImageBuf.roi**

These fields hold an ROI description of the pixel data window (roi) and the full (a.k.a. “display”) window (roi_full).

Example:

```python
buf = ImageBuf("tahoe.jpg")
print "Resolution is", buf.roi.width, "x", buf.roi.height
```

**ImageBuf.set_origin**(x, y, z=0)

Changes the “origin” of the data pixel data window to the specified coordinates.

Example:

```python
# Shift the pixel data so the upper left is at pixel (10, 10)
buf.set_origin (10, 10)
```

**ImageBuf.set_full**(xbegin, xend, ybegin, yend, zbegin, zend)

Changes the “full” (a.k.a. “display”) window to the specified ROI.

Example:

```python
buf.set_full (0, 1024, 0, 768, 0, 1)
```

**ImageBuf.pixels_valid**

Will be True if the file has already been read and the pixels are valid. (It is always True for writable ImageBuf’s.) There should be few good reasons to access these, since the spec and pixels will be automatically be read when they are needed.

**ImageBuf.pixeltype()**

Returns a TypeDesc describing the data type of the pixels stored within the ImageBuf.

**ImageBuf.copy_metadata**(other_imagebuf)

Replaces the metadata (all ImageSpec items, except for the data format and pixel data window size) with the corresponding metadata from the other ImageBuf.

**ImageBuf.copy_pixels**(other_imagebuf)

Replace the pixels in this ImageBuf with the values from the other ImageBuf.

**ImageBuf ImageBuf.copy**(format=TypeUnknown)

Return a full copy of this ImageBuf (with optional data format conversion, if format is supplied).

Example:

```python
A = ImageBuf("A.tif")

# Make a separate, duplicate copy of A
B = A.copy()

# Make another copy of A, but converting to float pixels
C = A.copy ("float")
```

**ImageBuf.copy**(other_imagebuf, format=TypeUnknown)

Make this ImageBuf a complete copy of the other ImageBuf. If a format is provided, this will get the specified pixel data type rather than using the same pixel format as the source ImageBuf.

Example:
A = ImageBuf("A.tif")

# Make a separate, duplicate copy of A
B = ImageBuf()
B.copy (A)

# Make another copy of A, but converting to float pixels
C = ImageBuf()
C.copy (A, oiio.FLOAT)

ImageBuf.swap(other_imagebuf)
Swaps the content of this ImageBuf and the other ImageBuf.

Example:

A = ImageBuf("A.tif")
B = ImageBuf("B.tif")
A.swap (B)
# Now B contains the "A.tif" image and A contains the "B.tif" image

tuple ImageBuf.getpixel (x, y, z=0, wrap="black")
Retrieves pixel (x,y,z) from the buffer and return it as a tuple of float values, one for each color channel. The x, y, z values are int pixel coordinates. The optional wrap parameter describes what should happen if the coordinates are outside the pixel data window (and may be: “black”, “clamp”, “periodic”, “mirror”).

Example:

buf = ImageBuf ("tahoe.jpg")
p = buf.getpixel (50, 50)
print p
> (0.37, 0.615, 0.97)

ImageBuf.getchannel(x, y, z, channel, wrap='black')
Retrieves just a single channel value from pixel (x,y,z) from the buffer and returns it as a float value. The optional wrap parameter describes what should happen if the coordinates are outside the pixel data window (and may be: “black”, “clamp”, “periodic”, “mirror”).

Example:

buf = ImageBuf ("tahoe.jpg")
green = buf.getchannel (50, 50, 0, 1)

ImageBuf.interppixel(x, y, wrap='black')
ImageBuf.interppixel_bicubic(x, y, wrap='black')
Interpolates the image value (bilinearly or bicubically) at coordinates $(x,y)$ and return it as a tuple of float values, one for each color channel. The x, y values are continuous float coordinates in “pixel space.” The optional wrap parameter describes what should happen if the coordinates are outside the pixel data window (and may be: “black”, “clamp”, “periodic”, “mirror”).

Example:

buf = ImageBuf ("tahoe.jpg")
midx = float(buf.xbegin + buf.xend) / 2.0
midy = float(buf.ybegin + buf.yend) / 2.0
p = buf.interpixel (midx, midy)
# Now p is the interpolated value from right in the center of
# the data window
ImageBuf.interppixel_NDC(x, y, wrap='black')

Interpolates the image value (bilinearly or bicubically) at coordinates (x,y) and return it as a tuple of float values, one for each color channel. The x, y values are continuous, normalized float coordinates in “NDC space,” where (0,0) is the upper left corner of the full (a.k.a. “display”) window, and (1,1) is the lower right corner of the full/display window. The wrap parameter describes what should happen if the coordinates are outside the pixel data window (and may be: “black”, “clamp”, “periodic”, “mirror”).

Example:

```python
buf = ImageBuf("tahoe.jpg")
p = buf.interppixel_NDC (0.5, 0.5)
# Now p is the interpolated value from right in the center of
# the display window
```

ImageBuf.setpixel(x, y, pixel_value)

Sets pixel (x,y,z) to be the pixel_value, expressed as a tuple of float (one for each color channel).

Example:

```python
buf = ImageBuf(ImageSpec (640, 480, 3, oiio.UINT8))

# Set the whole image to red (the dumb slow way, but it works):
for y in range(buf.ybegin, buf.yend) :
    for x in range(buf.xbegin, buf.xend) :
        buf.setpixel (x, y, (1.0, 0.0, 0.0))
```

ImageBuf.get_pixels(format=TypeFloat, roi=ROI.All)

Retrieves the rectangle of pixels (and channels) specified by roi from the image and returns them as an array of values with type specified by format.

As with the ImageInput read functions, the return value is a NumPy ndarray containing data elements indexed as [y][x][channel] for normal 2D images, or for 3D volumetric images, as [z][y][x][channel]). Returns True upon success, False upon failure.

Example:

```python
buf = ImageBuf("tahoe.jpg")
pixels = buf.get_pixels (oiio.FLOAT)  # no ROI means the whole image
```

ImageBuf.set_pixels(roi, data)

Sets the rectangle of pixels (and channels) specified by roi with values in the data, which is a NumPy ndarray of values indexed as [y][x][channel] for normal 2D images, or for 3D volumetric images, as [z][y][x][channel]). (It will also work fine if the array is 1D “flattened” version, as long as it contains the correct total number of values.) The data type is deduced from the contents of the array itself.

Example:

```python
buf = ImageBuf (...)
pixels = (....)
buf.set_pixels (ROI(), pixels)
```

ImageBuf.has_error

This field will be True if an error has occurred in the ImageBuf.

ImageBuf.geterror(clear=True)

Retrieve the error message (and clear the has_error flag).

Example:
buf = ImageBuf("in.tif")
buf.read()  # force a read
if buf.has_error :
    print "Error reading the file: ", buf.geterror()
buf.write("out.jpg")
if buf.has_error :
    print "Could not convert the file: ", buf.geterror()

ImageBuf.pixelindex(x, y, z, check_range=False)
Return the index of pixel (x,y,z).

ImageBuf.deep
Will be True if the file contains “deep” pixel data, or False for an ordinary images.

ImageBuf.deep_samples(x, y, z=0)
Return the number of deep samples for pixel (x,y,z).

ImageBuf.set_deep_samples(x, y, z, nsamples)
Set the number of deep samples for pixel (x,y,z).

ImageBuf.deep_insert_samples(x, y, z, samplepos, nsamples)
ImageBuf.deep_erase_samples(x, y, z, samplepos, nsamples)
Insert or erase nsamples samples starting at the given position of pixel (x,y,z).

ImageBuf.deep_value(x, y, z, channel, sample)
ImageBuf.deep_value_uint(x, y, z, channel, sample)
Return the value of the given deep sample (particular pixel, channel, and sample number) for a channel that is a float or an unsigned integer type, respectively.

ImageBuf.set_deep_value(x, y, z, channel, sample, value)
ImageBuf.set_deep_value_uint(x, y, z, channel, sample, value)
Set the value of the given deep sample (particular pixel, channel, and sample number) for a channel that is a float or an unsigned integer type, respectively.

DeepData ImageBuf.deepdata
A reference to the underlying DeepData of the image.

11.9 ImageBufAlgo

The C++ ImageBufAlgo functions are described in detail in Chapter ImageBufAlgo: Image Processing. They are also exposed to Python. For the majority of ImageBufAlgo functions, their use in Python is identical to C++; in those cases, we will keep our descriptions of the Python bindings minimal and refer you to Chapter ImageBufAlgo: Image Processing, saving the extended descriptions for those functions that differ from the C++ counterparts.

A few things about the parameters of the ImageBufAlgo function calls are identical among the functions, so we will explain once here rather than separately for each function:

- **dst** is an existing ImageBuf, which will be modified (it may be an uninitialized ImageBuf, but it must be an ImageBuf).
- **src** parameter is an initialized ImageBuf, which will not be modified (unless it happens to refer to the same image as dst).
roi, if supplied, is an roi specifying a region of interest over which to operate. If omitted, the region will be the entire size of the source image(s).

nthreads is the maximum number of threads to use. If not supplied, it defaults to 0, meaning to use as many threads as hardware cores available.

Just as with the C++ ImageBufAlgo functions, if dst is an uninitialized ImageBuf, it will be sized to reflect the roi (which, in turn, if undefined, will be sized to the union of the ROI’s of the source images).

### 11.9.1 Pattern generation

#### ImageBuf ImageBufAlgo.zero (roi, nthreads=0)

Zero out the destination buffer (or a specific region of it).

Example:

```python
# Initialize buf to a 640x480 3-channel FLOAT buffer of 0 values
buf = ImageBufAlgo.zero (ROI(0, 640, 0, 480, 0, 1, 0, 3))
```

#### ImageBuf ImageBufAlgo.fill (values, roi=ROI.All, nthreads=0)

Return a filled float image of size roi, or set the pixels of image dst within the ROI to a color or gradient.

Three fill options are available: (a) if one color tuple is supplied, the whole ROI will be filled with that constant value, (b) if two color tuples are supplied, a linear gradient will be applied from top to bottom, (c) if four color tuples are supplied, the ROI will be filled with values bilinearly interpolated from the four corner colors supplied.

Example:

```python
# Draw a red rectangle into buf
buf = ImageBuf (ImageSpec(640, 480, 3, TypeDesc.FLOAT)
ImageBufAlgo.fill (buf, (1,0,0), ROI(50, 100, 75, 85))
```

#### ImageBuf ImageBufAlgo.checker(width, height, depth, color1, color2, xoffset=0, yoffset=0, zoffset=0, roi=ROI.All, nthreads=0)

Return (or copy into dst) a checkerboard pattern. The colors are specified as tuples giving the values for each color channel.

Example:

```python
buf = ImageBuf(ImageSpec(640, 480, 3, oiio.UINT8))
ImageBufAlgo.checker (buf, 64, 64, 1, (0.1,0.1,0.1), (0.4,0.4,0.4))
```

#### ImageBuf ImageBufAlgo.noise (noisetype, A=0.0, B=0.1, mono=False, seed=0, roi=ROI.All, nthreads=0)

Return an image of pseudorandom noise, or add pseudorandom noise to the specified region of existing region dst.

For noise type “white” (and its synonym “uniform”), the values are uniformly distributed on the range (A, B) and independently chosen for each pixel. For noise type “blue”, the range will still be uniformly distributed on (A, B) as with “white”, except that the values have better spectral properties for sampling and dithering purposes. For noise “gaussian”, the noise will have a normal distribution with mean A and standard deviation B.
B. For noise “salt”, the value A will be stored in a random set of pixels whose proportion (of the overall image) is B.

For all noise types, choosing different seed values will result in a different pattern. If the mono flag is True, a single noise value will be applied to all channels specified by roi, but if mono is False, a separate noise value will be computed for each channel in the region.

Example:

```python
buf = ImageBuf(ImageSpec(640, 480, 3, oiio.UINT8))
ImageBufAlgo.zero (buf)
ImageBufAlgo.noise (buf, 'white', 0.25, 0.75)
```

**ImageBuf ImageBufAlgo.bluenoise_image ()**

Return a reference to a singleton ImageBuf containing a 4-channel float periodic blue noise image.

Example:

```python
buf = ImageBufAlgo.bluenoise_image ()
```

**ImageBufAlgo.render_point (dst, x, y, color=(1, 1, 1, 1))**

Render a point at pixel (x,y) of dst. The color (if supplied) is a tuple giving the per-channel colors. Return True for success, False for failure.

Example:

```python
buf = ImageBuf(ImageSpec(640, 480, 4, oiio.FLOAT))
ImageBufAlgo.render_point (buf, 10, 20, (1,0,0,1))
```

**bool ImageBufAlgo.render_line (dst, x1, y1, x2, y2, color=(1,1,1,1), skip_first_point=False)**

Render a line from pixel $(x_1,y_1)$ to $(x_2,y_2)$ into dst. The color (if supplied) is a tuple giving the per-channel colors.

Example:

```python
buf = ImageBuf(ImageSpec(640, 480, 4, oiio.FLOAT))
ImageBufAlgo.render_line (buf, 10, 10, 500, 20, (1,0,0,1))
```

**bool ImageBufAlgo.render_box (dst, x1, y1, x2, y2, color=(1,1,1,1), filled=False)**

Render a filled or unfilled box with corners at pixels $(x_1,y_1)$ and $(x_2,y_2)$ into dst. The color (if supplied) is a tuple giving the per-channel colors.

Example:

```python
buf = ImageBuf(ImageSpec(640, 480, 4, oiio.FLOAT))
ImageBufAlgo.render_box (buf, 150, 100, 240, 180, (0,1,1,1))
ImageBufAlgo.render_box (buf, 100, 50, 180, 140, (0.5, 0.5, 0, 0.5), True)
```

**bool ImageBufAlgo.render_text (dst, x, y, text, fontsize=16, fontname='', textcolor=(1,1,1,1), alignx='left', aligny='baseline', shadow=0, roi=ROI.All, nthreads=0)**

Render antialiased text into dst. The textcolor (if supplied) is a tuple giving the per-channel colors. Choices for alignx are “left”, “right”, and “center”, and choices for aligny are “baseline”, “top”, “bottom”, and “center”.

Example:

```python
buf = ImageBuf(ImageSpec(640, 480, 4, oiio.FLOAT))
ImageBufAlgo.render_text (buf, 50, 100, "Hello, world")
ImageBufAlgo.render_text (buf, 100, 200, "Go Big Red!", 60, "Arial Bold", (1,0,0,1))
```
ROI ImageBufAlgo.text_size (text, fontsize=16, fontname="")
Compute the size that will be needed for the text as an ROI and return it. The size will not be defined if an error occurred (such as not being a valid font name).

Example:

```python
A = ImageBuf(ImageSpec (640, 480, 4, oii.FLOAT))
Aroi = A.roi
size = ImageBufAlgo.text_size("Centered", 40, "Courier New")
if size.defined:
    x = Aroi.xbegin + Aroi.width/2 - (size.xbegin + size.width/2)
    y = Aroi.ybegin + Aroi.height/2 - (size.ybegin + size.height/2)
    ImageBufAlgo.render_text(A, x, y, "Centered", 40, "Courier New")

# Note: this was for illustration. An easier way to do this is:
# render_text(A, x, y, "Centered", 40, "Courier New", alignx="center")
```

11.9.2 Image transformations and data movement

ImageBuf ImageBufAlgo.channels(src, channelorder, newchannelnames=(), shuffle_channel_names=False, nthreads=0)
Return (or store in dst) shuffled channels of src, with channels in the order specified by the tuple channelorder. The length of channelorder specifies the number of channels to copy. Each element in the tuple channelorder may be one of the following:

- int: specifies the index (beginning at 0) of the channel to copy.
- str: specifies the name of the channel to copy.
- float: specifies a constant value to use for that channel.

If newchannelnames is supplied, it is a tuple of new channel names. (See the C++ version for more full explanation.)

Example:

```python
# Copy the first 3 channels of an RGBA, drop the alpha
RGBA = ImageBuf("rgba.tif")
RGB = ImageBufAlgo.channels (RGBA, (0, 1, 2))

# Copy just the alpha channel, making a 1-channel image
Alpha = ImageBufAlgo.channels (RGBA, ("A",))

# Swap the R and B channels
BGRA = ImageBufAlgo.channels (RGBA, (2, 1, 0, 3))

# Add an alpha channel with value 1.0 everywhere to an RGB image
RGBA = ImageBufAlgo.channels (RGB, ("R", "G", "B", 1.0),
            ("R", "G", "B", "A"))
```

ImageBuf ImageBufAlgo.channel_append (A, B, roi=ROI.All, nthreads=0)
bool ImageBufAlgo.channel_append (dst, A, B, roi=ROI.All, nthreads=0)
Append the channels of images A and B together into one image.

Example:
RGB = ImageBuf("rgba.exr")
Z = ImageBuf("z.exr")
RGBAZ = ImageBufAlgo.channel_append (RGB, Z)

ImageData ImageBufAlgo.copy (src, convert=TypeDesc.UNKNOWN, roi=ROI.All, nthreads=0)
bool ImageBufAlgo.copy (dst, src, convert=TypeDesc.UNKNOWN, roi=ROI.All, nthreads=0)
Copy the specified region of pixels of src at the same locations, optionally with the pixel type overridden by convert (if it is not UNKNOWN).

Example:

# Copy A's upper left 200x100 region into B
B = ImageBufAlgo.copy (A, ROI(0,200,0,100))

ImageData ImageBufAlgo.crop (src, roi=ROI.All, nthreads=0)
bool ImageBufAlgo.crop (dst, src, roi=ROI.All, nthreads=0)
Reset dst to be the specified region of src.

Example:

# Set B to be the upper left 200x100 region of A
A = ImageBuf("a.tif")
B = ImageBufAlgo.crop (A, ROI(0,200,0,100))

ImageData ImageBufAlgo.cut (src, roi=ROI.All, nthreads=0)
bool ImageBufAlgo.cut (dst, src, roi=ROI.All, nthreads=0)
Reset dst to be the specified region of src, but moved so that the resulting new image has its pixel data at the image plane origin.

Example:

# Set B to be the lower left 200x100 region of A, moved to the origin
A = ImageBuf("a.tif")
B = ImageBufAlgo.cut (A, ROI(0,200,380,480))

bool ImageBufAlgo.paste (dst, xbegin, ybegin, zbegin, chbegin, src, srcroi=ROI.All, nthreads=0)
Copy the specified region of src into dst with the given offset (xbegin, ybegin, zbegin).

Example:

# Paste small.exr on top of big.exr at offset (100,100)
Big = ImageBuf("big.exr")
Small = ImageBuf("small.exr")
ImageBufAlgo.paste (Big, 100, 100, 0, 0, Small)

ImageData ImageBufAlgo.rotate90 (src, roi=ROI.All, nthreads=0)
ImageData ImageBufAlgo.rotate180 (src, roi=ROI.All, nthreads=0)
ImageData ImageBufAlgo.rotate270 (src, roi=ROI.All, nthreads=0)
bool ImageBufAlgo.rotate90 (dst, src, roi=ROI.All, nthreads=0)
bool ImageBufAlgo.rotate180 (dst, src, roi=ROI.All, nthreads=0)
bool ImageBufAlgo.rotate270 (dst, src, roi=ROI.All, nthreads=0)
Copy while rotating the image by a multiple of 90 degrees.

Example:

A = ImageBuf("tahoe.exr")
B = ImageBufAlgo.rotate90 (A)
ImageBuf ImageBufAlgo.flip (src, roi=ROI.All, nthreads=0)
ImageBuf ImageBufAlgo.flop (src, roi=ROI.All, nthreads=0)
ImageBuf ImageBufAlgo.transpose (src, roi=ROI.All, nthreads=0)

bool ImageBufAlgo.flip (dst, src, roi=ROI.All, nthreads=0)
bool ImageBufAlgo.flop (dst, src, roi=ROI.All, nthreads=0)
bool ImageBufAlgo.transpose (dst, src, roi=ROI.All, nthreads=0)

Copy while reversing orientation vertically (flip) or horizontally (flop), or diagonally (transpose).

Example:

A = ImageBuf ("tahoe.exr")
B = ImageBufAlgo.flip (A)

ImageBuf ImageBufAlgo.reorient (src, nthreads=0)
bool ImageBufAlgo.reorient (dst, src, nthreads=0)

Copy src, applying whatever seties of rotations, flips, or flops are necessary to transform the pixels into the configuration suggested by the "Orientation" metadata of the image (and the "Orientation" metadata is then set to 1, ordinary orientation).

Example:

A = ImageBuf ("tahoe.jpg")
ImageBufAlgo.reorient (A, A)

ImageBuf ImageBufAlgo.circular_shift (src, xshift, yshift, zshift=0, roi=ROI.All, nthreads=0)
bool ImageBufAlgo.circular_shift (dst, src, xshift, yshift, zshift=0, roi=ROI.All, nthreads=0)

Copy while circularly shifting by the given amount.

Example:

A = ImageBuf ("tahoe.exr")
B = ImageBufAlgo.circular_shift (A, 200, 100)

ImageBuf ImageBufAlgo.rotate (src, angle, filtername="", filtersize=0.0, recompute_roi=False, roi=ROI.All, nthreads=0)
ImageBuf ImageBufAlgo.rotate (src, angle, center_x, center_y, filtername="", filtersize=0.0, recompute_roi=False, roi=ROI.All, nthreads=0)
bool ImageBufAlgo.rotate (dst, src, angle, filtername="", filtersize=0.0, recompute_roi=False, roi=ROI.All, nthreads=0)
bool ImageBufAlgo.rotate (dst, src, angle, center_x, center_y, filtername="", filtersize=0.0, recompute_roi=False, roi=ROI.All, nthreads=0)

Copy arotated version of the corresponding portion of src. The angle is in radians, with positive values indicating clockwise rotation. If the filter and size are not specified, an appropriate default will be chosen.

Example:

Src = ImageBuf ("tahoe.exr")
Dst = ImageBufAlgo.rotate (Src, math.radians(45.0))

ImageBuf ImageBufAlgo.warp (src, M, filtername="", filtersize=0.0, wrap="default", recompute_roi=False, roi=ROI.All, nthreads=0)
bool ImageBufAlgo.warp (dst, src, M, filtername="", filtersize=0.0, wrap="default", recompute_roi=False, roi=ROI.All, nthreads=0)

Compute a warped (transformed) copy of src, with the warp specified by M consisting of 9 floating-point numbers representing a 3x3 transformation matrix. If the filter and size are not specified, an appropriate default will be chosen.

Example:

M = (0.7071068, 0.7071068, 0, -0.7071068, 0.7071068, 0, 20, -8.284271, 1)
Src = ImageBuf ("tahoe.exr")
Dst = ImageBufAlgo.warp (Src, M)

ImageBuf ImageBufAlgo.resize (src, filtername="", filtersize=0.0, roi=ROI.All, nthreads=0)
bool ImageBufAlgo.resize (dst, src, filtername="", filtersize=0.0, roi=ROI.All, nthreads=0)
Compute a high-quality resized version of the corresponding portion of src. If the filter and size are not specified, an appropriate default will be chosen.

Example:
```
# Resize the image to 640x480, using the default filter
Src = ImageBuf ("tahoe.exr")
Dst = ImageBufAlgo.resize (Src, roi=ROI(0,640,0,480,0,1,0,3))
```

ImageBuf ImageBufAlgo.resample (src, interpolate=True, roi=ROI.All, nthreads=0)
bool ImageBufImageAlgo.resample (dst, src, interpolate=True, roi=ROI.All, nthreads=0)
Set dst over the ROI, to be a low-quality (but fast) resized version of the corresponding portion of src, either using a simple “closest pixel” choice or by bilinearly interpolating (depending on interpolate).

Example:
```
# Resample quickly to 320x240 to make a low-quality thumbnail
Src = ImageBuf ("tahoe.exr")
Dst = ImageBufAlgo.resample (Src, roi=ROI(0,640,0,480,0,1,0,3))
```

ImageBuf ImageBufAlgo.fit (src, filtername="", filtersize=0.0, fillmode="letterbox", exact=false, roi=ROI.All, nthreads=0)
bool ImageBufImageAlgo.fit (dst, src, filtername="", filtersize=0.0, fillmode="letterbox", exact=false, roi=ROI.All, nthreads=0)
Fit src into the roi while preserving the original aspect ratio, without stretching. If the filter and size are not specified, an appropriate default will be chosen.

Example:
```
# Resize to fit into a max of 640x480, preserving the aspect ratio
Src = ImageBuf ("tahoe.exr")
Dst = ImageBufAlgo.fit (Src, roi=ROI(0,640,0,480,0,1,0,3))
```

### 11.9.3 Image arithmetic

ImageBuf ImageBufAlgo.add (A, B, roi=ROI.All, nthreads=0)
bool ImageBufImageAlgo.add (dst, A, B, roi=ROI.All, nthreads=0)
Compute A + B. A and B each may be an ImageBuf, a float value (for all channels) or a tuple giving a float for each color channel.

Example:
```
# Add two images
buf = ImageBufAlgo.add (ImageBuf("a.exr"), ImageBuf("b.exr"))

# Add 0.2 to channels 0-2
ImageBufAlgo.add (buf, buf, (0.2,0.2,0.2,0))
```

ImageBuf ImageBufAlgo.sub (A, B, roi=ROI.All, nthreads=0)
bool ImageBufImageAlgo.sub (dst, A, B, roi=ROI.All, nthreads=0)
Compute A – B. A and B each may be an ImageBuf, a float value (for all channels) or a tuple giving a float for each color channel.

Example:
```
buf = ImageBufAlgo.sub (ImageBuf("a.exr"), ImageBuf("b.exr"))
```

ImageBuf ImageBufAlgo.absdiff (A, B, roi=ROI.All, nthreads=0)
bool ImageBufAlgo.absdiff (dst, A, B, roi=ROI.All, nthreads=0)
    Compute abs(A - B). A and B each may be an ImageBuf, a float value (for all channels) or a tuple giving a float for each color channel.
    Example:
    ```python
    buf = ImageBufAlgo.absdiff (ImageBuf("a.exr"), ImageBuf("b.exr"))
    ```

ImageBuf ImageBufAlgo.abs (A, roi=ROI.All, nthreads=0)
bool ImageBufAlgo.abs (dst, A, roi=ROI.All, nthreads=0)
    Compute abs(A). A is an ImageBuf.
    Example:
    ```python
    buf = ImageBufAlgo.abs (ImageBuf("a.exr"))
    ```

ImageBuf ImageBufAlgo.mul (A, B, roi=ROI.All, nthreads=0)
bool ImageBufAlgo.mul (dst, A, B, roi=ROI.All, nthreads=0)
    Compute A * B (channel-by-channel multiplication). A and B each may be an ImageBuf, a float value (for all channels) or a tuple giving a float for each color channel.
    Example:
    ```python
    # Multiply the two images
    buf = ImageBufAlgo.mul (ImageBuf("a.exr"), ImageBuf("b.exr"))
    # Reduce intensity of buf's channels 0-2 by 50%, in place
    ImageBufAlgo.mul (buf, buf, (0.5, 0.5, 0.5, 1.0))
    ```

ImageBuf ImageBufAlgo.div (A, B, roi=ROI.All, nthreads=0)
bool ImageBufAlgo.div (dst, A, B, roi=ROI.All, nthreads=0)
    Compute A / B (channel-by-channel division), where x/0 is defined to be 0. A and B each may be an ImageBuf, a float value (for all channels) or a tuple giving a float for each color channel.
    Example:
    ```python
    # Divide a.exr by b.exr
    buf = ImageBufAlgo.div (ImageBuf("a.exr"), ImageBuf("b.exr"))
    # Reduce intensity of buf's channels 0-2 by 50%, in place
    ImageBufAlgo.div (buf, buf, (2.0, 2.0, 2.0, 1.0))
    ```

ImageBuf ImageBufAlgo.mad (A, B, C, roi=ROI.All, nthreads=0)
bool ImageBufAlgo.mad (dst, A, B, C, roi=ROI.All, nthreads=0)
    Compute A * B + C (channel-by-channel multiplication and addition). A, B, and C each may be an ImageBuf, a float value (for all channels) or a tuple giving a float for each color channel.
    Example:
    ```python
    # Multiply a and b, then add c
    buf = ImageBufAlgo.mad (ImageBuf("a.exr"),
                           (1.0f, 0.5f, 0.25f), ImageBuf("c.exr"))
    ```

ImageBuf ImageBufAlgo.invert (A, roi=ROI.All, nthreads=0)
bool ImageBufAlgo.invert (dst, A, roi=ROI.All, nthreads=0)
    Compute 1-A (channel by channel color inverse). A is an ImageBuf.
    Example:
buf = ImageBufAlgo.invert (ImageBuf("a.exr"))

ImageBuf ImageBufAlgo.pow (A, B, roi=ROI.All, nthreads=0)
bool ImageBufAlgo.pow (dst, A, B, roi=ROI.All, nthreads=0)

Compute pow (A, B) (channel-by-channel exponentiation). A is an ImageBuf, and B may be a float (a single power for all channels) or a tuple giving a float for each color channel.

Example:

  # Linearize a 2.2 gamma-corrected image (channels 0-2 only)
  img = ImageBuf ("a.exr")
  buf = ImageBufAlgo.pow (img, (2.2, 2.2, 2.2, 1.0))

ImageBuf ImageBufAlgo.channel_sum (src, weights=(), roi=ROI.All, nthreads=0)
bool ImageBufAlgo.channel_sum (dst, src, weights=(), roi=ROI.All, nthreads=0)

Converts a multi-channel image into a 1-channel image via a weighted sum of channels. The weights is a tuple providing the weight for each channel (if not supplied, all channels will have weight 1.0).

Example:

  # Compute luminance via a weighted sum of R,G,B
  # (assuming Rec709 primaries and a linear scale)
  ImageBuf()
  weights = (.2126, .7152, .0722)
  luma = ImageBufAlgo.channel_sum (ImageBuf("a.exr"), weights)

ImageBuf ImageBufAlgo.contrast_remap (src, black=0.0, white=1.0, min=0.0, max=1.0, sthresh=0.0, scontrast=1.0, ROI roi={}, int nthreads=0)
bool ImageBufAlgo.contrast_remap (ImageBuf &dst, src, black=0.0, white=1.0, min=0.0, max=1.0, sthresh=0.0, scontrast=1.0, ROI roi={}, int nthreads=0)

Return (or copy into dst) pixel values that are a contrast-remap of the corresponding values of the src image, transforming pixel value domain [black, white] to range [min, max], either linearly or with optional application of a smooth sigmoidal remapping (if scontrast != 1.0).

Example:

  A = ImageBuf('tahoe.tif');

  # Simple linear remap that stretches input 0.1 to black, and input 0.75 to white.
  linstretch = ImageBufAlgo.contrast_remap (A, black=0.1, white=0.75)

  # Remapping 0->1 and 1->0 inverts the colors of the image, equivalent to ImageBufAlgo.invert().
  inverse = ImageBufAlgo.contrast_remap (A, black=1.0, white=0.0)

  # Use a sigmoid curve to add contrast but without any hard cutoffs. Use a contrast parameter of 5.0.
  sigmoid = ImageBufAlgo.contrast_remap (a, contrast=5.0)

ImageBuf ImageBufAlgo.saturate (src, scale=0.0, firstchannel=0, roi=ROI.All, nthreads=0)
bool ImageBufAlgo.saturate (dst, src, scale=0.0, firstchannel=0, roi=ROI.All, nthreads=0)

Copy pixels from src to dst, and scale the saturation of channels firstchannel to firstchannel+2 by the scale factor.

This function was added in OpenImageIO 2.4.

Example:
# In-place reduce saturation by 50%
A = ImageBuf("a.exr")
ImageBufAlgo.saturate (A, A, 0.5)

ImageBuf ImageBufAlgo.color_map (src, srcchannel, nknots, channels, knots, roi=ROI.All, nthreads=0)
bool ImageBufAlgo.color_map (dst, src, srcchannel, nknots, channels, knots, roi=ROI.All, nthreads=0)

Return an image (or copy into dst) pixel values determined by applying the color map to the values of src, using either the channel specified by srcchannel, or the luminance of src's RGB if srcchannel is -1.

In the first variant, the values linearly-interpolated color map are given by the tuple knots[nknots*channels].

In the second variant, just the name of a color map is specified. Recognized map names include: “inferno”, “viridis”, “magma”, “plasma”, all of which are perceptually uniform, strictly increasing in luminance, look good when converted to grayscale, and work for people with all types of colorblindness. The “turbo” color map is also nice in most of these ways (except for being strictly increasing in luminance). Also supported are the following color maps that do not have those desirable qualities (and are this not recommended): “blue-red”, “spectrum”, and “heat”. In all cases, the implied channels is 3.

Example:

heatmap = ImageBufAlgo.color_map (ImageBuf("a.jpg"), -1, "inferno")
heatmap = ImageBufAlgo.color_map (ImageBuf("a.jpg"), -1, 3, 3,
(0.25, 0.25, 0.25, 0, 0.5, 0, 1, 0, 0))

ImageBuf ImageBufAlgo.max (A, B, roi=ROI.All, nthreads=0)
bool ImageBufAlgo.max (dst, A, B, roi=ROI.All, nthreads=0)

Compute per-pixel, per-channel max(A, B), returning the result image. At least one of A and B must be an ImageBuf, the other may also be an ImageBuf, or a float value (for all channels), or a tuple giving a float for each color channel.

Example:

# Make an image that for each pixel and channel, is the maximum
# value of that pixel and channel of A and B.
A = ImageBuf("a.exr")
B = ImageBuf("b.exr")
maximg = ImageBufAlgo.max (A, B)

# Do an in-place clamp image A so that all values are at least 0
# (thus ensuring that there are no negative values).
ImageBufAlgo.max (A, A, 0.0)

ImageBuf ImageBufAlgo.min (A, B, roi=ROI.All, nthreads=0)
bool ImageBufAlgo.min (dst, A, B, roi=ROI.All, nthreads=0)

Compute per-pixel, per-channel min(A, B), returning the result image. At least one of A and B must be an ImageBuf, the other may also be an ImageBuf, or a float value (for all channels), or a tuple giving a float for each color channel.

Example:

# Make an image that for each pixel and channel, is the minimum
# value of that pixel and channel of A and B.
A = ImageBuf("a.exr")

(continues on next page)
B = ImageBuf("b.exr")
minimg = ImageBufAlgo.min (A, B)

# Do an in-place clamp image A so that the maximum value of each pixel
# is 0.5 (except for alpha, which may be up to 1.0):
ImageBufAlgo.min (A, A, (0.5, 0.5, 0.5, 1.0))

ImageBuf ImageBufAlgo.clamp (src, min, max, bool clampalpha01=False, roi=ROI.All, nthreads=0)
bool ImageBufAlgo.clamp (dst, src, min, max, bool clampalpha01=False, roi=ROI.All, nthreads=0)
Copy pixels while clamping between the min and max values. The min and max may either be tuples (one min and max value per channel), or single floats (same value for all channels). Additionally, if clampalpha01 is True, then any alpha channel is clamped to the 0–1 range.

Example:

# Clamp image buffer A in-place to the [0,1] range for all channels.
ImageBufAlgo.clamp (A, A, 0.0, 1.0)

ImageBuf ImageBufAlgo.maxchan (src, roi=ROI.All, nthreads=0)
bool ImageBufAlgo.maxchan (dst, src, roi=ROI.All, nthreads=0)
Return a one-channel image where each pixel has the maximum value found in any of the channels of src in that corresponding pixel.

This function was added in OpenImageIO 2.3.10.

Example:

A = ImageBuf("rgb.exr")
max_of_rgb = ImageBufAlgo.maxchan (A)

ImageBuf ImageBufAlgo.minchan (src, roi=ROI.All, nthreads=0)
bool ImageBufAlgo.minchan (dst, src, roi=ROI.All, nthreads=0)
Return a one-channel image where each pixel has the minimum value found in any of the channels of src in that corresponding pixel.

This function was added in OpenImageIO 2.3.10.

Example:

A = ImageBuf("rgb.exr")
min_of_rgb = ImageBufAlgo.minchan (A)

ImageBuf ImageBufAlgo.rangecompress (src, useluma=False, roi=ROI.All, nthreads=0)
bool ImageBufAlgo.rangecompress (dst, src, useluma=False, roi=ROI.All, nthreads=0)
ImageBuf ImageBufAlgo.rangeexpand (src, useluma=False, roi=ROI.All, nthreads=0)
bool ImageBufAlgo.rangeexpand (dst, src, useluma=False, roi=ROI.All, nthreads=0)
Copy from src, compressing (logarithmically) or expanding (by the inverse of the compressive transformation) the range of pixel values. Alpha and z channels are copied but not transformed.

If useluma is True, the luma of the first three channels (presumed to be R, G, and B) are used to compute a single scale factor for all color channels, rather than scaling all channels individually (which could result in a big color shift when performing rangecompress and rangeexpand).

Example:

# Resize the image to 640x480, using a Lanczos3 filter, which
# has negative lobes. To prevent those negative lobes from

(continues on next page)
# producing ringing or negative pixel values for HDR data,
# do range compression, then resize, then re-expand the range.

# 1. Read the original image
Src = ImageBuf("tahoeHDR.exr")

# 2. Range compress to a logarithmic scale
Compressed = ImageBufAlgo.rangecompress(Src)

# 3. Now do the resize
roi = ROI(0, 640, 0, 480, 0, 1, 0, Compressed.nchannels)
Dst = ImageBufAlgo.resize(Compressed, "lanczos3", 6.0, roi)

# 4. Expand range to be linear again (operate in-place)
ImageBufAlgo.rangeexpand(Dst, Dst)

ImageBuf ImageBufAlgo.over(A, B, roi=ROI.All, nthreads=0)
bool ImageBufAlgo.over(dst, A, B, roi=ROI.All, nthreads=0)
Composite ImageBuf A over ImageBuf B.

Example:

Comp = ImageBufAlgo.over(ImageBuf("fg.exr"), ImageBuf("bg.exr"))

ImageBuf ImageBufAlgo.zover(A, B, bool z_zeroisinf=False, roi=ROI.All, nthreads=0
bool ImageBufAlgo.zover(dst, A, B, bool z_zeroisinf=False, roi=ROI.All, nthreads=0)
Composite ImageBuf A and ImageBuf B using their respective Z channels to decide which is in front on a pixel-by-pixel basis.

Example:

Comp = ImageBufAlgo.zover(ImageBuf("fg.exr"), ImageBuf("bg.exr"))

11.9.4 Image comparison and statistics

PixelStats ImageBufAlgo.computePixelStats(src, roi=ROI.All, nthreads=0)
Compute statistics about the ROI of the image src. The PixelStats structure is defined as containing the following data fields: min, max, avg, stddev, nancount, infcount, finitecount, sum, sum2, each of which is a tuple with one value for each channel of the image.

Example:

A = ImageBuf("a.exr")
stats = ImageBufAlgo.computePixelStats(A)
print " min = ", stats.min
print " max = ", stats.max
print " average = ", stats.avg
print " standard deviation = ", stats.stddev
print " # NaN values = ", stats.nancount
print " # Inf values = ", stats.infcount
print " # finite values = ", stats.finitecount

CompareResults ImageBufAlgo.compare(A, B, failthresh, warnthresh, roi=ROI.All, nthreads=0)
Numerically compare two ImageBuf's, A and B. The failthresh and warnthresh supply failure and warning difference thresholds. The return value is a CompareResults object, which is defined as a class having the following members:
meanerror, rms_error, PSNR, maxerror  # error statistics
maxx, maxy, maxz, maxc  # pixel of biggest difference
nwarn, nfail  # number of warnings and failures
error  # True if there was an error

Example:

A = ImageBuf("a.exr")
B = ImageBuf("b.exr")
comp = ImageBufAlgo.compare(A, B, 1.0/255.0, 0.0)
if comp.nwarn == 0 and comp.nfail == 0 :
    print "Images match within tolerance"
else :
    print comp.nfail, "failures,", comp.nwarn, " warnings."
    print "Average error was ", comp.meanerror
    print "RMS error was ", comp.rms_error
    print "PSNR was ", comp.PSNR
    print "largest error was ", comp.maxerror
    print " on pixel", (comp.maxx, comp.maxy, comp.maxz)
    print " channel", comp.maxc

tuple ImageBufAlgo.isConstantColor (src, threshold=0.0, roi=ROI.All, nthreads=0)
If all pixels of src within the ROI have the same values (for the subset of channels described by roi), return a
tuple giving that color (one float for each channel), otherwise return None.

Example:

A = ImageBuf("a.exr")
color = ImageBufAlgo.isConstantColor (A)
if color != None :
    print "The image has the same value in all pixels:", color
else :
    print "The image is not a solid color."

bool ImageBufAlgo.isConstantChannel (src, channel, val, threshold=0.0, roi=ROI.All, nthreads=0)
Returns True if all pixels of src within the ROI have the given channel value val.

Example:

A = ImageBuf("a.exr")
alpha = A.spec.alpha_channel
if alpha < 0 :
    print "The image does not have an alpha channel"
elif ImageBufAlgo.isConstantChannel (A, alpha, 1.0) :
    print "The image has alpha = 1.0 everywhere"
else :
    print "The image has alpha < 1 in at least one pixel"

bool ImageBufAlgo.isMonochrome (src, threshold=0.0, roi=ROI.All, nthreads=0)
Returns True if the image is monochrome within the ROI.

Example:

A = ImageBuf("a.exr")
roi = A.roi
roi.chend = min (3, roi.chend)  # only test RGB, not alpha
if ImageBufAlgo.isMonochrome (A, roi) :
    print "a.exr is really grayscale"
ImageBufAlgo.color_range_check (src, low, high, roi=ROI.All, nthreads=0)
Count how many pixels in the src image (within the roi) are outside the value range described by low and hi (which each may be either one value or a tuple with per-channel values for each of roi.chbegin ... roi.chend. The result returned is a tuple containing three values: the number of values less than low, the number of values greater then hi, and the number of values within the range.

Example:

```python
A = ImageBuf("a.exr")
counts = ImageBufAlgo.color_range_check (A, 0.5, 0.75)
print ('{} values < 0.5, {} values > 0.75'.format(counts[0], counts[1]))
```

ROI ImageBufAlgo.nonzero_region (src, roi=ROI.All, nthreads=0)
Returns an ROI that tightly encloses the minimal region within roi that contains all pixels with nonzero values.

Example:

```python
A = ImageBuf("a.exr")
nonzero_roi = ImageBufAlgo.nonzero_region(A)
```

std::string ImageBufAlgo.computePixelHashSHA1 (src, extrainfo = ", roi=ROI.All, blocksize=0)
Compute the SHA-1 byte hash for all the pixels in the ROI of src.

Example:

```python
A = ImageBuf("a.exr")
hash = ImageBufAlgo.computePixelHashSHA1 (A, blocksize=64)
```

tuple histogram (src, channel=0, bins=256, min=0.0, max=1.0, ignore_empty=False, roi=ROI.All, nthreads=0)
Computes a histogram of the given channel of image src, within the ROI, returning a tuple of length bins containing count of pixels whose value was in each of the equally-sized range bins between min and max. If ignore_empty is True, pixels that are empty (all channels 0 including alpha) will not be counted in the total.

11.9.5 Convolutions

ImageBuf ImageBufAlgo.make_kernel (name, width, height, depth=1.0, normalize=True)
Create a 1-channel float image of the named kernel and dimensions. If normalize is True, the values will be normalized so that they sum to 1.0.

If depth > 1, a volumetric kernel will be created. Use with caution!

Kernel names can be: “gaussian”, “sharp-gaussian”, “box”, “triangle”, “mitchell”, “blackman-harris”, “bspline”, “catmull-rom”, “lanczos3”, “cubic”, “keys”, “simon”, “rifman”, “disk”, “binomial”, “laplacian”. Note that “catmull-rom” and “lanczos3” are fixed-size kernels that don’t scale with the width, and are therefore probably less useful in most cases.

Example:

```python
K = ImageBufAlgo.make_kernel ("gaussian", 5.0, 5.0)
```

ImageBuf ImageBufAlgo.convolve (src, kernel, normalize=True, roi=ROI.All, nthreads=0)
bool ImageBufAlgo.convolve (dst, src, kernel, normalize=True, roi=ROI.All, nthreads=0)
Replace the given ROI of dst with the convolution of src and a kernel (also an ImageBuf).

Example:
# Blur an image with a 5x5 Gaussian kernel

```cpp
Src = ImageBuf("tahoe.exr")
K = ImageBufAlgo.make_kernel (K, "gaussian", 5.0, 5.0)
Blurred = ImageBufAlgo.convolve (Src, K)
```

**ImageBuf ImageBufAlgo.laplacian (src, roi=ROI.All, nthreads=0)**

bool **ImageBufAlgo.laplacian (dst, src, roi=ROI.All, nthreads=0)**

Replace the given ROI of dst with the Laplacian of the corresponding part of src.

**Example:**

```cpp
Src = ImageBuf("tahoe.exr")
L = ImageBufAlgo.laplacian (Src)
```

**ImageBuf ImageBufAlgo.fft (src, roi=ROI.All, nthreads=0)**

bool **ImageBufAlgo.fft (dst, src, roi=ROI.All, nthreads=0)**

ImageBuf **ImageBufAlgo.ifft (src, roi=ROI.All, nthreads=0)**

bool **ImageBufAlgo.ifft (dst, src, roi=ROI.All, nthreads=0)**

Compute the forward or inverse discrete Fourier Transform.

**Example:**

```cpp
Src = ImageBuf("tahoe.exr")

# Take the DFT of the first channel of Src
Freq = ImageBufAlgo.fft (Src)

# At this point, Freq is a 2-channel float image (real, imag)
# Convert it back from frequency domain to a spatial iamge
Spatial = ImageBufAlgo.ifft (Freq)
```

**ImageBuf ImageBufAlgo.complex_to_polar (src, roi=ROI.All, nthreads=0)**

bool **ImageBufAlgo.complex_to_polar (dst, src, roi=ROI.All, nthreads=0)**

ImageBuf **ImageBufAlgo.polar_to_complex (src, roi=ROI.All, nthreads=0)**

bool **ImageBufAlgo.polar_to_complex (dst, src, roi=ROI.All, nthreads=0)**

Transform a 2-channel image from complex (real, imaginary) representation to polar (amplitude, phase), or vice versa.

**Example:**

```cpp
Polar = ImageBuf("polar.exr")
Complex = ImageBufAlgo.polar_to_complex (Polar)

# At this point, Complex is a 2-channel complex image (real, imag)
# Convert it back from frequency domain to a spatial iamge
Spatial = ImageBufAlgo.ifft (Complex)
```
11.9.6 Image Enhancement / Restoration

ImageBuf ImageBufAlgo.fixNonFinite (src, mode=NONFINITE_BOX3, roi=ROI.All, nthreads=0)
bool ImageBufAlgo.fixNonFinite (dst, src, mode=NONFINITE_BOX3, roi=ROI.All, nthreads=0)

Copy pixel values from src and repair any non-finite (NaN or Inf) pixels.

How the non-finite values are repaired is specified by one of the following modes:

- OpenImageIO.NONFINITE_NONE
- OpenImageIO.NONFINITE_BLACK
- OpenImageIO.NONFINITE_BOX3

Example:

```python
Src = ImageBuf("tahoe.exr")
ImageBufAlgo.fixNonFinite(Src, Src, OpenImageIO.NONFINITE_BOX3)
```

ImageBuf ImageBufAlgo.fillholes_pushpull (src, roi=ROI.All, nthreads=0)
bool ImageBufAlgo.fillholes_pushpull (dst, src, roi=ROI.All, nthreads=0)

Copy the specified ROI of src and fill any holes (pixels where alpha < 1) with plausible values using a push-pull technique. The src image must have an alpha channel. The dst image will end up with a copy of src, but will have an alpha of 1.0 everywhere, and any place where the alpha of src was < 1, dst will have a pixel color that is a plausible “filling” of the original alpha hole.

Example:

```python
Src = ImageBuf("holes.exr")
Filled = ImageBufAlgo.fillholes_pushpull(Src)
```

bool ImageBufAlgo.median_filter (dst, src, width=3, height=-1, roi=ROI.All, nthreads=0)

Replace the given ROI of dst with the width x height median filter of the corresponding region of src using the “unsharp mask” technique.

Example:

```python
Noisy = ImageBuf("tahoe.exr")
Clean = ImageBuf()
ImageBufAlgo.median_filter(Clean, Noisy, 3, 3)
```

ImageBuf ImageBufAlgo.dilate (src, width=3, height=-1, roi=ROI.All, nthreads=0)
bool ImageBufAlgo.dilate (dst, src, width=3, height=-1, roi=ROI.All, nthreads=0)
bool ImageBufAlgo.erode (dst, src, width=3, height=-1, roi=ROI.All, nthreads=0)

Compute a dilated or eroded version of the corresponding region of src.

Example:

```python
Source = ImageBuf("source.tif")
Dilated = ImageBufAlgo.dilate(Source, 3, 3)
```

ImageBuf ImageBufAlgo.unsharp_mask (src, kernel="gaussian", width=3.0, contrast=1.0, threshold=0.0, roi=ROI.All, nthreads=0)
bool ImageBufAlgo.unsharp_mask (dst, src, kernel="gaussian", width=3.0, contrast=1.0, threshold=0.0)

Compute a sharpened version of the corresponding region of src using the “unsharp mask” technique.

Example:

```python
Blurry = ImageBuf("tahoe.exr")
Sharp = ImageBufAlgo.unsharp_mask(Blurry, "gaussian", 5.0)
```
OpenImageIO, Release 2.4.1

11.9.7 Color manipulation

ImageBuf ImageBufAlgo.colorconvert (src, fromspace, tospace, unpremult=True, context_key=""
bool ImageBufAlgo.colorconvert (dst, src, fromspace, tospace, unpremult=True, context_key="
Apply a color transform to the pixel values.
Example:
Src = ImageBuf ("tahoe.jpg")
Dst = ImageBufAlgo.colorconvert (Src, "sRGB", "linear")

ImageBuf ImageBufAlgo.colormatrixtransform (src, M, unpremult=True, roi=ROI.All, nthreads=0
bool ImageBufAlgo.colormatrixtransform (dst, src, M, unpremult=True, roi=ROI.All, nthreads=
NEW in 2.1
Apply a 4x4 matrix color transform to the pixel values. The matrix can be any tuple of 16 float values.
Example:
Src = ImageBuf ("tahoe.jpg")
M = ( .8047379, .5058794, -.3106172, 0,
-.3106172, .8047379, .5058794, 0,
.5058794, -.3106172, .8047379, 0,
0,
0,
0,
1)
Dst = ImageBufAlgo.colormatrixtransform (Src, M)

ImageBuf ImageBufAlgo.ociolook (src, looks, fromspace, tospace, unpremult=True, inverse=Fal
bool ImageBufAlgo.ociolook (dst, src, looks, fromspace, tospace, unpremult=True, inverse=Fa
Apply an OpenColorIO “look” transform to the pixel values.
Example:
Src = ImageBuf ("tahoe.jpg")
Dst = ImageBufAlgo.ociolook (Src, "look", "vd8", "lnf",
context_key="SHOT", context_value="pe0012")

ImageBuf ImageBufAlgo.ociodisplay (src, display, view, fromspace="", looks="", unpremult=Tr
bool ImageBufAlgo.ociodisplay (dst, src, display, view, fromspace="", looks="", unpremult=T
Apply an OpenColorIO “display” transform to the pixel values.
Example:
Src = ImageBuf ("tahoe.exr")
Dst = ImageBufAlgo.ociodisplay (Src, "sRGB", "Film", "lnf",
context_key="SHOT", context_value="pe0012")

ImageBuf ImageBufAlgo.ociofiletransform (src, name, unpremult=True, inverse=False, colorcon
bool ImageBufAlgo.ociofiletransform (dst, src, name, unpremult=True, inverse=False, colorco
Apply an OpenColorIO “file” transform to the pixel values. In-place operations (dst and src being the same
image) are supported.
Example:
Src = ImageBuf ("tahoe.exr")
Dst = ImageBufAlgo.ociofiletransform (Src, "foottransform.csp")

ImageBuf ImageBufAlgo.unpremult (src, roi=ROI.All, nthreads=0)
bool ImageBufAlgo.unpremult (dst, src, roi=ROI.All, nthreads=0)
ImageBuf ImageBufAlgo.premult (src, roi=ROI.All, nthreads=0)

11.9. ImageBufAlgo

337


bool ImageBufAlgo.premult (dst, src, roi=ROI.All, nthreads=0)
ImageBuf ImageBufAlgo.repremult (src, roi=ROI.All, nthreads=0)
bool ImageBufAlgo.repremult (dst, src, roi=ROI.All, nthreads=0)

Copy pixels from src to dst, and un-premultiply, premultiply, or re-premultiply the colors by alpha.

unpremult divides colors by alpha, but preserves original color if alpha is 0. premult multiplies colors by alpha (even if alpha is 0). repreumlt is the true inverse of unpremult, multiplying color by alpha, but preserving color values in the alpha = 0 case.

Example:

```python
# Convert in-place from associated alpha to unassociated alpha
A = ImageBuf("a.exr")
ImageBufAlgo.unpremult (A, A)
```

11.9.8 Import / export

bool ImageBufAlgo.make_texture (mode, input, outputfilename, config=ImageSpec())

Turn an input image (either an ImageBuf or a string giving a filename) into a tiled, MIP-mapped, texture file and write to the file named by (outputfilename). The mode describes what type of texture file we are creating and may be one of the following:

- OpenImageIO.MakeTxTexture
- OpenImageIO.MakeTxEnvLatl
- OpenImageIO.MakeTxEnvLatlFromLightProbe

The config, if supplied, is an ImageSpec that contains all the information and special instructions for making the texture. The full list of supported configuration options is given in Section Import / export.

The return value is True for success, False if errors occurred, in which case the error message will be retrievable from the global `oiio.geterror()`.

Example:

```python
# This command line:
#   maketx in.exr --hicomp --filter lanczos3 --opaque-detect \
#   -o texture.exr
# performs the same operations as:

import OpenImageIO as oiio
Input = oiio.ImageBuf("in.exr")
config = oiio.ImageSpec()
config.attribute("maketx:highlightcomp", 1)
config.attribute("maketx:filtername", "lanczos3")
config.attribute("maketx:opaque_detect", 1)
ok = oiio.ImageBufAlgo.make_texture (oiio.MakeTxTexture, Input,
                                       "texture.exr", config)
if not ok :
    print("error:", oiio.geterror())
```

ImageBuf ImageBufAlgo::capture_image (cameranum, convert = OpenImageIO.UNKNOWN)

Capture a still image from a designated camera.

Example:

```python
WebcamImage = ImageBufAlgo.capture_image (0, OpenImageIO.UINT8)
WebcamImage.write ("webcam.jpg")
```
11.9.9 Functions specific to deep images

**ImageBuf ImageBufAlgo.deepen (src, zvalue=1.0, roi=ROI.All, nthreads=0)**

Convert a flat image to a deep one that has one depth sample per pixel (but no depth samples for the pixels corresponding to those in the source image that have infinite “Z” or that had 0 for all color channels and no “Z” channel).

Example:

```
Deep = ImageBufAlgo.deepen (ImageBuf("az.exr"))
```

**ImageBuf ImageBufAlgo.flatten (src, roi=ROI.All, nthreads=0)**

Composite the depth samples within each pixel of “deep” ImageBuf `src` to produce a “flat” ImageBuf.

Example:

```
Flat = ImageBufAlgo.flatten (ImageBuf("deepalpha.exr"))
```

**ImageBuf ImageBufAlgo.deep_merge (A, B, occlusion_cull, roi=ROI.All, nthreads=0)**

Merge the samples of two deep images `A` and `B` into a deep result. If `occlusion_cull` is `True`, samples beyond the first opaque sample will be discarded, otherwise they will be kept.

Example:

```
DeepA = ImageBuf("hardsurf.exr")
DeepB = ImageBuf("volume.exr")
Merged = ImageBufAlgo.deep_merge (DeepA, DeepB)
```

**ImageBuf ImageBufAlgo.deep_holdout (src, holdout, roi=ROI.All, nthreads=0)**

Return the pixels of `src`, but only copying the samples that are closer than the opaque frontier of image `holdout`. That is, `holdout` will serve as a depth holdout mask, but no samples from `holdout` will actually be copied to `dst`.

Example:

```
Img = ImageBuf("image.exr")
Mask = ImageBuf("mask.exr")
Thresholded = ImageBufAlgo.deep_holdout (Img, Mask)
```

11.9.10 Other ImageBufAlgo methods that understand deep images

In addition to the previously described methods that are specific to deep images, the following ImageBufAlgo methods (described in their respective sections) work with deep inputs:

```python
ImageBufAlgo.add
ImageBufAlgo.channels
ImageBufAlgo.compare
ImageBufAlgo.computePixelStats
ImageBufAlgo.crop
ImageBufAlgo.div
ImageBufAlgo.fixNonFinite
ImageBufAlgo.mul
```

(continues on next page)
11.10 Miscellaneous Utilities

In the main OpenImageIO module, there are a number of values and functions that are useful. These correspond to the C++ API functions explained in Section Global Attributes, please refer there for details.

openimageio_version

The OpenImageIO version number is an int, 10000 for each major version, 100 for each minor version, 1 for each patch. For example, OpenImageIO 1.2.3 would return a value of 10203.

gterror(clear=True)

Retrieves the latest global error, as a string.

attribute(name, typedesc, value)

attribute(name, int_value)

attribute(name, float_value)

attribute(name, str_value)

Sets a global attribute (see Section Global Attributes for details), returning True upon success, or False if it was not a recognized attribute.

Example:

```python
oiio.attribute("threads", 0)
```

getattribute(name, typedesc)

get_int_attribute(name, defaultval=0)

get_float_attribute(name, defaultval=0.0)

get_string_attribute(name, defaultval="")

Retrieves an attribute value from the named set of global OIIO options. (See Section Global Attributes.) The getattribute() function returns the value regardless of type, or None if the attribute does not exist. The typed variety will only succeed if the attribute is actually of that type specified. Type varity with the type in the name also takes a default value.

Example:

```python
formats = oiio.get_string_attribute("format_list")
```

is_imageio_format_name(name)

Returns True if name is the name of a known and supported file format, False if it is not.

Example:

```python
>>> print (oiio.is_imageio_format_name('tiff'))
True
>>> print (oiio.is_imageio_format_name('Bob'))
False
```
11.11 Python Recipes

This section illustrates the Python syntax for doing many common image operations from Python scripts, but that aren’t already given as examples in the earlier function descriptions. All example code fragments assume the following boilerplate:

```python
#!/usr/bin/env python
import OpenImageIO as oiio
from OpenImageIO import ImageBuf, ImageSpec, ImageBufAlgo
```

Subroutine to create a constant-colored image

```python
# Create an ImageBuf holding a n image of constant color, given the
# resolution, data format (defaulting to UINT8), fill value, and image
# origin.
def make_constimage (xres, yres, chans=3, format=oiio.UINT8, value=(0,0,0),
    xoffset=0, yoffset=0) :
    spec = ImageSpec (xres,yres,chans,format)
    spec.x = xoffset
    spec.y = yoffset
    b = ImageBuf (spec)
    oiio.ImageBufAlgo.fill (b, value)
    return b
```

The image is returned as an ImageBuf, then up to the caller what to do with it next.

Subroutine to save an image to disk, printing errors

```python
# Save an ImageBuf to a given file name, with optional forced image format
# and error handling.
def write_image (image, filename, format=oiio.UNKNOWN) :
    if not image.has_error :
        image.write (filename, format)
    if image.has_error :
        print "Error writing", filename, ":", image.geterror()
```

Converting between file formats

```python
img = ImageBuf ("input.png")
write_image (img, "output.tif")
```
Comparing two images and writing a difference image

```python
A = ImageBuf("A.tif")
B = ImageBuf("B.tif")
compresults = ImageBufAlgo.compare (A, B, 1.0e-6, 1.0e-6)
if compresults.nfail > 0 :
    print "Images did not match, writing difference image diff.tif"
    diff = ImageBufAlgo.absdiff (A, B)
    image_write (diff, "diff.tif")
```

Changing the data format or bit depth

```python
img = ImageBuf("input.exr")
# presume that it's a "half" OpenEXR file
# write it back out as a "float" file:
write_image (img, "output.exr", oiio.FLOAT)
```

Changing the compression

The following command converts writes a TIFF file, specifically using LZW compression:

```python
img = ImageBuf("in.tif")
img.specmod().attribute ("compression", "lzw")
write_image (img, "compressed.tif")
```

The following command writes its results as a JPEG file at a compression quality of 50 (pretty severe compression):

```python
img = ImageBuf("big.jpg")
img.specmod().attribute ("quality", 50)
write_image (img, "small.jpg")
```

Converting between scanline and tiled images

```python
img = ImageBuf("scan.tif")
img.set_write_tiles (64, 64)
write_image (img, "tile.tif")

img = ImageBuf("tile.tif")
img.set_write_tiles (0, 0)
write_image (img, "scan.tif")
```
Adding captions or metadata

```python
img = ImageBuf("foo.jpg")
# Add a caption:
img.specmod().attribute("ImageDescription", "Hawaii vacation")
# Add keywords:
img.specmod().attribute("keywords", "volcano,lava")
write_image(img, "foo.jpg")
```

Changing image boundaries

Change the origin of the pixel data window:

```python
img = ImageBuf("in.exr")
img.set_origin(256, 80)
write_image(img, "offset.exr")
```

Change the display window:

```python
img = ImageBuf("in.exr")
img.set_full(16, 1040, 16, 784)
write_image(img, "out.exr")
```

Change the display window to match the data window:

```python
img = ImageBuf("in.exr")
img.set_full(img.roi())
write_image(img, "out.exr")
```

Cut (trim and extract) a 128x128 region whose upper left corner is at location (900,300), moving the result to the origin (0,0) of the image plane and setting the display window to the new pixel data window:

```python
img = ImageBuf("in.exr")
b = ImageBufAlgo.cut(img, oiio.ROI(900,1028,300,428))
write_image(b, "out.exr")
```

Extract just the named channels from a complicated many-channel image, and add an alpha channel that is 1 everywhere

```python
img = ImageBuf("allmysaovs.exr")
write_image(b, "spec.tif")
```
Fade 30% of the way between two images

```python
a = ImageBufAlgo.mul (ImageBuf("A.exr"), 0.7)
b = ImageBufAlgo.mul (ImageBuf("B.exr"), 0.3)
fade = ImageBufAlgo.add (a, b)
write_image (fade, "fade.exr")
```

Composite of small foreground over background, with offset

```python
fg = ImageBuf ("fg.exr")
fg.set_origin (512, 89)
bg = ImageBuf ("bg.exr")
comp = ImageBufAlgo.over (fg, bg)
write_image (comp, "composite.exr")
```

Write multiple ImageBufs into one multi-subimage file

```python
bufs = (...)  # Suppose that bufs is a tuple of ImageBuf
specs = (...)  # specs is a tuple of the specs that describe them

# Open with intent to write the subimages
out = ImageOutput.create ("multipart.exr")
out.open ("multipart.exr", specs)
for s in range(len(bufs)) :
    if s > 0 :
        out.open ("multipart.exr", specs[s], "AppendSubimage")
    bufs[s].write (out)
out.close()
```
12.1 Overview

The oiiotool program will read images (from any file format for which an ImageInput plugin can be found), perform various operations on them, and write images (in any format for which an ImageOutput plugin can be found).

The oiiotool utility is invoked as follows:

    oiiotool args

oiiotool maintains an image stack, with the top image in the stack also called the current image. The stack begins containing no images.

oiiotool arguments consist of image names, actions, and flags.

- Image names: When an image name is encountered, that image is pushed on the stack and becomes the new current image.
- Actions: Alter the current image (replacing it with the alteration), or in some cases will pull more than one image off the stack (such as the current image and the next item on the stack) and then push a new result image onto the stack.
- Flags: A small number of arguments are non-positional – the order doesn’t matter and their effect applies to the entire oiiotool execution.

12.1.1 Argument order matters!

oiiotool processes actions and inputs in order. Thus, the order of operations on the command line is extremely important. For example,

    oiiotool in.tif -resize 640x480 -o out.tif

has the effect of reading in.tif (thus making it the current image), resizing it (taking the original off the stack, and placing the resized result back on the stack), and then writing the new current image to the file out.tif. Contrast that with the following subtly-incorrect command:

    oiiotool in.tif -o out.tif -resize 640x480

has the effect of reading in.tif (thus making it the current image), saving the current image to the file out.tif (note that it will be an exact copy of in.tif), resizing the current image, and then... exiting. Thus, the resized image is never saved, and out.tif will be an unaltered copy of in.tif.

The exceptions to this are non-positional flags, which affect the entire oiiotool command regardless of where they appear on the command line.
12.1.2 Optional modifiers

Some arguments stand completely on their own (like --flip), others take one or more subsequent command line arguments (like --resize or -o):

\texttt{oiiotool foo.jpg --flip --resize 640x480 -o out.tif}

A few arguments take optional modifiers for options that are so rarely-used or confusing that they should not be required arguments. In these cases, they are appended to the command name, after a colon (:) and with a \texttt{name=value} format. Multiple optional modifiers can be chained together, with colon separators. As an example:

\texttt{oiiotool in.tif --text:x=400:y=600:color=1,0,0 "Hello" -o out.tif}

The \texttt{value} itself may be a single- or double-quoted string, and this is how you would make a value that itself contains a : character (which would otherwise denote the beginning of the next modifier).

12.1.3 Expression evaluation and substitution

\texttt{oiiotool} can perform \textit{expression evaluation and substitution} on command-line arguments. As command-line arguments are needed, they are scanned for containing braces \{ \}. If found, the braces and any text they enclose will be evaluated as an expression and replaced by its result. The contents of an expression may be any of:

- \texttt{number}  
  A numerical value (e.g., 1 or 3.14159).

- \texttt{imagename.metadata}  
  The named metadata of an image.

  The \texttt{imagename} may be one of: \texttt{TOP} (the top or current image), \texttt{IMG[i]} describing the i-th image on the stack (thus \texttt{TOP} is a synonym for \texttt{IMG[0]}, the next image on the stack is \texttt{IMG[1]}, etc.), or \texttt{IMG[name]} to denote an image named by filename or by label name. Remember that the positions on the stack (including \texttt{TOP}) refer to \textit{at that moment}, with successive commands changing the contents of the top image.

  The \texttt{metadata} may be any of:
  
  - the name of any standard metadata of the specified image (e.g., \texttt{ImageDescription}, \texttt{or width})
  - \texttt{filename} : the name of the file (e.g., \texttt{foo.tif})
  - \texttt{file_extension} : the extension of the file (e.g., \texttt{tif})
  - \texttt{geom} : the pixel data size in the form \texttt{640x480+0+0}
  - \texttt{full_geom} : the “full” or “display” size
  - \texttt{MINCOLOR} : the minimum value in each channel (channels are comma-separated)
  - \texttt{MAXCOLOR} : the maximum value in each channel (channels are comma-separated)
  - \texttt{AVGCOLOR} : the average pixel value of the image (channels are comma-separated)
  - \texttt{METABRIEF} : a string containing the brief one-line description that would be printed with \texttt{oiiotool -info}.  

• META: a multi-line string containing the full metadata that would be printed with `oiiotool -info -v`.

• STATS: a multi-line string containing the image statistics that would be printed with `oiiotool -stats`.

• `imagename.'metadata'`

If the metadata name is not a "C identifier" (initial letter followed by any number of letter, number, or underscore), it is permissible to use single or double quotes to enclose the metadata name. For example, suppose you want to retrieve metadata named "foo/bar", you could say

```
(TOP.'foo/bar')
```

Without the quotes, it might try to retrieve `TOP.foo` (which doesn’t exist) and divide it by `bar`.

• Arithmetic

Sub-expressions may be joined by `+`, `-`, `*`, `/`, `//`, and `%` for arithmetic operations. (Note that like in Python 3, `/` is floating point division, while `//` signifies integer division.) Parentheses are supported, and standard operator precedence applies.

• Numeric and logical comparisons

Comparisons between numbers may be made with `<`, `<=`, `>`, `>=`, `==`, and `!=`. In each case, the result will be 0 if the comparison is false, 1 if the comparison is true.

The `<=>` operator is a three-way comparison, returning -1, 0, or 1, depending on whether the first operand is less than, equal to, or greater than the second operand.

The `&&` operator has a result of 1 if both the left and right expressions are nonzero, otherwise 0. And `||` has a result of 1 if either the left or right are nonzero, 0 if both evaluate to 0.

• User variables

User variables are set by the `--set` command. A reference to a user variable in an expression will be replaced by the value of the variable.

• Special variables

  - `FRAME_NUMBER`: the number of the frame in this iteration of wildcard expansion.

  - `FRAME_NUMBER_PAD`: like `FRAME_NUMBER`, but 0-padded based on the value set on the command line by `--framepadding`.

• Functions

  - `getattribute(name)`: returns the global attribute that would be retrieved by `OIIO::getattribute(name, ...)`. The name may be enclosed in single or double quotes or be a single unquoted sequence of characters. (Added in OIIO 2.3.)

To illustrate how this works, consider the following command, which trims a four-pixel border from all sides and outputs a new image prefixed with "cropped_", without needing to know the resolution or filename of the original image:

```
oiiotool input.exr -cut "(TOP.width-2*4)x(TOP.height-2*4)+(TOP.x+4)+(TOP.y+4)" \ 
   -o cropped_(TOP.filename)
```

If you should come across filenames that contain braces (these are vary rare, but have been known to happen), you temporarily disable expression evaluation with the `--evaloff` end `--evalon` flags. For example:
12.1.4 Control flow

Scriptability is provided by the use of control flow statements. The usual programming constructs are supported:

- **Conditionals:**
  - `--if` *condition* `--then` *commands*... `--else` *commands*... `--endif`

- **General looping:**
  - `--while` *condition* *commands*...

- **Iteration:**
  - `--for` *variable* *range* *commands*... `--endfor`

The range is a sequence of one to three comma-separated numbers: `begin, end, and step`; `begin` and `end` (step is assumed to be 1); or just `end` (begin assumed to be 0, step assumed to be 1). As in Python, the range has an “exclusive end” – when the *variable* is equal to `end`, the loop will terminate, without actually running the commands for the `end` value itself.

Section *oiiotool commands for control flow* contains more detailed descriptions of these commands and some examples to more clearly illustrate their behavior.

12.1.5 Frame sequences

It is also possible to have *oiiotool* operate on numbered sequences of images. In effect, this will execute the *oiiotool* command several times, making substitutions to the sequence arguments in turn.

Image sequences are specified by having filename arguments to *oiiotool* use either a numeric range wildcard (designated such as `1-10#` or a *printf*-like notation `1-10%d`), or spelling out a more complex pattern with `--frames`. For example:

```
oiiotool big.1-3#.tif --resize 100x100 -o small.1-3#.tif
oiiotool big.1-3%04d.tif --resize 100x100 -o small.1-3%04d.tif
oiiotool --frames 1-3 big.#.tif --resize 100x100 -o small.#.tif
oiiotool --frames 1-3 big.%04d.tif --resize 100x100 -o small.%04d.tif
```

Any of those will be the equivalent of having issued the following sequence of commands:

```
oiiotool big.0001.tif --resize 100x100 -o small.0001.tif
oiiotool big.0002.tif --resize 100x100 -o small.0002.tif
oiiotool big.0003.tif --resize 100x100 -o small.0003.tif
oiiotool --frames 3,4,10-20x2 blah.#.tif
```

The frame range may be forwards (`1-5`) or backwards (`5-1`), and may give a step size to skip frames (`1-5x2` means `1, 3, 5`) or take the complement of the step size set (`1-5y2` means `2, 4`) and may combine subsequences with a comma.

If you are using the # or @ wildcards, then the wildcard characters themselves specify how many digits to pad with leading zeroes, with # indicating 4 digits and @ indicating one digit (these may be combined: `#@` means 6 digits). An optional `--framepadding` can also be used to override the number of padding digits. For example:

```
oiiotool --framepadding 3 --frames 3,4,10-20x2 blah.#.tif
```
would match `blah.003.tif, blah.004.tif, blah.010.tif, blah.012.tif, blah.014.tif, blah.016.tif, blah.018.tif, blah.020.tif`

Alternately, you can use the `printf` notation, such as:

```
oiiootool --frames 3,4,10-20x2 blah.%03d.tif
```

When using frame ranges, keep in mind that by default, any error (such as an input file not being found) on any frame will exit oiiotool right away. However, the `--skip-bad-frames` command line option causes an error to skip the rest of the processing for that frame, but try to continue iteration with the next frame.

Two special command line arguments can be used to disable numeric wildcard expansion: `--wildcardoff` disables numeric wildcard expansion for subsequent command line arguments, until `--wildcardon` re-enables it for subsequent command line arguments. Turning wildcard expansion off for selected arguments can be helpful if you have arguments that must contain the wildcard characters themselves. For example:

```
oiiootool input.@@.tif --wildcardoff --sattrib Caption "lg@openimageio.org" \
--wildcardon -o output.@@.tif
```

In this example, the `@` characters in the filenames should be expanded into numeric file sequence wildcards, but the `@` in the caption (denoting an email address) should not.

### 12.1.6 Stereo wildcards

`oiiotool` can also handle image sequences with separate left and right images per frame using `views`. The `%V` wildcard will match the full name of all views and `%v` will match the first character of each view. View names default to “left” and “right”, but may be overridden using the `--views` option. For example:

```
oiiootool --frames 1-5 blah_%V.#.tif
```

would match `blah_left.0001.tif, blah_right.0001.tif, blah_left.0002.tif, blah_right.0002.tif, blah_left.0003.tif, blah_right.0003.tif, blah_left.0004.tif, blah_right.0004.tif, blah_left.0005.tif, blah_right.0005.tif, and`

```
oiiootool --frames 1-5 blah_%v.#.tif
```

would match `blah_l.0001.tif, blah_r.0001.tif, blah_l.0002.tif, blah_r.0002.tif, blah_l.0003.tif, blah_r.0003.tif, blah_l.0004.tif, blah_r.0004.tif, blah_l.0005.tif, blah_r.0005.tif, but`

```
oiiootool --views left --frames 1-5 blah_%v.#.tif
```

would only match `blah_l.0001.tif, blah_l.0002.tif, blah_l.0003.tif, blah_l.0004.tif, blah_l.0005.tif`.

### 12.1.7 Dealing with multi-subimage/multi-part files

Some file formats allow storing multiple images in one file (notably OpenEXR, which calls them “multi-part”). There are some special behaviors to be aware of for multi-subimage files.

Using `oiiotool` for a simple input-to-output copy will preserve all of the subimages (assuming that the output format can accommodate multiple subimages):

```
oiiootool multipart.exr -o another.exr
```
Most **oiiotool** commands by default work on just the *first* subimage of their input, discarding the others. For example:

```shell
oiiotool multipart.exr --colorconvert lnf aces -o out.exr
```

In this example, only the first subimage in `multipart.exr` will be color transformed and output to `out.exr`. Any other subimages in the input will not be used or copied.

Using the `-a` command tells **oiiotool** to try to preserve all subimages from the inputs and apply all computations to all subimages:

```shell
oiiotool -a multipart.exr --colorconvert lnf aces -o out.exr
```

Now all subimages of `multipart.exr` will be transformed and output.

But that might not be enough. Perhaps there are some subimages that need the color conversion, and others that do not. Many **oiiotool** commands take an optional modifier `:subimages=...` that can restrict the operation to certain subimages. The argument is a comma-separated list of any of the following: (a) an integer index of a subimage to include, or a minus sign (`-`) followed by an integer index of a subimage to exclude; (b) the name (as returned by the metadata “oiio:subimagename”) of a subimage to include, or to exclude if preceded by a `-`; (c) the special string “all”, meaning all subimages. Examples:

```shell
# Color convert only subimages 0, 3, and 4, leave the rest as-is
oiiotool -a multipart.exr --colorconvert:subimages=0,3,4 lnf aces -o out.exr
```

```shell
# Color convert all subimages EXCEPT the one named "normal"
oiiotool -a multipart.exr --colorconvert:subimages=-normal lnf aces -o out.exr
```

### 12.2 oiiotool Tutorial / Recipes

This section will give quick examples of common uses of **oiiotool** to get you started. They should be fairly intuitive, but you can read the subsequent sections of this chapter for all the details on every command.

#### 12.2.1 Printing information about images

To print the name, format, resolution, and data type of an image (or many images):

```shell
oiiotool --info *.tif
```

To also print the full metadata about each input image, use both `--info` and `-v`:

```shell
oiiotool --info -v *.tif
```

or:

```shell
oiiotool --info:verbose=1 *.tif
```

To print info about all subimages and/or MIP-map levels of each input image, use the `-a` flag:

```shell
oiiotool --info -v -a mipmap.exr
```

To print statistics giving the minimum, maximum, average, and standard deviation of each channel of an image, as well as other information about the pixels:
OpenImageIO, Release 2.4.1

```
oiiotool --stats img_2012.jpg
```

The --info, --stats, -v, and -a flags may be used in any combination.

### 12.2.2 Converting between file formats

It’s a snap to convert among image formats supported by OpenImageIO (i.e., for which ImageInput and ImageOutput plugins can be found). The `oiiotool` utility will simply infer the file format from the file extension. The following example converts a PNG image to JPEG:

```
oiiotool lena.png -o lena.jpg
```

The first argument (`lena.png`) is a filename, causing `oiiotool` to read the file and makes it the current image. The -o command outputs the current image to the filename specified by the next argument.

Thus, the above command should be read to mean, “Read `lena.png` into the current image, then output the current image as `lena.jpg` (using whatever file format is traditionally associated with the `.jpg` extension).”

### 12.2.3 Comparing two images

To print a report of the differences between two images of the same resolution:

```
oiiotool old.tif new.tif --diff
```

If you also want to save an image showing just the differences:

```
oiiotool old.tif new.tif --diff --absdiff -o diff.tif
```

This looks complicated, but it’s really simple: read `old.tif`, read `new.tif` (pushing `old.tif` down on the image stack), report the differences between them, subtract `new.tif` from `old.tif` and replace them both with the difference image, replace that with its absolute value, then save that image to `diff.tif`.

Sometimes you want to compare images but allow a certain number of small difference, say allowing the comparison to pass as long as no more than 1% of pixels differs by more than 1/255, and as long as no single pixel differs by more than 2/255. You can do this with thresholds:

```
oiiotool old.tif new.tif --fail 0.004 -failpercent 1 --hardfail 0.008 --diff
```

### 12.2.4 Changing the data format or bit depth

Just use the -d option to specify a pixel data format for all subsequent outputs. For example, assuming that `in.tif` uses 16-bit unsigned integer pixels, the following will convert it to an 8-bit unsigned pixels:

```
oiiotool in.tif -d uint8 -o out.tif
```

For formats that support per-channel data formats, you can override the format for one particular channel using -d 
CHNAME=TYPE. For example, assuming `rgbaz.exr` is a float RGBAZ file, and we wish to convert it to be half for RGBA, and float for Z. That can be accomplished with the following command:

```
oiiotool rgbaz.tif -d half -d Z=float -o rgbaz2.exr
```
When converting from a high bit depth data type (like float or half) to a very low bit depth data type (such as uint8), you may notice “banding” artifacts in smooth gradients. To combat this, you can use the `--dither` option to add random dither before the low bit depth quantization, which has the effect of masking the banding:

```
oiiotool half.exr -d uint8 --dither -o out8.tif
```

Note that `--dither` turns dither on for all 8 bit (or fewer) output files. Alternately, you can enable dither for individual outputs using a modifier to `-o` (the value of the dither modifier is the random seed that will be used):

```
oiiotool half.exr -d uint8 -o:dither=1 out8.tif
```

### 12.2.5 Changing the compression

The following command converts writes a TIFF file, specifically using LZW compression:

```
oiiotool in.tif --compression lzw -o compressed.tif
```

The following command writes its results as a JPEG file at a compression quality of 50 (pretty severe compression), illustrating how some compression methods allow a quality metric to be optionally appended to the name:

```
iconvert --compression jpeg:50 50 big.jpg small.jpg
```

### 12.2.6 Converting between scanline and tiled images

Convert a scanline file to a tiled file with 16x16 tiles:

```
oiiotool s.tif --tile 16 16 -o t.tif
```

Convert a tiled file to scanline:

```
oiiotool t.tif --scanline -o s.tif
```

### 12.2.7 Adding captions or metadata

Add a caption to the metadata:

```
oiiotool foo.jpg --caption "Hawaii vacation" -o bar.jpg
```

Add keywords to the metadata:

```
oiiotool foo.jpg --keyword "volcano,lava" -o bar.jpg
```

Add other arbitrary metadata:

```
oiiotool in.exr --attrib "FStop" 22.0
\--attrib "IPTC:City" "Berkeley" -o out.exr

oiiotool in.exr --attrib:type=timecode smpte:TimeCode "11:34:04:00"
\-o out.exr

oiiotool in.exr --attrib:type=int[4] FaceBBox "140,300,219,460"
\-o out.exr
```
12.2.8 Changing image boundaries and borders

Change the origin of the pixel data window:

```
oiiotool in.exr --origin +256+80 -o offset.exr
```

Change the display window:

```
oiiotool in.exr --fullsize 1024x768+16+16 -o out.exr
```

Change the display window to match the data window:

```
oiiotool in.exr --fullpixels -o out.exr
```

Crop (trim) an image to a 128x128 region whose upper left corner is at location (900,300), leaving the remaining pixels in their original positions on the image plane (i.e., the resulting image will have origin at 900,300), and retaining its original display window:

```
oiiotool in.exr --crop 128x128+900+300 -o out.exr
```

Cut (trim and extract) a 128x128 region whose upper left corner is at location (900,300), moving the result to the origin (0,0) of the image plane and setting the display window to the new pixel data window:

```
oiiotool in.exr --cut 128x128+900+300 -o out.exr
```

Put a constant-color border around all sides of an image, without needing to know the resolution of the input image:

```
# BW: Border width
BW=40
COLOR=.2,.2,.2,1.0
oiiotool in.tif
   --pattern constant:color=$COLOR "($TOP.width+2*$BW)x($TOP.height+2*$BW)" "($TOP.˓→nchannels)" --paste "+$BW+$BW" 
   -o out.tif
```

12.2.9 Scale the values in an image

Reduce the brightness of the R, G, and B channels by 10%, but leave the A channel at its original value:

```
oiiotool original.exr --mulc 0.9,0.9,0.9,1.0 -o out.exr
```

12.2.10 Remove gamma-correction from an image

Convert a gamma-corrected image (with gamma = 2.2) to linear values:

```
oiiotool corrected.exr --powc 2.2,2.2,2.2,2.2,1.0 -o linear.exr
```
12.2.11 Resize an image

Resize to a specific resolution:

```
oiiotool original.tif --resize 1024x768 -o specific.tif
```

Resize both dimensions by a known scale factor:

```
oiiotool original.tif --resize 200% -o big.tif
oiiotool original.tif --resize 25% -o small.tif
```

Resize each dimension, independently, by known scale factors:

```
oiiotool original.tif --resize 300%x200% -o big.tif
oiiotool original.tif --resize 100%x25% -o small.tif
```

Resize to a known resolution in one dimension, with the other dimension automatically computed to preserve aspect ratio (just specify 0 as the resolution in the dimension to be automatically computed):

```
oiiotool original.tif --resize 200x0 -o out.tif
oiiotool original.tif --resize 0x1024 -o out.tif
```

Resize to fit into a given resolution, keeping the original aspect ratio and padding with black where necessary to fit into the specified resolution:

```
oiiotool original.tif --fit 640x480 -o fit.tif
```

12.2.12 Color convert an image

This command linearizes a JPEG assumed to be in sRGB, saving as an HDRI OpenEXR file:

```
oiiotool photo.jpg --colorconvert sRGB linear -o output.exr
```

And the other direction:

```
oiiotool render.exr --colorconvert linear sRGB -o fortheweb.png
```

This converts between two named color spaces (presumably defined by your facility’s OpenColorIO configuration):

```
oiiotool in.dpx --colorconvert lg10 lnf -o out.exr
```

12.2.13 Grayscale and RGB

Turn a single channel image into a 3-channel gray RGB:

```
oiiotool gray.tif --ch 0,0,0 -o rgb.tif
```

Convert a color image to luminance grayscale:

```
oiiotool RGB.tif --chsum:weight=.2126,.7152,.0722 -o luma.tif
```
12.2.14 Channel reordering and padding

Copy just the color from an RGBA file, truncating the A, yielding RGB only:

```
oiiotool rgba.tif --ch R,G,B -o rgb.tif
```

Zero out the red and green channels:

```
oiiotool rgb.tif --ch R=0,G=0,B -o justblue.tif
```

Swap the red and blue channels from an RGBA image:

```
oiiotool rgba.tif --ch R=B,G,B=R,A -o bgra.tif
```

Extract just the named channels from a many-channel image, as efficiently as possible (avoiding memory and I/O for the unused channels):

```
oiiotool -i:ch=R,G,B manychannels.exr -o rgb.exr
```

Add an alpha channel to an RGB image, setting it to 1.0 everywhere, and naming it “A” so it will be recognized as an alpha channel:

```
oiiotool rgb.tif --ch R,G,B,A=1.0 -o rgba.tif
```

Add an alpha channel to an RGB image, setting it to be the same as the R channel and naming it “A” so it will be recognized as an alpha channel:

```
oiiotool rgb.tif --ch R,G,B,A=R -o rgba.tif
```

Add a z channel to an RGBA image, setting it to 3.0 everywhere, and naming it “Z” so it will be recognized as a depth channel:

```
oiiotool rgba.exr --ch R,G,B,A,Z=3.0 -o rgbaz.exr
```

12.2.15 Copy metadata from one image to another

Suppose you have a (non-OIIO) application that consumes input Exr files and produces output Exr files, but along the way loses crucial metadata from the input files that you want carried along. This command will add all the metadata from the first image to the pixels of the second image:

```
oiiotool metaonly.exr pixelsonly.exr -pastemeta -o combined.exr
```

12.2.16 Fade between two images

Fade 30% of the way from A to B:

```
oiiotool A.exr --mulc 0.7 B.exr --mulc 0.3 --add -o fade.exr
```
12.2.17 Simple compositing

Simple “over” composite of aligned foreground and background:

```bash
oiiotool fg.exr bg.exr --over -o composite.exr
```

Composite of small foreground over background, with offset:

```bash
oiiotool fg.exr --origin +512+89 bg.exr --over -o composite.exr
```

12.2.18 Creating an animated GIF from still images

Combine several separate JPEG images into an animated GIF with a frame rate of 8 frames per second:

```bash
oiiotool foo???.jpg --siappendall --attrib FramesPerSecond 10.0 -o anim.gif
```

12.2.19 Frame sequences: composite a sequence of images

Composite foreground images over background images for a series of files with frame numbers in their names:

```bash
oiiotool fg.1-50%04d.exr bg.1-50%04d.exr --over -o comp.1-50%04d.exr
```

Or:

```bash
oiiotool --frames 1-50 fg.%04d.exr bg.%04d.exr --over -o comp.%04d.exr
```

12.2.20 Expression example: annotate the image with its caption

This command reads a file, and draws any text in the “ImageDescription” metadata, 30 pixels from the bottom of the image:

```bash
oiiotool input.exr --text:x=30:y={TOP.height-30} {TOP.ImageDescription} -o out.exr
```

Note that this works without needing to know the caption ahead of time, and will always put the text 30 pixels from the bottom of the image without requiring you to know the resolution.

12.2.21 Contrast enhancement: stretch pixel value range to exactly fit [0-1]

This command reads a file, subtracts the minimum pixel value and then divides by the (new) maximum value, per channel, thus expanding its pixel values to the full [0-1] range:

```bash
oiiotool input.tif -subc {TOP.MINCOLOR} -divc {TOP.MAXCOLOR} -o out.tif
```

Note that this is a naive way to improve contrast and because each channel is handled independently, it may result in color hue shifts.
12.2.22 Split a multi-image file into separate files

Take a multi-image TIFF file, split into its constituent subimages and output each one to a different file, with names sub0001.tif, sub0002.tif, etc.:

```
oiiotool multi.tif -sisplit -o:all=1 sub%04d.tif
```

12.3 oiiotool commands: general flags

```
--help
  Prints full usage information to the terminal, as well as information about image formats supported, known color spaces, filters, OIIO build options and library dependencies.

-v
  Verbose status messages — print out more information about what oiiotool is doing at every step.

-q
  Quiet mode — print out less information about what oiiotool is doing (only errors).

-n
  No saved output — do not save any image files. This is helpful for certain kinds of tests, or in combination with --runstats or --debug, for getting detailed information about what a command sequence will do and what it costs, but without producing any saved output files.

--debug
  Debug mode — print lots of information about what operations are being performed.

--runstats
  Print timing and memory statistics about the work done by oiiotool.

-a
  Performs all operations on all subimages and/or MIPmap levels of each input image. Without -a, generally each input image will really only read the top-level MIPmap of the first subimage of the file.

--no-clobber
  Sets “no clobber” mode, in which existing images on disk will never be overridden, even if the -o command specifies that file.

--threads <n>
  Use n execution threads if it helps to speed up image operations. The default (also if n=0) is to use as many threads as there are cores present in the hardware.

--cache <size>
  Set the underlying ImageCache size (in MB). See Section ImageCache API.

--oiioattrib <name> <value>
  Adds or replaces a global OpenImageIO attribute with the given name to have the specified value.

  Optional appended modifiers include:

  * type=typename : Specify the metadata type.

  If the optional type= specifier is used, that provides an explicit type for the metadata. If not provided, it will try to infer the type of the metadata from the value: if the value contains only numerals (with optional leading
minus sign), it will be saved as \texttt{int} metadata; if it also contains a decimal point, it will be saved as \texttt{float} metadata; otherwise, it will be saved as a \texttt{string} metadata.

Examples:

```
oiioattrib debug 1 in.jpg -o out.jpg
```

### 12.4 \texttt{oiio} commands for control flow

--\texttt{set} \texttt{<name>} \texttt{<value>}

Adds or replaces a “user variable”. User variables may be referenced by name in expression substitution.

Optional appended modifiers include:

- type= \texttt{typename} : Specify the metadata type.

If the optional \texttt{type=} specifier is used, that provides an explicit type for the variable. If not provided, it will try to infer the type from the value: if the value contains only numerals (with optional leading minus sign), it will be saved as \texttt{int}; if it also contains a decimal point, it will be saved as a \texttt{float}; otherwise, it will be saved as a \texttt{string}.

This command was added in OIIO 2.4.0.

Examples:

```
$ oiiotool --set i 42 --echo "i = \{i\}"
i = 42
```

--\texttt{if} \texttt{<condition>} \texttt{true-cmds...} --\texttt{endif}

--\texttt{if} \texttt{<condition>} \texttt{true-cmds...} --\texttt{else} \texttt{false-cmds...} --\texttt{endif}

If the \texttt{condition} is true, execute \texttt{true-cmds}, otherwise execute \texttt{false-cmds}.

The \texttt{condition} is considered false if it is integer 0 or float 0.0 or the empty string "", or any of the strings \texttt{off}, \texttt{false}, or \texttt{no} (without regard to capitalization). All other values or strings are assumed to be considered “true” for the evaluation of the condition.

Examples:

```
# Read in.exr, and if it only has 3 channels, add an alpha channel
# that is 1.0 everywhere, but if it already has 4 channels, leave
# it alone. Then output the result to out.exr.
$ oiiotool in.exr --if "\{TOP.nchannels == 3\}" --ch ,,,A=1.0 --endif -o rgba.exr
```

--\texttt{for} \texttt{<variable>} \texttt{<range>} \texttt{commands...} --\texttt{endfor}

Iterate a \texttt{variable} over a \texttt{range}, executing the \texttt{commands} for each iteration. The range may be one, two, or three numbers separated by commas, indicating

- \texttt{end} : Iterate from 0 to \texttt{end}, incrementing by 1 each time.
- \texttt{begin , end} [Iterate from \texttt{begin} to \texttt{end}, incrementing] by 1 each time.
- \texttt{begin , end , step} : Iterate from \texttt{begin} to \texttt{end}, incrementing by \texttt{step} each time.

Note that the \texttt{end} value is “exclusive,” that is, the loop will terminate once the value is equal to \texttt{end}, and the loop body will not be executed for the \texttt{end} value.

Examples:
$ oiiotool --for i 5 --echo "i = {i}" --endfor
0
1
2
3
4

$ oiiotool --for i 5,10 --echo "i = {i}" --endfor
5
6
7
8
9

$ oiiotool --for i 5,10,2 --echo "i = {i}" --endfor
5
7
9

--while <condition> commands... --endwhile
If the condition is true, execute commands, and keep doing that until the condition is false.

The condition is considered false if it is integer 0 or float 0.0 or the empty string ".", or any of the strings off, false, or no (without regard to capitalization). All other values or strings are assumed to be considered “true” for the evaluation of the condition.

Examples:

$ oiiotool -set i 0 --while "{i < 5}" --echo "i = {i}" -set i "{i + 1}" --endwhile
0
1
2
3
4

--frames <seq>
--framepadding <n>
Describes the frame range to substitute for the # or %Nd numeric wildcards. The sequence is a comma-separated list of subsequences; each subsequence is a single frame (e.g., 100), a range of frames (100–150), or a frame range with step (100–150x4 means 100, 104, 108, ...).

The frame padding is the number of digits (with leading zeroes applied) that the frame numbers should have. It defaults to 4.

For example,

  oiiotool --framepadding 3 --frames 3,4,10-20x2 blah.#.tif

would match blah.003.tif, blah.004.tif, blah.010.tif, blah.012.tif, blah.014.tif, blah.016.tif, blah.018.tif, blah.020.tif.

--views <name1,name2,...>
Supplies a comma-separated list of view names (substituted for %V and %v). If not supplied, the view list will be left,right.

--skip-bad-frames
When iterating over a frame range, if this option is used, any errors will cease processing that frame, but continue iterating with the next frame (rather than the default behavior of exiting immediately and not even attempting the other frames in the range).
--wildcardoff, --wildcardon
These *positional* options turn off (or on) numeric wildcard expansion for subsequent command line arguments. This can be useful in selectively disabling numeric wildcard expansion for a subset of the command line.

--evaloff, --evalon
These *positional* options turn off (or on) expression evaluation (things with `{ }`) for subsequent command line arguments. This can be useful in selectively disabling expression evaluation expansion for a subset of the command line, for example if you actually have filenames containing curly braces.

### 12.5 oiiotool commands: reading and writing images

The commands described in this section read images, write images, or control the way that subsequent images will be written upon output.

#### 12.5.1 Reading images

```
<filename>
-i <filename>
```

If a command-line option is the name of an image file, that file will be read and will become the new current image, with the previous current image pushed onto the image stack.

The `-i` command may be used, which allows additional options that control the reading of just that one file.

Optional appended modifiers include:

- `:now=int` If 1, read the image now, before proceeding to the next command.
- `:autocc=int` Enable or disable `--autocc` for this input image (the default is to use the global setting).
- `:unpremult=int` If autocc is used for this image, should any color transformation be done on unassociated colors (unpremultiplied by alpha). The default is 0.
- `:info=int` Print info about this file (even if the global `--info` was not used) if nonzero. If the value is 2, print full verbose info (like `--info -v`).
- `:infoformat=name` When printing info, the format may be one of: *text* (default) for readable text, or *xml* for an XML description of the image metadata.
- `:type=name` Upon reading, convert the pixel data to the named type. This can override the default behavior of internally storing whatever type is the most precise one found in the file.
- `:ch=name...` Causes the input to read only the specified channels. This is equivalent to following the input with a `--ch` command, except that by integrating into the `-i`, it potentially can avoid the I/O of the unneeded channels.

```
--iconfig <name> <value>
```

Sets configuration hint metadata that will apply to the next input file read. Input configuration hint settings are cleared after an image is read, and must be specified separately for every `-i` or image filename to read.

Optional appended modifiers include:

- `type=typename` Specify the metadata type.

If the optional `type=` specifier is used, that provides an explicit type for the metadata. If not provided, it will try to infer the type of the metadata from the value: if the value contains only numerals (with optional leading minus sign), it will be saved as `int` metadata; if it also contains a decimal point, it will be saved as `float` metadata; otherwise, it will be saved as a `string` metadata.
12.5.2 Options that control the reading of all images

These are all non-positional flags that affect how all images are read in the `oiiotool` command.

**--autocc**

Turns on automatic color space conversion: Every input image file will be immediately converted to a scene-referred linear color space, and every file written will be first transformed to an appropriate output color space based on the filename or type. Additionally, if the name of an output file contains a color space and that color space is associated with a particular data format, it will output that data format (akin to `-d`).

The rules for deducing color spaces are as follows, in order of priority:

1. If the filename (input or output) contains as a substring the name of a color space from the current Open-ColorIO configuration, that will be assumed to be the color space of input data (or be the requested color space for output).
2. For input files, if the ImageInput set the "oiio:ColorSpace" metadata, it will be honored if the filename did not override it.
3. When outputting to JPEG files, assume that sRGB is the desired output color space (since JPEG requires sRGB), but still this only occurs if the filename does not specify something different.

If the implied color transformation is unknown (for example, involving a color space that is not recognized), a warning will be printed, but it the rest of `oiiotool` processing will proceed (but without having transformed the colors of the image).

Optional appended modifiers include:

:unpremult= **int** If nonzero, when autocc is performed on an image containing an alpha channel, the image will first be unpremultiplied by alpha, then color transformed, then re-premultiplied by alpha, so that the color transformation is done with unassociated color values. The default is 0, meaning that the color transformation will be done directly on the associated color values.

Example:

If the input file `in_lgl10.dpx` is in the lgl10 color space, and you want to read it in, brighten the RGB uniformly by 10% (in a linear space, of course), and then save it as a 16 bit integer TIFF file encoded in the vd16 color space, you could specify the conversions explicitly:

```
oiiotool in_lgl10.dpx --colorconvert lgl10 linear
   --mulc 1.1,1.1,1.1,1.0 -colorconvert linear vd16
   -d uint16 -o out_vd16.tif
```

or rely on the naming convention matching the OCIO color space names and use automatic conversion:

```
oiiotool --autocc in_lgl10.dpx --mulc 1.1 -o out_vd16.tif
```

**--autopremult** (default), **-no-autopremult**

By default, OpenImageIO's format readers convert any “unassociated alpha” (color values that are not “premultiplied” by alpha) to the usual associated/premultiplied convention. If the **--no-autopremult** flag is found, subsequent inputs will not do this premultiplication. It can be turned on again via **--autopremult**.
--autoorient
Automatically do the equivalent of --reorient on every image as it is read in, if it has a nonstandard orientation. This is generally a good idea to use if you are using oiio tool to combine images that may have different orientations.

--native
Normally, all images read by oiio tool are read into an ImageBuf backed by an underlying ImageCache, and are automatically converted to float pixels for internal storage (because any subsequent image processing is usually much faster and more accurate when done on floating-point values).

This option causes (1) input images to be stored internally in their native pixel data type rather than converted to float, and (2) to bypass the ImageCache (reading directly into an ImageBuf) if the pixel data type is not one of the types that is supported internally to ImageCache (UINT8, uint16, half, and float).

images whose pixels are comprised of data types that are not natively representable exactly in the ImageCache to bypass the ImageCache and be read directly into an ImageBuf.

The typical use case for this is when you know you are dealing with unusual pixel data types that might lose precision if converted to float (for example, if you have images with uint32 or double pixels). Another use case is if you are using oiio tool merely for file format or data format conversion, with no actual image processing math performed on the pixel values – in that case, you might save time and memory by bypassing the conversion to float.

--autotile <tilesize>
For the underlying ImageCache, turn on auto-tiling with the given tile size. Setting tileSize to 0 turns off auto-tiling (the default is off). If auto-tile is turned on, The ImageCache “autoscanline” feature will also be enabled. See Section ImageCache API for details.

--missingfile <value>
Determines the behavior when an input file is not found, and no file of that name exists at all. An error is always printed and the oiio tool program always has an error-indicating exit code. But how it proceeds with the rest of the commands may vary depending on the option value:

- error: (default) Consider it a full error for that frame iteration.
- black: After the error is printed, try to continue with the rest of the command, substituting an opaque black image for the missing file.
- checker [After the error is printed, try to continue with the rest] of the command, substituting a checkerboard image for the missing file.

Note that the resolution, channels, and format (but not arbitrary metadata) of the missing file substitution image will be the same as the first image that was successfully read. If the first image requested is missing (thus, nothing had been successfully read when the missing image is needed), it will be HD resolution, 1920x1080, RGBA.

--info
Print metadata information about each input image as it is read. If verbose mode is turned on (-v), all the metadata for the image is printed. If verbose mode is not turned on, only the resolution and data format are printed.

Optional appended modifiers include:

- format=name: The format name may be one of: text (default) for readable text, or xml for an XML description of the image metadata.
- verbose=1: If nonzero, the information will contain all metadata, not just the minimal amount.

Note that this is a non-positional flag that will cause metadata to be printed for every input file. There is a separate --printinfo action that immediately prints metadata about the current image at the top of the stack (see oiio tool commands that print information about the current image).
--metamatch <regex>, --no-metamatch <regex>

Regular expressions to restrict which metadata are output when using oiiotool --info -v. The
--metamatch expression causes only metadata whose name matches to print; non-matches are not output.
The --no-metamatch expression causes metadata whose name matches to be suppressed; others (non-
matches) are printed. It is not advised to use both of these options at the same time (probably nothing bad
will happen, but it’s hard to reason about the behavior in that case).

--stats

Print detailed statistical information about each input image as it is read.

Note that this is a non-positional flag that will cause statistics to be printed for every input file. There is a
separate --printstats action that immediately prints statistics about the current image at the top of the
stack (see oiiotool commands that print information about the current image).

--hash

Print the SHA-1 hash of the pixels of each input image as it is read.

--dumpdata

Print to the console the numerical values of every pixel, for each input image as it is read.

Optional appended modifiers include:

- C= name: If present, will cause the output of the data to be in the correct syntax of declaring a C array
  with the given name. (This was added in OpenImageIO v2.3.9.)

- empty= verbose: If 0, will cause deep images to skip printing of information about pixels with no
  samples.

Examples:

```
$ oiiotool --dumpdata image.exr
image.exr : 256 x 256, 4 channel, float openexr
  Pixel (0, 0): 0.517036676 0.261921108 0.017822538 0.912108004
  Pixel (1, 0): 0.653315008 0.527794302 0.359594107 0.277836263
  ...
```

```
$ oiiotool --dumpdata:C=foo image.exr
// image.exr : 256 x 256, 4 channel, float openexr
float foo[256][256][4] =
{
  /* (0, 0): */ { 0.517036676, 0.261921108, 0.017822538, 0.912108004 },
  /* (1, 0): */ { 0.653315008, 0.527794302, 0.359594107, 0.277836263 },
  ...
};
```

12.5.3 Writing images

-o <filename>

Outputs the current image to the named file. This does not remove the current image from the image stack, it
merely saves a copy of it.

Optional appended modifiers include:

- type= name Set the pixel data type (like -d) for this output image (e.g., :uint8, uint16,
  half, float, etc.).

- bits= int Set the bits per pixel (if nonstandard for the datatype) for this output image.

- dither= int Turn dither on or off for this output. When writing floating point data to an 8 bit or
  less data type in the file, dither can reduce banding artifacts. (default: 0)
:autocc= int  Enable or disable --autocc for this output image (the default is to use the global setting).

:unpremult= int  If autocc is used for this image, should any color transformation be done on unassociated colors (unpremultiplied by alpha). The default is 0.

:autocrop= int  Enable or disable --autocrop for this output image.

:autotrim= int  Enable or disable --autotrim for this output image.

:separate= int, contig= int  Set separate or contiguous planar configuration for this output.

:fileformatname= string  Specify the desired output file format, overriding any guess based on file name extension.

:scanline= int  If nonzero, force scanline output.

:tile= int x int  Force tiling with given size.

:all= n  Output all images currently on the stack using a pattern. See further explanation below.

The all=n option causes all images on the image stack to be output, with the filename argument used as a pattern assumed to contain a %d, which will be substituted with the index of the image (beginning with n). For example, to take a multi-image TIFF and extract all the subimages and save them as separate files:

```
oiiotool multi.tif -sisplit -o:all=1 sub%04d.tif
```

This will output the subimages as separate files sub0001.tif, sub0002.tif, and so on.

-otex <filename>
-oenv <filename>
-obump <filename>

Outputs the current image to the named file, as a MIP-mapped texture or environment map, identical to that which would be output by maketx (Chapter Making Tiled MIP-Map Texture Files With maketx or oiiotool).

The advantage of using oiiotool rather than maketx is simply that you can have a complex oiiotool command line sequence of image operations, culminating in a direct saving of the results as a texture map, rather than saving to a temporary file and then separately invoking maketx.

In addition to all the optional arguments of -o, optional appended arguments for -otex, -oenv, and -obump also include:

:wrap= string  Set the default $s$ and $t$ wrap modes of the texture, to one of: :black, clamp, periodic, mirror.

:swrap= string  Set the default $s$ wrap mode of the texture.

:twrap= string  Set the default $t$ wrap mode of the texture.

:resize= int  If nonzero, resize to a power of 2 before starting to create the MIPmap levels. (default: 0)

:nomipmap= int  If nonzero, do not create MIP-map levels at all. (default: 0)

:updatemode= int  If nonzero, do not create and overwrite the existing texture if it appears to already match the source pixels. (default: 0)

:constant_color_detect= int  Detect images that are entirely one color, and change them to be low resolution. (default: 0)

:monochrome_detect= int  Detect monochrome (R=G=B) images and turn them into 1-channel textures. (default: 0)

:opaque_detect= int  Detect opaque (A=1) images and drop the alpha channel from the texture. (default: 0)
:compute_average= int  Compute and store the average color of the texture. (default: 1)
:unpremult= int  Unpremultiply colors before any per-MIP-level color conversions, and re-
premultiply after. (default: 0)
:incolorspace= string  Specify color space conversion.
:outcolorspace= string  ...
:highlightcomp= int  Use highlight compensation for HDR images when resizing for MIP-map
levels. (default: 0)
:sharpen= float  Additional sharpening factor when resizing for MIP-map levels. (default: 0.0)
:filter= string  Specify the filter for MIP-map level resizing. (default: box)
:prman_metadata= int  Turn all all options required to make the resulting texture file compatible
with PRMan (particular tile sizes, formats, options, and metadata). (default: 0)
:prman_options= int  Include the metadata that PRMan’s texture system wants. (default: 0)
:bumpformat= string  For -obump only, specifies the interpretation of 3-channel source images
as one of: height, normal, auto (default).
:uvsslopes_scale= float  For -obump only, specifies the amount to scale the bump-map slopes
by. (default: 0.0, meaning not to use this feature)
:cdf= int  If nonzero, will add to the texture metadata the forward and inverse Gaussian CDF, which
can be used by shaders to implement Histogram-Preserving blending. (default: 0)
:cdfsigma= float  In conjunction with cdf=1, specifies the sigma value to use for the CDF (de-
fault: 1.0/6.0).
:cdfbits= int  In conjunction with cdf=1, specifies the number of bits to use for the size of the
CDF table (default: 8, meaning 256 bins).
:handed= string  Specifies the handedness of a vector displacement map or normal map when
using tangent space coordinates. Valid values are “left” or “right” (default: none).

Examples:

```bash
oiiotool in.tif -otex out.tx
oiiotool in.jpg --colorconvert sRGB linear -d uint16 -otex out.tx
oiiotool --pattern:checker 512x512 3 -d uint8 -otex:wrap=periodic checker.tx
oiiotool in.exr -otex:hilightcomp=1:sharpen=0.5 out.exr
```

-d <datatype>
-d <channelname>=<datatype>
-d <subimagename>.*=<datatype>
-d <subimagename>.<channelname>=<datatype>

Attempts to set the pixel data type of all subsequent outputs. If no channel or subimage name is given, sets all
channels to be the specified data type. If a specific channel is named, then the data type will be overridden for just
that channel (multiple -d commands may be used). If both a subimage name and channel name are specified,
the hint is only for the named channel when encountered in a named subimage. And if the specification is of the
form subimagename.*=type, then all channels of that subimage will be output with the given type.

Valid types are: uint8, sint8, uint16, sint16, half, float, double. The types uint10 and
uint12 may be used to request 10- or 12-bit unsigned integers. If the output file format does not support
them, uint16 will be substituted.

12.5. oiiotool commands: reading and writing images
If the `-d` option is not supplied, the output data type will be deduced from the data format of the input files, if possible.

In any case, if the output file type does not support the requested data type, it will instead use whichever supported data type results in the least amount of precision lost.

`--scanline`
Requests that subsequent output files be scanline-oriented, if scanline orientation is supported by the output file format. By default, the output file will be scanline if the input is scanline, or tiled if the input is tiled.

`--tile <x> <y>`
Requests that subsequent output files be tiled, with the given \( x \times y \) tile size, if tiled images are supported by the output format. By default, the output file will take on the tiledness and tile size of the input file.

`--compression <method>`

`--compression <method:quality>`
Sets the compression method, and optionally a quality setting, for the output image. Each ImageOutput plugin will have its own set of methods that it supports.

`--quality <q>`
Sets the compression quality, on a 1-100 floating-point scale. This only has an effect if the particular compression method supports a quality metric (as JPEG does).

This is considered deprecated, and in general we now recommend just appending the quality metric to the --compression name:qual.

`--dither`
Turns on dither when outputting to 8-bit or less image files (does not affect other data types). This adds just a bit of noise that reduces visible banding artifacts. The dither seed will be selected based on a hash of the output filename, and therefore will be a different random pattern for different files. It only has an effect when outputting to a file of 8 or fewer bits per sample, and only when the data being saved starts off with higher than 8 bit precision.

`--planarconfig <config>`
Sets the planar configuration of subsequent outputs (if supported by their formats). Valid choices are: config for contiguous (or interleaved) packing of channels in the file (e.g., RGBRGBRGB...), separate for separate channel planes (e.g., RRRR...GGGG...BBBB...), or default for the default choice for the given format. This command will be ignored for output files whose file format does not support the given choice.

`--adjust-time`
When this flag is present, after writing each output, the resulting file’s modification time will be adjusted to match any "DateTime" metadata in the image. After doing this, a directory listing will show file times that match when the original image was created or captured, rather than simply when oiiotool was run. This has no effect on image files that don’t contain any "DateTime" metadata.

`--noautocrop`
For subsequent outputs, do not automatically crop images whose formats don’t support separate pixel data and full/display windows. Without this, the default is that outputs will be cropped or padded with black as necessary when written to formats that don’t support the concepts of pixel data windows and full/display windows. This is a non-issue for file formats that support these concepts, such as OpenEXR.

`--autotrim`
For subsequent outputs, if the output format supports separate pixel data and full/display windows, automatically trim the output so that it writes the minimal data window that contains all the non-zero valued pixels. In other words, trim off any all-black border rows and columns before writing the file.
--metamerge
When this flag is used, most image operations will try to merge the metadata found in all of their source input
images into the output. The default (if this is not used) is that image operations with multiple input images will
just take metadata from the first source image.

(This was added for OpenImageIO 2.1.)

12.6 oiiotool commands that print information about the current image

--echo <message>
Prints the message to the console, at that point in the left-to-right execution of command line arguments. The
message may contain expressions for substitution.

Optional appended modifiers include:

• newline=n: The number of newlines to print after the message (default is 1, but 0 will suppress the
newline, and a larger number will make more vertical space.

Examples:

```bash
oiiotool test.tif --resize 256x0 --echo "result is {TOP.width}x{TOP.height}"
```

This will resize the input to be 256 pixels wide and automatically size it vertically to preserve the original aspect
ratio, and then print a message to the console revealing the resolution of the resulting image.

--list-formats
Prints the complete list of file formats supported by this build of OpenImageIO, and for each one, the list of file
extensions that it presumes are associated with the file format. (Added in OIIO 2.2.13.)

--printinfo
Prints information and all metadata about the current image.

--printstats
Prints detailed statistical information about the current image.

Optional appended modifiers include:

• :window=geom: If present, restricts the statistics to a rectangular subset of the image. The default, if not
present is to print the statistics of the full data window of the image. The rectangle can be specified
using either of these image geometry notations:

- width x height [+/- xoffset [+/- yoffset
- xmin,ymin,xmax,ymax

• :allsubimages=int: If nonzero, stats will be printed about all subimages of the current image. (The
default is zero, meaning that stats will only be printed for the first subimage of the current image.)

--colorcount r1,g1,b1,...:r2,g2,b2,...:
Given a list of colors separated by colons or semicolons, where each color is a list of comma-separated values
(for each channel), examine all pixels of the current image and print a short report of how many pixels matched
each of the colors.

Optional appended modifiers include:

• eps=r,g,b,...: Tolerance for matching colors (default: 0.001 for all channels).

Examples:
might produce the following output:

<table>
<thead>
<tr>
<th>Value</th>
<th>Color</th>
</tr>
</thead>
<tbody>
<tr>
<td>10290</td>
<td>0.792,0,0,1</td>
</tr>
<tr>
<td>11281</td>
<td>0.722,0,0,1</td>
</tr>
</tbody>
</table>

Notice that use of double quotes " " around the list of color arguments, in order to make sure that the command shell does not interpret the semicolon (;) as a statement separator. An alternate way to specify multiple colors is to separate them with a colon (:), for example:

```
[97x660]oiiotool test.tif --colorcount 0.792,0,0,1:0.722,0,0,1
```

Another example:

```
[97x680]oiiotool test.tif --colorcount:eps=.01,.01,.01,1000 "0.792,0,0,1"
```

This example sets a larger epsilon for the R, G, and B channels (so that, for example, a pixel with value [0.795,0,0] would also match), and by setting the epsilon to 1000 for the alpha channel, it effectively ensures that alpha will not be considered in the matching of pixels to the color value.

**--rangecheck** Rlow,Glow,Blow,... Rhi,Bhi,Ghi,...

Given a two colors (each a comma-separated list of values for each channel), print a count of the number of pixels in the image that has channel values outside the [low,hi] range. Any channels not specified will assume a low of 0.0 and high of 1.0.

Example:

```
[97x396]oiiotool test.exr --rangecheck 0,0,0 1,1,1
```

might produce the following output:

<table>
<thead>
<tr>
<th>Value</th>
<th>Pixel Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>&lt; 0,0,0</td>
</tr>
<tr>
<td>221</td>
<td>&gt; 1,1,1</td>
</tr>
<tr>
<td>65315</td>
<td>within range</td>
</tr>
</tbody>
</table>

**--diff**

**--fail** <A> **--failpercent** <B> **--hardfail** <C>

**--warn** <A> **--warnpercent** <B> **--hardwarn** <C>

This command computes the difference of the current image and the next image on the stack, and prints a report of those differences (how many pixels differed, the maximum amount, etc.). This command does not alter the image stack.

The **--fail**, **--failpercent**, and **--hardfail** options set thresholds for FAILURE: if more than B % of pixels (on a 0-100 floating point scale) are greater than A different, or if any pixels are more than C different. The defaults are to fail if more than 0% (any) pixels differ by more than 0.00001 (1e-6), and C is infinite.

The **--warn**, **--warnpercent**, and **hardwarn** options set thresholds for WARNING: if more than B % of pixels (on a 0-100 floating point scale) are greater than A different, or if any pixels are more than C different. The defaults are to warn if more than 0% (any) pixels differ by more than 0.00001 (1e-6), and C is infinite.

**--pdiff**

This command computes the difference of the current image and the next image on the stack using a perceptual metric, and prints whether or not they match according to that metric. This command does not alter the image stack.
12.7 oiiotool commands that change the current image metadata

This section describes oiiotool commands that alter the metadata of the current image, but do not alter its pixel values. Only the current (i.e., top of stack) image is affected, not any images further down the stack.

If the -a flag has previously been set, these commands apply to all subimages or MIPmap levels of the current top image. Otherwise, they only apply to the highest-resolution MIPmap level of the first subimage of the current top image.

--attrib <name> <value>
--sattrib <name> <value>
Adds or replaces metadata with the given name to have the specified value.

Optional appended modifiers include:

• type=typename: Specify the metadata type.

If the optional type= specifier is used, that provides an explicit type for the metadata. If not provided, it will try to infer the type of the metadata from the value: if the value contains only numerals (with optional leading minus sign), it will be saved as int metadata; if it also contains a decimal point, it will be saved as float metadata; otherwise, it will be saved as a string metadata.

The --sattrib command is equivalent to --attrib:type=string.

Examples:

```
oiiotool in.jpg --attrib "IPTC:City" "Berkeley" -o out.jpg
oiiotool in.jpg --attrib:type=string "Name" "0" -o out.jpg
oiiotool in.exr --attrib:type=matrix worldtocam \"1,0,0,0,0,1,0,0,0,0,1,0,2.3,2.1,0,1\" -o out.exr
oiiotool in.exr --attrib:type=timecode smpte:TimeCode "11:34:04:00" \-o out.exr
```

--caption <text>
Sets the image metadata "ImageDescription". This has no effect if the output image format does not support some kind of title, caption, or description metadata field. Be careful to enclose *text in quotes if you want your caption to include spaces or certain punctuation!

--keyword <text>
Adds a keyword to the image metadata "Keywords". Any existing keywords will be preserved, not replaced, and the new keyword will not be added if it is an exact duplicate of existing keywords. This has no effect if the output image format does not support some kind of keyword field.

Be careful to enclose *text in quotes if you want your keyword to include spaces or certain punctuation. For image formats that have only a single field for keywords, OpenImageIO will concatenate the keywords, separated by semicolon (;), so don’t use semicolons within your keywords.

--clear-keywords
Clears all existing keywords in the current image.

--nosoftwareattrib
When set, this prevents the normal adjustment of “Software” and “ImageHistory” metadata to reflect what oiiotool is doing.

--sansattrib
When set, this edits the command line inserted in the “Software” and “ImageHistory” metadata to omit any verbose --attrib and --sattrib commands.
--eraseattrib <pattern>
Removes any metadata whose name matches the regular expression pattern. The pattern will be case insensitive.

Examples:

```bash
# Remove one item only
oiiotool in.jpg --eraseattrib "smpte:TimeCode" -o no_timecode.jpg

# Remove all GPS tags
oiiotool in.jpg --eraseattrib "GPS:.*" -o no_gps_metadata.jpg

# Remove all metadata
oiiotool in.exr --eraseattrib ".*" -o no_metadata.exr
```

--orientation <orient>
Explicitly sets the image's "Orientation" metadata to a numeric value (see Section Display hints for the numeric codes). This only changes the metadata field that specifies how the image should be displayed, it does NOT alter the pixels themselves, and so has no effect for image formats that don't support some kind of orientation metadata.

--orientcw
--orientccw
--orient180
Adjusts the image's "Orientation" metadata by rotating the suggested viewing orientation 90° clockwise, 90° degrees counter-clockwise, or 180°, respectively, compared to its current setting. This only changes the metadata field that specifies how the image should be displayed, it does NOT alter the pixels themselves, and so has no effect for image formats that don't support some kind of orientation metadata.

See the --rotate90, --rotate180, --rotate270, and --reorient commands for true rotation of the pixels (not just the metadata).

--origin <neworigin>
Set the pixel data window origin, essentially translating the existing pixel data window to a different position on the image plane. The new data origin is in the form:

```
[+][-]x[+][-]y
```

Examples:

```
--origin +20+10 x=20, y=10
--origin +0-40 x=0, y=-40
```

--originoffset <offset>
Alter the data window origin, translating the existing pixel data window by this relative amount. The offset is in the form:

```
[+][-]x[+][-]y
```

Examples:

```
# Assuming the old origin was +100+20...
--originoffset +20+10      # new x=120, y=30
--originoffset +0-40       # new x=100, y=-20
```

--fullsize <size>
Set the display/full window size and/or offset. The size is in the form

```
width x height [+][-]xoffset [+][-]yoffset
```
If either the offset or resolution is omitted, it will remain unchanged.

Examples:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--fullsize 1920x1080</code></td>
<td>resolution w=1920, h=1080, offset unchanged</td>
</tr>
<tr>
<td><code>--fullsize -20-30</code></td>
<td>resolution unchanged, x=-20, y=-30</td>
</tr>
<tr>
<td><code>--fullsize 1024x768+100+0</code></td>
<td>resolution w=1024, h=768, offset x=100, y=0</td>
</tr>
</tbody>
</table>

`--fullpixels`
Set the full/display window range to exactly cover the pixel data window.

`--chnames <name-list>`
Rename some or all of the channels of the top image to the given comma-separated list. Any completely empty channel names in the list will not be changed. For example:

```
oiiotool in.exr --chnames ",,,A,Z" -o out.exr
```

will rename channel 3 to be “A” and channel 4 to be “Z”, but will leave channels 0–3 with their old names.

Optional appended modifiers include:

:subimages= indices-or-names Include/exclude subimages (see Dealing with multi-subimage/multi-part files). Only included subimages will have their channels renamed.

12.8 oiiotool commands that shuffle channels or subimages

`--selectmip <level>`
If the current image is MIP-mapped, replace the current image with a new image consisting of only the given level of the MIPmap. Level 0 is the highest resolution version, level 1 is the next-lower resolution version, etc.

`--unmip`
If the current image is MIP-mapped, discard all but the top level (i.e., replacing the current image with a new image consisting of only the highest-resolution level). Note that this is equivalent to `--selectmip 0`.

`--subimage <n>`
If the current image has multiple subimages, replace it with just the specified subimage. The subimage specifier n is either an integer giving the index of the subimage to extract (starting with 0), or the name of the subimage to extract (comparing to the "oiio:subimagename" metadata).

Additionally, this command can be used to remove one subimage (leaving the others) by using the optional modifier `--subimage:delete=1`.

`--sisplit`
Remove the top image from the stack, split it into its constituent subimages, and push them all onto the stack (first to last).

`--siappend`
Replaces the top two (or more) images on the stack with a single new multi-subimage comprised of the original images appended together as subimages within the same single image.

Optional appended modifiers include:

:n= number-of-subimages Specify the number (if more than 2) of images to combine into a single multi-subimage image. This will be clamped between 2 and the total number of images on the stack.
--siappendall
Replace all of the individual images on the stack with a single new image comprised of the subimages of all original images appended together.

--ch <channellist>
Replaces the top image with a new image whose channels have been reordered as given by the channellist. The channellist is a comma-separated list of channel designations, each of which may be

- an integer channel index of the channel to copy,
- the name of a channel to copy,
- newname = oldname, which copies a named channel and also renames it,
- = float, which will set the channel to a constant value, or
- newname = float, which sets the channel to a constant value as well as names the new channel.

Example channel lists include: R,G,B, R=0.0, G,B,A=1.0, R=B, G,B=R, 4, 5, 6, A.

Channel numbers outside the valid range of input channels, or unknown names, will be replaced by black channels. If the channellist is shorter than the number of channels in the source image, unspecified channels will be omitted.

If the channel list does not specify any changes (neither order, nor name, nor value), then this will just leave the images as-is, without any unnecessary expense or pointless copying of images in memory.

--chappend
Replaces the top two (or more) images on the stack with a single new image comprised of the channels of the input images appended together.

Optional appended modifiers include:

: n=number-of-subimages Specify the number (if more than 2) of images whose channels should be combined into a single image. This will be clamped between 2 and the total number of images on the stack.

:subimages=indices-or-names Include/exclude subimages (see Dealing with multi-subimage/multi-part files).

12.9 oiiotool commands that adjust the image stack

--pop
Pop the image stack, discarding the current image and thereby making the next image on the stack into the new current image.

--dup
Duplicate the current image and push the duplicate on the stack. Note that this results in both the current and the next image on the stack being identical copies.

--swap
Swap the current image and the next one on the stack.

--label <name>
Gives a name to (and saves) the current image at the top of the stack. Thereafter, the label name may be used to refer to that saved image, in the usual manner that an ordinary input image would be specified by filename.
12.10 oiiotool commands that make entirely new images

**--create** `<size> <channels>`
Create new black image with the given size and number of channels, pushing it onto the image stack and making it the new current image.

The `size` is in the form

`width x height [+-] xoffset [+-] yoffset`

If the offset is omitted, it will be `x=0, y=0`. Optional appended arguments include:

- **type**=`name`: Create the image in memory with the named data type (default: float).

Examples:

```
--create 1920x1080 3             # RGB with w=1920, h=1080, x=0, y=0
--create 1024x768+100+0 4        # RGBA with w=1024, h=768, x=100, y=0
--create:type=uint8 1920x1080 3   # RGB, store internally as uint8
```

**--pattern** `<patternname> <size> <channels>`
Create new image with the given size and number of channels, initialize its pixels to the named pattern, and push it onto the image stack to make it the new current image.

The `size` is in the form

`width x height [+-] xoffset [+-] yoffset`

If the offset is omitted, it will be `x=0, y=0`. Optional appended arguments include:

- **type**=`name`: Create the image in memory with the named data type (default: float).

The patterns recognized include the following:

- **black**: A black image (all pixels 0.0)
- **constant**: A constant color image, defaulting to white, but the color can be set with the optional `:color=r,g,b,...` arguments giving a numerical value for each channel.
- **checker**: A black and white checkerboard pattern. The optional modifier `:width=` sets the width of the checkers (defaulting to 8 pixels), `:height=` sets the height of the checkers (defaulting to equal height and width). Optional modifiers `:color1=r,g,b,...` and `:color2=r,g,b,...` set the colors of the alternating squares (defaulting to black and white, respectively).
- **fill**: A constant color or gradient, depending on the optional colors. Argument `:color=r,g,b,...` results in a constant color. Argument `:top=r,g,b,...:bottom=...` results in a top-to-bottom gradient. Argument `:left=r,g,b,...:right=...` results in a left-to-right gradient. Argument `:topleft=r,g,b,...:topright=...:bottomleft=...:bottomright=...` results in a 4-corner bilinear gradient.
- **noise**: Create a noise image, with the option `:type=` specifying the kind of noise: (1) `gaussian` (default) for normal distribution noise with mean and standard deviation given by `:mean=` and `:stddev=`, respectively (defaulting to 0 and 0.1); (2) `white` (or `uniform`) for uniformly-distributed white noise over the range of values given by options `:min=` and `:max=` (defaults: 0 and 0.1); (3) `blue` for uniformly-distributed blue noise over the range of values given by options `:min=` and `:max=` (defaults: 0 and 0.1); (4) `salt` for “salt and pepper” noise where a portion of pixels given by option `:portion=` (default: 0.1) is replaced with value given by option `:value=` (default: 0). For any of these noise types, the option `:seed=` can be used to change the random number seed and `:mono=1` can be used to make monochromatic noise (same value in all channels).

Examples:
A constant 4-channel, 640x480 image with all pixels (0.5, 0.5, 0.1, 1):

```
--pattern constant:color=0.3,0.5,0.1,1.0 640x480 4
```

A 256x256 RGB image with a 16-pixel-wide checker pattern:

```
--pattern checker:width=16;height=16 256x256 3
```

Horizontal, vertical, or 4-corner gradients:

```
--pattern fill:top=0.1,0.1,0.1;bottom=0,0,0.5 640x480 3
--pattern fill:left=0.1,0.1,0.1:right=0,0.75,0 640x480 3
--pattern fill:topleft=0.1,0.1;topright=1,0,0;bottomleft=0,1,
 bottomright=0,0,1 640x480 3
```
The first example puts uniform noise independently in 3 channels, while the second generates a single greyscale noise and replicates it in all channels.

```bash
oiiotool --pattern noise:type=uniform:min=1:max=1 256x256 3 -o colornoise.jpg
```

```bash
oiiotool --pattern noise:type=uniform:min=0:max=1:mono=1 256x256 3 -o greynoise.jpg
```

Generate Gaussian noise with mean 0.5 and standard deviation 0.2 for each channel:

```bash
oiiotool --pattern noise:type=gaussian:mean=0.5:stddev=0.2 256x256 3 -o greynoise.jpg
```

12.10. oiiotool commands that make entirely new images
**--kernel** <name> <size>

Create new 1-channel float image big enough to hold the named kernel and size (size is expressed as width x height, e.g. 5x5). The width and height are allowed to be floating-point numbers. The kernel image will have its origin offset so that the kernel center is at (0,0), and will be normalized (the sum of all pixel values will be 1.0).

Kernel names can be: gaussian, sharp-gaussian, box, triangle, blackman-harris, mitchell, b-spline, cubic, keys, simon, rifman, disk. There are also catmull-rom and lanczos3 (and its synonym, nuke-lanczos6), but they are fixed-size kernels that don’t scale with the width, and are therefore probably less useful in most cases.

Examples:

```
oiiotool --kernel gaussian 11x11 -o gaussian.exr
```

**--capture**

Capture a frame from a camera device, pushing it onto the image stack and making it the new current image.

Optional appended arguments include:

- `camera=num`: Select which camera number to capture (default: 0).

Examples:

```
--capture   # Capture from the default camera
--capture:camera=1  # Capture from camera #1
```

### 12.11 oiiotool commands that do image processing

**--add**

**--addc** <value>

**--addc** <value0,value1,value2...>

Replace the two top images with a new image that is the pixel-by-pixel sum of those images (**--add**), or add a constant color value to all pixels in the top image (**--addc**).

For **--addc**, if a single constant value is given, it will be added to all color channels. Alternatively, a series of comma-separated constant values (with no spaces!) may be used to specify a different value to add to each channel in the image.

Optional appended modifiers include:

- `:subimages=indices-or-names` Include/exclude subimages (see Dealing with multi-subimage/multi-part files).
Examples:

```
oiiotool imageA.tif imageB.tif --add -o sum.jpg

oiiotool tahoe.jpg --addc 0.5 -o addc.jpg
```

```
--sub
-- subc <value>
-- subc <value0,value1,value2...>
```

Replace the two top images with a new image that is the pixel-by-pixel difference between the first and second images (``--sub``), or subtract a constant color value from all pixels in the top image (``--subc``).

For ``--subc``, if a single constant value is given, it will be subtracted from all color channels. Alternatively, a series of comma-separated constant values (with no spaces!) may be used to specify a different value to subtract from each channel in the image.

Optional appended modifiers include:

```
:subimages=indices-or-names Include/exclude subimages (see Dealing with multi-subimage/multi-part files).
```

```
--mul
-- mulc <value>
-- mulc <value0,value1,value2...>
```

Replace the two top images with a new image that is the pixel-by-pixel multiplicative product of those images (``--mul``), or multiply all pixels in the top image by a constant value (``--mulc``).

For ``--mulc``, if a single constant value is given, it will be multiplied to all color channels. Alternatively, a series of comma-separated constant values (with no spaces!) may be used to specify a different value to multiply with each channel in the image.

Optional appended modifiers include:
:subimages= indices-or-names  Include/exclude subimages  (see  Dealing with multi-subimage/multi-part files).

Example:

```
# Scale image brightness to 20% of its original
oiiotool tahoe.jpg --mulc 0.2 -o mulc.jpg
```

---

**--div**

-- divc <value>

Replace the two top images with a new image that is the pixel-by-pixel, channel-by-channel result of the first image divided by the second image (--div), or divide all pixels in the top image by a constant value (--divc). Division by zero is defined as resulting in 0.

For --divc, if a single constant value is given, all color channels will have their values divided by the same value. Alternatively, a series of comma-separated constant values (with no spaces!) may be used to specify a different multiplier for each channel in the image, respectively.

Optional appended modifiers include:

:subimages= indices-or-names  Include/exclude subimages  (see  Dealing with multi-subimage/multi-part files).

---

**--mad**

Replace the three top images A, B, and C (C being the top of stack, B below it, and A below B), and compute A*B+C, placing the result on the stack. Note that A B C --mad is equivalent to A B --mul C --add, though using --mad may be somewhat faster and preserve more precision.

Optional appended modifiers include:

:subimages= indices-or-names  Include/exclude subimages  (see  Dealing with multi-subimage/multi-part files).
--invert
Replace the top image with its color inverse. By default, it only inverts the first three channels in order to preserve alpha, but you can override the channel range of the inversion with optional modifiers chbegin and chend. Channels outside this range will simply be copied, without inversion.

Optional appended modifiers include:

:chbegin= int Override the beginning of the range of channels to be inverted (defaults to 0.)
:chend= int Override the end of the range of channels to be inverted (defaults to 3). Remember that this is one more than the index of the last channel to be inverted.
:subimages= indices-or-names Include/exclude subimages (see Dealing with multi-subimage/multi-part files).

Example:

```bash
tahoe.jpg --inverse -o inverse.jpg
```

--absdiff
--absdiffc <value>
--absdiffc <value0,value1,value2...>
Replace the two top images with a new image that is the absolute value of the difference between the first and second images (--absdiff), or replace the top image by the absolute value of the difference between each pixel and a constant color (--absdiffc).

Optional appended modifiers include:

:subimages= indices-or-names Include/exclude subimages (see Dealing with multi-subimage/multi-part files).

--abs
Replace the current image with a new image that has each pixel consisting of the absolute value of the old pixel value.

Optional appended modifiers include:

:subimages= indices-or-names Include/exclude subimages (see Dealing with multi-subimage/multi-part files).
--powc <value>
--powc <value0, value1, value2...>

Raise all the pixel values in the top image to a constant power value. If a single constant value is given, all color channels will have their values raised to this power. Alternatively, a series of comma-separated constant values (with no spaces!) may be used to specify a different exponent for each channel in the image, respectively.

Optional appended modifiers include:

:subimages= indices-or-names Include/exclude subimages (see Dealing with multi-subimage/multi-part files).

--noise

Alter the top image to introduce noise, with the option :type= specifying the kind of noise: (1) gaussian (default) for normal distribution noise with mean and standard deviation given by :mean= and :stddev=, respectively (defaulting to 0 and 0.1); (2) white (or uniform) for uniformly-distributed independent noise over the range of values given by options :min= and :max= (defaults: 0 and 0.1); (3) blue is also uniformly distributed between :min= and :max= (defaults: 0 and 0.1), but rather than independent values, low frequencies are suppressed; (4) salt for “salt and pepper” noise where a portion of pixels given by option portion= (default: 0.1) is replaced with value given by option value= (default: 0).

Optional appended modifiers include:

:seed= int Can be used to change the random number seed.
:mono=1 Make monochromatic noise (same value in all channels).
:nchannels= int Limit which channels are affected by the noise.
:subimages= indices-or-names Include/exclude subimages (see Dealing with multi-subimage/multi-part files).

Example:

```
# Add color gaussian noise to an image
oiiotool tahoe.jpg --noise:type=gaussian:stddev=0.1 -o noisy.jpg

# Simulate bad pixels by turning 1% of pixels black, but only in RGB
# channels (leave A alone)
oiiotool tahoe-rgba.tif --noise:type=salt:value=0:portion=0.01:mono=1:nchannels=3
   -o dropouts.tif
```

| white noise | blue noise | gaussian noise added | salt & pepper dropouts |
--chsum
Replaces the top image by a copy that contains only 1 color channel, whose value at each pixel is the sum of all channels of the original image. Using the optional weight allows you to customize the weight of each channel in the sum.

Optional appended modifiers include:

weight=r,g,... Specify the weight of each channel (default: 1).

:subimages=indices-or-names Include/exclude subimages (see Dealing with multi-subimage/multi-part files).

Example:

```
oiiotool RGB.tif --chsum:weight=.2126,.7152,.0722 -o luma.tif
```

--contrast
Remap pixel values from [black, white] to [min, max], with an optional smooth sigmoidal contrast stretch as well.

Optional appended modifiers include:

black=vals Specify black value(s), default 0.0.

white=vals Specify white value(s), default 1.0.

min=vals Specify the minimum range value(s), default 0.0.

max=vals Specify the maximum range value(s), default 1.0.

scontrast=vals Specify sigmoidal contrast slope value(s),
default 1.0. sthresh=vals

Specify sigmoidal threshold value(s) giving the position of maximum slope, default 0.5.
clamp= on  If on is nonzero, will optionally clamp all result channels to [min,max].

:subimages= indices-or-names Include/exclude subimages (see Dealing with multi-
subimage/multi-part files).

Each vals may be either a single floating point value for all channels, or a comma-separated list of per-channel values.

Examples:

```bash
oiiootool tahoe.tif --contrast:black=0.1:white=0.75 -o linstretch.tif
oiiootool tahoe.tif --contrast:black=1.0:white=0.0:clamp=0 -o inverse.tif
oiiootool tahoe.tif --contrast:contrast=5 -o sigmoid.tif
```

--saturate <scale>
Scale the saturation of the first three color channels of the image by the scale: 0.0 fully desaturates the image into its greyscale luminance equivalent image, 1.0 leaves the image unchanged, scale values inside this range interpolate between them, and scale > 1 would increase apparent color saturation.

Optional appended modifiers include:

:subimages= indices-or-names Include/exclude subimages (see Dealing with multi-
subimage/multi-part files).

Examples:

```bash
oiiootool tahoe.exr --saturate 0 -o grey.exr
oiiootool tahoe.exr --saturate 2 -o colorful.exr
```

This command was added in OIIO 2.4.

--colormap <mapname>
Creates an RGB color map based on the luminance of the input image. The mapname may be one of: “magma”, “inferno”, “plasma”, “viridis”, “turbo”, “blue-red”, “spectrum”, and “heat”. Or, mapname may also be a comma-separated list of RGB triples, to form a custom color map curve.

Note that “magma”, “inferno”, “plasma”, “viridis” are perceptually uniform, strictly increasing in luminance, look good when converted to grayscale, and work for people with all types of colorblindness. The “turbo” color
map also shares all of these qualities except for being strictly increasing in luminance. These are all desirable qualities that are lacking in the other, older, crappier maps (blue-red, spectrum, and heat). Don’t be fooled by the flashy “spectrum” colors — it is an empirically bad color map compared to the preferred ones.

Optional appended modifiers include:

```
:subimages= indices-or-names  Include/exclude subimages (see Dealing with multi-subimage/multi-part files).
```

Example:

```
oiiotool tahoe.jpg --colormap inferno -o inferno.jpg
oiiotool tahoe.jpg --colormap viridis -o viridis.jpg
oiiotool tahoe.jpg --colormap turbo -o turbo.jpg
oiiotool tahoe.jpg --colormap .25,.25,.25,0,.5,0,1,0,0 -o custom.jpg
```

```
original               inferno              viridis              turbo              custom values
```

```
--paste <location>
```

Takes two images: the first is the “foreground” and the second is the “background” — and uses the pixels of the foreground to replace those of the background, with foreground pixel (0,0) being pasted to the background at the location specified (expressed as +xpos+ypos, e.g., +100+50, or of course using – for negative offsets). Only pixels within the actual data region of the foreground image are pasted in this manner.

Note that if location is +0+0, the foreground image’s data region will be copied to its same position in the background image (this is useful if you are pasting an image that already knows its correct data window offset).

Optional appended modifiers include:

```
• mergeroi=1: If the value is nonzero, the result image will be sized to be the union of the input images (versus being the same data window as the background image). (The mergeroi modifier was added in OIIO 2.1.)
```

```
• all=1: If the value is nonzero, will paste all images on the image stack, not just the top two images. This can be useful to paste-merge many images at once, for example, if you have rendered a large image in abutting tiles and wish to re-assemble them into a single image. (The all modifier was added in OIIO 2.1.)
```

Examples:

```
# Result will be the size of bg, but with fg on top and with an
# offset of (100,100).
oiiotool fg.exr bg.exr -paste +100+100 -o out.exr

# Use "merge" mode, so result will be sized to contain both fg
# and bg. Also, paste fg into its natural position given by its
# data window.
oiiotool fg.exr bg.exr -paste:mergeroi=1 +0+0 -o out.exr

# Merge many non-overlapping "tiles" into one combined image
oiiotool img*.exr -paste:mergeroi=1:all=1 +0+0 -o combined.exr
```
--pastemeta <location>
Takes two images – the first will be a source of metadata only, and the second the source of pixels – and produces a new copy of the second image with the metadata from the first image added.

The output image’s pixels will come only from the second input. Metadata from the second input will be preserved if no identically-named metadata was present in the first input image.

Examples:

```
# Add all the metadata from meta.exr to pixels.exr and write the # combined image to out.exr.
oiio tool meta.exr pixels.exr --pastemeta -o out.exr
```

--mosaic <size>
Removes $w \times h$ images from the stack, dictated by the size, and turns them into a single image mosaic – an image that comprises $w \times h$ “cells” each containing one of the constituent images.

If there are fewer images on the stack than the number of cells requested, the last cells will be black.

By default, the size of the “cell” is simply the largest of the constituent images, but the optional fit parameter can instead dictate the cell size and constituent images will be resized to fit this cell size.

Optional appended modifiers include:

- `fit=WxH`: Sets the dimensions to which the constituent images will be resized as they are assembled into the mosaic.
- `pad=num`: Select the number of pixels of black padding to add between images (default: 0).

Examples:

```
oiio tool left.tif right.tif --mosaic:pad=16 2x1 -o out.tif
oiiotool 0.tif 1.tif 2.tif 3.tif 4.tif --mosaic:pad=16:fit=320x240 2x2 -o out.tif
```

--over
Replace the two top images with a new image that is the Porter/Duff “over” composite with the first image as the foreground and the second image as the background. Both input images must have the same number and order of channels and must contain an alpha channel.

Optional appended modifiers include:

- `:subimages=indices-or-names`: Include/exclude subimages (see Dealing with multi-subimage/multi-part files).

--zover
Replace the two top images with a new image that is a depth composite of the two images – the operation is the Porter/Duff “over” composite, but each pixel individually will choose which of the two images is the foreground and which background, depending on the “Z” channel values for that pixel (larger Z means farther away). Both input images must have the same number and order of channels and must contain both depth/Z and alpha channels. Optional appended modifiers include:
**zeroisinf**= **num** If nonzero, indicates that z=0 pixels should be treated as if they were infinitely far away. (The default is 0, meaning that “zero means zero.”).

**:subimages=** **indices-or-names** Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

---

**--rotate90**
Replace the current image with a new image that is rotated 90 degrees clockwise.

Optional appended modifiers include:

**:subimages=** **indices-or-names** Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

Example:

```
oiiootool grid.jpg --rotate90 -o rotate90.jpg
```

---

**--rotate180**
Replace the current image with a new image that is rotated by 180 degrees.

Optional appended modifiers include:

**:subimages=** **indices-or-names** Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

Example:

```
oiiootool grid.jpg --rotate180 -o rotate180.jpg
```
```
oiiootool grid.jpg --rotate270 -o rotate270.jpg
```

**--rotate270**

Replace the current image with a new image that is rotated 270 degrees clockwise (or 90 degrees counterclockwise).

Optional appended modifiers include:

: **subimages= indices-or-names** Include/exclude subimages (see Dealing with multi-subimage/multi-part files).

Example:

```
oiiootool grid.jpg --rotate270 -o rotate270.jpg
```

```
oiiootool grid.jpg --flip -o flip.jpg
```

**--flip**

Replace the current image with a new image that is flipped vertically, with the top scanline becoming the bottom, and vice versa.

Optional appended modifiers include:

: **subimages= indices-or-names** Include/exclude subimages (see Dealing with multi-subimage/multi-part files).

Example:

```
oiiootool grid.jpg --flip -o flip.jpg
```
--flop
Replace the current image with a new image that is flopped horizontally, with the leftmost column becoming the rightmost, and vice versa.

Optional appended modifiers include:

: subimages = indices-or-names Include/exclude subimages (see Dealing with multi-subimage/multi-part files).

Example:

```
oiiotool grid.jpg --flop -o flop.jpg
```

--reorient
Replace the current image with a new image that is rotated and/or flipped as necessary to move the pixels to match the Orientation metadata that describes the desired display orientation.

Example:
--transpose
Replace the current image with a new image that is reflected about the x-y axis (x and y coordinates and sizes are swapped).

Optional appended modifiers include:

:subimages=indices-or-names Include/exclude subimages (see Dealing with multi-subimage/multi-part files).

Example:

```
oiiootool grid.jpg --transpose -o transpose.jpg
```

--cshift <offset>
Circularly shift the pixels of the image by the given offset (expressed as +10+100 to move by 10 pixels horizontally and 100 pixels vertically, or +50-30 to move by 50 pixels horizontally and -30 pixels vertically. Circular shifting means that the pixels wrap to the other side as they shift.

Optional appended modifiers include:

:subimages=indices-or-names Include/exclude subimages (see Dealing with multi-subimage/multi-part files).

Example:

```
oiiootool grid.jpg --cshift +70+30 -o cshift.jpg
```
--crop <size>
Replace the current image with a new copy with the given size, cropping old pixels no longer needed, padding black pixels where they previously did not exist in the old image, and adjusting the offsets if requested.

The size is in the form

\[ \text{width} \times \text{height} [+-] \text{xoffset} [+-] \text{yoffset} \]

or

\[ \text{xmin}, \text{ymin}, \text{xmax}, \text{ymax} \]

Note that crop does not reposition pixels, it only trims or pads to reset the image’s pixel data window to the specified region.

If oiiotool’s global -a flag is used (all subimages), or if the optional --crop:allsubimages=1 is employed, the crop will be applied identically to all subimages.

Examples:

```
# Both of these crop to a 100x120 region that begins at x=35,y=40
oiiotool tahoe.exr --crop 100x120+35+40 -o crop.exr
oiiotool tahoe.exr --crop 35,40,134,159 -o crop.exr
```

--croptofull
Replace the current image with a new image that is cropped or padded as necessary to make the pixel data window exactly cover the full/display window.

--trim
Replace the current image with a new image that is cropped to contain the minimal rectangular ROI that contains all of the nonzero-valued pixels of the original image.

Examples:
--cut <size>
Replace the current image with a new copy with the given size, cropping old pixels no longer needed, padding black pixels where they previously did not exist in the old image, repositioning the cut region at the image origin (0,0) and resetting the full/display window to be identical to the new pixel data window. (In other words, --cut is equivalent to --crop followed by --origin +0+0 --fullpixels.)

The size is in the form

width \times height \pm xoffset \pm yoffset

or

xmin, ymin, xmax, ymax

Examples:

```bash
# Both of these crop to a 100x20 region that begins at x=35, y=40
oiiootool tahoe.exr --cut 100x20+35+40 -o cut.exr
oiiootool tahoe.exr --cut 35,40,134,159 -o cut.exr
```

--resample <size>
Replace the current image with a new image that is resampled to the given pixel data resolution rapidly, but at a low quality, either by simple bilinear interpolation or by just copying the “closest” pixel. The size is in the form of any of these:

width \times height

width \times height \pm xoffset \pm yoffset

xmin, ymin, xmax, ymax

wscale% \times hscale%

if width or height is 0, that dimension will be automatically computed so as to preserve the original aspect ratio.

Optional appended modifiers include:
**interp** = bool  If set to zero, it will just copy the “closest” pixel; if nonzero, bilinear interpolation of the surrounding 4 pixels will be used.

**:subimages** = indices-or-names Include/exclude subimages (see Dealing with multi-subimage/multi-part files).

Examples (suppose that the original image is 640x480):

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--resample 1024x768</td>
<td># new resolution w=1024, h=768</td>
</tr>
<tr>
<td>--resample 50%</td>
<td># reduce resolution to 320x240</td>
</tr>
<tr>
<td>--resample 300%</td>
<td># increase resolution to 1920x1440</td>
</tr>
<tr>
<td>--resample 400x0</td>
<td># new resolution will be 400x300</td>
</tr>
</tbody>
</table>

**--resize <size>**
Replace the current image with a new image whose display (full) size is the given pixel data resolution and offset. The **size** is in the form

\[
\text{width} \times \text{height} \\
\text{width} \times \text{height} [\pm x\text{offset}] [\pm y\text{offset}] \\
\text{xmin}, \text{ymin}, \text{xmax}, \text{ymax} \\
\text{scale}\% \\
\text{wscale}\% \times \text{hscale}\%
\]

if width or height is 0, that dimension will be automatically computed so as to preserve the original aspect ratio.

Optional appended modifiers include:

- **:filter** = name  Filter name. The default is blackman-harris when increasing resolution, lanczos3 when decreasing resolution.
- **:highlightcomp** = val If nonzero, does highlight compensation by surrounding the filtered operation with the equivalent of --rangecompress and --rangeexpand, which can reduce visible ringing artifacts when a filter with negative lobes is used on a very high-contrast HDR image.
- **:subimages** = indices-or-names Include/exclude subimages (see Dealing with multi-subimage/multi-part files).

Examples (suppose that the original image is 640x480):

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--resize 1024x768</td>
<td># new resolution w=1024, h=768</td>
</tr>
<tr>
<td>--resize 50%</td>
<td># reduce resolution to 320x240</td>
</tr>
<tr>
<td>--resize 300%</td>
<td># increase resolution to 1920x1440</td>
</tr>
<tr>
<td>--resize 400x0</td>
<td># new resolution will be 400x300</td>
</tr>
</tbody>
</table>

**--fit <size>**
Replace the current image with a new image that is resized to fit into the given pixel data resolution, keeping the original aspect ratio and padding with black pixels if the requested image size does not have the same aspect ratio. The **size** is in the form

\[
\text{width} \times \text{height} \\
\text{width} \times \text{height} [\pm x\text{offset}] [\pm y\text{offset}]
\]

Optional appended modifiers include:

- **filter** = name  Filter name. The default is blackman-harris when increasing resolution, lanczos3 when decreasing resolution.
• highlightcomp= val: If nonzero, does highlight compensation by surrounding the filtered operation with the equivalent of --rangecompress and --rangeexpand, which can reduce visible ringing artifacts when a filter with negative lobes is used on a very high-contrast HDR image.

• fillmode= mode: determines which of several methods will be used to determine how the image will fill the new frame, if its aspect ratio does not precisely match the original source aspect ratio:
  – “width” exactly fills the width of the new frame, either cropping or letterboxing the height if it isn’t precisely the right size to preserve the original aspect ratio.
  – “height” exactly fills the height of the new frame, either cropping or letterboxing the width if it isn’t precisely the right size to preserve the original aspect ratio.
  – “letterbox” (the default) chooses whichever of “width” or “height” will maximally fill the new frame with no image data lost (it will only letterbox, never crop).

• pad= p: If the argument is nonzero, will pad with black pixels to make the resulting image exactly the size specified, if the source and desired size are not the same aspect ratio.

• exact= e: If the argument is nonzero, will result in an exact match on aspect ratio and centering (partial pixel shift if necessary), whereas the default (0) will only preserve aspect ratio and centering to the precision of a whole pixel.

• wrap= wrapmode: For “exact” aspect ratio fitting, this determines the wrap mode used for the resizing kernel (default: black, other choices include clamp, periodic, mirror).

Examples:

```bash
oiiotool in.exr --fit:pad=1:exact=1 640x480 -o out.exr
oiiotool in.exr --fit 1024x1024 -o out.exr
```
Examples of an image being fit into a frame that is wider than the original aspect ratio with fill mode: (a) original, (b) “width”, (c) “height”, (d) “letterbox”.

![Examples of an image being fit into a frame that is wider than the original aspect ratio with fill mode: (a) original, (b) “width”, (c) “height”, (d) “letterbox”.

**--pixelaspect** <aspect>

Replace the current image with a new image that scales up the width or height in order to match the requested pixel aspect ratio. If displayed in a manner that honors the PixelAspectRatio, it should look the same, but it will have different pixel dimensions than the original. It will always be the same or higher resolution, so it does not lose any detail present in the original.

As an example, if you have a 512x512 image with pixel aspect ratio 1.0, **--pixelaspect** 2.0 will result in a 512x1024 image that has “PixelAspectRatio” metadata set to 2.0.

Optional appended modifiers include:

- **:filter=** *name*: Filter name. The default is lanczos3.
- **:highlightcomp=** *val*: If nonzero, does highlight compensation by surrounding the filtered operation with the equivalent of **--rangecompress** and **--rangeexpand**, which can reduce visible ringing artifacts when a filter with negative lobes is used on a very high-contrast HDR image.

Examples:
oiiotool mandrill.tif --pixelaspect 2.0 -o widepixels.tif

**--rotate <angle>**
Replace the current image with a new image that is rotated by the given angle (in degrees). Positive angles mean to rotate counter-clockwise, negative angles mean clockwise. By default, the center of rotation is at the exact center of the display window (a.k.a. “full” image), but can be explicitly set with the optional `center=x,y` option.

Optional appended modifiers include:

: `center=x,y` Alternate center of rotation.

: `filter=name` Filter name. The default is `lanczos3`.

: `highlightcomp=val` If nonzero, does highlight compensation by surrounding the filtered operation with the equivalent of `--rangecompress` and `--rangeexpand`, which can reduce visible ringing artifacts when a filter with negative lobes is used on a very high-contrast HDR image.

: `recompute_roi=val` If nonzero, recompute the pixel data window to exactly hold the transformed image (default=0).

: `subimages=indices-or-names` Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

Examples:

```bash
oiiotool mandrill.tif --rotate 45 -o rotated.tif

oiiotool mandrill.tif --rotate:center=80,91.5:filter=lanczos3 45 -o rotated.tif
```
**--warp** <M33>

Replace the current image with a new image that is warped by the given 3x3 matrix (presented as a comma-separated list of values, without any spaces).

Optional appended modifiers include:

- :**filter**= name  
  Filter name. The default is **lanczos3**.

- :**highlightcomp**= val  
  If nonzero, does highlight compensation by surrounding the filtered operation with the equivalent of --rangecompress and --rangeexpand, which can reduce visible ringing artifacts when a filter with negative lobes is used on a very high-contrast HDR image.

- :**recompute_roi**= val  
  If nonzero, recompute the pixel data window to exactly hold the transformed image (default=0).

- :**wrap**= wrapmode  
  The wrap mode to use when sampling the image for the warp. The default is black; other choices include clamp, periodic, mirror.

- :**subimages**= indices-or-names  
  Include/exclude subimages (see Dealing with multi-subimage/multi-part files).

Examples:

```
oiiotool mandrill.tif --warp "0.707,0.707,0,-0.707,0.707,0,128,-53.02,1" -o warped.tif
```

**--st_warp**

Use the top image as a set of normalized st image coordinates to warp the second image in the stack.

Optional appended modifiers include:

- :**filter**= name  
  Filter name. The default is **lanczos3**.

- :**chan_s**= index  
  The index of the s channel in the st image (default=0).

- :**chan_t**= index  
  The index of the t channel in the st image (default=1).

- :**flip_s**= bool  
  If nonzero, mirror the s coordinates along the horizontal axis. Useful for coordinates authored in terms of an origin other than the upper-left corner (default=0).

- :**flip_t**= bool  
  If nonzero, mirror the t coordinates along the vertical axis. Useful for coordinates authored in terms of an origin other than the upper-left corner (default=0).

Examples:

```
oiiotool mandrill.tif distortion_st.tif --st_warp -o mandrill_distorted.tif
```

# Using an `st` map authored in terms of a lower-left origin (e.g. by Nuke), so flip the vertical (`t`) coordinate.

```
oiiotool mandrill.tif st_from_nuke.tif --st_warp:filter=triangle:flip_t=1 -o mandrill_distorted.tif
```

**--convolve**

Use the top image as a kernel to convolve the next image farther down the stack, replacing both with the result.

Optional appended modifiers include:

- :**subimages**= indices-or-names  
  Include/exclude subimages (see Dealing with multi-subimage/multi-part files).

Examples:
# Use a kernel image already prepared
oiiotool image.exr kernel.exr --convolve -o output.exr

# Construct a kernel image on the fly with --kernel
oiiotool image.exr --kernel gaussian 5x5 --convolve -o blurred.exr

**--blur <size>**
Blur the top image with a blur kernel of the given size expressed as *width x height*. (The sizes may be floating point numbers.)

Optional appended modifiers include:

`kernel=name` Kernel name. The default is *gaussian*.

`:subimages=indices-or-names` Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

Examples:

```
oiiotool image.jpg --blur 5x5 -o blurred.jpg
```
```
oiiotool image.jpg --blur:kernel=bspline 7x7 -o blurred.jpg
```

**--median <size>**
Perform a median filter on the top image with a window of the given size expressed as *width x height*. (The sizes are integers.) This helps to eliminate noise and other unwanted high-frequency detail, but without blurring long edges the way a **--blur** command would.

Optional appended modifiers include:

`:subimages=indices-or-names` Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

Examples:

```
oiiotool noisy.jpg --median 3x3 -o smoothed.jpg
```
--dilate <size>
--erode <size>

Perform dilation or erosion on the top image with a window of the given size expressed as width x height. (The sizes are integers.) Dilation takes the maximum of pixel values inside the window, and makes bright features wider and more prominent, dark features thinner, and removes small isolated dark spots. Erosion takes the minimum of pixel values inside the window, and makes dark features wider, bright features thinner, and removes small isolated bright spots.

Optional appended modifiers include:

:subimages=indices-or-names Include/exclude subimages (see Dealing with multi-subimage/multi-part files).

Examples:

<table>
<thead>
<tr>
<th>Original</th>
<th>Dilate</th>
<th>Erode</th>
<th>Open</th>
<th>Close</th>
<th>Gradient</th>
<th>Tophat</th>
<th>Bottomhat</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image1.png" alt="Original Image" /></td>
<td><img src="image2.png" alt="Dilated Image" /></td>
<td><img src="image3.png" alt="Eroded Image" /></td>
<td><img src="image4.png" alt="Open Image" /></td>
<td><img src="image5.png" alt="Closed Image" /></td>
<td><img src="image6.png" alt="Gradient Image" /></td>
<td><img src="image7.png" alt="Tophat Image" /></td>
<td><img src="image8.png" alt="Bottomhat Image" /></td>
</tr>
</tbody>
</table>

--laplacian

Calculates the Laplacian of the top image.

Optional appended modifiers include:

:subimages=indices-or-names Include/exclude subimages (see Dealing with multi-subimage/multi-part files).

Examples:
```
oiiotool tahoe.jpg --laplacian tahoe-laplacian.exr
```

**--unsharp**

Unblur the top image using an “unsharp mask.”

Optional appended modifiers include:

- **kernel=** *name* Name of the blur kernel (default: `gaussian`). If the kernel name is `median`, the unsharp mask algorithm will use a median filter rather than a blurring filter in order to compute the low-frequency image.
- **width=** *w* Width of the blur kernel (default: 3).
- **contrast=** *c* Contrast scale (default: 1.0)
- **threshold=** *t* Threshold for applying the difference (default: 0)
- **:subimages=** *indices-or-names* Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

Examples:

```
oiiotool image.jpg --unsharp -o sharper.jpg
```

```
oiiotool image.jpg --unsharp:width=5:contrast=1.5 -o sharper.jpg
```

```
oiiotool image.jpg --unsharp:kernel=median -o sharper.jpg
# Note: median filter helps emphasize compact high-frequency details
# without over-sharpening long edges as the default unsharp filter
# sometimes does.
```

**--fft**

**--ifft**

Performs forward and inverse unitized discrete Fourier transform. The forward FFT always transforms only the first channel of the top image on the stack, and results in a 2-channel image (with real and imaginary channels). The inverse FFT transforms the first two channels of the top image on the stack (assuming they are real and imaginary, respectively) and results in a single channel result (with the real component only of the spatial domain result).

Optional appended modifiers include:

- **:subimages=** *indices-or-names* Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

Examples:
# Select the blue channel and take its DCT
oiiotool image.jpg --ch 2 --fft -o fft.exr

# Reconstruct from the FFT
oiiotool fft.exr --ifft -o reconstructed.exr

# Output the power spectrum: real^2 + imag^2
oiiotool fft.exr --dup --mul --chsum -o powerspectrum.exr

--polar
--unpolar
The --polar transforms a 2-channel image whose channels are interpreted as complex values (real and imaginary components) into the equivalent values expressed in polar form of amplitude and phase (with phase between 0 and 2\(\pi\)).

The unpolar performs the reverse transformation, converting from polar values (amplitude and phase) to complex (real and imaginary).

Optional appended modifiers include:

:subimages=indices-or-names Include/exclude subimages (see Dealing with multi-subimage/multi-part files).

Examples:

```
oiiotool complex.exr --polar -o polar.exr
oiiotool polar.exr --unpolar -o complex.exr
```

--fixnan <strategy>
Replace the top image with a copy in which any pixels that contained NaN or Inf values (hereafter referred to collectively as “nonfinite”) are repaired. If strategy is black, nonfinite values will be replaced with 0. If strategy is box3, nonfinite values will be replaced by the average of all the finite values within a 3x3 region surrounding the pixel. If strategy is error, nonfinite values will be left alone, but it will result in an error that will terminate oiiotool.

--max
--maxc <value>
--maxc <value0,value1,value2...>
--min
--minc <value>
--minc <value0,value1,value2...>
Replace the two top images with a new image that is the pixel-by-pixel maximum of those images (--max) or minimum (--min) of the corresponding pixels of each image, or the min/max of each pixel of one image with a constant color (--maxc, --minc).

For --maxc and --minc, if a single constant value is given, it will be used for all color channels. Alternatively, a series of comma-separated constant values (with no spaces) may be used to specify a different value to add to each channel in the image.

Optional appended modifiers include:

:subimages=indices-or-names Include/exclude subimages (see Dealing with multi-subimage/multi-part files).

Examples:

```
oiiotool imageA.tif imageB.tif --min -o minimum.tif
```

# Clamp all channels to a minimum of 0 (all negative values are # changed to 0). oiiotool input.exr --min 0.0 -o nonegatives.exr
--clamp
Replace the top image with a copy in which pixel values have been clamped. Optional arguments include:

Optional appended modifiers include:

- \( \text{min=} \text{val} \) : Specify a minimum value for all channels.
- \( \text{min=} \text{val0, val1, ...} \) : Specify minimum value for each channel individually.
- \( \text{max=} \text{val} \) : Specify a maximum value for all channels.
- \( \text{max=} \text{val0, val1, ...} \) : Specify maximum value for each channel individually.
- \( \text{clampalpha=} \text{val} \) : If \( \text{val} \) is nonzero, will additionally clamp the alpha channel to \([0,1]\). (Default: 0, no additional alpha clamp.)

If no value is given for either the minimum or maximum, it will NOT clamp in that direction. For the variety of minimum and maximum that specify per-channel values, a missing value indicates that the corresponding channel should not be clamped.

Examples:

- \(--\text{clamp: min}=0\) : Clamp all channels to a minimum of 0 (all negative values are changed to 0).
- \(--\text{clamp: min}=0, \text{max}=1\) : Clamp all channels to \([0,1]\).
- \(--\text{clamp: clampalpha}=1\) : Clamp the designated alpha channel to \([0,1]\).
- \(--\text{clamp: min}=,,0, \text{max}=,,3.0\) : Clamp the third channel to \([0,3]\), do not clamp & other channels.

--maxchan
--minchan
Replace the top image with a single channel image that, for each pixel, contains the maximum value (for --maxchan) or minimum value (for --minchan) of all the channels in the corresponding pixel of the original image.

This command was first added to OpenImageIO 2.4.0.

Optional appended modifiers include:

- \( \text{subimages=} \) include/exclude subimages (see Dealing with multi-subimage/multi-part files).

Examples:

- \( \text{oiiotool RGB.tif --maxchan -o max_of_RGB.tif} \)

--rangecompress
--rangeexpand
Range compression re-maps input values to a logarithmic scale. Range expansion is the inverse mapping back to a linear scale. Range compression and expansion only applies to color channels; alpha or z channels will not be modified.

By default, this transformation will happen to each color channel independently. But if the optional \( \text{luma} \) argument is nonzero and the image has at least 3 channels and the first three channels are not alpha or depth, they will be assumed to be RGB and the pixel scaling will be done using the luminance and applied equally to all color channels. This can help to preserve color even when remapping intensity.

Optional appended modifiers include:

- \( \text{luma=} \text{val} \) : \( \text{val} \) is 0, turns off the luma behavior.
- \( \text{subimages=} \) include/exclude subimages (see Dealing with multi-subimage/multi-part files).
Range compression and expansion can be useful in cases where high contrast super-white (> 1) pixels (such as very bright highlights in HDR captured or rendered images) can produce undesirable artifacts, such as if you resize an HDR image using a filter with negative lobes – which could result in objectionable ringing or even negative result pixel values. For example:

```
oiiootool hdr.exr --rangecompress --resize 512x512 --rangeexpand -o resized.exr
```

**--fillholes**

Replace the top image with a copy in which any pixels that had $\alpha < 1$ are “filled” in a smooth way using data from surrounding $\alpha > 0$ pixels, resulting in an image that is $\alpha = 1$ and plausible color everywhere. This can be used both to fill internal “holes” as well as to extend an image out.

**--box <x1,y1,x2,y2>**

Draw (rasterize) a filled or unfilled box with opposite corners $(x1,y1)$ and $(x2,y2)$. Additional optional arguments include:

- `color=r,g,b,...` specify the color of the lines
- `fill=bool` if nonzero, fill in the box
- `:subimages=indices-or-names` Include/exclude subimages (see Dealing with multi-subimage/multi-part files).

The default color, if not supplied, is opaque white.

Examples:

```
oiiootool checker.exr --box:color=0,1,1,1 150,100,240,180
   --box:color=0.5,0.5,0,0.5:fill=1 100,50,180,140 -o out.exr
```

**--line <x1,y1,x2,y2,...>**

Draw (rasterize) an open polyline connecting the list of pixel positions, as a comma-separated list of alternating x and y values. Additional optional arguments include:

- `color=r,g,b,...` specify the color of the line
- `:subimages=indices-or-names` Include/exclude subimages (see Dealing with multi-subimage/multi-part files).

The default color, if not supplied, is opaque white.

Examples:

```
oiiootool checker.exr --line:color=1,0,0 10,60,250,20,100,190 -o out.exr
```
**--point** <x1,y1,x2,y2,...>

Draw single points at the list of pixel positions, as a comma-separated list of alternating x and y values. Additional optional arguments include:

- **color=** r,g,b,... specify the color of the line
- **subimages=** indices-or-names Include/exclude subimages (see *Dealing with multi-subimage/multi-part files*).

The default color, if not supplied, is opaque white.

Examples:

```
oiiootool checker.exr --point:color=1,0,0 10,60,250,20,100,190 -o out.exr
```

**--fill** <size>

Alter the top image by filling the ROI specified by *size*. The fill can be a constant color, vertical gradient, horizontal gradient, or four-corner gradient.

Optional modifiers for constant color:

- **color=** r,g,b,... the color of the constant

Optional modifiers for vertical gradient:

- **top=** r,g,b,... the color for the top edge of the region
- **bottom=** r,g,b,... the color for the bottom edge of the region

Optional modifiers for horizontal gradient:

- **left=** r,g,b,... the color for the left edge of the region
- **right=** r,g,b,... the color for the right edge of the region

Optional modifiers for 4-corner gradient:

- **topleft=** r,g,b,... the color for the top left corner of the region
- **topright=** r,g,b,... the color for the top right corner of the region
- **bottomleft=** r,g,b,... the color for the bottom left corner of the region

402 Chapter 12. **oiiootool**: the OIIo Swiss Army Knife
**bottomright= r,g,b,...**  the color for the bottom right corner of the region

Examples:

```bash
# make a grey-to-blue vertical gradient
oiiotool --create 640x480 3
   --fill:top=0,0,1:bottom=0,0,0.5 640x480 -o gradient.tif

# make a grey-to-green horizontal gradient
oiiotool --create 640x480 3
   --fill:left=0,0.1,.1:right=0,0.75,0 640x480 -o gradient.tif

# four-corner interpolated gradient
oiiotool --create 640x480 3
   -fill:topleft=.1,.1,.1:topright=1,0,0:bottomleft=0,1,0:bottomright=0,0,1
   640x480 -o gradient.tif
```

**--text <words>**
Draw (rasterize) text overtop of the current image.

Optional appended modifiers include:

- **x= xpos**  x position (in pixel coordinates) of the text
- **y= ypos**  y position (in pixel coordinates) of the text
- **size= size**  font size (height, in pixels)
- **font= name**  font name, full path to the font file on disk (use double quotes "name" if the path includes spaces or a colon)
- **color= r,g,b,...**  specify the color of the text
- **xalign= val**  controls horizontal text alignment: left (default), right, center.
- **yalign= val**  controls vertical text alignment: base (default), top, bottom, center.
- **shadow= size**  if nonzero, will make a dark shadow halo to make the text more clear on bright backgrounds.
- **:subimages= indices-or-names**  Include/exclude subimages (see Dealing with multi-subimage/multi-part files).

The default positions the text starting at the center of the image, drawn 16 pixels high in opaque white in all channels (1,1,1,...), and using a default font (which may be system dependent).

Examples:

```bash
oiiotool --create 320x240 3 --text:x=10:y=400:size=40 "Hello world" \ 
   --text:x=100:y=200:font="Arial Bold":color=1,0,0:size=60 "Go Big Red!" \ 
   --tocolorspace sRGB -o text.jpg

oiiotool --create 320x240 3 --text:x=160:y=120:xalign=center "Centered" \ 
   --tocolorspace sRGB -o textcentered.jpg

oiiotool tahoe-small.jpg \ 
   --text:x=160:y=40:xalign:center:size=40:shadow=0 "shadow = 0" \ 
   --text:x=160:y=80:xalign:center:size=40:shadow=1 "shadow = 1" \ 
   --text:x=160:y=120:xalign:center:size=40:shadow=2 "shadow = 2" \ 
   --tocolorspace sRGB -o textshadowed.jpg
```

Note that because of slightly differing fonts and versions of Freetype available, we do not expect drawn text to be pixel-for-pixel identical on different platforms supported by OpenImageIO.
12.12 oiiotool commands for color management

Many of the color management commands depend on an installation of OpenColorIO (http://opencolorio.org).

If OIIIO has been compiled with OpenColorIO support and the environment variable $OCIO is set to point to a valid OpenColorIO configuration file, you will have access to all the color spaces that are known by that OCIO configuration. Alternately, you can use the --colorconfig option to explicitly point to a configuration file. If no valid configuration file is found (either in $OCIO or specified by --colorconfig) or OIIIO was not compiled with OCIO support, then the only color space transforms available are linear to Rec709 (and vice versa) and linear to sRGB (and vice versa).

If you ask for oiiotool help (oiiotool --help), at the very bottom you will see the list of all color spaces, looks, and displays that oiiotool knows about.

--iscolorspace <colorspace>
Alter the metadata of the current image so that it thinks its pixels are in the named color space. This does not alter the pixels of the image, it only changes oiiotool’s understanding of what color space those those pixels are in.

--colorconfig <filename>
Instruct oiiotool to read an OCIO configuration from a custom location. Without this, the default is to use the $OCIO environment variable as a guide for the location of the configuration file.

--colorconvert <fromspace> <tospace>
Replace the current image with a new image whose pixels are transformed from the named fromspace color space into the named tospace (disregarding any notion it may have previously had about the color space of the current image). Optional appended modifiers include:

• key= name, value= str :
  Adds a key/value pair to the “context” that OpenColorIO will used when applying the look. Multiple key/value pairs may be specified by making each one a comma-separated list.

• unpremult= val :
  If the numeric val is nonzero, the pixel values will be “un-premultiplied” (divided by alpha) prior to the actual color conversion, and then re-multiplied by alpha afterwards. The default is 0, meaning the color transformation not will be automatically bracketed by divide-by-alpha / mult-by-alpha operations.

• strict= val :
  When nonzero (the default), an inability to perform the color transform will be a hard error. If strict is 0, inability to find the transformation will just print a warning and simply copy the image without changing colors.

:subimages= indices-or-names Include/exclude subimages (see Dealing with multi-subimage/multi-part files).

--tocolorspace <tospace>
Replace the current image with a new image whose pixels are transformed from their existing color space (as best understood or guessed by OIIIO) into the named tospace. This is equivalent to a use of oiiotool --colorconvert where the fromspace is automatically deduced.

Optional appended modifiers include:

:subimages= indices-or-names Include/exclude subimages (see Dealing with multi-subimage/multi-part files).

--ccmatrix <m00,m01,...>
NEW 2.1
Replace the current image with a new image whose colors are transformed according to the 3x3 or 4x4 matrix formed from the 9 or 16 comma-separated floating-point values in the subsequent argument (spaces are allowed only if the whole collection of values is enclosed in quotes so that they are a single command-line argument).

The values fill in the matrix left to right, first row, then second row, etc. This means that colors are treated as “row vectors” that are post-multiplied by the matrix (C*M).

Optional appended modifiers include:

- `unpremult=val`:
  
  If the numeric `val` is nonzero, the pixel values will be “un-premultiplied” (divided by alpha) prior to the actual color conversion, and then re-multiplied by alpha afterwards. The default is 0, meaning the color transformation not will be automatically bracketed by divide-by-alpha / mult-by-alpha operations.

- `invert=val`:
  
  If nonzero, this will cause the matrix to be inverted before being applied.

- `transpose=val`:
  
  If nonzero, this will cause the matrix to be transposed (this allowing you to more easily specify it as if the color values were column vectors and the transformation as M*C).

- `subimages=indices-or-names` Include/exclude subimages (see Dealing with multi-subimage/multi-part files).

Example:

```bash
# Convert ACES to ACEScg using a matrix
oiiotool aces.exr --ccmatrix:transpose=1 \
  "1.454,-0.237,-0.215,-0.077,1.176,-0.010,0.008,-0.006, 0.998" \
  -o acescg.exr
```

`--ociolook <lookname>`

Replace the current image with a new image whose pixels are transformed using the named OpenColorIO look description. Optional appended arguments include:

- `from=val`
  
  Assume the image is in the named color space. If no `from=` is supplied, it will try to deduce it from the image’s metadata or previous `--iscolors` directives. If no such hints are available, it will assume the pixel data are in the default linear scene-referred color space.

- `to=val`
  
  Convert to the named space after applying the look.

- `inverse=val`
  
  If `val` is nonzero, inverts the color transformation and look application.

- `key=name,value=str`
  
  Adds a key/value pair to the “context” that OpenColorIO will used when applying the look. Multiple key/value pairs may be specified by making each one a comma-separated list.

- `unpremult=val`:
  
  If the numeric `val` is nonzero, the pixel values will be “un-premultiplied” (divided by alpha) prior to the actual color conversion, and then re-multiplied by alpha afterwards. The default is 0, meaning the color transformation not will be automatically bracketed by divide-by-alpha / mult-by-alpha operations.

- `subimages=indices-or-names` Include/exclude subimages (see Dealing with multi-subimage/multi-part files).
This command is only meaningful if OIIO was compiled with OCIO support and the environment variable $OCIO is set to point to a valid OpenColorIO configuration file. If you ask for oiiotool help (oiiotool --help), at the very bottom you will see the list of all looks that oiiotool knows about.

Examples:

```
oiiotool in.jpg --ociolook:from=vd8:to=vd8:key=SHOT:value=pe0012 match -o cc.jpg
```

```
oiiotool in.exr --ociodisplay:from=lnf:key=SHOT:value=pe0012 sRGB Film -o cc.jpg
```

```
oiiotool in.jpg --ociofiletransform footransform.csp -o out.jpg
```

```
oiiotool in.jpg --unpremult
```

---

**--ociodisplay <displayname> <viewname>**

Replace the current image with a new image whose pixels are transformed using the named OpenColorIO “display” transformation given by the `displayname` and `viewname`. An empty string for `displayname` means to use the default display, and an empty string for `viewname` means to use the default view on that display.

Optional appended modifiers include:

- `from= val` Assume the image is in the named color space. If no `from=` is supplied, it will try to deduce it from the image’s metadata or previous `--iscolorspece` directives. If no such hints are available, it will assume the pixel data are in the default linear scene-referred color space.

- `key= name, value= str` Adds a key/value pair to the “context” that OpenColorIO will used when applying the look. Multiple key/value pairs may be specified by making each one a comma-separated list.

- `unpremult= val`: If the numeric `val` is nonzero, the pixel values will be “un-premultiplied” (divided by alpha) prior to the actual color conversion, and then re-multiplied by alpha afterwards. The default is 0, meaning the color transformation not will be automatically bracketed by divide-by-alpha / mult-by-alpha operations.

- `:subimages= indices-or-names` Include/exclude subimages (see Dealing with multi-subimage/multi-part files).

This command is only meaningful if OIIO was compiled with OCIO support and the environment variable $OCIO is set to point to a valid OpenColorIO configuration file. If you ask for oiiotool help (oiiotool --help), at the very bottom you will see the list of all looks that oiiotool knows about.

Examples:

```
oiiotool in.exr --ociodisplay:from=lnf:key=SHOT:value=pe0012 sRGB Film -o cc.jpg
```

---

**--ociofiletransform <name>**

Replace the current image with a new image whose pixels are transformed using the named OpenColorIO file transform. Optional appended arguments include:

- `inverse= val`:
  
  If `val` is nonzero, inverts the color transformation.

- `unpremult= val`:
  
  If the numeric `val` is nonzero, the pixel values will be “un-premultiplied” (divided by alpha) prior to the actual color conversion, and then re-multiplied by alpha afterwards. The default is 0, meaning the color transformation not will be automatically bracketed by divide-by-alpha / mult-by-alpha operations.

- `:subimages= indices-or-names` Include/exclude subimages (see Dealing with multi-subimage/multi-part files).

Examples:

```
oiiotool in.jpg --ociofiletransform footransform.csp -o out.jpg
```

---

**--unpremult**

Divide all color channels (those not alpha or z) of the current image by the alpha value, to “un-premultiply”
them. This presumes that the image starts of as “associated alpha,” a.k.a. “premultiplied.” Pixels in which the alpha channel is 0 will not be modified (since the operation is undefined in that case). This is a no-op if there is no identified alpha channel.

Optional appended modifiers include:

```
:subimages= indices-or-names  Include/exclude subimages  (see Dealing with multi-subimage/multi-part files).
```

`--premult`

Multiply all color channels (those not alpha or z) of the current image by the alpha value, to “premultiply” them. This presumes that the image starts of as “unassociated alpha,” a.k.a. “non-premultiplied.”

Optional appended modifiers include:

```
:subimages= indices-or-names  Include/exclude subimages  (see Dealing with multi-subimage/multi-part files).
```

### 12.13 oiiotool commands for deep images

A number of oiiotool operations are designed to work with “deep” images. These are detailed below. In general, operations not listed in this section should not be expected to work with deep images.

#### 12.13.1 Commands specific to deep images

`--deepen`

If the top image is not deep, then turn it into the equivalent “deep” image. Pixels with non-infinite $z$ or with any non-zero color channels will get a single depth sample in the resulting deep image. Pixels in the source that have 0 in all channels, and either no “Z” channel or a $z$ value indicating an infinite distance, will result in a pixel with no depth samples.

Optional appended modifiers include:

```
z= val  The depth to use for deep samples if the source image did not have a “Z” channel.  (The default is 1.0.)
:subimages= indices-or-names  Include/exclude subimages  (see Dealing with multi-subimage/multi-part files).
```

`--flatten`

If the top image is “deep,” then “flatten” it by compositing the depth samples in each pixel.

Optional appended modifiers include:

```
:subimages= indices-or-names  Include/exclude subimages  (see Dealing with multi-subimage/multi-part files).
```

`--deepmerge`

Replace the two top images with a new deep image that is the “deep merge” of the inputs. Both input images must be deep images, have the same number and order of channels and must contain an alpha channel and depth channel.

Optional appended modifiers include:
OpenImageIO, Release 2.4.1

:subimages= indices-or-names  Include/exclude subimages (see Dealing with multi-subimage/multi-part files).

--deepholdout
Replace the two top images with a new deep image that is the "deep holdout" of the first image by the second — that is, the samples from the first image that are closer than the opaque frontier of the second image. Both input inputs must be deep images.

Optional appended modifiers include:

:subimages= indices-or-names  Include/exclude subimages (see Dealing with multi-subimage/multi-part files).

12.13.2 General commands that also work for deep images

--addc, --subc, --mulc, --divc
Adding, subtracting, multiplying, or dividing a per-channel constant will work for deep images, performing the operation for every sample in the image.

--autotrim
For subsequent outputs, automatically --trim before writing the file.

--ch <channelist>
Reorder, rename, remove, or add channels to a deep image. See Section oiiotool commands that shuffle channels or subimages

--crop <size>
Crop (adjust the pixel data window), removing pixels or adding empty pixels as needed.

--paste <position>
Replace one image’s pixels with another’s (at an arbitrary offset).

(This functionality was extended to deep images in OIIO 2.1.)

--resample <size>
Resampling (resize without filtering or interpolation, just choosing the closest deep pixel to copy for each output pixel).

Optional appended modifiers include:

• interp= val : If 0, the “closest” single pixel will be copied for each sample. If 1, the nearest 4 pixels will be interpolated to produce each sample. (Default: 1)

--diff
Report on the difference of the top two images.

--dumpdata
Print to the console detailed information about the values in every pixel.

Optional appended modifiers include:

• empty= val : If 0, will cause deep images to skip printing of information about pixels with no samples, and cause non-deep images to skip printing information about pixels that are entirely 0.0 value in all channels.

--info
Prints information about each input image as it is read.
--trim
   Replace the current image with a new image that is cropped to contain the minimal rectangular ROI that contains all of the non-empty pixels of the original image.

--scanline
--tile <x> <y>
   Convert to scanline or to tiled representations upon output.

--stats
   Prints detailed statistical information about each input image as it is read.

--fixnan <strategy>
   Replace the top image with a copy in which any pixels that contained NaN or Inf values (hereafter referred to collectively as “nonfinite”) are repaired. The strategy may be either black or error.
CHAPTER
THIRTEEN

GETTING IMAGE INFORMATION WITH IINFO

The `iinfo` program will print either basic information (name, resolution, format) or detailed information (including all metadata) found in images. Because `iinfo` is built on top on OpenImageIO, it will print information about images of any formats readable by ImageInput plugins on hand.

13.1 Using iinfo

The `iinfo` utility is invoked as follows:

\[
\text{iinfo options filename}
\]

Where `filename` (and any following strings) names the image file(s) whose information should be printed. The image files may be of any format recognized by OpenImageIO (i.e., for which ImageInput plugins are available).

In its most basic usage, it simply prints the resolution, number of channels, pixel data type, and file format type of each of the files listed:

```bash
$ iinfo img_6019m.jpg grid.tif lenna.png

img_6019m.jpg : 1024 x 683, 3 channel, uint8 jpeg  
grid.tif : 512 x 512, 3 channel, uint8 tiff  
lenna.png : 120 x 120, 4 channel, uint8 png
```

The `–s` flag also prints the uncompressed sizes of each image file, plus a sum for all of the images:

```bash
$ iinfo -s img_6019m.jpg grid.tif lenna.png

img_6019m.jpg : 1024 x 683, 3 channel, uint8 jpeg (2.00 MB)  
grid.tif : 512 x 512, 3 channel, uint8 tiff (0.75 MB)  
lenna.png : 120 x 120, 4 channel, uint8 png (0.05 MB)  
Total size: 2.81 MB
```

The `–v` option turns on emph{verbose mode}, which exhaustively prints all metadata about each image:

```bash
$ iinfo -v img_6019m.jpg grid.tif lenna.png

img_6019m.jpg : 1024 x 683, 3 channel, uint8 jpeg  
   channel list: R, G, B  
   Color space: sRGB  
   ImageDescription: "Family photo"  
   Make: "Canon"  
   Model: "Canon EOS DIGITAL REBEL XT"  
   Orientation: 1 (normal)  
   XResolution: 72  
   YResolution: 72
```

(continues on next page)
If the input file has multiple subimages, extra information summarizing the subimages will be printed:

```
$ iinfo img_6019m.tx

img_6019m.tx : 1024 x 1024, 3 channel, uint8 tiff (11 subimages)
```

Furthermore, the `-a` option will print information about all individual subimages:

```
$ iinfo -a ../sample-images/img_6019m.tx

img_6019m.tx : 1024 x 1024, 3 channel, uint8 tiff (11 subimages)
subimage 0: 1024 x 1024, 3 channel, uint8 tiff
subimage 1: 512 x 512, 3 channel, uint8 tiff
subimage 2: 256 x 256, 3 channel, uint8 tiff
subimage 3: 128 x 128, 3 channel, uint8 tiff
subimage 4: 64 x 64, 3 channel, uint8 tiff
subimage 5: 32 x 32, 3 channel, uint8 tiff
subimage 6: 16 x 16, 3 channel, uint8 tiff
subimage 7: 8 x 8, 3 channel, uint8 tiff
subimage 8: 4 x 4, 3 channel, uint8 tiff
subimage 9: 2 x 2, 3 channel, uint8 tiff
subimage 10: 1 x 1, 3 channel, uint8 tiff
```

(continues on next page)
13.2 iinfo command-line options

--help
Prints usage information to the terminal.

-v
Verbose output — prints all metadata of the image files.

-a
Print information about all subimages in the file(s).

-f
Print the filename as a prefix to every line. For example:

$ iinfo -v -f img_6019m.jpg

img_6019m.jpg : 1024 x 683, 3 channel, uint8 jpeg
img_6019m.jpg : channel list: R, G, B
img_6019m.jpg : Color space: sRGB
img_6019m.jpg : ImageDescription: "Family photo"
img_6019m.jpg : Make: "Canon"
...

-m pattern
Match the pattern (specified as an extended regular expression) against data metadata field names and print only data fields whose names match. The default is to print all data fields found in the file (if --v is given).

For example:

$ iinfo -v -f -m ImageDescription test*.jpg

test3.jpg : ImageDescription: "Birthday party"
test4.jpg : ImageDescription: "Hawaii vacation"
test5.jpg : ImageDescription: "Bob's graduation"
test6.jpg : ImageDescription: <unknown>

Note: the --m option is probably not very useful without also using the --v and -f options.

--hash
Displays a SHA-1 hash of the pixel data of the image (and of each subimage if combined with the --a flag).

-s
Show the image sizes, including a sum of all the listed images.
14.1 Overview

The `iconvert` program will read an image (from any file format for which an ImageInput plugin can be found) and then write the image to a new file (in any format for which an ImageOutput plugin can be found). In the process, `iconvert` can optionally change the file format or data format (for example, converting floating-point data to 8-bit integers), apply gamma correction, switch between tiled and scanline orientation, or alter or add certain metadata to the image.

The `iconvert` utility is invoked as follows:

```
iconvert options input output
```

Where `input` and `output` name the input image and desired output filename. The image files may be of any format recognized by OpenImageIO (i.e., for which ImageInput plugins are available). The file format of the output image will be inferred from the file extension of the output filename (e.g., `foo.tif` will write a TIFF file).

Alternately, any number of files may be specified as follows:

```
iconvert --inplace [options] file1 file2 ...
```

When the `--inplace` option is used, any number of file names ≥ 1 may be specified, and the image conversion commands are applied to each file in turn, with the output being saved under the original file name. This is useful for applying the same conversion to many files, or simply if you want to replace the input with the output rather than create a new file with a different name.

14.2 `iconvert` Recipes

This section will give quick examples of common uses of `iconvert`.

14.2.1 Converting between file formats

It’s a snap to converting among image formats supported by OpenImageIO (i.e., for which ImageInput and ImageOutput plugins can be found). The `iconvert` utility will simply infer the file format from the file extension. The following example converts a PNG image to JPEG:

```
iconvert lena.png lena.jpg
```
14.2.2 Changing the data format or bit depth

Just use the -d option to specify a pixel data format. For example, assuming that in.tif uses 16-bit unsigned integer pixels, the following will convert it to an 8-bit unsigned pixels:

```
iconvert -d uint8 in.tif out.tif
```

14.2.3 Changing the compression

The following command converts writes a TIFF file, specifically using zip compression:

```
iconvert --compression zip in.tif out.tif
```

The following command writes its results as a JPEG file at a compression quality of 50 (pretty severe compression), illustrating how some compression methods allow a quality metric to be optionally appended to the name:

```
iconvert --compression jpeg:50 50 big.jpg small.jpg
```

14.2.4 Gamma-correcting an image

The following gamma-corrects the pixels, raising all pixel values to $$x^{1/2.2}$$ upon writing:

```
iconvert -g 2.2 in.tif out.tif
```

14.2.5 Converting between scanline and tiled images

Convert a scanline file to a tiled file with $16 \times 16$ tiles:

```
iconvert --tile 16 16 s.tif t.tif
```

Convert a tiled file to scanline:

```
iconvert --scanline t.tif s.tif
```

14.2.6 Converting images in place

You can use the --inplace flag to cause the output to emph{replace} the input file, rather than create a new file with a different name. For example, this will re-compress all of your TIFF files to use ZIP compression (rather than whatever they currently are using):

```
iconvert --inplace --compression zip *.tif
```
14.2.7 Change the file modification time to the image capture time

Many image formats (including JPEGs from digital cameras) contain an internal time stamp indicating when the image was captured. But the time stamp on the file itself (what you’d see in a directory listing from your OS) most likely shows when the file was last copied, not when it was created or captured. You can use the following command to re-stamp your files so that the file system modification time matches the time that the digital image was originally captured:

```bash
iconvert --inplace --adjust-time *.jpg
```

14.2.8 Add captions, keywords, IPTC tags

For formats that support it, you can add a caption/image description, keywords, or arbitrary string metadata:

```bash
iconvert --inplace --adjust-time --caption "Hawaii vacation" *.jpg
iconvert --inplace --adjust-time --keyword "John" img18.jpg img21.jpg
iconvert --inplace --adjust-time --attrib IPTC:State "HI" \
    --attrib IPTC:City "Honolulu" *.jpg
```

14.3 `iconvert` command-line options

---help
Prints usage information to the terminal.

--v
Verbose status messages.

--threads n
Use n execution threads if it helps to speed up image operations. The default (also if n = 0) is to use as many threads as there are cores present in the hardware.

--inplace
Causes the output to replace the input file, rather than create a new file with a different name.

Without this flag, `iconvert` expects two file names, which will be used to specify the input and output files, respectively.

But when --inplace option is used, any number of file names ≥ 1 may be specified, and the image conversion commands are applied to each file in turn, with the output being saved under the original file name. This is useful for applying the same conversion to many files.

For example, the following example will add the caption “Hawaii vacation” to all JPEG files in the current directory:

```bash
iconvert --inplace --adjust-time --caption "Hawaii vacation" *.jpg
```

-d datatype
Attempt to sets the output pixel data type to one of: UINT8, sint8, uint16, sint16, half, float, double.

The types uint10 and uint12 may be used to request 10- or 12-bit unsigned integers. If the output file format does not support them, uint16 will be substituted.
If the \texttt{-d} option is not supplied, the output data type will be the same as the data format of the input file, if possible.

In any case, if the output file type does not support the requested data type, it will instead use whichever supported data type results in the least amount of precision lost.

\texttt{-g \textit{gamma}}

Applies a gamma correction of \(1/\textit{gamma}\) to the pixels as they are output.

\texttt{--sRGB}

Explicitly tags the image as being in sRGB color space. Note that this does not alter pixel values, it only marks which color space those values refer to (and only works for file formats that understand such things). An example use of this command is if you have an image that is not explicitly marked as being in any particular color space, but you know that the values are sRGB.

\texttt{--tile \textit{x} \textit{y}}

Requests that the output file be tiled, with the given \(\textit{x} \times \textit{y}\) tile size, if tiled images are supported by the output format. By default, the output file will take on the tiledness and tile size of the input file.

\texttt{--scanline}

Requests that the output file be scanline-oriented (even if the input file was tile-oriented), if scanline orientation is supported by the output file format. By default, the output file will be scanline if the input is scanline, or tiled if the input is tiled.

\texttt{--separate}\n
\texttt{--contig}

Forces either “separate” (e.g., RRR...GGG...BBB) or “contiguous” (e.g., RGBRGBRGB...) packing of channels in the file. If neither of these options are present, the output file will have the same kind of channel packing as the input file. Of course, this is ignored if the output file format does not support a choice or does not support the particular choice requested.

\texttt{--compression \textit{method}}\n
\texttt{--compression \textit{method}:\textit{quality}}

Sets the compression method, and optionally a quality setting, for the output image. Each ImageOutput plugin will have its own set of methods that it supports.

By default, the output image will use the same compression technique as the input image (assuming it is supported by the output format, otherwise it will use the default compression method of the output plugin).

\texttt{--quality \textit{q}}

Sets the compression quality to \(\textit{q}\), on a 1–100 floating-point scale. This only has an effect if the particular compression method supports a quality metric (as JPEG does).

DEPRECATED(2.1): This is considered deprecated, and in general we now recommend just appending the quality metric to the compression name:qual.

\texttt{--no-copy-image}

Ordinarily, \texttt{iconvert} will attempt to use \texttt{ImageOutput::copy_image} underneath to avoid de/recompression or alteration of pixel values, unless other settings clearly contradict this (such as any settings that must alter pixel values). The use of \texttt{--no-copy-image} will force all pixels to be decompressed, read, and compressed/written, rather than copied in compressed form. We’re not exactly sure when you would need to do this, but we put it in just in case.

\texttt{--adjust-time}

When this flag is present, after writing the output, the resulting file’s modification time will be adjusted to match any “DateTime” metadata in the image. After doing this, a directory listing will show file times that match when the original image was created or captured, rather than simply when \texttt{iconvert} was run. This has no effect on image files that don’t contain any “DateTime” metadata.
--caption text
Sets the image metadata "ImageDescription". This has no effect if the output image format does not support some kind of title, caption, or description metadata field. Be careful to enclose text in quotes if you want your caption to include spaces or certain punctuation!

--keyword text
Adds a keyword to the image metadata "Keywords". Any existing keywords will be preserved, not replaced, and the new keyword will not be added if it is an exact duplicate of existing keywords. This has no effect if the output image format does not support some kind of keyword field.

Be careful to enclose text in quotes if you want your keyword to include spaces or certain punctuation. For image formats that have only a single field for keywords, OpenImageIO will concatenate the keywords, separated by semicolon (;), so don’t use semicolons within your keywords.

--clear-keywords
Clears all existing keywords in the image.

--attrib text
Sets the named image metadata attribute to a string given by text. For example, you could explicitly set the IPTC location metadata fields with:

```
iconvert --attrib "IPTC:City" "Berkeley" in.jpg out.jpg
```

--orientation orient
Explicitly sets the image’s "Orientation" metadata to a numeric value (see Display hints for the numeric codes). This only changes the metadata field that specifies how the image should be displayed, it does NOT alter the pixels themselves, and so has no effect for image formats that don’t support some kind of orientation metadata.

--rotcw
--rotccw
--rot180
Adjusts the image’s "Orientation" metadata by rotating it 90° clockwise, 90° degrees counter-clockwise, or 180°, respectively, compared to its current setting. This only changes the metadata field that specifies how the image should be displayed, it does NOT alter the pixels themselves, and so has no effect for image formats that don’t support some kind of orientation metadata.
The `igrep` program search one or more image files for metadata that match a string or regular expression.

### 15.1 Using `igrep`

The `igrep` utility is invoked as follows:

```
igrep [options] pattern filename ...
```

Where `pattern` is a POSIX.2 regular expression (just like the Unix/Linux `grep(1)` command), and `filename` (and any following names) specify images or directories that should be searched. An image file will “match” if any of its metadata contains values contain substring that are recognized regular expression. The image files may be of any format recognized by OpenImageIO (i.e., for which ImageInput plugins are available).

Example:

```
$ igrep Jack *.jpg
bar.jpg: Keywords = Carly; Jack
foo.jpg: Keywords = Jack
test7.jpg: ImageDescription = Jack on vacation
```

### 15.2 `igrep` command-line options

- **--help**
  - Prints usage information to the terminal.

- **-d**
  - Print directory names as it recurses. This only happens if the `-r` option is also used.

- **-E**
  - Interpret the pattern as an extended regular expression (just like `egrep` or `grep -E`).

- **-f**
  - Match the expression against the filename, as well as the metadata within the file.

- **-i**
  - Ignore upper/lower case distinctions. Without this flag, the expression matching will be case-sensitive.

- **-l**
  - Simply list the matching files by name, suppressing the normal output that would include the metadata name and values that matched. For example:
$ igrep Jack *.jpg
bar.jpg: Keywords = Carly; Jack
foo.jpg: Keywords = Jack
test7.jpg: ImageDescription = Jack on vacation

$ igrep -l Jack *.jpg
bar.jpg
foo.jpg
test7.jpg

-r
Recurse into directories. If this flag is present, any files specified that are directories will have any image file contained therein to be searched for a match (and so on, recursively).

-v
Invert the sense of matching, to select image files that do not match the expression.
16.1 Overview

The `idiff` program compares two images, printing a report about how different they are and optionally producing a third image that records the pixel-by-pixel differences between them. There are a variety of options and ways to compare (absolute pixel difference, various thresholds for warnings and errors, and also an optional perceptual difference metric).

Because `idiff` is built on top on OpenImageIO, it can compare two images of any formats readable by ImageInput plugins on hand. They may have any (or different) file formats, data formats, etc.

16.2 Using `idiff`

The `idiff` utility is invoked as follows:

```
 idiff [options] image1 image2
```

Where `input1` and `input2` are the names of two image files that should be compared. They may be of any format recognized by OpenImageIO (i.e., for which image-reading plugins are available).

If the two input images are not the same resolutions, or do not have the same number of channels, the comparison will return FAILURE immediately and will not attempt to compare the pixels of the two images. If they are the same dimensions, the pixels of the two images will be compared, and a report will be printed including the mean and maximum error, how many pixels were above the warning and failure thresholds, and whether the result is PASS, WARNING, or FAILURE. For example:

```
$ idiff a.jpg b.jpg
Comparing "a.jpg" and "b.jpg"
  Mean error = 0.00450079
  RMS error = 0.00764215
  Peak SNR = 42.3357
  Max error = 0.254902 @ (700, 222, B)
  574062 pixels (82.1%) over 1e-06
  574062 pixels (82.1%) over 1e-06
  FAILURE
```

The “mean error” is the average difference (per channel, per pixel). The “max error” is the largest difference in any pixel channel, and will point out on which pixel and channel it was found. It will also give a count of how many pixels were above the warning and failure thresholds.

The metadata of the two images (e.g., the comments) are not currently compared; only differences in pixel values are taken into consideration.
16.2.1 Raising the thresholds

By default, if any pixels differ between the images, the comparison will fail. You can allow some differences to still pass by raising the failure thresholds. The following example will allow images to pass the comparison test, as long as no more than 10% of the pixels differ by 0.004 (just above a 1/255 threshold):

```
iddiff -fail 0.004 -failpercent 10 a.jpg b.jpg
```

But what happens if a just a few pixels are very different? Maybe you want that to fail, also. The following adjustment will fail if at least 10% of pixels differ by 0.004, or if any pixel differs by more than 0.25:

```
iddiff -fail 0.004 -failpercent 10 -hardfail 0.25 a.jpg b.jpg
```

If none of the failure criteria are met, and yet some pixels are still different, it will still give a WARNING. But you can also raise the warning threshold in a similar way:

```
iddiff -fail 0.004 -failpercent 10 -hardfail 0.25 -warn 0.004 -warnpercent 3 a.jpg b.jpg
```

The above example will PASS as long as fewer than 3% of pixels differ by more than 0.004. If it does, it will be a WARNING as long as no more than 10% of pixels differ by 0.004 and no pixel differs by more than 0.25, otherwise it is a FAILURE.

16.2.2 Output a difference image

Ordinary text output will tell you how many pixels failed or were warnings, and which pixel had the biggest difference. But sometimes you need to see visually where the images differ. You can get idiff to save an image of the differences between the two input images:

```
iddiff -o diff.tif -abs a.jpg b.jpg
```

The -abs flag saves the absolute value of the differences (i.e., all positive values or zero). If you omit the -abs, pixels in which a.jpg have smaller values than b.jpg will be negative in the difference image (be careful in this case of using a file format that doesn’t support negative values).

You can also scale the difference image with the -scale, making them easier to see. And the -od flag can be used to output a difference image only if the comparison fails, but not if the images pass within the designated threshold (thus saving you the trouble and space of saving a black image).

16.3 idiff Command Line Argument Reference

The various command-line options are discussed below:
16.3.1 General options

--help
  Prints usage information to the terminal.

-v
  Verbose output — more detail about what it finds when comparing images, even when the comparison does not fail.

-q
  Quiet mode – output nothing for successful match), output only minimal error messages to stderr for failure / no match. The shell return code also indicates success or failure (successful match returns 0, failure returns nonzero).

-a
  Compare all subimages. Without this flag, only the first subimage of each file will be compared.

16.3.2 Thresholds and comparison options

-fail A
-failpercent B
-hardfail C
  Sets the threshold for FAILURE: if more than B % of pixels (on a 0-100 floating point scale) are greater than A different, or if any pixels are more than C different. The defaults are to fail if more than 0% (any) pixels differ by more than 0.00001 (1e-6), and C is infinite.

-warn A
-warnpercent B
-hardwarn C
  Sets the threshold for WARNING: if more than B % of pixels (on a 0-100 floating point scale) are greater than A different, or if any pixels are more than C different. The defaults are to warn if more than 0% (any) pixels differ by more than 0.00001 (1e-6), and C is infinite.

-p
  Does an additional test on the images to attempt to see if they are perceptually different (whether you are likely to discern a difference visually), using Hector Yee’s metric. If this option is enabled, the statistics will additionally show a report on how many pixels failed the perceptual test, and the test overall will fail if more than the “fail percentage” failed the perceptual test.

16.3.3 Difference image output

-o outputfile
  Outputs a difference image to the designated file. This difference image pixels consist are each of the value of the corresponding pixel from image1 minus the value of the pixel image2.

  The file extension of the output file is used to determine the file format to write (e.g., out.tif will write a TIFF file, out.jpg will write a JPEG, etc.). The data format of the output file will be format of whichever of the two input images has higher precision (or the maximum precision that the designated output format is capable of, if that is less than either of the input images).

  Note that pixels whose value is lower in image1 than in image2, this will result in negative pixels (which may be clamped to zero if the image format does not support negative values)), unless the --abs option is also used.

--abs
  Will cause the output image to consist of the absolute value of the difference between the two input images (so all values in the difference image ≥ 0).
-scale factor
   Scales the values in the difference image by the given (floating point) factor. The main use for this is to make small actual differences more visible in the resulting difference image by giving a large scale factor.

-od
   Causes a difference image to be produce only if the image comparison fails. That is, even if the -o option is used, images that are within the comparison threshold will not write out a useless black (or nearly black) difference image.

16.3.4 Process return codes

The idiff program will return a code that can be used by scripts to indicate the results:

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>OK: the images match within the warning and error thresholds.</td>
</tr>
<tr>
<td>1</td>
<td>Warning: the errors differ a little, but within error thresholds.</td>
</tr>
<tr>
<td>2</td>
<td>Failure: the errors differ a lot, outside error thresholds.</td>
</tr>
<tr>
<td>3</td>
<td>The images weren’t the same size and couldn’t be compared.</td>
</tr>
<tr>
<td>4</td>
<td>File error: could not find or open input files, etc.</td>
</tr>
</tbody>
</table>
MAKING TILED MIP-MAP TEXTURE FILES WITH **MAKETX** OR **OIIOTOOL**

17.1 Overview

The TextureSystem (Chapter chap-texturesystem_) will exhibit much higher performance if the image files it uses as textures are tiled (versus scanline) orientation, have multiple subimages at different resolutions (MIP-mapped), and include a variety of header or metadata fields appropriately set for texture maps. Any image that you intend to use as input to TextureSystem, therefore, should first be converted to have these properties. An ordinary image will work as a texture, but without this additional step, it will be drastically less efficient in terms of memory, disk or network I/O, and time.

This can be accomplished programmatically using the ImageBufAlgo `make_texture()` function (see Section Import / export for C++ and Section Import / export for Python).

OpenImageIO includes two command-line utilities capable of converting ordinary images into texture files: **maketx** and **oiiotool**.

17.2 make\_tx

The **maketx** program will convert ordinary images to efficient textures. The **maketx** utility is invoked as follows:

```
maketx [options] input... -o output
```

Where `input` and `output` name the input image and desired output filename. The input files may be of any image format recognized by OpenImageIO (i.e., for which ImageInput plugins are available). The file format of the output image will be inferred from the file extension of the output filename (e.g., `filename:`*foo.tif* will write a TIFF file).

Command-line arguments are:

```
--help
   Prints usage information to the terminal.

-v
   Verbose status messages, including runtime statistics and timing.

--runstats
   Print runtime statistics and timing.

-o outputname
   Sets the name of the output texture.
```

Why are there two programs? Historical artifact – **maketx** existed first, and much later **oiiotool** was extended to be capable of directly writing texture files. If you are simply converting an image into a texture, **maketx** is more straightforward and foolproof, in that you can’t accidentally forget to turn it into a texture, as you might do with and much later **oiiotool** was extended to be capable of directly writing texture files.
--threads \<n\>
Use \(n\) execution threads if it helps to speed up image operations. The default (also if \(n=0\)) is to use as many threads as there are cores present in the hardware.

--format \<formatname\>
Specifies the image format of the output file (e.g., “tiff”, “OpenEXR”, etc.). If --format is not used, maketx will guess based on the file extension of the output filename; if it is not a recognized format extension, TIFF will be used by default.

-d \<datatype\>
Attempt to sets the output pixel data type to one of: UINT8, sint8, uint16, sint16, half, float, double.

If the -d option is not supplied, the output data type will be the same as the data format of the input file.

In either case, the output file format itself (implied by the file extension of the output filename) may trump the request if the file format simply does not support the requested data type.

--tile \<x\> \<y\>
Specifies the tile size of the output texture. If not specified, maketx will make 64 x 64 tiles.

--separate
Forces “separate” (e.g., RRR...GGG...BBB) packing of channels in the output file. Without this option specified, “contiguous” (e.g., RGBRGBRGB...) packing of channels will be used for those file formats that support it.

--compression \<method\>
Sets the compression method, and optionally a quality setting, for the output image (the default is to try to use “zip” compression, if it is available).

-u
Ordinarily, textures are created unconditionally (which could take several seconds for large input files if read over a network) and will be stamped with the current time.

The -u option enables update mode: if the output file already exists, and has the same time stamp as the input file, and the command-line arguments that created it are identical to the current ones, then the texture will be left alone and not be recreated. If the output file does not exist, or has a different time stamp than the input file, or was created using different command line arguments, then the texture will be created and given the time stamp of the input file.

--wrap \<wrapmode\>
--swrap \<wrapmode\>, --twrap \<wrapmode\>
Sets the default wrap mode for the texture, which determines the behavior when the texture is sampled outside the [0,1] range. Valid wrap modes are: black, clamp, periodic, mirror. The default, if none is set, is black. The --wrap option sets the wrap mode in both directions simultaneously, while the --swrap and --twrap may be used to set them individually in the s (horizontal) and t (vertical) directions.

Although this sets the default wrap mode for a texture, note that the wrap mode may have an override specified in the texture lookup at runtime.

--resize
Causes the highest-resolution level of the MIP-map to be a power-of-two resolution in each dimension (by rounding up the resolution of the input image). There is no good reason to do this for the sake of OIIO’s texture system, but some users may require it in order to create MIP-map images that are compatible with both OIIO and other texturing systems that require power-of-2 textures.

--filter \<name\>
By default, the resizing step that generates successive MIP levels uses a triangle filter to bilinearly combine pixels (for MIP levels with even number of pixels, this is also equivalent to a box filter, which merely averages
groups of 4 adjacent pixels). This is fast, but for source images with high frequency content, can result in aliasing or other artifacts in the lower-resolution MIP levels.

The `--filter` option selects a high-quality filter to use when resizing to generate successive MIP levels. Choices include `lanczos3` (our best recommendation for highest-quality filtering, a 3-lobe Lanczos filter), `box`, `triangle`, `catrom`, `blackman-harris`, `gaussian`, `mitchell`, `bspline`, `cubic`, `keys`, `simon`, `rifman`, `radial-lanczos3`, `disk`, `sinc`.

If you select a filter with negative lobes (including `lanczos3`, `sinc`, `lanczos3`, `keys`, `simon`, `rifman`, or `catrom`), and your source image is an HDR image with very high contrast regions that include pixels with values >1, you may also wish to use the `--rangecompress` option to avoid ringing artifacts.

**--hicomp**
Perform highlight compensation. When HDR input data with high-contrast highlights is turned into a MIP-mapped texture using a high-quality filter with negative lobes (such as `lanczos3`), objectionable ringing could appear near very high-contrast regions with pixel values >1. This option improves those areas by using range compression (transforming values from a linear to a logarithmic scale that greatly compresses the values > 1) prior to each image filtered-resize step, and then expanded back to a linear format after the resize, and also clamping resulting pixel values to be non-negative. This can result in some loss of energy, but often this is a preferable alternative to ringing artifacts in your upper MIP levels.

**--sharpen <contrast>**
EXPERIMENTAL: USE AT YOUR OWN RISK!
This option will run an additional sharpening filter when creating the successive MIP-map levels. It uses an unsharp mask (much like in Section sec-iba-unsharpmask) to emphasize high-frequency details to make features “pop” visually even at high MIP-map levels. The `contrast` controls the degree to which it does this. Probably a good value to enhance detail but not go overboard is 0.5 or even 0.25. A value of 1.0 may make strange artifacts at high MIP-map levels. Also, if you simultaneously use `--filter unsharp-median`, a slightly different variant of unsharp masking will be used that employs a median filter to separate out the low-frequencies, this may tend to help emphasize small features while not over-emphasizing large edges.

**--nomipmap**
Causes the output to not be MIP-mapped, i.e., only will have the highest-resolution level.

**--nchannels <n>**
Sets the number of output channels. If `n` is less than the number of channels in the input image, the extra channels will simply be ignored. If `n` is greater than the number of channels in the input image, the additional channels will be filled with 0 values.

**--chnames a,b,...**
Renames the channels of the output image. All the channel names are concatenated together, separated by commas. A “blank” entry will cause the channel to retain its previous value (for example, `--chnames ,,,A` will rename channel 3 to be “A” and leave channels 0-2 as they were.

**--checknan**
Checks every pixel of the input image to ensure that no `NaN` or `Inf` values are present. If such non-finite pixel values are found, an error message will be printed and `maketx` will terminate without writing the output image (returning an error code).

**--fixnan strategy**
Repairs any pixels in the input image that contained `NaN` or `Inf` values (hereafter referred to collectively as “nonfinite”). If `strategy` is `black`, nonfinite values will be replaced with 0. If `strategy` is `box3`, nonfinite values will be replaced by the average of all the finite values within a 3x3 region surrounding the pixel.

**--fullpixels**
Resets the “full” (or “display”) pixel range to be the “data” range. This is used to deal with input images that appear, in their headers, to be crop windows or overscanned images, but you want to treat them as full 0–1 range images over just their defined pixel data.

17.2. `maketx`
--Mcamera <...16 floats...>
--Mscreen <...16 floats...>
Sets the camera and screen matrices (sometimes called N1 and NF, respectively, by some renderers) in the texture file, overriding any such matrices that may be in the input image (and would ordinarily be copied to the output texture).

--prman-metadata
Causes metadata “PixarTextureFormat” to be set, which is useful if you intend to create an OpenEXR texture or environment map that can be used with PRMan as well as OIIO.

--attrib <name> <value>
Adds or replaces metadata with the given name to have the specified value.

It will try to infer the type of the metadata from the value: if the value contains only numerals (with optional leading minus sign), it will be saved as int metadata; if it also contains a decimal point, it will be saved as float metadata; otherwise, it will be saved as a string metadata.

For example, you could explicitly set the IPTC location metadata fields with:

```
oiiotool --attrib "IPTC:City" "Berkeley" in.jpg out.jpg
```

--sattrib <name> <value>
Adds or replaces metadata with the given name to have the specified value, forcing it to be interpreted as a string. This is helpful if you want to set a string metadata to a value that the --attrib command would normally interpret as a number.

--sansattrib
When set, this edits the command line inserted in the “Software” and “ImageHistory” metadata to omit any verbose --attrib and --sattrib commands.

--constant-color-detect
Detects images in which all pixels are identical, and outputs the texture at a reduced resolution equal to the tile size, rather than filling endless tiles with the same constant color. That is, by substituting a low-res texture for a high-res texture if it’s a constant color, you could save a lot of save disk space, I/O, and texture cache size. It also sets the "ImageDescription" to contain a special message of the form ConstantColor=[r,g,...].

--monochrome-detect
Detects multi-channel images in which all color components are identical, and outputs the texture as a single-channel image instead. That is, it changes RGB images that are gray into single-channel gray scale images.

--opaque-detect
Detects images that have a designated alpha channel for which the alpha value for all pixels is 1.0 (fully opaque), and omits the alpha channel from the output texture. So, for example, an RGBA input texture where A=1 for all pixels will be output just as RGB. The purpose is to save disk space, texture I/O bandwidth, and texturing time for those textures where alpha was present in the input, but clearly not necessary.

--ignore-unassoc
Ignore any header tags in the input images that indicate that the input has “unassociated” alpha. When this option is used, color channels with unassociated alpha will not be automatically multiplied by alpha to turn them into associated alpha. This is also a good way to fix input images that really are associated alpha, but whose headers incorrectly indicate that they are unassociated alpha.

--prman
PRMan is will crash in strange ways if given textures that don’t have its quirky set of tile sizes and other specific metadata. If you want maketx to generate textures that may be used with either OpenImageIO or PRMan, you should use the --prman option, which will set several options to make PRMan happy, overriding any contradictory settings on the command line or in the input texture.

Specifically, this option sets the tile size (to 64x64 for 8 bit, 64x32 for 16 bit integer, and 32x32 for float or half images), uses “separate” planar configuration (--separate), and sets PRMan-specific metadata...
OpenImageIO, Release 2.4.1

(-prman-metadata). It also outputs sint16 textures if uint16 is requested (because PRMan for some reason
does not accept true uint16 textures), and in the case of TIFF files will omit the Exif directory block which will
not be recognized by the older version of libtiff used by PRMan.

OpenImageIO will happily accept textures that conform to PRMan’s expectations, but not vice versa. But
OpenImageIO’s TextureSystem has better performance with textures that use maketx’s default settings rather
than these oddball choices. You have been warned!

--oiio
This sets several options that we have determined are the optimal values for OpenImageIO’s TextureSystem,
overriding any contradictory settings on the command line or in the input texture.

Specifically, this is the equivalent to using

--separate --tile 64 64

--colorconvert <inspace> <outspace>
Convert the color space of the input image from <inspace> to <outspace>. If OpenColorIO is installed and finds a
valid configuration, it will be used for the color conversion. If OCIO is not enabled (or cannot find a valid
configuration, OIIO will at least be able to convert among linear, sRGB, and Rec709.

--colorconfig <name>
Explicitly specify a custom OpenColorIO configuration file. Without this, the default is to use the $OCIO
environment variable as a guide for the location of the OpenColorIO configuration file.

--unpremult
When undergoing some color conversions, it is helpful to “un-premultiply” the alpha before converting color
channels, and then re-multiplying by alpha. Caveat emptor – if you don’t know exactly when to use this, you
probably shouldn’t be using it at all.

--mipimage <filename>
Specifies the name of an image file to use as a custom MIP-map level, instead of simply downsizing the last one.
This option may be used multiple times to specify multiple levels. For example:

maketx 256.tif --mipimage 128.tif --mipimage 64.tif -o out.tx

This will make a texture with the first MIP level taken from 256.tif, the second level from 128.tif, the
third from 64.tif, and then subsequent levels will be the usual downsizings of 64.tif.

--envlatl
Creates a latitude-longitude environment map, rather than an ordinary texture map.

--lightprobe
Creates a latitude-longitude environment map, but in contrast to --envlatl, the original input image is as-
sumed to be formatted as a light probe image. (See http://www.pauldebevec.com/Probes/ for examples and an
explanation of the geometric layout.)

--bumpslopes
For a single channel input image representing height (that you would ordinarily use for a bump or displacement),
this produces a 6-channel texture that contains the first and second moments of bump slope, which can be used
to implement certain bump-to-roughness techniques. The channel layout is as follows:

<table>
<thead>
<tr>
<th>index</th>
<th>channel name</th>
<th>data at MIP level 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>b0_h</td>
<td>h (height)</td>
</tr>
<tr>
<td>1</td>
<td>b1_dhds</td>
<td>∂h/∂s</td>
</tr>
<tr>
<td>2</td>
<td>b2_dhdt</td>
<td>∂h/∂t</td>
</tr>
<tr>
<td>3</td>
<td>b3_dhds2</td>
<td>(∂h/∂s)^2</td>
</tr>
<tr>
<td>4</td>
<td>b4_dhdt2</td>
<td>(∂h/∂t)^2</td>
</tr>
<tr>
<td>5</td>
<td>b5_dhdsdt</td>
<td>(∂h/∂s)·(∂h/∂t)</td>
</tr>
</tbody>
</table>

17.2. maketx 431
(The strange channel names are to guarantee they are in alphabetical order, to prevent reordering by OpenEXR. And also note that the simple relationships between channels 1 & 2, and 3-6, is only for the highest-resolution level of the MIP-map, and will differ for the lower-res filtered versions, and those differences is what gives us the slope moments that we need.)

A reference for explaining how this can be used is here:

--bumpformat <bformat>
In conjunction with --bumpslopes, this option can specify the strategy for determining whether a 3-channel source image specifies a height map or a normal map. The value “height” indicates it is a height map (only the first channel will be used). The value “normal” indicates it is a normal map (all three channels will be used for x, y, z). The default value, “auto”, indicates that it should be interpreted as a height map if and only if the R, G, B channel values are identical in all pixels, otherwise it will be interpreted as a 3-channel normal map.

--uvslopes_scale <scalefactor>
Used in conjunction with --bumpslopes, this computes derivatives for the bumpslopes data in UV space rather than in texel space, and divides them by a scale factor. If the value is 0 (default), this is disabled. For a nonzero value, it will be the scale factor. If you use this feature, a suggested value is 256.

(This option was added for OpenImageIO 2.3.)

---cdf
---cdfsigma <SIGMA>
---cdfbits <BITS>
When --cdf is used, the output texture will write a Gaussian CDF and Inverse Gaussian CDF as per-channel metadata in the texture, which can be used by shaders to implement Histogram-Preserving Blending. This is only useful when the texture being created is written to an image format that supports arbitrary metadata (e.g. OpenEXR).

When --cdf has been enabled, the additional options --cdfsigma may be used to specify the CDF sigma value (defaulting to 1.0/6.0), and --cdfbits specifies the number of bits to use for the size of the CDF table (defaulting to 8, which means 256 bins).

References:
• Histogram-Preserving Blending for Randomized Texture Tiling,” JCGT 8(4), 2019.
• Benedikt Bitterli https://benedikt-bitterli.me/histogram-tiling/

These options were first added in OpenImageIO 2.3.10.

--handed <value>
Adds a “handed” metadata to the resulting texture, which reveals the handedness of vector displacement maps or normal maps, when expressed in tangent space. Possible values are left or right.

This option was first added in OpenImageIO 2.4.0.2.
17.3 oiiotool

The **oiiotool** utility (Chapter *oiiotool: the OIIO Swiss Army Knife*) is capable of writing textures using the `-otex` option, lat-long environment maps using the `-oenv` option, and bump/normal maps that include normal distribution moments. Roughly speaking,

```
maketx [maketx-options] input -o output
maketx -envlat1 [maketx-options] input -o output
maketx -bumpslopes [maketx-options] input -o output
```

are equivalent to, respectively,

```
oiiotool input [oiiotool-options] -otex output
oiiotool input [oiiotool-options] -oenv output
oiiotool input [oiiotool-options] -obump output
```

However, the notation for the various options are not identical between the two programs, as will be explained by the remainder of this section.

The most important difference between **oiiotool** and **maketx** is that **oiiotool** can do so much more than convert an existing input image to a texture – literally any image creation or manipulation you can do via **oiiotool** may be output directly as a full texture file using `-otex` (or as a lat-long environment map using `-oenv`).

Note that it is vitally important that you use one of the texture output commands (`-otex` or `-oenv`) when creating textures with **oiiotool** — if you inadvertently forget and use an ordinary `-o`, you will end up with an output image that is much less efficient to use as a texture.

17.3.1 Command line arguments useful when creating textures

As with any use of **oiiotool**, you may use the following to control the run generally:

```
--help
-v
--runstats
--threads <n>
```

and as with any use of **oiiotool**, you may use the following command-line options to control aspects of the any output files (including those from `-otex` and `-oenv`, as well as `-o`). Only brief descriptions are given below, please consult Chapter oiiotool for detailed explanations.

```
-d <datatype>
    Specify the pixel data type (UINT8, uint16, half, float, etc.) if you wish to override the default of writing the same data type as the first input file read.

--tile <x> <y>
    Explicitly override the tile size (though you are strongly urged to use the default, and not use this command).

--compression <method>
    Explicitly override the default compression methods when writing the texture file.

--ch <channellist>
    Shuffle, add, delete, or rename channels (see sec-oiiotool-ch).

--chnames a,b,...
    Renames the channels of the output image.
```
--fixnan <strategy>
Repairs any pixels in the input image that contained NaN or Inf values (if the strategy is box3 or black), or to simply abort with an error message (if the strategy is error).

--fullpixels
Resets the “full” (or “display”) pixel range to be the “data” range.

--planarconfig separate
Forces “separate” (e.g., RRR...GGG...BBB) packing of channels in the output texture. This is almost always a bad choice, unless you know that the texture file must be readable by PRMan, in which case it is required.

--attrib <name> <value>
oiiotool’s --attrib command may be used to set attributes in the metadata of the output texture.

--attrib:type=matrix worldtocam <...16 comma-separated floats...>
--attrib:type=matrix screentocam <...16 comma-separated floats...>
Set/override the camera and screen matrices.

17.3.2 Optional arguments to -otex, -oenv, -obump

As with many oiiotool commands, the -otex and -oenv may have various optional arguments appended, in the form :name=value (see Section sec-oiiotooloptionalargs).

Optional arguments supported by -otex and -oenv include all the same options as -o (Section Writing images) and also the following (explanations are brief, please consult Section sec-maketx for more detailed explanations of each, for the corresponding maketx option):

17.3.3 Examples

```
oiiotool in.tif -otex out.tx
oiiotool in.jpg --colorconvert sRGB linear -d uint16 -otex out.tx
oiiotool --pattern:checker 512x512 3 -d uint8 -otex:wrap=periodic checker.tx
oiiotool in.exr -otex:hlilightcomp=1:sharpen=0.5 out.exr
```
METADATA CONVENTIONS

The ImageSpec class, described thoroughly in Image Specification: ImageSpec, provides the basic description of an image that are essential across all formats — resolution, number of channels, pixel data format, etc. Individual images may have additional data, stored as name/value pairs in the extra_attribs field. Though literally anything can be stored in extra_attribs — it’s specifically designed for format- and user-extensibility — this chapter establishes some guidelines and lays out all of the field names that OpenImageIO understands.

18.1 Description of the image

"ImageDescription" : string
    The image description, title, caption, or comments.

"Keywords" : string
    Semicolon-separated keywords describing the contents of the image. (Semicolons are used rather than commas because of the common case of a comma being part of a keyword itself, e.g., “Kurt Vonnegut, Jr.” or “Washington, DC.”)

"Artist" : string
    The artist, creator, or owner of the image.

"Copyright" : string
    Any copyright notice or owner of the image.

"DateTime" : string
    The creation date of the image, in the following format: YYYY:MM:DD HH:MM:SS (exactly 19 characters long, not including a terminating NULL). For example, 7:30am on Dec 31, 2008 is encoded as "2008:12:31 07:30:00".

    Usually this is simply the time that the image data was last modified. It may be wise to also store the "Exif:DateTimeOriginal" and "Exif:DateTimeDigitized" (see Section Exif metadata) to further distinguish the original image and its conversion to digital media.

"DocumentName" : string
    The name of an overall document that this image is a part of.

"Software" : string
    The software that was used to create the image.

"HostComputer" : string
    The name or identity of the computer that created the image.
18.2 Display hints

"Orientation" : int
   By default, image pixels are ordered from the top of the display to the bottom, and within each scanline, from left to right (i.e., the same ordering as English text and scan progression on a CRT). But the “Orientation” field can suggest that it should be displayed with different orientation, according to the TIFF/EXIF conventions:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>normal (top to bottom, left to right)</td>
</tr>
<tr>
<td>1</td>
<td>flipped horizontally (top to bottom, right to left)</td>
</tr>
<tr>
<td>2</td>
<td>rotated 180° (bottom to top, right to left)</td>
</tr>
<tr>
<td>3</td>
<td>flipped vertically (bottom to top, left to right)</td>
</tr>
<tr>
<td>4</td>
<td>transposed (left to right, top to bottom)</td>
</tr>
<tr>
<td>5</td>
<td>rotated 90° clockwise (right to left, top to bottom)</td>
</tr>
<tr>
<td>6</td>
<td>transverse (right to left, bottom to top)</td>
</tr>
<tr>
<td>7</td>
<td>rotated 90° counter-clockwise (left to right, bottom to top)</td>
</tr>
</tbody>
</table>

"PixelAspectRatio" : float
   The aspect ratio \( \frac{x}{y} \) of the size of individual pixels, with square pixels being 1.0 (the default).

"XResolution" : float
"YResolution" : float
"ResolutionUnit" : string
   The number of horizontal (x) and vertical (y) pixels per resolution unit. This ties the image to a physical size (where applicable, such as with a scanned image, or an image that will eventually be printed).

   Different file formats may dictate different resolution units. For example, the TIFF ImageIO plugin supports none, in, and cm.

"oiio:Movie" : int
   If nonzero, a hint that a multi-image file is meant to be interpreted as an animation (i.e., that the subimages are a time sequence).

"oiio:subimages" : int
   If nonzero, the number of subimages in the file. Not all image file formats can know this without reading the entire file, and in such cases, this attribute will not be set or will be 0. If the value is present and greater than zero, it can be trusted, but if not, nothing should be inferred and you will have to repeatedly seek to subimages to find out how many there are.

"FramesPerSecond" : rational
   For a multi-image file intended to be played back as an animation, the frame refresh rate. (It’s technically a rational, but it may be retrieved as a float also, if you are ok with imprecision.)

18.3 Color information

"oiio:ColorSpace" : string
   The name of the color space of the color channels. Values include:
   - "Linear": Color pixel values are known to be scene-linear and using facility-default color primaries (presumed sRGB/Rec709 color primaries if otherwise unknown.
   - "sRGB": Using standard sRGB response and primaries.
   - "Rec709": Using standard Rec709 response and primaries.
   - "ACES": ACES color space encoding.
- "AdobeRGB": Adobe RGB color space.
- "KodakLog": Kodak logarithmic color space.
- "GammaX.Y": Color values have been gamma corrected (raised to the power $1/\gamma$). The $X,Y$ is the numeric value of the gamma exponent.
- "arbitrary": The name of any color space known to OpenColorIO (if OCIO support is present).

"oiio:Gamma": float
If the color space is “GammaX.Y”, this value is the gamma exponent. (Optional/deprecated; if present, it should match the suffix of the color space.)

"oiio:BorderColor": float[nchannels]
The color presumed to be filling any parts of the display/full image window that are not overlapping the pixel data window. If not supplied, the default is black (0 in all channels).

"ICCProfile": uint8[]
The ICC color profile takes the form of an array of bytes (unsigned 8 bit chars). The length of the array is the length of the profile blob.

### 18.4 Disk file format info/hints

"oiio:BitsPerSample": int
Number of bits per sample in the file.

Note that this may not match the reported ImageSpec::format, if the plugin is translating from an unsupported format. For example, if a file stores 4 bit grayscale per channel, the "oiio:BitsPerSample" may be 4 but the format field may be TypeDesc::UINT8 (because the OpenImageIO APIs do not support fewer than 8 bits per sample).

"oiio:UnassociatedAlpha": int
Whether the data in the file stored alpha channels (if any) that were unassociated with the color (i.e., color not "premultiplied" by the alpha coverage value).

"planarconfig": string
contig indicates that the file has contiguous pixels (RGB RGB RGB...), whereas separate indicate that the file stores each channel separately (RRR...GGG...BBB...).

Note that only contiguous pixels are transmitted through the OpenImageIO APIs, but this metadata indicates how it is (or should be) stored in the file, if possible.

"compression": string
Indicates the type of compression the file uses. Supported compression modes will vary from file format to file format, and each reader/writer plugin should document the modes it supports. If ImageOutput::open is called with an ImageSpec that specifies an compression mode not supported by that ImageOutput, it will choose a reasonable default. As an example, the OpenEXR writer supports none, rle, zip, zips, piz, pxr24, b44, b44a, dwaa, or dwab.

The compression name is permitted to have a quality value to be appended after a colon, for example dwaa:60. The exact meaning and range of the quality value can vary between different file formats and compression modes, and some don’t support quality values at all (it will be ignored if not supported, or if out of range).

"CompressionQuality": int
DEPRECATED(2.1)

This is a deprecated method of separately specifying the compression quality. Indicates the quality of compression to use (0–100), for those plugins and compression methods that allow a variable amount of compression, with higher numbers indicating higher image fidelity.
18.5 Substituting an IOPProxy for custom I/O overrides

Format readers and writers that respond positively to `supports("ioproxy")` have the ability to read or write using an I/O proxy object. Among other things, this lets an ImageOutput write the file to a memory buffer rather than saving to disk, and for an ImageInput to read the file from a memory buffer. This behavior is controlled by a special attributes

```
"oiio:ioproxy" : pointer
    Pointer to a Filesystem::IOProxy that will handle the I/O.
```

An explanation of how this feature is used may be found in Sections *Custom I/O proxies (and reading the file from a memory buffer)* and *Custom I/O proxies (and writing the file to a memory buffer)*.

In addition to communicating IOProxy information via this attribute, it is also allowed (and probably preferred) to directly supply the IOProxy information via calls to `ImageInput::open()`, `create()`, and `set_ioproxy()`, `ImageOutput::create()` and `set_ioproxy()`, and `ImageBuf::ImageBuf()`, `reset()`, and `set_write_ioproxy()`.

18.6 Photographs or scanned images

The following metadata items are specific to photos or captured images.

```
"Make" : string
    For captured or scanned image, the make of the camera or scanner.

"Model" : string
    For captured or scanned image, the model of the camera or scanner.

"ExposureTime" : float
    The exposure time (in seconds) of the captured image.

"FNumber" : float
    The f/stop of the camera when it captured the image.
```

18.7 Thumbnails / postage stamps / preview images

Some image file formats allow for storing a thumbnail – a lower-resolution image suitable for an icon or other small preview. These are retrievable separately via `ImageInput::get_thumbnail()`, `ImageBuf::thumbnail()`, or `ImageCache::get_thumbnail()`. In addition, if a thumbnail is available, the `ImageSpec` should also contain the following metadata:

```
"thumbnail_width" : int
    The thumbnail width, in pixels.

"thumbnail_height" : int
    The thumbnail height, in pixels.

"thumbnail_nchannels" : int
    The number of color channels in the thumbnail image.
```
18.8 Texture Information

Several standard metadata are very helpful for images that are intended to be used as textures (especially for OpenImageIO’s TextureSystem).

"textureformat" : string
   The kind of texture that this image is intended to be. We suggest the following names:

<table>
<thead>
<tr>
<th>Plain Texture</th>
<th>Ordinary 2D texture</th>
</tr>
</thead>
<tbody>
<tr>
<td>Volume Texture</td>
<td>3D volumetric texture</td>
</tr>
<tr>
<td>Shadow</td>
<td>Ordinary z-depth shadow map</td>
</tr>
<tr>
<td>CubeFace Shadow</td>
<td>Cube-face shadow map</td>
</tr>
<tr>
<td>Volume Shadow</td>
<td>Volumetric (“deep”) shadow map</td>
</tr>
<tr>
<td>LatLong Environment</td>
<td>Latitude-longitude (rectangular) environment map</td>
</tr>
<tr>
<td>CubeFace Environment</td>
<td>Cube-face environment map</td>
</tr>
</tbody>
</table>

"wrapmodes" : string
   Give the intended texture wrap mode indicating what happens with texture coordinates outside the [0...1] range. We suggest the following names: black, periodic, clamp, mirror. If the wrap mode is different in each direction, they should simply be separated by a comma. For example, black means black wrap in both directions, whereas clamp,periodic means to clamp in \( u \) and be periodic in \( v \).

"fovcot" : float
   The cotangent (\( x/y \)) of the field of view of the original image (which may not be the same as the aspect ratio of the pixels of the texture, which may have been resized).

"worldtocamera" : matrix44
   For shadow maps or rendered images this item (of type TypeDesc::PT_MATRIX) is the world-to-camera matrix describing the camera position.

"worldtoscreen" : matrix44
   For shadow maps or rendered images this item (of type TypeDesc::PT_MATRIX) is the world-to-screen matrix describing the full projection of the 3D view onto a \([-1...1] \times [-1...1]\) 2D domain.

"worldtoNDC" : matrix44
   For shadow maps or rendered images this item (of type TypeDesc::PT_MATRIX) is the world-to-NDC matrix describing the full projection of the 3D view onto a \([0...1] \times [0...1]\) 2D domain.

"oiio:updirection" : string
   For environment maps, indicates which direction is “up” (valid values are \( y \) or \( z \)), to disambiguate conventions for environment map orientation.

"oiio:sampleborder" : int
   If not present or 0 (the default), the conversion from pixel integer coordinates \((i,j)\) to texture coordinates \((s,t)\) follows the usual convention of \( s = (i + 0.5)/xres \) and \( t = (j + 0.5)/yres \). However, if this attribute is present and nonzero, the first and last row/column of pixels lie exactly at the \( s \) or \( t \) = 0 or 1 boundaries, i.e., \( s = i/(xres - 1) \) and \( t = j/(yres - 1) \).

"oiio:ConstantColor" : string
   If present, is a hint that the texture has the same value in all pixels, and the metadata value is a string containing the channel values as a comma-separated list (no spaces, for example: 0.73,0.9,0.11,1.0).

"oiio:AverageColor" : string
   If present, is a hint giving the average value of all pixels in the texture, as a string containing a comma-separated list of the channel values (no spaces, for example: 0.73,0.9,0.11,1.0).

"oiio:SHA-1" : string
   If present, is a 40-byte SHA-1 hash of the input image (possibly salted with various maketx options) that can serve
to quickly compare two separate textures to know if they contain the same pixels. While it’s not, technically, 100%
guaranteed that no separate textures will match, it’s so astronomically unlikely that we discount the possibility
(you’d be rendering movies for centuries before finding a single match).

18.9 Exif metadata

The following Exif metadata tags correspond to items in the “standard” set of metadata.

<table>
<thead>
<tr>
<th>Exif tag</th>
<th>OpenImageIO metadata convention</th>
</tr>
</thead>
<tbody>
<tr>
<td>ColorSpace</td>
<td>(reflected in “oiio:ColorSpace”)</td>
</tr>
<tr>
<td>ExposureTime</td>
<td>ExposureTime</td>
</tr>
<tr>
<td>FNumber</td>
<td>FNumber</td>
</tr>
</tbody>
</table>

The other remaining Exif metadata tags all include the Exif: prefix to keep it from clashing with other names that
may be used for other purposes.

"Exif:ExposureProgram" : int
The exposure program used to set exposure when the picture was taken:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>unknown</td>
</tr>
<tr>
<td>1</td>
<td>manual</td>
</tr>
<tr>
<td>2</td>
<td>normal program</td>
</tr>
<tr>
<td>3</td>
<td>aperture priority</td>
</tr>
<tr>
<td>4</td>
<td>shutter priority</td>
</tr>
<tr>
<td>5</td>
<td>Creative program (biased toward depth of field)</td>
</tr>
<tr>
<td>6</td>
<td>Action program (biased toward fast shutter speed)</td>
</tr>
<tr>
<td>7</td>
<td>Portrait mode (closeup photo with background out of focus)</td>
</tr>
<tr>
<td>8</td>
<td>Landscape mode (background in focus)</td>
</tr>
</tbody>
</table>

"Exif:SpectralSensitivity" : string
The camera’s spectral sensitivity, using the ASTM conventions.

"Exif:ISOSpeedRatings" : int
The ISO speed and ISO latitude of the camera as specified in ISO 12232.

"Exif:DateTimeOriginal" : string
"Exif:DateTimeDigitized" : string
Date and time that the original image data was generated or captured, and the time/time that the image was
stored as digital data. Both are in YYYY:MM:DD HH:MM:SS format.

To clarify the role of these (and also with respect to the standard DateTime metadata), consider an ana-
log photograph taken in 1960 (Exif:DateTimeOriginal), which was scanned to a digital image in
2010 (Exif:DateTimeDigitized), and had color corrections or other alterations performed in 2015
(DateTime).

"Exif:CompressedBitsPerPixel" : float
The compression mode used, measured in compressed bits per pixel.

"Exif:ShutterSpeedValue" : float
Shutter speed, in APEX units: \(- \log_2(\text{exposuretime})\)

"Exif:ApertureValue" : float
Aperture, in APEX units: \(2 \log_2(\text{fnumber})\)
"Exif:BrightnessValue" : float
   Brightness value, assumed to be in the range of $-99.99 – 99.99$.

"Exif:ExposureBiasValue" : float
   Exposure bias, assumed to be in the range of $-99.99 – 99.99$.

"Exif:MaxApertureValue" : float
   Smallest F number of the lens, in APEX units: $2 \log_2(fnumber)$

"Exif:SubjectDistance" : float
   Distance to the subject, in meters.

"Exif:MeteringMode" : int
   The metering mode:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>unknown</td>
</tr>
<tr>
<td>1</td>
<td>average</td>
</tr>
<tr>
<td>2</td>
<td>center-weighted average</td>
</tr>
<tr>
<td>3</td>
<td>spot</td>
</tr>
<tr>
<td>4</td>
<td>multi-spot</td>
</tr>
<tr>
<td>5</td>
<td>pattern</td>
</tr>
<tr>
<td>6</td>
<td>partial</td>
</tr>
<tr>
<td>255</td>
<td>other</td>
</tr>
</tbody>
</table>

"Exif:LightSource" : int
   The kind of light source:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>unknown</td>
</tr>
<tr>
<td>1</td>
<td>daylight</td>
</tr>
<tr>
<td>2</td>
<td>tungsten (incandescent light)</td>
</tr>
<tr>
<td>4</td>
<td>flash</td>
</tr>
<tr>
<td>9</td>
<td>fine weather</td>
</tr>
<tr>
<td>10</td>
<td>cloudy weather</td>
</tr>
<tr>
<td>11</td>
<td>shade</td>
</tr>
<tr>
<td>12</td>
<td>daylight fluorescent (D 5700-7100K)</td>
</tr>
<tr>
<td>13</td>
<td>day white fluorescent (N 4600-5400K)</td>
</tr>
<tr>
<td>14</td>
<td>cool white fluorescent (W 3900 - 4500K)</td>
</tr>
<tr>
<td>15</td>
<td>white fluorescent (WW 3200 - 3700K)</td>
</tr>
<tr>
<td>17</td>
<td>standard light A</td>
</tr>
<tr>
<td>18</td>
<td>standard light B</td>
</tr>
<tr>
<td>19</td>
<td>standard light C</td>
</tr>
<tr>
<td>20</td>
<td>D55</td>
</tr>
<tr>
<td>21</td>
<td>D65</td>
</tr>
<tr>
<td>22</td>
<td>D75</td>
</tr>
<tr>
<td>23</td>
<td>D50</td>
</tr>
<tr>
<td>24</td>
<td>ISO studio tungsten</td>
</tr>
<tr>
<td>255</td>
<td>other light source</td>
</tr>
</tbody>
</table>

"Exif:Flash" int

A sum of:
1  if the flash fired
0  no strobe return detection function
4  strobe return light was not detected
6  strobe return light was detected
8  compulsory flash firing
16 compulsory flash suppression
24 auto-flash mode
32 no flash function (0 if flash function present)
64 red-eye reduction supported (0 if no red-eye reduction mode)

"Exif:FocalLength" : float
   Actual focal length of the lens, in mm.

"Exif:SecurityClassification" : string
   Security classification of the image: C = confidential, R = restricted, S = secret, T = top secret, U = unclassified.

"Exif:ImageHistory" : string
   Image history.

"Exif:SubsecTime" : string
   Fractions of a second to augment the "DateTime" (expressed as text of the digits to the right of the decimal).

"Exif:SubsecTimeOriginal" : string
   Fractions of a second to augment the Exif:DateTimeOriginal (expressed as text of the digits to the right of the decimal).

"Exif:SubsecTimeDigitized" : string
   Fractions of a second to augment the Exif:DateTimeDigital (expressed as text of the digits to the right of the decimal).

"Exif:PixelXDimension" : int
"Exif:PixelYDimension" : int
   The x and y dimensions of the valid pixel area.

"Exif:FlashEnergy" : float
   Strobe energy when the image was captured, measured in Beam Candle Power Seconds (BCPS).

"Exif:FocalPlaneXResolution" : float
"Exif:FocalPlaneYResolution" : float
"Exif:FocalPlaneResolutionUnit" : int
   The number of pixels in the x and y dimension, per resolution unit. The codes for resolution units are:

<table>
<thead>
<tr>
<th>Code</th>
<th>Unit</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>none</td>
</tr>
<tr>
<td>2</td>
<td>inches</td>
</tr>
<tr>
<td>3</td>
<td>cm</td>
</tr>
<tr>
<td>4</td>
<td>mm</td>
</tr>
<tr>
<td>5</td>
<td>𝜇m</td>
</tr>
</tbody>
</table>

"Exif:ExposureIndex" : float
   The exposure index selected on the camera.

"Exif:SensingMethod" : int
   The image sensor type on the camera:
one-chip color area sensor

two-chip color area sensor

three-chip color area sensor

color sequential area sensor

trilinear sensor

color trilinear sensor

"Exif:FileSource" : int
The source type of the scanned image, if known:

film scanner
reflection print scanner
digital camera

"Exif:SceneType" : int
Set to 1, if a directly-photographed image, otherwise it should not be present.

"Exif:CustomRendered" : int
Set to 0 for a normal process, 1 if some custom processing has been performed on the image data.

"Exif:ExposureMode" : int
The exposure mode:

auto
manual
auto-bracket

"Exif:WhiteBalance" : int
Set to 0 for auto white balance, 1 for manual white balance.

"Exif:DigitalZoomRatio" : float
The digital zoom ratio used when the image was shot.

"Exif:FocalLengthIn35mmFilm" : int
The equivalent focal length of a 35mm camera, in mm.

"Exif:SceneCaptureType" : int
The type of scene that was shot:

standard
landscape
portrait
night scene

"Exif:GainControl" : float
The degree of overall gain adjustment:

none
low gain up
high gain up
low gain down
high gain down
"Exif:Contrast" : int
The direction of contrast processing applied by the camera:

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>normal</td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>soft</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>hard</td>
<td></td>
</tr>
</tbody>
</table>

"Exif:Saturation" : int
The direction of saturation processing applied by the camera:

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>normal</td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>low saturation</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>high saturation</td>
<td></td>
</tr>
</tbody>
</table>

"Exif:Sharpness" : int
The direction of sharpness processing applied by the camera:

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>normal</td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>soft</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>hard</td>
<td></td>
</tr>
</tbody>
</table>

"Exif:SubjectDistanceRange" : int
The distance to the subject:

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>unknown</td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>macro</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>close</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>distant</td>
<td></td>
</tr>
</tbody>
</table>

"Exif:ImageUniqueID" : string
A unique identifier for the image, as 16 ASCII hexadecimal digits representing a 128-bit number.

18.10 GPS Exif metadata

The following GPS-related Exif metadata tags correspond to items in the “standard” set of metadata.

"GPS:LatitudeRef" : string
Whether the GPS:Latitude tag refers to north or south: N or S.

"GPS:Latitude" : float[3]
The degrees, minutes, and seconds of latitude (see also GPS:LatitudeRef).

"GPS:LongitudeRef" : string
Whether the GPS:Longitude tag refers to east or west: E or W.

"GPS:Longitude" : float[3]
The degrees, minutes, and seconds of longitude (see also GPS:LongitudeRef).

"GPS:AltitudeRef" : string
A value of 0 indicates that the altitude is above sea level, 1 indicates below sea level.
"GPS:Altitude" : float
    Absolute value of the altitude, in meters, relative to sea level (see GPS:AltitudeRef for whether it's above
    or below sea level).

"GPS:TimeStamp" : float[3]
    Gives the hours, minutes, and seconds, in UTC.

"GPS:Satellites" : string
    Information about what satellites were visible.

"GPS:Status" : string
    A indicates a measurement in progress, V indicates measurement interoperability.

"GPS:MeasureMode" : string
    2 indicates a 2D measurement, 3 indicates a 3D measurement.

"GPS:DOP" : float
    Data degree of precision.

"GPS:SpeedRef" : string
    Indicates the units of the related GPS:Speed tag: K for km/h, M for miles/h, N for knots.

"GPS:Speed" : float
    Speed of the GPS receiver (see GPS:SpeedRef for the units).

"GPS:TrackRef" : string
    Describes the meaning of the GPS:Track field: T for true direction, M for magnetic direction.

"GPS:Track" : float
    Direction of the GPS receiver movement (from 0–359.99). The related GPS:TrackRef indicate whether it's
    true or magnetic.

"GPS:ImgDirectionRef" : string
    Describes the meaning of the GPS:ImgDirection field: T for true direction, M for magnetic direction.

"GPS:ImgDirection" : float
    Direction of the image when captured (from 0–359.99). The related GPS:ImgDirectionRef indicate whether it’s
    true or magnetic.

"GPS:MapDatum" : string
    The geodetic survey data used by the GPS receiver.

"GPS:DestLatitudeRef" : string
    Whether the GPS:DestLatitude tag refers to north or south: N or S.

"GPS:DestLatitude" : float[3]
    The degrees, minutes, and seconds of latitude of the destination (see also GPS:DestLatitudeRef).

"GPS:DestLongitudeRef" : string
    Whether the GPS:DestLongitude tag refers to east or west: E or W.

"GPS:DestLongitude" : float[3]
    The degrees, minutes, and seconds of longitude of the destination (see also GPS:DestLongitudeRef).

"GPS:DestBearingRef" : string
    Describes the meaning of the GPS:DestBearing field: T for true direction, M for magnetic direction.

"GPS:DestBearing" : float
    Bearing to the destination point (from 0–359.99). The related GPS:DestBearingRef indicate whether it's
    true or magnetic.

"GPS:DestDistanceRef" : string
    Indicates the units of the related GPS:DestDistance tag: K for km, M for miles, N for knots.
"GPS:DestDistance" : float
Distance to the destination (see GPS:DestDistanceRef for the units).

"GPS:ProcessingMethod" : string
Processing method information.

"GPS:AreaInformation" : string
Name of the GPS area.

"GPS:DateStamp" : string
Date according to the GPS device, in format YYYY:MM:DD.

"GPS:Differential" : int
If 1, indicates that differential correction was applied.

"GPS:HPositioningError" : float
Positioning error.

18.11 IPTC metadata

The IPTC (International Press Telecommunications Council) publishes conventions for storing image metadata, and this standard is growing in popularity and is commonly used in photo-browsing programs to record captions and keywords.

The following IPTC metadata items correspond exactly to metadata in the OpenImageIO conventions, so it is recommended that you use the standards and that plugins supporting IPTC metadata respond likewise:

<table>
<thead>
<tr>
<th>IPTC tag</th>
<th>OpenImageIO metadata convention</th>
</tr>
</thead>
<tbody>
<tr>
<td>Caption</td>
<td>&quot;ImageDescription&quot;</td>
</tr>
<tr>
<td>Keyword</td>
<td>IPTC keywords should be concatenated, separated by semicolons (;), and stored as the Keywords attribute.</td>
</tr>
<tr>
<td>Exposure-Time</td>
<td>ExposureTime</td>
</tr>
<tr>
<td>Copyright-Notice</td>
<td>Copyright</td>
</tr>
<tr>
<td>Creator</td>
<td>Artist</td>
</tr>
</tbody>
</table>

The remainder of IPTC metadata fields should use the following names, prefixed with IPTC: to avoid conflicts with other plugins or standards.

"IPTC:ObjectTypeReference" : string
Object type reference.

"IPTC:ObjectAttributeReference" : string
Object attribute reference.

"IPTC:ObjectName" : string
The name of the object in the picture.

"IPTC:EditStatus" : string
Edit status.

"IPTC:SubjectReference" : string
Subject reference.

"IPTC:Category" : string
Category.
"IPTC:ContentLocationCode" : string
  Code for content location.

"IPTC:ContentLocationName" : string
  Name of content location.

"IPTC:ReleaseDate" : string
"IPTC:ReleaseTime" : string
  Release date and time.

"IPTC:ExpirationDate" : string
"IPTC:ExpirationTime" : string
  Expiration date and time.

"IPTC:Instructions" : string
  Special instructions for handling the image.

"IPTC:ReferenceService" : string
"IPTC:ReferenceDate" : string
"IPTC:ReferenceNumber" : string
  Reference date, service, and number.

"IPTC:DateCreated" : string
"IPTC:TimeCreated" : string
  Date and time that the image was created.

"IPTC:DigitalCreationDate" : string
"IPTC:DigitalCreationTime" : string
  Date and time that the image was digitized.

"IPTC:ProgramVersion" : string
  The version number of the creation software.

"IPTC:AuthorsPosition" : string
  The job title or position of the creator of the image.

"IPTC:City" : string
"IPTC:Sublocation" : string
"IPTC:State" : string
"IPTC:Country" : string
"IPTC:CountryCode" : string
  The city, sublocation within the city, state, country, and country code of the location of the image.

"IPTC:Headline" : string
  Any headline that is meant to accompany the image.

"IPTC:Provider" : string
  The provider of the image, or credit line.

"IPTC:Source" : string
  The source of the image.

"IPTC:Contact" : string
  The contact information for the image (possibly including name, address, email, etc.).

"IPTC:CaptionWriter" : string
  The name of the person who wrote the caption or description of the image.

"IPTC:JobID" : string
"IPTC:MasterDocumentID" : string
"IPTC:ShortDocumentID" : string
"IPTC:UniqueDocumentID" : string
"IPTC:OwnerID" : string
    Various identification tags.
"IPTC:Prefs" : string
"IPTC:ClassifyState" : string
"IPTC:SimilarityIndex" : string
    Who knows what the heck these are?
"IPTC:DocumentNotes" : string
    Notes about the image or document.
"IPTC:DocumentHistory" : string
    The history of the image or document.

18.12 SMPTE metadata

    SMPTE time code, encoded as an array of 2 32-bit integers (as a TypeDesc, it will be tagged with vecsemantics
    TIMECODE).
"smpte:KeyCode" : int[7]
    SMPTE key code, encoded as an array of 7 32-bit integers (as a TypeDesc, it will be tagged with vecsemantics
    KEYCODE).

18.13 Extension conventions

To avoid conflicts with other plugins, or with any additional standard metadata names that may be added in future
versions of OpenImageIO, it is strongly advised that writers of new plugins should prefix their metadata with the name
of the format, much like the "Exif:" and "IPTC:" metadata.
Channel  One of several data values present in each pixel. Examples include red, green, blue, alpha, etc. The data in one channel of a pixel may be represented by a single number, whereas the pixel as a whole requires one number for each channel.

Client  A client (as in “client application”) is a program or library that uses OpenImageIO or any of its constituent libraries.

Data format  The representation used to store a piece of data. Examples include 8-bit unsigned integers, 32-bit floating-point numbers, etc.

Image File Format  The specification and data layout of an image on disk. For example, TIFF, JPEG/JFIF, OpenEXR, etc.

Image Format Plugin  A DSO/DLL that implements the ImageInput and ImageOutput classes for a particular image file format.

Format Plugin  See image format plugin.

Metadata  Data about data. As used in OpenImageIO, this means information about an image, beyond describing the values of the pixels themselves. Examples include the name of the artist that created the image, the date that an image was scanned, the camera settings used when a photograph was taken, etc.

Multi-part image / multi-part file  This is what OpenEXR calls a file containing multiple subimages.

Native data format  The data format used in the disk file representing an image. Note that with OpenImageIO, this may be different than the data format used by an application to store the image in the computer’s RAM.

Pixel  One pixel element of an image, consisting of one number describing each channel of data at a particular location in an image.

Plugin  See image format plugin.

Scanline  A single horizontal row of pixels of an image. See also tile.

Scanline Image  An image whose data layout on disk is organized by breaking the image up into horizontal scanlines, typically with the ability to read or write an entire scanline at once. See also tiled image.

Subimage  Some image file formats allow the storage of multiple images in each file. These are called subimages in OpenImageIO. Note that in OpenEXR, these are called multi-part files.

Thumbnail  A small, lower-resolution preview image that is stored in an image file, in addition to the main image that the file represents. Not all image file formats support thumbnails.

Tile  A rectangular region of pixels of an image. A rectangular tile is more spatially coherent than a scanline that stretches across the entire image — that is, a pixel’s neighbors are most likely in the same tile, whereas a pixel in a scanline image will typically have most of its immediate neighbors on different scanlines (requiring additional scanline reads in order to access them).
**Tiled Image**  An image whose data layout on disk is organized by breaking the image up into rectangular regions of pixels called tiles. All the pixels in a tile can be read or written at once, and individual tiles may be read or written separately from other tiles.

**Volume Image**  A 3-D set of pixels that has not only horizontal and vertical dimensions, but also a “depth” dimension.
Symbols

"Artist" : string
  command line option, 435
