
pyqubes Documentation

Release 0.0.1

Tom Milligan

May 01, 2017

Contents:

1	Installation	1
1.1	Use	1
2	Examples	3
3	API	5
3.1	Pythonic Classes	5
3.2	Direct command wrapping	7
3.3	Utilities	8
4	Indices and tables	11
	Python Module Index	13

CHAPTER 1

Installation

Install with pip:

```
pip install pyqubes
```

Use

Todo

General use on AppVMs

dom0

Todo

Special use on dom0 without installation

CHAPTER 2

Examples

Todo

Examples

- pythonic
 - direct
-

CHAPTER 3

API

This API documentation is automatically generated.

Pythonic Classes

VM

The top level VM object holds common methods for VMs.

It should not be instanciated directly - use the lower level TemplateVM and AppVM objects instead.

class pyqubes.vm.VM(name, proactive=False, operating_system='fedora-23')

The VM object represants a QubesOS VM. Its methods are common accross both AppVMs and TemplateVMs.

VM should not be instanciated directly - use TemplateVM or AppVM.

By default, all VMs are Fedora 23 based. Other values are listed in pyqubes.constants

enact(args)

Enact a list of command arguments using the VM's enact_function

Any one of the functions in pyqubes.qubes, "pyqubes.qubesdb" or pyqubes.qvm will return arguments in the correct format.

firewall(kwargs)**

Edit the VM firewall

firewall_close()

Can be explicity called to close the VM firewall to 'deny'.

firewall_open()

Can be explicity called to open the VM firewall to 'allow'.

In most cases you should use "with vm.internet":

```
vm = TemplateVM('foo')
with vm.animate:
    # Templates are offline by default
    with vm.internet:
        # Template now has unrestricted internet access
        vm.run('curl http://ipecho.net/plain')
    # Firewall is restored automatically
    # This will now fail
    vm.run('curl http://ipecho.net/plain')
```

info (*info*)

Echo information from pyqubes using the VM's enact method

remove (**kwargs)

Remove the VM

run (*command*, *quote=True*, **kwargs)

Run a command on the VM.

Please note: * --pass-io is always set, to run commands synchronously * Commands are automatically encapsulated in single quotes:

```
vm = TemplateVM('spam')
vm.run('echo "foo bar"')
# produces: qvm-run spam 'echo "foo bar"'
```

Parameters **quote** (*bool*) – By default command is single quoted - set False to disable

shutdown (**kwargs)

Shutdown the

Please note: * --wait is always set, to run commands synchronously

start (**kwargs)

Start the VM explicitly.

In most cases you should use “with vm.animate“:

```
vm = TemplateVM('foo')
# Template is not started on instantiation
with vm.animate:
    # Template is now running
    vm.update()
# VM is shut down automatically
```

TemplateVM & AppVM

These represent the actual VMs within QubesOS.

Methods mentioned here are specific to the VM type.

class pyqubes.vm.TemplateVM (*args, **kwargs)

TemplateVM - for installing apps

clone (*clone_name*, **kwargs)

Clone the TemplateVM and return a new TemplateVM

Parameters **clone_name** (*string*) – Name of the new VM

Returns The new TemplateVM instance

create_app (*app_name*, ***kwargs*)

Create and return a new AppVM based on the TemplateVM.

Please note: * If `label` is not set, it will default to `red`

Parameters `app_name` (*string*) – Name of the new VM

Returns The new AppVM instance

update()

Smartly runs the relevant package manager updates for the TemplateVM

class `pyqubes.vm.AppVM(*args, **kwargs)`

AppVM - for running apps

Helper Classes

Direct command wrapping

qubes- commands

qubesdb- commands

qvm- commands

`pyqubes.qvm.qvm_clone(vm_name, clone_name, quiet=False, path='')`
qvm-clone

`pyqubes.qvm.qvm_create(vm_name, template='', label='', proxy=False, net=False, hvm=False, hvm_template=False, root_move_from='', root_copy_from='', standalone=False, mem=0, vcpus=0, internal=False, force_root=False, quiet=False)`
qvm-create

`pyqubes.qvm.qvm_firewall(vm_name, list_view=False, add_rule='', del_rule='', set_policy='', set_icmp='', set_dns='', set_yum_proxy='', numeric=False)`
qvm-firewall

`pyqubes.qvm.qvm_remove(vm_name, quiet=False, just_db=False, force_root=False)`
qvm-remove

`pyqubes.qvm.qvm_run(vm_name, command, quiet=False, auto=False, user='', tray=False, all_vms=False, exclude=[], wait=False, shutdown=False, pause=False, unpause=False, pass_io=False, localcmd='', force=False)`
qvm-run

`pyqubes.qvm.qvm_shutdown(vm_name, quiet=False, force=False, wait=False, all_vms=False, exclude=[])`
qvm-shutdown

`pyqubes.qvm.qvm_start(vm_name, quiet=False, no_guid=False, console=False, dvm=False, custom_config='')`
qvm-start

Utilities

Compile

The `compile` module converts instructions from pythonic data structures into flat lists.abs

These may require further processing before being passed to the `enact` module for action.

`pyqubes.compile.flags_boolean(flags)`

Return a list of string values, corresponding to the given keys whose values evaluate to True

All keys and values will be converted to strings.

Parameters `flags` (`dict`) – A dictionary in the form {`--flag`: `boolean`}, where `boolean` is used to determine whether `--flag` is included in the output.

Returns A flat list of strings

`pyqubes.compile.flags_store(flags)`

Return a list of string values, corresponding to the given keys and values whose values evaluate to True

The output is a flat list of all strings.

All keys and values will be converted to strings.

Parameters `flags` (`dict`) – A dictionary in the form {`--flag`: `value`}, where `value` is used to determine whether the entry is included in the output.

Returns A flat list of strings

`pyqubes.compile.flags_store_iterable(flags)`

Calls `flags_store` for each value within each key in `flags`.

e.g. {`'-fruits'`: [`'apple'`, `'pear'`] } results in [`'-fruits'`, `'apple'`, `'-fruits'`, `'pear'`]

Parameters `flags` (`dict`) – A dictionary in the form {`--flag`: `value`}, where `value` is an iterable.

Returns A flat list of strings

Raises `TypeError` if values are not iterable

`pyqubes.compile.info(info, quote=True, style=True)`

Returns the given string `info` as a set of echo arguments.

Optionally provides quoting and terminal styling.

Parameters

- `info` (`string`) – Info string to add to script
- `quote` (`bool`) – By default quote given sting in single quotes
- `style` (`bool`) – By default add

Returns A flat list of strings

Constants

Enact

The `enact` module contains functions that act on a list of command-line arguments,

The two most important ones are:

- * Direct execution with `call` (proactive mode)
- * Echoing an execution-ready script with `echo` (reactive mode)

`pyqubes.enact.call(args, **kwargs)`
Thin wrapper for builtin subprocess.call

`pyqubes.enact.call_quiet(args)`
Uses the `call` function, but throws away stdout and stderr.
Should be used for internal unit tests wherever possible.

`pyqubes.enact.echo(args, file=None)`
Echo a list of arguments (as given to `subprocess.call`) to the given stream.
This defaults to `stdout`, but can be changed to any stream-like object such as a file handle.

Parameters

- `args` – A string or list of strings
- `file` – A file-like object to stream output to. Defaults to `sys.stdout`

Utils

Utility functions for pyqubes

Utilities have no dependencies.

`pyqubes.utils.assert_list_items_equal_in_nested(actual_nested, expected_list)`
Assert that the given `expected_list` matches one pf the lists within `actual_nested`, using the comparison `sorted(list)`

Parameters

- `actual_nested(list)` – A list of lists (usually generated by test)
- `expected_list(list)` – A list of expected values

`pyqubes.utils.flatten_list(nested_list)`

Flatten a nested list one level.

Parameters `nested_list(list)` – A nested list

Return type list

`pyqubes.utils.object_fullname(obj)`
Returns the full absolute name of the object provided

`pyqubes.utils.object_logger(obj)`
Returns a correctly named logger for the given object.
Call as `self.logger = object_logger(self)`

Validate

Validate functions for pyqubes

These will return the original value if validation passes. Otherwise, `ValueError` will be raised

`pyqubes.validate.firewall_policy(policy)`
qvm-firewall policy string should match ^(allow|deny) \$

Parameters `policy(string)` – Policy string to check

Returns policy if valid, else ValueError

`pyqubes.validate.label_color(color)`

VM label color should be one of: * red * orange * yellow * green * blue * purple * black * gray

Parameters `color` (*string*) – Label color string to check

Returns color if valid, else ValueError

`pyqubes.validate.linux_hostname(hostname)`

Linux hostnames are recommended to match ^ [a-zA-Z0-9-] + (\. [a-zA-Z0-9-] +) * \$

Parameters `hostname` (*string*) – Hostname to check

Returns hostname if valid, else ValueError

`pyqubes.validate.linux_username(username)`

Linux usernames are recommended to match ^ [a-zA-Z_][a-zA-Z0-9_-]*\\$? \$

Parameters `username` (*string*) – Username to check

Returns username if valid, else ValueError

CHAPTER 4

Indices and tables

- genindex
- modindex
- search
