`pyscses` is a Python module that implements a site-explicit, one-dimensional Poisson-Boltzmann solver, used for modelling ionic space charge properties in solid materials. Space charge properties such as electrostatic potential, charge density and charge carrier distributions over the space charge region can be calculated using the Poisson-Boltzmann equation from the input of defect segregation energies and atomically resolved charge carrier positions. The grain boundary resistivity and activation energy can be calculated by extending the model using the calculated charge carrier distributions. `pyscses` also accounts for different approximations typically assumed when space charge formation is considered. These approximations include site explicit vs. continuum modelling, Mott-Schottky (single mobile defect species) and Gouy-Chapman (all defect species mobile) conditions, and whether the charge of the non-defective species should be considered. Full mathematical derivations, definitions and example code can be found in the [userguide](#).

API documentation can be found *here*:

Source code is available as a git repository at <https://github.com/bjmorgan/pyscses/tree/master/pyscses>.

# CHAPTER 1

---

## Installation

---

The simplest way to install `pyscscs` is to use `pip` to install from [PyPI](#):

```
pip install pyscscs
```

Alternatively, you can download the latest release from [GitHub](#), and install directly:

```
cd pyscscs
pip install -e .
```

which installs an editable (-e) version of `pyscscs` in your userspace.

Or clone the latest version from *GitHub* <<https://github.com/bjmorgan/pyscscs/releases>> with:

```
git clone git@github.com:bjmorgan/pyscscs.git
```

and install the same way:

```
cd pyscscs
pip install -e .
```

## CHAPTER 2

---

### Tests

---

Jupyter notebooks that can be used to check the output of the calculations can be found in:

`pyscscs/tests/test_notebooks`

The test notebooks can be found on github [here](#).

There are four directories with varying conditions. In each there is a Jupyter notebook which can be run. The input for the calculations is stored in the `input_data` directory and the output for the calculations will be stored in the `generated_data` directory and can be compared to the verified data in the `expected_outputs` directory. A list of the input parameters used in the notebooks is reiterated in each of the four test folders in the `input_parameters` file.

## CHAPTER 3

---

### Documentation

---

Once installed, the `pyscscs` code is imported into, and run using a [Jupyter notebook](#). An overview of the capabilities of `pyscscs`, with example code for running the code and varying the simulation conditions can be found in:

```
pyscscs/userguides/userguide.ipynb
```

or the Jupyter notebook can be found on GitHub [here](#).

API documentation is available [here](#).

## CHAPTER 4

---

### Scientific context

---

In polycrystalline solid materials, grain boundaries and interfaces exist separating different crystalline domains. The structural distortion at these interfaces causes segregation of charge carriers to, or away from the grain boundary core. Due to this, the grain boundary core carries a net charge which causes the depletion or accumulation of charge carriers in the regions adjacent, known as space charge regions. Due to the variation on charge carrier concentrations, the ionic conductivity of the material can be strongly affected by the presence of grain boundaries.

## 5.1 pyscses

### 5.1.1 pyscses package

#### Submodules

#### **pyscses.calculation module**

**class** pyscses.calculation.**Calculation**(*grid, bulk\_x\_min, bulk\_x\_max, alpha, convergence,*  
*dielectric, temp, boundary\_conditions*)

The Calculation class contains methods for calculating the relevant space charge properties for any given system, such as electrostatic potential, charge density, defect mole fractions and parallel and perpendicular grain boundary resistivities.

**Parameters**

- **grid** (`pyscses.Grid`) – A `pyscses.Grid` object. This contains properties of the grid including the x coordinates and the volumes.
- **bulk\_x\_min** (`float`) – The minimum x coordinate defining a region of bulk.
- **bulk\_x\_max** (`float`) – The maximum x coordinate defining a region of bulk.
- **alpha** (`float`) – A damping parameter for updating the potential at each iteration.
- **convergence** (`float`) – The convergence limit. The difference between the updated phi and the phi from the previous iteration must be below this for the calculation to be sufficiently converged.
- **dielectric** (`float`) – The dielectric constant for the studied material.
- **temp** (`float`) – The temperature that the calculation is run.
- **boundary\_conditions** (`str`) – Specified boundary conditions for the matrix solver. Allowed values are *dirichlet* and *periodic*. Default = *dirichlet*.

**calculate\_average** (`grid, min_cut_off, max_cut_off, sc_property`)

Calculate the average of a given space charge property over a given region.

**Parameters**

- **grid** (`pyscses.Grid`) – Contains properties of the grid including the x coordinates and the volumes. Used to access the x coordinates.
- **min\_cut\_off** (`float`) – Minimum x coordinate value defining the calculation region.
- **max\_cut\_off** (`float`) – Maximum x coordinate value defining the calculation region.
- **sc\_property** (`list`) – Value of space charge property at all sites.

**Returns** The average value for the property over the given sites.

**Return type** float

**calculate\_debye\_length** ()

Calculate the [Debye length](#).

The output is stored as a Calculation attribute. `Calculation.debye_length` (float): The Debye length as derived from Poisson-Boltzmann equation.

**Parameters** None –

**calculate\_delta\_x** (`grid, min_cut_off, max_cut_off`)

Calculates the distance between the midpoints of each consecutive site. Inserts the calculated distance to the next grid point outside of the calculation region to the first and last position as the `delta_x` value for the endmost sites.

**Parameters**

- **grid** (`pyscses.Grid`) – Contains properties of the grid including the x coordinates and the volumes. Used to access the x coordinates.
- **min\_cut\_off** (`float`) – Minimum x coordinate value defining the calculation region.
- **max\_cut\_off** (`float`) – Maximum x coordinate value defining the calculation region.

**Returns** Distance between consecutive sites.

**Return type** list

**calculate\_mobile\_defect\_conductivities** (*pos\_or\_neg\_scr*, *scr\_limit*, *species*, *mobility\_scaling=False*)

Calculate the conductivity ratio between the space charge region and the bulk both perpendicular and parallel to the grain boundary.

A *Set\_of\_Sites* object is created for the sites in the space charge region, and the defect distributions calculated. The width of the space charge region is calculated and a bulk region of the same width is defined. A *Set\_of\_Sites* object for the bulk region is created and the defect distributions calculated. Taking each site as a resistor in series or parallel respectively, the conductivity is calculated and the ratio between the space charge region and the bulk is taken.

#### Parameters

- **pos\_or\_neg\_scr** (*str*) – ‘positive’ - for a positive space charge potential. ‘negative’ - for a negative space charge potential.
- **scr\_limit** (*float*) – The minimum electrostatic potential that the electrostatic potential must exceed to be included in the space charge region.
- **species** (*str*) – The species for which the conductivity is being calculated.
- **mobility\_scaling** (*bool*) – For particles on a lattice which only interact through volume exclusion, the mobility exhibits a blocking term. True if the blocking term is to be included, False if the blocking term is not to be included. Default = False.

**Returns** The perpendicular conductivity ratio. The conductivity ratio between the bulk and the space charge region perpendicular to the grain boundary. float: The parallel conductivity ratio. The conductivity ratio between the bulk and the space charge region parallel to the grain boundary.

**Return type** float

**calculate\_offset** (*grid*, *min\_cut\_off*, *max\_cut\_off*)

Calculate the offset between the midpoint of the last x coordinate in the calculation region and the x coordinate outside of the calculation region.

#### Parameters

- **grid** (*pyscses.Grid*) – Contains properties of the grid including the x coordinates and the volumes. Used to access the x coordinates.
- **min\_cut\_off** (*float*) – Minimum x coordinate value defining the calculation region.
- **max\_cut\_off** (*float*) – Maximum x coordinate value defining the calculation region.

**Returns** Offset for the minimum x coordinate. float: Offset for the maximum x coordinate.

**Return type** float

**calculate\_resistivity\_ratio** (*pos\_or\_neg\_scr*, *scr\_limit*, *mobility\_scaling=False*)

Each species present in the system is looped over and the perpendicular and parallel conductivity ratios are calculated and appended to separate lists. Once all species have been added to the list, the conductivities are summed and the reciprocal taken to give the resistivity ratios perpendicular and parallel to the grain boundary. The outputs are stored as calculation attributes, *Calculation.perpendicular\_resistivity\_ratio(float)*, *Calculation.parallel\_resistivity\_ratio(float)*:  $r_{gb}^{\perp}$ ,  $r_{gb}^{\parallel}$ : The perpendicular and parallel grain boundary resistivity ratios. :param pos\_or\_neg\_scr: ‘positive’ - for a positive space charge potential.

‘negative’ - for a negative space charge potential.

#### Parameters

- **scr\_limit** (*float*) – The minimum electrostatic potential that the electrostatic potential must exceed to be included in the space charge region.

- **mobility\_scaling** (*bool*) – For particles on a lattice which only interact through volume exclusion, the mobility exhibits a blocking term. True if the blocking term is to be included, False if the blocking term is not to be included. Default = False.

**calculate\_space\_charge\_width** (*valence*)

Calculate the approximate space charge width from the Debye length. The output is stores as a Calculation attribute. Calculation.space\_charge\_width (*float*): The approximate space charge width.

**Parameters** **valence** (*float*) – The charge of the mobile defect species.

**create\_space\_charge\_region** (*grid, pos\_or\_neg\_scr, scr\_limit*)

Calculate the space charge region. The space charge region is defined as the region when the electrostatic potential is greater than a predefined limit.

**Parameters**

- **grid** (*pyscses.Grid*) – Grid object - contains properties of the grid including the x coordinates and the volumes. Used to access the x coordinates.
- **pos\_or\_neg\_scr** (*str*) – ‘positive’ - for a positive space charge potential. ‘negative’ - for a negative space charge potential.
- **scr\_limit** (*float*) – The minimum electrostatic potential that the electrostatic potential must exceed to be included in the space charge region.

**Returns** List of x coordinates for sites within the space charge region.

**Return type** list

**create\_subregion\_sites** (*grid, min\_cut\_off, max\_cut\_off*)

Creates a *pyscses.Set\_of\_Sites* object for a defined region of the grid.

**Parameters**

- **grid** (*object*) – Grid object - contains properties of the grid including the x coordinates and the volumes. Used to access the x coordinates.
- **min\_cut\_off** (*float*) – Minimum x coordinate value defining the calculation region.
- **max\_cut\_off** (*float*) – Maximum x coordinate value defining the calculation region.

**Returns** Set of Sites object for a given subregion of the grid.

**Return type** *pyscses.SetOfSites*

**find\_index** (*grid, min\_cut\_off, max\_cut\_off*)

Calculates the indices of the grid positions closest to a minimum and maximum value.

**Parameters**

- **grid** (*pyscses.Grid*) – *pyscses.Grid* object. This contains properties of the grid including the x coordinates and the volumes. Used to access the x coordinates.
- **min\_cut\_off** (*float*) – Minimum x coordinate value defining the calculation region.
- **max\_cut\_off** (*float*) – Maximum x coordinate value defining the calculation region.

**Returns** Index for minimum cutoff; index for maximum cutoff

**Return type** int, int

**form\_subgrids** (*site\_labels*)

Creates a *pyscses.Grid* object for each species in the system. The output is a dictionary of separate Grid classes for the different site species and is stored as Calculation.subgrids.

Parameters **site\_labels** (*list*) – List of strings for the different site species.

**mole\_fraction\_correction** (*target\_mole\_fractions, approximation, initial\_guess*)

Starting from an initial guess for the appropriate input mole fractions, minimises the error between the target bulk mole fraction and the output mole fraction from the iterative Poisson-Boltzmann solver. The output is stored as a Calculation attribute. Calculation.initial\_guess (*list*): The optimum values to be used as the input mole fractions for the iterative Poisson-Boltzmann solver so that the output bulk mole fractions are the target bulk mole fractions.

#### Parameters

- **target\_mole\_fractions** (*list*) – The value that the mole fractions should be in the bulk.
- **approximation** (*str*) – The defect mobility approximation. Either ‘mott-schottky’ to enforce only a single mobile defect, or ‘gouy-chapman’ to allow all defect species to redistribute.
- **initial\_guess** (*list*) – Values for an initial guess for the defect mole fractions used in the error minimisation.

**mole\_fraction\_error** (*input\_mole\_fractions, target\_mole\_fractions, approximation*)

Calculates the sum of squares error between the output mole fractions calculated from the input mole fractions, compared to the target mole fractions.

#### Parameters

- **input\_mole\_fractions** (*list*) – Mole fractions for each of the species used in the iterative Poisson-Boltzmann solver.
- **target\_mole\_fractions** (*list*) – The value that the mole fractions should be in the bulk.

**Returns** Sum of squares error between output and target mole fractions.

**Return type** float

**mole\_fraction\_output** (*input\_mole\_fractions, approximation*)

Calculates the output mole fraction for a given input mole fraction when solving the Poisson-Boltzmann equation.

#### Parameters

- **input\_mole\_fractions** (*list*) – Mole fractions for each of the species used in the iterative Poisson-Boltzmann solver.
- **approximation** (*str*) – The defect mobility approximation. Either ‘mott-schottky’ to enforce only a single mobile defect, or ‘gouy-chapman’ to allow all defect species to redistribute.

**Returns** Mole fractions that are calculated from the iterative Poisson-Boltzmann solver.

**Return type** list

**mole\_fractions** ()

Calculate the mole fractions (probability of defects occupation) for each site on the subgrid for each species. The output is stored as a Calculation attribute. Calculation.mf (*dict*): A dictionary of the defect species mole fractions for each site on the subgrid for each site species. :param None:

**solve** (*approximation*)

Self-consistent solving of the Poisson-Boltzmann equation. Iterates until the convergence is less than the convergence limit. The outputs are stored as Calculation attributes. Calculation.phi (*array*): Electrostatic

potential on a one-dimensional grid. `Calculation.rho` (array): Charge density on a one-dimensional grid. `Calculation.niter` (int): Number of iterations performed to reach convergence.

**Parameters** `approximation` (*str*) – Approximation used for the defect behaviour. ‘mott-schottky’ - Some defects immobile / fixed to bulk mole fractions. ‘gouy-chapman’ - All defects mobile / able to redistribute.

`solve_MS_approx_for_phi` (*valence*)

**Calculate the space-charge potential,  $\phi_0$ , from the grain-boundary resistivity ratio, within the Mott-Schottky approx**

Within the Mott-Schottky approximation the grain boundary resistivity is related to the space-charge potential (the electrostatic potential at the grain boundary core, compared to the bulk value) according to

$$r_{gb} =$$

$$\frac{\rho_{gb}}{\rho_{\infty}} = \frac{\exp(z_{\phi_0} / V_{th})}{2z_{\phi_0} / V_{th}}$$

where

$$V_{th} =$$

$$\frac{k_B T}{q}.$$

(See e.g. S. Kim, Phys. Chem. Chem. Phys. 18, 19787 (2016).)

This allows a Mott-Schottky space-charge potential,  $\phi_{0,MS}$ , to be calculated using the [LambertW](#) function:

$$\phi_{0,MS} = -\text{LambertW} ($$

$$\frac{1}{2} \frac{r_{gb}}{V_{th}} z_{\phi_0} )$$

The output is stored as a `Calculation` attribute. `Calculation.ms_phi` (float):  $\phi_{0,MS}$ . The space charge potential calculated from Mott-Schottky model.

**Args:** `valence` (float): Charge of the mobile defect species.

**Raises:** `ValueError`: If the calculated resistivity ratio is less than 1.36, the `LambertW` function returns a complex, non-physical value.

`pyscscs.calculation.calculate_activation_energies` (*ratios, temp*)

Solves the Arrhenius equation using the calculated resistivity ratio for a series of temperatures to calculate the activation energy for single defect segregation.

Uses a central difference approach so endpoints filled in with NaN to create an array with the same length as the args.

**Parameters**

- `ratios` (*list*) – Resistivity ratios calculated for a range of temperatures.
- `temp` (*list*) – Temperature (values used to calculate resistivity ratio values).

**Returns** The activation energy calculated for different temperatures.

**Return type** `numpy.array`

`pyscscs.calculation.diff_central` (*x, y*)

Calculate the numerical derivative of x,y data using a central difference approximation.

**Parameters**

- **x** (*numpy.array*) – x values.
- **y** (*numpy.array*) – y values.

**Returns** numerical derivative of x,y

**Return type** numpy.array

## pyscses.constants module

## pyscses.defect\_at\_site module

**class** pyscses.defect\_at\_site.**Defect\_at\_Site** (*label, valence, mole\_fraction, mobility, energy, site, fixed=False*)

The Defect\_at\_Site class contains the information about each defect at each site, its valence, mole fraction and the segregation energy for that defect at that site.

The methods in this class combine to give the correct statistics for site occupation in solid electrolytes, derived from the electrochemical potentials of a Fermi-Dirac like distribution. This term has been split into three functions for simplicity. The resulting equations take into account that the probability that a site is occupied by a defect can not exceed 1, and also accounts for competition of like charged defects. A Mott-Schottky approximation can be enforced. The defects can be fixed to their bulk mole fractions throughout the system, equivalent to assuming that the defects are immobile and not allowed to redistribute through the system.

### **label**

string describing the defect species i.e. ‘Vo’ for an oxygen vacancy.

**Type** string

### **valence**

The charge of the defect, in atomic units.

**Type** float

### **mole\_fraction**

The bulk mole fraction of the defect present in the system.

**Type** float

### **mobility**

The bulk mobility of the defect species. Default = 0.0.

**Type** float

### **energy**

The segregation energy for the defect when occupying the respective site.

**Type** float

### **site**

The pyscses.Site object that corresponding to each defect at each x coordinate.

**Type** Site

### **fixed**

set whether this defect species can redistribute to an equilibrium distribution. Default=False.

**Type** bool

### **boltzmann\_one** (*phi, temp*)

Boltzmann statistics calculation - part one

$$\exp\left(\frac{\Phi z + \Delta E}{k_B T}\right)$$

#### Parameters

- **phi** (*float*) – Electrostatic potential.
- **temp** (*float*) – Temperature of calculation.

**Returns** Boltzmann statistics

**Return type** float

**boltzmann\_three** (*phi, temp*)

Boltzmann statistics calculation - part three

$$x \left( \exp \left( \frac{\Phi z + \Delta E}{K_B T} \right) - 1 \right)$$

#### Parameters

- **phi** (*float*) – Electrostatic potential.
- **temp** (*float*) – Temperature of calculation.

**Returns** ( Boltzmann statistics - 1 ) \* mole fraction.

**Return type** float

**boltzmann\_two** (*phi, temp*)

Boltzmann statistics calculation - part two

$$x \exp \left( \frac{\Phi z + \Delta E}{K_B T} \right)$$

#### Parameters

- **phi** (*float*) – Electrostatic potential.
- **temp** (*float*) – Temperature of calculation.

**Returns** Boltzmann statistics \* mole fraction

**Return type** float

**potential\_energy** (*phi*)

Potential energy for the defect at this site.

**Parameters** **phi** (*float*) – electrostatic potential at this site

**Returns** The electrochemical potential.

**Return type** float

### pyscses.defect\_species module

**class** pyscses.defect\_species.**DefectSpecies** (*label, valence, mole\_fraction, mobility=0.0, fixed=False*)

The DefectSpecies class includes the properties of each defect species present in the system.

#### Parameters

- **label** (*string*) – refers to what the defect is called i.e. ‘Vo’ for an oxygen vacancy.
- **valence** (*float*) – The charge of the defect, in atomic units.
- **mole\_fraction** (*float*) – The bulk mole fraction of the defect present in the system.

- **fixed** (*bool*) – Whether the defect species can redistribute to an equilibrium distribution or whether the defect species is considered immobile and fixed to it's bulk mole fraction. Default=False.
- **mobility** (*float*) – Mobility of the defect species. Default = 0.0.

## pyscses.grid module

**class** pyscses.grid.**Grid**(*x\_coordinates, b, c, limits, limits\_for\_laplacian, set\_of\_sites*)

**average\_site\_energies** (*method='mean'*)

Returns the average segregation energy for all grid points based on a specified method

**Parameters** **method** (*str*) – The method in which the average segregation energies will be calculated. 'mean' - Returns the sum of all values at that site divided by the number of values at that site. 'min' - Returns the minimum segregation energy value for that site (appropriate for low temperature calculations).

**Returns** Average segregation energies on a 1D grid.

**Return type** average site energies (np.array)

**charge** (*phi, temp*)

Calculates the overall charge at each point on a grid.

**Parameters**

- **phi** (*np.array*) – Electrostatic potential on a 1D grid.
- **temp** (*float*) – Temperature of calculation.

**Returns** Overall charge at each point on a 1D grid.

**Return type** charge (np.array)

**defect\_valences** ()

**Returns** Valences for each defect from self.defects

**Return type** (np.array)

**classmethod** **grid\_from\_set\_of\_sites** (*set\_of\_sites, limits, limits\_for\_laplacian, b, c*)

Creates a grid from a given Set\_of\_Sites object.

**Parameters**

- **set\_of\_sites** (*object*) – Set\_of\_Sites object containing a set of all Site objects.
- **limits** (*list*) – distance between the midpoint of the endmost sites and the midpoint of the next site outside of the calculation region for the first and last sites respectively.
- **limits\_for\_laplacian** (*list*) – distance between the endmost sites and the next site outside of the calculation region for the first and last sites respectively.
- **b** (*float*) – b dimension for every grid-point.
- **c** (*float*) – c dimension for every grid-point.

**Returns** Grid object for the given set of sites.

**Return type** *Grid*

**interpolated\_energies** ()

**Returns** The average site energies linearly interpolated onto a regularly spaced grid

**Return type** energies (list)

**rho** (*phi*, *temp*)

Calculates charge density at each point on a grid, by dividing the overall charge at that grid point by the grid point volume.

**Parameters**

- **phi** (*np.array*) – Electrostatic potential on a 1D grid.
- **temp** (*float*) – Temperature of calculation.

**Returns** The charge density at each point on a grid.

**Return type** rho (*np.array*)

**subgrid** (*subset\_species*)

Creates a subgrid for each species.

**Parameters** **subset\_species** (*str*) – Site species to separate into subgrid.

**Returns** Grid object for subset of data.

**Return type** *Grid*

**class** pyscses.grid.**Grid\_Point** (*x*, *volume*)

The Grid\_Point class contains the information and calculations for each grid point individually

**average\_site\_energy** (*method='mean'*)

Returns the average segregation energy for all sites based on a specified method

**Parameters** **method** (*str*) – The method in which the average segregation energies will be calculated. 'mean' - Returns the sum of all values at that site divided by the number of values at that site. 'min' - Returns the minimum segregation energy value for that site (appropriate for low temperature calculations).

**Returns** Average segregation energies on a 1D grid.

**Return type** average site energies (*np.array*)

pyscses.grid.**avg** (*energies*, *method='mean'*)

Returns the average segregation energy for a site based on a specified method

**Parameters**

- **energies** (*np.array*) – Segregation energies on 1D grid.
- **method** (*str*) – The method in which the average segregation energies will be calculated. 'mean' - Returns the sum of all values at that site divided by the number of values at that site. 'min' - Returns the minimum segregation energy value for that site (appropriate for low temperature calculations).

**Returns** Average segregation energies on a 1D grid.

**Return type** average site energies (*np.array*)

pyscses.grid.**closest\_index** (*myList*, *myNumber*)

Assumes myList is sorted. Returns index of closest value to myNumber. If two numbers are equally close, return the index of the smallest number.

**Parameters**

- **myList** (*list*) – List of numbers to compare against. This should be sorted.
- **myNumber** (*float*) – The number to compare against myList.

**Returns** Index of position of number in myList which is closest to myNumber.

**Return type** pos (int)

`pyscses.grid.delta_x_from_grid(coordinates, limits)`

Calculates the distance between the midpoints of each consecutive site. Inserts the calculated distance to the next grid point outside of the calculation region to the first and last position as the delta\_x value for the endmost sites. :param coordinates: 1D grid of ordered numbers over a region. :type coordinates: np.array :param limits: Distance between the midpoint of the endmost sites and the midpoint of the repective site outside of the calculation region. :type limits: list

**Returns** Distance between the midpoints of each consecutive site.

**Return type** delta\_x (np.array)

`pyscses.grid.energy_at_x(energy, coordinates, x)`

Assigns each site x coordinate a grid point and returns the segregation energy at the grid point closest to the x coordinate.

**Parameters**

- **energy** (np.array) – Segregation energies on 1D grid.
- **coordinates** (np.array) – 1D grid of ordered numbers over a region.
- **x** (float) – Site x coordinate.

**Returns** The segregation energy at the x coordinate with position [index].

**Return type** energy[index] (float)

`pyscses.grid.index_of_grid_at_x(coordinates, x)`

Assigns each site x coordinate to a position on a regularly or irregularly spaced grid. Returns the index of the grid point closest to the value x

**Parameters**

- **coordinates** (np.array) – 1D grid of ordered numbers over a region.
- **x** (float) – Site x coordinate

**Returns** Index of grid position closest to the site x coordinate.

**Return type** closest\_index (int)

`pyscses.grid.phi_at_x(phi, coordinates, x)`

Assigns each site x coordinate a grid point and returns the electrostatic potential at the grid point closest to the x coordinate.

**Parameters**

- **phi** (np.array) – electrostatic potential on 1D grid.
- **coordinates** (np.array) – 1D grid of ordered numbers over a region.
- **x** (float) – Site x coordinate.

**Returns** The electrostatic potential at the x coordinate with position [index].

**Return type** phi[index] (float)

## pyscses.matrix\_solver module

`class pyscses.matrix_solver.MatrixSolver(grid, dielectric, temp, boundary_conditions='dirichlet')`

Contains the functions for the finite difference methods used to solve the Poisson-Boltzmann equation on a one-dimensional grid.

**laplacian\_new\_fullmatrix()**

Creates the full tridiagonal matrix used to solve the Poisson-Boltzmann equation using a finite element method. *deltax* is taken as the width of each grid point, from the center point between itself and the next grid point on either side. Using a finite difference approximation the diagonal becomes  $-2.0 / (\text{deltax}_1 * \text{deltax}_2)$ , the upper diagonal becomes  $2.0 / ((\text{deltax}_1 + \text{deltax}_2) * \text{deltax}_2)$  and the lower diagonal becomes  $2.0 / ((\text{deltax}_1 + \text{deltax}_2) * \text{deltax}_1)$ . If *boundary\_conditions* are 'periodic', the corner elements of the matrix are filled.

**Parameters** *None* –

**Returns** Full tridiagonal matrix.

**Return type** A (matrix)

**laplacian\_sparse()**

Creates a sparse matrix from a full matrix by taking only the tridiagonal values. :param *None*:

**Returns** Sparse tridiagonal matrix.

**Return type** A (matrix)

**solve(*phi\_old*)**

Uses matrix inversion to solve the Poisson-Boltzmann equation through finite difference methods. The defect mole fractions are calculated from the electrostatic potential, the charge density is calculated from the defect mole fractions and the electrostatic potential is then updated using the updated charge density. If *boundary\_conditions* are 'periodic', the charge density is minimised before the matrix inversion.

**Parameters** *phi\_old* (*array*) – Electrostatic potential on a one-dimensional grid.

**Returns** Updated electrostatic potential on a one-dimensional grid. *rho* (*array*): Updated charge density on a one-dimensional grid.

**Return type** *predicted\_phi* (*array*)

**pyscses.set\_of\_sites module****class pyscses.set\_of\_sites.Set\_of\_Sites(*sites*)**

The *Set\_of\_Sites* object groups together all of the *Site* objects into one object and contains functions for the calculations that provide properties of all of the sites together rather than individually.

**calculate\_defect\_density(*grid, phi, temp*)**

Calculates the defect density at each site.

**Parameters**

- **grid** (*object*) – Grid object - contains properties of the grid including the x coordinates and the volumes. Used to access the x coordinates.
- **phi** (*array*) – electrostatic potential on a one-dimensional grid.
- **temp** (*float*) – Absolute temperature.

**Returns** defect density for each site using their grid points

**Return type** *array*

**calculate\_energies\_on\_grid(*grid, phi*)**

Returns an array of energies at their points on a one-dimensional grid.

**Parameters**

- **grid** (*object*) – Grid object - contains properties of the grid including the x coordinates and the volumes. Used to access the x coordinates.

- **phi** (*array*) – electrostatic potential on a one-dimensional grid.

**Returns** energies at their grid points

**Return type** array

**calculate\_probabilities** (*grid, phi, temp*)

Calculates the probability of a site being occupied by its corresponding defect.

**Parameters**

- **grid** (*object*) – Grid object - contains properties of the grid including the x coordinates and the volumes. Used to access the x coordinates.
- **phi** (*array*) – electrostatic potential on a one-dimensional grid.
- **temp** (*float*) – Absolute temperature.

**Returns** probabilities of defects occupying each site using their grid points

**Return type** array

**classmethod core\_width\_analysis** (*input\_data, limits, defect\_species, site\_charge, core, temperature*)

Calculated the width of the ‘core’ region. This is given as the region where the segregation energies in the system are within a region of positive to negative kT.

**Parameters**

- **input\_data** (*file*) – A .txt file where each line includes information about a site.
- **limits** (*list*) – Minimum and maximum x coordinates defining the calculation region.
- **defect\_species** (*object*) – Class object containing information about the defect species present in the system.
- **site\_charge** (*bool*) – The site charge refers to the contribution to the overall charge of a site given by the original, non-defective species present at that site. True if the site charge contribution is to be included in the calculation, False if it is not to be included.
- **core** (*str*) – Core definition. Allowed keywords: ‘single’ = Single segregation energy used to define the core. ‘multi-site’ = Layered segregation energies used to define the core while the energies fall in the region of positive and negative kT. ‘all’ = All sites between a minimum and maximum x coordinate used in calculation.
- **temperature** (*float*) – Temperature that the calculation is being run at.

**Returns** Distance between the minimum and maximum x coordinates where the segregation energy is in the range of positive to negative kT.

**Return type** float

**form\_continuum\_sites** (*x\_min, x\_max, n\_points, b, c, defect\_species, limits\_for\_laplacian, site\_labels, defect\_labels*)

Creates a Set\_of\_Sites object for sites interpolated onto a regular grid, this is equivalent to assuming a continuum approximation.

**Parameters**

- **all\_sites** (*object*) – Original Set\_of\_Sites object from full data.
- **x\_min** (*float*) – Minimum x coordinate value defining the calculation region.
- **x\_max** (*float*) – Maximum x coordinate value defining the calculation region.
- **n\_points** (*int*) – Number of points that the data should be interpolated on to.

- **b** (*float*) – b dimension for every grid point.
- **c** (*float*) – c dimension for every grid point.
- **defect\_species** (*object*) – Class object containing information about the defect species present in the system.
- **for\_laplacian** (*limits*) – distance between the endmost sites and the midpoint of the next site outside of the calculation region for the first and last sites respectively.
- **site\_labels** (*list*) – List of strings for the different site species.
- **defect\_labels** (*list*) – List of strings for the different defect species.

**Returns** Sites interpolated onto a regular grid.

**Return type** *Set\_of\_Sites*

**get\_coords** (*label*)

Returns a list of the x coordinates for all the sites which contain a particular defect

**Parameters** **label** (*str*) – Label identifying the required defect species.

**Returns** List of sites for a specific defect species.

**Return type** *list*

**classmethod** **set\_of\_sites\_from\_input\_data** (*input\_data*, *limits*, *defect\_species*, *site\_charge*, *core*, *temperature*, *offset=0.0*)

Takes the data from the input file and creates a *Set\_of\_Sites* object for those sites. The input data file is a .txt file where each line in the file corresponds to a site. The values in each line are formatted and separated into the corresponding properties before creating a *Site* object for each site.

**Parameters**

- **input\_data** (*file*) – A .txt file where each line includes the information about a site.
- **limits** (*list*) – Minimum and maximum x coordinated defining the calculation region.
- **defect\_species** (*object*) – Class object containing information about the defect species present in the system.
- **site\_charge** (*bool*) – The site charge refers to the contribution to the overall charge of a site given by the original, non-defective species present at that site. True if the site charge contribution is to be included in the calculation, False if it is not to be included.
- **core** (*str*) – Core definition. ‘single’ = Single segregation energy used to define the core. ‘multi-site’ = Layered segregation energies used to define the core while the energies fall in the region of positive and negative kT. ‘all’ = All sites between a minimum and maximum x coordinate used in calculation.
- **temperature** (*float*) – Temperature that the calculation is being run at.

**Returns** *Set\_of\_Sites* object for the input data.

**Return type** *Set\_of\_Sites*

**subgrid\_calculate\_defect\_density** (*sub\_grid*, *full\_grid*, *phi*, *temp*)

Calculates the defect density at each site for a given subset of sites.

**Parameters**

- **subgrid** (*object*) – Grid object - contains properties of the grid including the x coordinates and the volumes. Used to access the x coordinates. For a given subset of sites.
- **full\_grid** (*object*) – Grid object - contains properties of the grid including the x coordinates and the volumes. Used to access the x coordinates. For all sites.

- **phi** (*array*) – electrostatic potential on a one-dimensional grid.
- **temp** (*float*) – Absolute temperature.

**Returns** defect density for each site using their grid points

**Return type** array

**subset** (*label*)

Returns a list of all the sites which contain a particular defect

## pyscses.set\_up\_calculation module

`pyscses.set_up_calculation.average_similar_sites` (*input\_data*)

Corrects for rounding errors in the input data. Sites within 0.02nm are taken as the same site, therefore the x coordinate values are averaged to prevent the formation of separate sites.

**Parameters** **input\_data** (*str*) – The input file.

**Returns** The input file, formatted with x coordinate values within 0.02nm averaged and set to the same value.

**Return type** str

`pyscses.set_up_calculation.calculate_grid_offsets` (*filename, x\_min, x\_max, system*)

Reads in the input data calculates the distance to the next site outside of the defined calculation region. Allows calculation of the delta\_x and volume values for the endmost grid points.

**Parameters**

- **filename** (*string*) – Filename for importing the input data.
- **x\_min** (*float*) – Minimum x coordinate value defining the calculation region.
- **x\_max** (*float*) – Maximum x coordinate value defining the calculation region.
- **system** (*str*) – ‘single’ for single grain boundary systems, ‘double’ for systems where the input data has been mirrored to give two grain boundaries.

**Returns** distance between the midpoint of the endmost sites and the midpoint of the next site outside of the calculation region for the first and last sites respectively. Distance between the endmost sites and the next site outside of the calculation region for the first and last sites respectively.

**Return type** list, list

`pyscses.set_up_calculation.format_line` (*line, site\_charge, offset=0.0*)

Each line in the input file is formatted into separate site properties.

**Parameters**

- **line** (*str*) – A line in the input file.
- **site\_charge** (*bool*) – The site charge refers to the contribution to the overall charge of a site given by the original, non-defective species present at that site. True if the site charge contribution is to be included in the calculation, False if it is not to be included.

**Returns** line from the input file, split into individual values.

**Return type** list

`pyscses.set_up_calculation.load_site_data` (*filename, x\_min, x\_max, site\_charge, offset=0.0*)

Reads in the input data and formats the input data if the x coordinate values are within the calculation region.

**Parameters**

- **filename** (*string*) – Filename for importing the input data.
- **x\_min** (*float*) – Minimum x coordinate value defining the calculation region.
- **x\_max** (*float*) – Maximum x coordinate value defining the calculation region.
- **site\_charge** (*bool*) – True if site charges are to be included in the calculation, false if they are not to be included.

**Returns** formatted data for calculation.

**Return type** list

`pyscscs.set_up_calculation.site_from_input_file(site, defect_species, site_charge, core, temperature)`

Takes the data from the input file and converts it into a site. The input data file is a .txt file where each line in the file corresponds to a site. The values in each line are formatted and separated into the corresponding properties before creating a Site object for each site.

**Parameters**

- **site** (*str*) – A line in the input file.
- **defect\_species** (*object*) – Class object containing information about the defect species present in the system.
- **site\_charge** (*bool*) – The site charge refers to the contribution to the overall charge of a site given by the original, non-defective species present at that site. True if the site charge contribution is to be included in the calculation, False if it is not to be included.

**Returns** Site

## pyscscs.site module

**class** `pyscscs.site.Site` (*label, x, defect\_species, defect\_energies, scaling=None, valence=0*)

The site class contains all the information about a given site and the defect occupying that site. This class contains functions for the calculations which correspond to each individual site, rather than the system as a whole.

**Parameters**

- **label** (*str*) – refers to what the defect is called i.e. ‘Vo’ for an oxygen vacancy.
- **x** (*float*) – x coordinate of the site.
- **defect\_energies** (*list*) – List of segregation energies for all defects present at the site.
- **defect\_species** (*list*) – List of defect species for all defects present at the site.
- **defects** (*list*) – List of Defect\_at\_Site objects, containing the properties of all individual defects at the site.
- **scaling** (*float*) – A scaling factor that can be applied in the charge calculation.
- **valence** (*float*) – The charge of the defect present at the site (in atomic units).
- **defects** – List of Defect\_Species objects for all defects present at the site.
- **sites** (*list*) – List containing all x coordinates and corresponding defect segregation energies.

**average\_local\_energy** (*method*='mean')

Returns the average local segregation energy for each site based on a specified method

**Parameters** **method** (*str*) – The method in which the average segregation energies will be calculated. ‘mean’ - Returns the sum of all values at that site divided by the number of values at that site. ‘min’ - Returns the minimum segregation energy value for that site (appropriate for low temperature calculations).

**Returns** Average segregation energies on the site coordinates grid.

**Return type** numpy.array

**charge** (*phi*, *temp*)

Calculates the overall charge in Coulombs at each site.

**Parameters**

- **phi** (*float*) – Electrostatic potential at this site.
- **temp** (*float*) – Temperature of calculation.

**Returns** The charge on a 1D grid.

**Return type** np.array

**charge\_boltz** (*phi*, *temp*)

Calculates the charge in Coulombs at each site using Boltzmann probabilities.

**Parameters**

- **phi** (*float*) – Electrostatic potential at this site
- **temp** (*float*) – Temperature of calculation.

**Returns** The charge on a 1D grid.

**Return type** np.array

**defect\_valences** ()

Returns an array of valences for each defect from self.defects

**defect\_with\_label** (*label*)

Returns a list of defects which correspond to the given label

**Parameters** **label** (*str*) – Label to identify defect species.

**Returns** List of Defect\_at\_Site objects for a specific defect species.

**Return type** list

**energies** ()

Returns a list of the segregation energies for each defect from self.defects

**probabilities** (*phi*, *temp*)

Calculates the probability of each site being occupied. Derived from the chemical potential term for a Fermi-Dirac like distribution.

**Parameters**

- **phi** (*float*) – Electrostatic potential at this site.
- **temp** (*float*) – Temperature of calculation.

**Returns** Probabilities of site occupation on a 1D grid.

**Return type** list

**probabilities\_boltz** (*phi*, *temp*)

Calculates the probability of each site being occupied by a given defect. Derived from the chemical potential including a Boltzmann distribution.

**Parameters**

- **phi** (*float*) – Electrostatic potential at this site.
- **temp** (*float*) – Temperature of calculation.

**Returns** Probabilities of site occupation on a 1D grid.

**Return type** list

**sum\_of\_boltzmann\_three** (*phi*, *temp*)

Calculates the sum of the calculated boltzmann\_three values for each defect at each site. i

$$\sum (x_i \exp(-\Phi_x z / kT) - 1)$$

**Parameters**

- **phi** (*float*) – Electrostatic potential at the site.
- **temp** (*float*) – Temperature of calculation in Kelvin.

**Returns** The sum of Boltzmann terms.

**Return type** float

**Module contents**
