TensorLayer is a Deep Learning (DL) and Reinforcement Learning (RL) library extended from Google TensorFlow. It provides popular DL and RL modules that can be easily customized and assembled for tackling real-world machine learning problems.

Note: If you got problem to read the docs online, you could download the repository on GitHub, then go to /docs/_build/html/index.html to read the docs offline. The _build folder can be generated in docs using make html.

CHAPTER 1

User Guide

The TensorLayer user guide explains how to install TensorFlow, CUDA and cuDNN, how to build and train neural networks using TensorLayer, and how to contribute to the library as a developer.

1.1 Installation

TensorLayer has some prerequisites that need to be installed first, including TensorFlow, numpy and matplotlib. For GPU support CUDA and cuDNN are required.

If you run into any trouble, please check the TensorFlow installation instructions which cover installing the TensorFlow for a range of operating systems including Mac OX, Linux and Windows, or ask for help on tensorlayer@gmail.com or FQA.

1.1.1 Step 1 : Install dependencies

TensorLayer is build on the top of Python-version TensorFlow, so please install Python first.

Note: We highly recommend python3 instead of python2 for the sake of future.

Python includes pip command for installing additional modules is recommended. Besides, a virtual environment via virtualenv can help you to manage python packages.

Take Python3 on Ubuntu for example, to install Python includes pip, run the following commands:

```
sudo apt-get install python3
sudo apt-get install python3-pip
sudo pip3 install virtualenv
```

To build a virtual environment and install dependencies into it, run the following commands: (You can also skip to Step 3, automatically install the prerequisites by TensorLayer)

```
virtualenv env
env/bin/pip install matplotlib
env/bin/pip install numpy
env/bin/pip install scipy
env/bin/pip install scikit-image
```

To check the installed packages, run the following command:

```
env/bin/pip list
```

After that, you can run python script by using the virtual python as follow.

```
env/bin/python *.py
```

1.1.2 Step 2: TensorFlow

The installation instructions of TensorFlow are written to be very detailed on TensorFlow website. However, there are something need to be considered. For example, TensorFlow officially supports GPU acceleration for Linux, Mac OX and Windows at present.

Warning: For ARM processor architecture, you need to install TensorFlow from source.

1.1.3 Step 3: TensorLayer

The simplest way to install TensorLayer is as follow, it will also install the numpy and matplotlib automatically.

```
[stable version] pip install tensorlayer
[master version] pip install git+https://github.com/zsdonghao/tensorlayer.git
```

However, if you want to modify or extend TensorLayer, you can download the repository from Github and install it as follow.

```
cd to the root of the git tree pip install -e .
```

This command will run the setup.py to install TensorLayer. The -e reflects editable, then you can edit the source code in tensorlayer folder, and import the edited TensorLayer.

1.1.4 Step 4 : GPU support

Thanks to NVIDIA supports, training a fully connected network on a GPU, which may be 10 to 20 times faster than training them on a CPU. For convolutional network, may have 50 times faster. This requires an NVIDIA GPU with CUDA and cuDNN support.

CUDA

The TensorFlow website also teach how to install the CUDA and cuDNN, please see TensorFlow GPU Support. Download and install the latest CUDA is available from NVIDIA website:

· CUDA download and install

If CUDA is set up correctly, the following command should print some GPU information on the terminal:

```
python -c "import tensorflow"
```

cuDNN

Apart from CUDA, NVIDIA also provides a library for common neural network operations that especially speeds up Convolutional Neural Networks (CNNs). Again, it can be obtained from NVIDIA after registering as a developer (it take a while):

Download and install the latest cuDNN is available from NVIDIA website:

· cuDNN download and install

To install it, copy the *.h files to /usr/local/cuda/include and the lib* files to /usr/local/cuda/lib64.

1.1.5 Windows User

TensorLayer is built on the top of Python-version TensorFlow, so please install Python first. NoteWe highly recommend installing Anaconda. The lowest version requirements of Python is py35.

Anaconda download

GPU support

Thanks to NVIDIA supports, training a fully connected network on a GPU, which may be 10 to 20 times faster than training them on a CPU. For convolutional network, may have 50 times faster. This requires an NVIDIA GPU with CUDA and cuDNN support.

1. Installing Microsoft Visual Studio

You should preinstall Microsoft Visual Studio (VS) before installing CUDA. The lowest version requirements is VS2010. We recommend installing VS2015 or VS2013. CUDA7.5 supports VS2010, VS2012 and VS2013. CUDA8.0 also supports VS2015.

2. Installing CUDA

Download and install the latest CUDA is available from NVIDIA website:

CUDA download

We do not recommend modifying the default installation directory.

3. Installing cuDNN

The NVIDIA CUDA® Deep Neural Network library (cuDNN) is a GPU-accelerated library of primitives for deep neural networks. Download and extract the latest cuDNN is available from NVIDIA website:

cuDNN download

After extracting cuDNN, you will get three folders (bin, lib, include). Then these folders should be copied to CUDA installation. (The default installation directory is *C:\Program Files\NVIDIA GPU Computing Toolkit\CUDA\v8.0*)

1.1. Installation 5

Installing TensorLayer

You can easily install Tensorlayer using pip in CMD

```
pip install tensorflow #CPU version
pip install tensorflow-gpu #GPU version (GPU version and CPU version just choose_
→one)
pip install tensorlayer #Install tensorlayer
```

Test

Enter "python" in CMD. Then:

```
import tensorlayer
```

If there is no error and the following output is displayed, the GPU version is successfully installed.

```
successfully opened CUDA library cublas64_80.dll locally successfully opened CUDA library cuDNN64_5.dll locally successfully opened CUDA library cufft64_80.dll locally successfully opened CUDA library nvcuda.dll locally successfully opened CUDA library curand64_80.dll locally
```

If there is no error, the CPU version is successfully installed.

1.1.6 Issue

If you get the following output when import tensorlayer, please read FQA.

```
_tkinter.TclError: no display name and no $DISPLAY environment variable
```

1.2 Tutorial

For deep learning, this tutorial will walk you through building handwritten digits classifiers using the MNIST dataset, arguably the "Hello World" of neural networks. For reinforcement learning, we will let computer learns to play Pong game from the original screen inputs. For nature language processing, we start from word embedding, and then describe language modeling and machine translation.

This tutorial includes all modularized implementation of Google TensorFlow Deep Learning tutorial, so you could read TensorFlow Deep Learning tutorial as the same time [en] [cn] .

Note: For experts: Read the source code of InputLayer and DenseLayer, you will understand how TensorLayer work. After that, we recommend you to read the codes on Github directly.

1.2.1 Before we start

The tutorial assumes that you are somewhat familiar with neural networks and TensorFlow (the library which Tensor-Layer is built on top of). You can try to learn the basic of neural network from the Deeplearning Tutorial.

For a more slow-paced introduction to artificial neural networks, we recommend Convolutional Neural Networks for Visual Recognition by Andrej Karpathy et al., Neural Networks and Deep Learning by Michael Nielsen.

To learn more about TensorFlow, have a look at the TensorFlow tutorial. You will not need all of it, but a basic understanding of how TensorFlow works is required to be able to use TensorLayer. If you're new to TensorFlow, going through that tutorial.

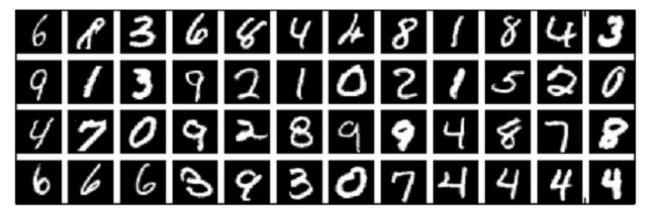

1.2.2 TensorLayer is simple

The following code shows a simple example of TensorLayer, see tutorial_mnist_simple.py. We provide a lot of simple functions like fit(), test()), however, if you want to understand the details and be a machine learning expert, we suggest you to train the network by using TensorFlow's methods like sess.run(), see tutorial_mnist.py for more details.

```
import tensorflow as tf
import tensorlayer as tl
sess = tf.InteractiveSession()
# prepare data
X_train, y_train, X_val, y_val, X_test, y_test = \
                                tl.files.load_mnist_dataset(shape=(-1,784))
# define placeholder
x = tf.placeholder(tf.float32, shape=[None, 784], name='x')
y_ = tf.placeholder(tf.int64, shape=[None, ], name='y_')
# define the network
network = tl.layers.InputLayer(x, name='input_layer')
network = tl.layers.DropoutLayer(network, keep=0.8, name='drop1')
network = tl.layers.DenseLayer(network, n_units=800,
                                act = tf.nn.relu, name='relu1')
network = t1.layers.DropoutLayer(network, keep=0.5, name='drop2')
network = tl.layers.DenseLayer(network, n_units=800,
                                act = tf.nn.relu, name='relu2')
network = t1.layers.DropoutLayer(network, keep=0.5, name='drop3')
\# the softmax is implemented internally in tl.cost.cross_entropy(y, y_, 'cost') to
# speed up computation, so we use identity here.
# see tf.nn.sparse_softmax_cross_entropy_with_logits()
network = tl.layers.DenseLayer(network, n_units=10,
                                act = tf.identity,
                                name='output laver')
# define cost function and metric.
y = network.outputs
cost = tl.cost.cross_entropy(y, y_, 'cost')
correct_prediction = tf.equal(tf.argmax(y, 1), y_)
acc = tf.reduce_mean(tf.cast(correct_prediction, tf.float32))
y_op = tf.argmax(tf.nn.softmax(y), 1)
# define the optimizer
train_params = network.all_params
train_op = tf.train.AdamOptimizer(learning_rate=0.0001, beta1=0.9, beta2=0.999,
                            epsilon=1e-08, use_locking=False).minimize(cost, var_
→list=train_params)
# initialize all variables in the session
tl.layers.initialize_global_variables(sess)
```

(continues on next page)

1.2.3 Run the MNIST example

In the first part of the tutorial, we will just run the MNIST example that's included in the source distribution of TensorLayer. MNIST dataset contains 60000 handwritten digits that is commonly used for training various image processing systems, each of digit has 28x28 pixels.

We assume that you have already run through the *Installation*. If you haven't done so already, get a copy of the source tree of TensorLayer, and navigate to the folder in a terminal window. Enter the folder and run the tutorial_mnist.py example script:

```
python tutorial_mnist.py
```

If everything is set up correctly, you will get an output like the following:

```
tensorlayer: GPU MEM Fraction 0.300000
Downloading train-images-idx3-ubyte.gz
Downloading train-labels-idx1-ubyte.gz
Downloading t10k-images-idx3-ubyte.gz
Downloading t10k-labels-idx1-ubyte.gz

 val acc: 0.983700
```

The example script allows you to try different models, including Multi-Layer Perceptron, Dropout, Dropconnect, Stacked Denoising Autoencoder and Convolutional Neural Network. Select different models from if __name__ == ' main ':.

```
main_test_layers(model='relu')
main_test_denoise_AE(model='relu')
main_test_stacked_denoise_AE(model='relu')
main_test_cnn_layer()
```

1.2.4 Understand the MNIST example

Let's now investigate what's needed to make that happen! To follow along, open up the source code.

Preface

The first thing you might notice is that besides TensorLayer, we also import numpy and tensorflow:

```
import tensorflow as tf
import tensorlayer as t1
from tensorlayer.layers import set_keep
import numpy as np
import time
```

As we know, TensorLayer is built on top of TensorFlow, it is meant as a supplement helping with some tasks, not as a replacement. You will always mix TensorLayer with some vanilla TensorFlow code. The set_keep is used to access the placeholder of keeping probabilities when using Denoising Autoencoder.

Loading data

The first piece of code defines a function <code>load_mnist_dataset()</code>. Its purpose is to download the MNIST dataset (if it hasn't been downloaded yet) and return it in the form of regular numpy arrays. There is no TensorLayer involved at all, so for the purpose of this tutorial, we can regard it as:

X_train.shape is (50000, 784), to be interpreted as: 50,000 images and each image has 784 pixels. y_train.shape is simply (50000,), which is a vector the same length of X_train giving an integer class label for each image – namely, the digit between 0 and 9 depicted in the image (according to the human annotator who drew that digit).

For Convolutional Neural Network example, the MNIST can be load as 4D version as follow:

```
X_train, y_train, X_val, y_val, X_test, y_test = \
    tl.files.load_mnist_dataset(shape=(-1, 28, 28, 1))
```

X_train.shape is (50000, 28, 28, 1) which represents 50,000 images with 1 channel, 28 rows and 28 columns each. Channel one is because it is a grey scale image, every pixel have only one value.

Building the model

This is where TensorLayer steps in. It allows you to define an arbitrarily structured neural network by creating and stacking or merging layers. Since every layer knows its immediate incoming layers, the output layer (or output layers) of a network double as a handle to the network as a whole, so usually this is the only thing we will pass on to the rest of the code.

As mentioned above, tutorial_mnist.py supports four types of models, and we implement that via easily exchangeable functions of the same interface. First, we'll define a function that creates a Multi-Layer Perceptron (MLP) of a fixed architecture, explaining all the steps in detail. We'll then implement a Denosing Autoencoder (DAE), after that we will then stack all Denoising Autoencoder and supervised fine-tune them. Finally, we'll show how to create a Convolutional Neural Network (CNN). In addition, a simple example for MNIST dataset in tutorial_mnist_simple.py, a CNN example for CIFAR-10 dataset in tutorial_cifar10_tfrecord.py.

Multi-Layer Perceptron (MLP)

The first script, main_test_layers(), creates an MLP of two hidden layers of 800 units each, followed by a softmax output layer of 10 units. It applies 20% dropout to the input data and 50% dropout to the hidden layers.

To feed data into the network, TensofFlow placeholders need to be defined as follow. The None here means the network will accept input data of arbitrary batchsize after compilation. The x is used to hold the X_train data and y_ is used to hold the y_train data. If you know the batchsize beforehand and do not need this flexibility, you should give the batchsize here – especially for convolutional layers, this can allow TensorFlow to apply some optimizations.

```
x = tf.placeholder(tf.float32, shape=[None, 784], name='x')
y_ = tf.placeholder(tf.int64, shape=[None, ], name='y_')
```

The foundation of each neural network in TensorLayer is an *InputLayer* instance representing the input data that will subsequently be fed to the network. Note that the InputLayer is not tied to any specific data yet.

```
network = tl.layers.InputLayer(x, name='input_layer')
```

Before adding the first hidden layer, we'll apply 20% dropout to the input data. This is realized via a DropoutLayer instance:

```
network = tl.layers.DropoutLayer(network, keep=0.8, name='drop1')
```

Note that the first constructor argument is the incoming layer, the second argument is the keeping probability for the activation value. Now we'll proceed with the first fully-connected hidden layer of 800 units. Note that when stacking a <code>DenseLayer</code>.

```
network = tl.layers.DenseLayer(network, n_units=800, act = tf.nn.relu, name='relu1')
```

Again, the first constructor argument means that we're stacking network on top of network. n_units simply gives the number of units for this fully-connected layer. act takes an activation function, several of which are defined in tensorflow.nn and *tensorlayer.activation*. Here we've chosen the rectifier, so we'll obtain ReLUs. We'll now add dropout of 50%, another 800-unit dense layer and 50% dropout again:

```
network = tl.layers.DropoutLayer(network, keep=0.5, name='drop2')
network = tl.layers.DenseLayer(network, n_units=800, act = tf.nn.relu, name='relu2')
network = tl.layers.DropoutLayer(network, keep=0.5, name='drop3')
```

Finally, we'll add the fully-connected output layer which the n_units equals to the number of classes. Note that, the softmax is implemented internally in tf.nn.sparse_softmax_cross_entropy_with_logits() to speed up computation, so we used identity in the last layer, more details in tl.cost.cross_entropy().

As mentioned above, each layer is linked to its incoming layer(s), so we only need the output layer(s) to access a network in TensorLayer:

```
y = network.outputs
y_op = tf.argmax(tf.nn.softmax(y), 1)
cost = tf.reduce_mean(tf.nn.sparse_softmax_cross_entropy_with_logits(y, y_))
```

Here, network.outputs is the 10 identity outputs from the network (in one hot format), y_op is the integer output represents the class index. While cost is the cross-entropy between target and predicted labels.

Denoising Autoencoder (DAE)

Autoencoder is an unsupervised learning model which is able to extract representative features, it has become more widely used for learning generative models of data and Greedy layer-wise pre-train. For vanilla Autoencoder see Deeplearning Tutorial.

The script main_test_denoise_AE() implements a Denoising Autoencoder with corrosion rate of 50%. The Autoencoder can be defined as follow, where an Autoencoder is represented by a DenseLayer:

To train the DenseLayer, simply run ReconLayer.pretrain(), if using denoising Autoencoder, the name of corrosion layer (a DropoutLayer) need to be specified as follow. To save the feature images, set save to True. There are many kinds of pre-train metrices according to different architectures and applications. For sigmoid activation, the Autoencoder can be implemented by using KL divergence, while for rectifer, L1 regularization of activation outputs can make the output to be sparse. So the default behaviour of ReconLayer only provide KLD and cross-entropy for sigmoid activation function and L1 of activation outputs and mean-squared-error for rectifing activation function. We recommend you to modify ReconLayer to achieve your own pre-train metrice.

In addition, the script $main_test_stacked_denoise_AE$ () shows how to stacked multiple Autoencoder to one network and then fine-tune.

Convolutional Neural Network (CNN)

Finally, the main_test_cnn_layer() script creates two CNN layers and max pooling stages, a fully-connected hidden layer and a fully-connected output layer. More CNN examples can be found in the tutorial scripts, like tutorial_cifar10_tfrecord.py.

At the begin, we add a <code>Conv2dLayer</code> with 32 filters of size 5x5 on top, follow by max-pooling of factor 2 in both dimensions. And then apply a <code>Conv2dLayer</code> with 64 filters of size 5x5 again and follow by a max_pool again. After that, flatten the 4D output to 1D vector by using <code>FlattenLayer</code>, and apply a dropout with 50% to last hidden layer. The ? represents arbitrary batch size.

Note, tutorial_mnist.py introduces the simplified CNN API for beginner.

```
network = tl.layers.InputLayer(x, name='input_layer')
network = tl.layers.Conv2dLayer(network,
                        act = tf.nn.relu,
                        shape = [5, 5, 1, 32], # 32 features for each 5x5 patch
                        strides=[1, 1, 1, 1],
                        padding='SAME',
                        name ='cnn_layer1')
                                               # output: (?, 28, 28, 32)
network = tl.layers.PoolLayer(network,
                        ksize=[1, 2, 2, 1],
                        strides=[1, 2, 2, 1],
                        padding='SAME',
                        pool = tf.nn.max_pool,
                        name ='pool_layer1',)
                                               # output: (?, 14, 14, 32)
network = tl.layers.Conv2dLayer(network,
                        act = tf.nn.relu,
                        shape = [5, 5, 32, 64], # 64 features for each 5x5 patch
                        strides=[1, 1, 1, 1],
                        padding='SAME',
                        name = 'cnn_layer2')
                                                # output: (?, 14, 14, 64)
network = tl.layers.PoolLayer(network,
                        ksize=[1, 2, 2, 1],
                        strides=[1, 2, 2, 1],
                        padding='SAME',
                        pool = tf.nn.max_pool,
                        name = 'pool_layer2',)
                                                # output: (?, 7, 7, 64)
network = tl.layers.FlattenLayer(network, name='flatten_layer')
                                                # output: (?, 3136)
network = tl.layers.DropoutLayer(network, keep=0.5, name='drop1')
                                                 # output: (?, 3136)
network = tl.layers.DenseLayer(network, n_units=256, act = tf.nn.relu, name='relu1')
                                                 # output: (?, 256)
network = tl.layers.DropoutLayer(network, keep=0.5, name='drop2')
                                                 # output: (?, 256)
network = tl.layers.DenseLayer(network, n_units=10,
                act = tf.identity, name='output_layer')
                                                # output: (?, 10)
```

Note: For experts: Conv2dLayer will create a convolutional layer using tensorflow.nn.conv2d, TensorFlow's default convolution.

Training the model

The remaining part of the tutorial_mnist.py script copes with setting up and running a training loop over the MNIST dataset by using cross-entropy only.

Dataset iteration

An iteration function for synchronously iterating over two numpy arrays of input data and targets, respectively, in mini-batches of a given number of items. More iteration function can be found in tensorlayer.iterate

```
tl.iterate.minibatches(inputs, targets, batchsize, shuffle=False)
```

Loss and update expressions

Continuing, we create a loss expression to be minimized in training:

```
y = network.outputs
y_op = tf.argmax(tf.nn.softmax(y), 1)
cost = tf.reduce_mean(tf.nn.sparse_softmax_cross_entropy_with_logits(y, y_))
```

More cost or regularization can be applied here, take main_test_layers() for example, to apply max-norm on the weight matrices, we can add the following line:

Depending on the problem you are solving, you will need different loss functions, see tensorlayer.cost for more.

Having the model and the loss function defined, we create update expressions for training the network. TensorLayer do not provide many optimizers, we used TensorFlow's optimizer instead:

For training the network, we fed data and the keeping probabilities to the feed dict.

```
feed_dict = {x: X_train_a, y_: y_train_a}
feed_dict.update( network.all_drop )
sess.run(train_op, feed_dict=feed_dict)
```

While, for validation and testing, we use slightly different way. All dropout, dropconnect, corrosion layers need to be disable. tl.utils.dict_to_one set all network.all_drop to 1.

```
dp_dict = tl.utils.dict_to_one( network.all_drop )
feed_dict = {x: X_test_a, y_: y_test_a}
feed_dict.update(dp_dict)
err, ac = sess.run([cost, acc], feed_dict=feed_dict)
```

As an additional monitoring quantity, we create an expression for the classification accuracy:

```
correct_prediction = tf.equal(tf.argmax(y, 1), y_)
acc = tf.reduce_mean(tf.cast(correct_prediction, tf.float32))
```

What Next?

We also have a more advanced image classification example in tutorial_cifar10_tfrecord.py. Please read the code and notes, figure out how to generate more training data and what is local response normalization. After that, try to implement Residual Network (Hint: you may want to use the Layer.outputs).

1.2.5 Run the Pong Game example

In the second part of the tutorial, we will run the Deep Reinforcement Learning example that is introduced by Karpathy in Deep Reinforcement Learning: Pong from Pixels.

```
python tutorial_atari_pong.py
```

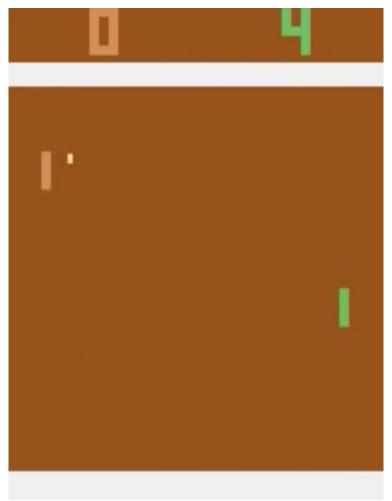

Before running the tutorial code, you need to install OpenAI gym environment which is a benchmark for Reinforcement Learning. If everything is set up correctly, you will get an output like the following:

```
[2016-07-12 09:31:59,760] Making new env: Pong-v0
  [TL] InputLayer input_layer (?, 6400)
  [TL] DenseLayer relu1: 200, relu
  [TL] DenseLayer output_layer: 3, identity
 param 0: (6400, 200) (mean: -0.000009, median: -0.000018 std: 0.017393)
 param 1: (200,) (mean: 0.000000, median: 0.000000 std: 0.000000)

episode 0: game 19 took 0.08674s, reward: -1.000000
episode 0: game 20 took 0.09628s, reward: -1.000000
resetting env. episode reward total was -20.000000. running mean: -20.000000
episode 1: game 0 took 0.09910s, reward: -1.000000
episode 1: game 1 took 0.17056s, reward: -1.000000
episode 1: game 2 took 0.09306s, reward: -1.000000
episode 1: game 3 took 0.09556s, reward: -1.000000
episode 1: game 4 took 0.12520s, reward: 1.000000 !!!!!!!!!
episode 1: game 5 took 0.17348s, reward: -1.000000
episode 1: game 6 took 0.09415s, reward: -1.000000
```

This example allow computer to learn how to play Pong game from the screen inputs, just like human behavior. After training for 15,000 episodes, the computer can win 20% of the games. The computer win 35% of the games at 20,000 episode, we can seen the computer learn faster and faster as it has more winning data to train. If you run it for 30,000 episode, it start to win.

```
render = False
resume = False
```

Setting render to True, if you want to display the game environment. When you run the code again, you can set resume to True, the code will load the existing model and train the model basic on it.

1.2.6 Understand Reinforcement learning

Pong Game

To understand Reinforcement Learning, we let computer to learn how to play Pong game from the original screen inputs. Before we start, we highly recommend you to go through a famous blog called Deep Reinforcement Learning: Pong from Pixels which is a minimalistic implementation of Deep Reinforcement Learning by using python-numpy and OpenAI gym environment.

python tutorial_atari_pong.py

Policy Network

In Deep Reinforcement Learning, the Policy Network is the same with Deep Neural Network, it is our player (or "agent") who output actions to tell what we should do (move UP or DOWN); in Karpathy's code, he only defined 2 actions, UP and DOWN and using a single simgoid output; In order to make our tutorial more generic, we defined 3 actions which are UP, DOWN and STOP (do nothing) by using 3 softmax outputs.

Then when our agent is playing Pong, it calculates the probabilities of different actions, and then draw sample (action) from this uniform distribution. As the actions are represented by 1, 2 and 3, but the softmax outputs should be start from 0, we calculate the label value by minus 1.

```
prob = sess.run(
    sampling_prob,
    feed_dict={states_batch_pl: x}
)
# action. 1: STOP 2: UP 3: DOWN
action = np.random.choice([1,2,3], p=prob.flatten())
...
ys.append(action - 1)
```

Policy Gradient

Policy gradient methods are end-to-end algorithms that directly learn policy functions mapping states to actions. An approximate policy could be learned directly by maximizing the expected rewards. The parameters of a policy function (e.g. the parameters of a policy network used in the pong example) could be trained and learned under the guidance of the gradient of expected rewards. In other words, we can gradually tune the policy function via updating its parameters, such that it will generate actions from given states towards higher rewards.

An alternative method to policy gradient is Deep Q-Learning (DQN). It is based on Q-Learning that tries to learn a value function (called Q function) mapping states and actions to some value. DQN employs a deep neural network to represent the Q function as a function approximator. The training is done by minimizing temporal-difference errors. A neurobiologically inspired mechanism called "experience replay" is typically used along with DQN to help improve its stability caused by the use of non-linear function approximator.

You can check the following papers to gain better understandings about Reinforcement Learning.

- Reinforcement Learning: An Introduction. Richard S. Sutton and Andrew G. Barto
- Deep Reinforcement Learning. David Silver, Google DeepMind
- · UCL Course on RL

The most successful applications of Deep Reinforcement Learning in recent years include DQN with experience replay to play Atari games and AlphaGO that for the first time beats world-class professional GO players. AlphaGO used the policy gradient method to train its policy network that is similar to the example of Pong game.

- Atari Playing Atari with Deep Reinforcement Learning
- Atari Human-level control through deep reinforcement learning
- AlphaGO Mastering the game of Go with deep neural networks and tree search

Dataset iteration

In Reinforcement Learning, we consider a final decision as an episode. In Pong game, a episode is a few dozen games, because the games go up to score of 21 for either player. Then the batch size is how many episode we consider to update the model. In the tutorial, we train a 2-layer policy network with 200 hidden layer units using RMSProp on batches of 10 episodes.

Loss and update expressions

Continuing, we create a loss expression to be minimized in training:

The loss in a batch is relate to all outputs of Policy Network, all actions we made and the corresponding discounted rewards in a batch. We first compute the loss of each action by multiplying the discounted reward and the cross-entropy between its output and its true action. The final loss in a batch is the sum of all loss of the actions.

What Next?

The tutorial above shows how you can build your own agent, end-to-end. While it has reasonable quality, the default parameters will not give you the best agent model. Here are a few things you can improve.

First of all, instead of conventional MLP model, we can use CNNs to capture the screen information better as Playing Atari with Deep Reinforcement Learning describe.

Also, the default parameters of the model are not tuned. You can try changing the learning rate, decay, or initializing the weights of your model in a different way.

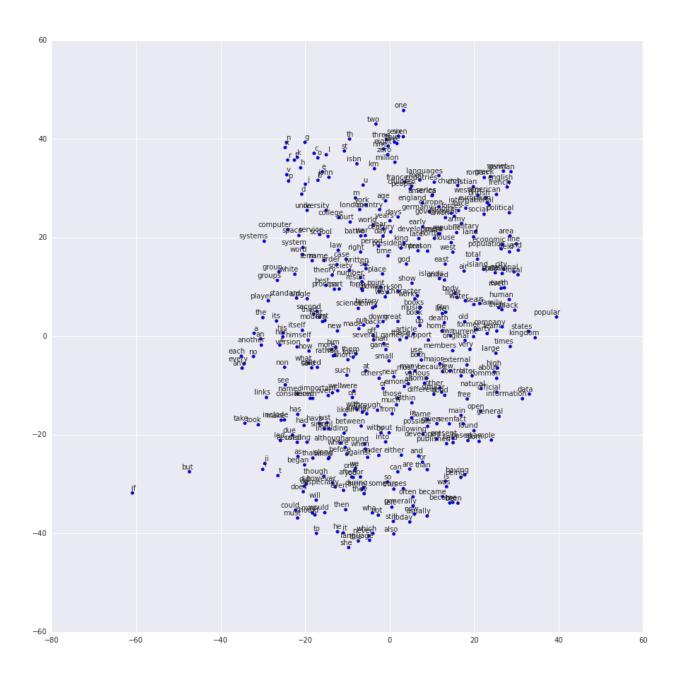

Finally, you can try the model on different tasks (games).

1.2.7 Run the Word2Vec example

In this part of the tutorial, we train a matrix for words, where each word can be represented by a unique row vector in the matrix. In the end, similar words will have similar vectors. Then as we plot out the words into a two-dimensional plane, words that are similar end up clustering nearby each other.

```
python tutorial_word2vec_basic.py
```

If everything is set up correctly, you will get an output in the end.

1.2.8 Understand Word Embedding

Word Embedding

We highly recommend you to read Colah's blog Word Representations to understand why we want to use a vector representation, and how to compute the vectors. (For chinese reader please click. More details about word2vec can be found in Word2vec Parameter Learning Explained.

Bascially, training an embedding matrix is an unsupervised learning. As every word is refected by an unique ID, which is the row index of the embedding matrix, a word can be converted into a vector, it can better represent the meaning. For example, there seems to be a constant male-female difference vector: woman man = queen - king, this means one dimension in the vector represents gender.

The model can be created as follow.

```
# train_inputs is a row vector, a input is an integer id of single word.
# train_labels is a column vector, a label is an integer id of single word.
# valid_dataset is a column vector, a valid set is an integer id of single word.
train_inputs = tf.placeholder(tf.int32, shape=[batch_size])
train_labels = tf.placeholder(tf.int32, shape=[batch_size, 1])
valid_dataset = tf.constant(valid_examples, dtype=tf.int32)
# Look up embeddings for inputs.
emb_net = tl.layers.Word2vecEmbeddingInputlayer(
       inputs = train_inputs,
        train_labels = train_labels,
        vocabulary_size = vocabulary_size,
        embedding_size = embedding_size,
        num_sampled = num_sampled,
        nce_loss_args = {},
        E_init = tf.random_uniform_initializer(minval=-1.0, maxval=1.0),
        E_init_args = {}
        nce_W_init = tf.truncated_normal_initializer(
                          stddev=float(1.0/np.sqrt(embedding_size))),
        nce_W_init_args = {},
        nce_b_init = tf.constant_initializer(value=0.0),
       nce_b_init_args = {},
       name = 'word2vec_layer',
    )
```

Dataset iteration and loss

Word2vec uses Negative Sampling and Skip-Gram model for training. Noise-Contrastive Estimation Loss (NCE) can help to reduce the computation of loss. Skip-Gram inverts context and targets, tries to predict each context word from its target word. We use tl.nlp.generate_skip_gram_batch to generate training data as follow, see tutorial_generate_text.py.

Restore existing Embedding matrix

In the end of training the embedding matrix, we save the matrix and corresponding dictionaries. Then next time, we can restore the matrix and directories as follow. (see main_restore_embedding_layer() in tutorial_generate_text.py)

```
vocabulary_size = 50000
embedding_size = 128
model file name = "model word2vec 50k 128"
batch_size = None
print("Load existing embedding matrix and dictionaries")
all_var = tl.files.load_npy_to_any(name=model_file_name+'.npy')
data = all_var['data']; count = all_var['count']
dictionary = all_var['dictionary']
reverse_dictionary = all_var['reverse_dictionary']
tl.nlp.save_vocab(count, name='vocab_'+model_file_name+'.txt')
del all_var, data, count
load_params = tl.files.load_npz(name=model_file_name+'.npz')
x = tf.placeholder(tf.int32, shape=[batch_size])
y_ = tf.placeholder(tf.int32, shape=[batch_size, 1])
emb_net = tl.layers.EmbeddingInputlayer(
                inputs = x,
                vocabulary_size = vocabulary_size,
                embedding_size = embedding_size,
                name ='embedding_layer')
tl.layers.initialize_global_variables(sess)
tl.files.assign_params(sess, [load_params[0]], emb_net)
```

1.2.9 Run the PTB example

Penn TreeBank (PTB) dataset is used in many LANGUAGE MODELING papers, including "Empirical Evaluation and Combination of Advanced Language Modeling Techniques", "Recurrent Neural Network Regularization". It consists of 929k training words, 73k validation words, and 82k test words. It has 10k words in its vocabulary.

The PTB example is trying to show how to train a recurrent neural network on a challenging task of language modeling.

Given a sentence "I am from Imperial College London", the model can learn to predict "Imperial College London" from "from Imperial College". In other word, it predict the next word in a text given a history of previous words. In the previous example, num_steps (sequence length) is 3.

```
python tutorial_ptb_lstm.py
```

The script provides three settings (small, medium, large), where a larger model has better performance. You can choose different settings in:

```
flags.DEFINE_string(
   "model", "small",
   "A type of model. Possible options are: small, medium, large.")
```

If you choose the small setting, you can see:

```
Epoch: 1 Learning rate: 1.000
0.004 perplexity: 5220.213 speed: 7635 wps
0.104 perplexity: 828.871 speed: 8469 wps
```

(continues on next page)

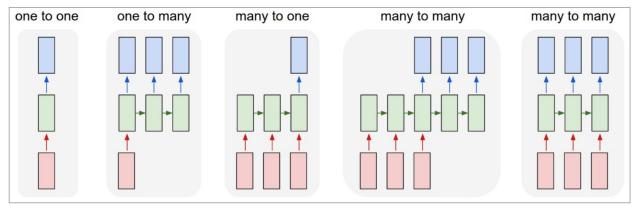

```
0.204 perplexity: 614.071 speed: 8839 wps
0.304 perplexity: 495.485 speed: 8889 wps
0.404 perplexity: 427.381 speed: 8940 wps
0.504 perplexity: 383.063 speed: 8920 wps
0.604 perplexity: 345.135 speed: 8920 wps
0.703 perplexity: 319.263 speed: 8949 wps
0.803 perplexity: 298.774 speed: 8975 wps
0.903 perplexity: 279.817 speed: 8986 wps
Epoch: 1 Train Perplexity: 265.558
Epoch: 1 Valid Perplexity: 178.436
Epoch: 13 Learning rate: 0.004
0.004 perplexity: 56.122 speed: 8594 wps
0.104 perplexity: 40.793 speed: 9186 wps
0.204 perplexity: 44.527 speed: 9117 wps
0.304 perplexity: 42.668 speed: 9214 wps
0.404 perplexity: 41.943 speed: 9269 wps
0.504 perplexity: 41.286 speed: 9271 wps
0.604 perplexity: 39.989 speed: 9244 wps
0.703 perplexity: 39.403 speed: 9236 wps
0.803 perplexity: 38.742 speed: 9229 wps
0.903 perplexity: 37.430 speed: 9240 wps
Epoch: 13 Train Perplexity: 36.643
Epoch: 13 Valid Perplexity: 121.475
Test Perplexity: 116.716
```

The PTB example shows that RNN is able to model language, but this example did not do something practically interesting. However, you should read through this example and "Understand LSTM" in order to understand the basics of RNN. After that, you will learn how to generate text, how to achieve language translation, and how to build a question answering system by using RNN.

1.2.10 Understand LSTM

Recurrent Neural Network

We personally think Andrey Karpathy's blog is the best material to Understand Recurrent Neural Network, after reading that, Colah's blog can help you to Understand LSTM Network [chinese] which can solve The Problem of Long-Term Dependencies. We will not describe more about the theory of RNN, so please read through these blogs before you go on.

Each rectangle is a vector and arrows represent functions (e.g. matrix multiply). Input vectors are in red, output vectors are in blue and green vectors hold the RNN's state (more on this soon). From left to right: (1) Vanilla mode of processing without RNN, from fixed-sized input to fixed-sized output (e.g. image classification). (2) Sequence output (e.g. image captioning takes an image and outputs a sentence of words). (3) Sequence input (e.g. sentiment analysis where a given sentence is classified as expressing positive or negative sentiment). (4) Sequence input and sequence output (e.g. Machine Translation: an RNN reads a sentence in English and then outputs a sentence in French). (5) Synced sequence input and output (e.g. video classification where we wish to label each frame of the video). Notice that in every case are no pre-specified constraints on the lengths sequences because the recurrent transformation (green) is fixed and can be applied as many times as we like.

Image by Andrey Karpathy

Synced sequence input and output

The model in PTB example is a typical type of synced sequence input and output, which was described by Karpathy as "(5) Synced sequence input and output (e.g. video classification where we wish to label each frame of the video). Notice that in every case there are no pre-specified constraints on the lengths of sequences because the recurrent transformation (green) can be applied as many times as we like."

The model is built as follows. Firstly, we transfer the words into word vectors by looking up an embedding matrix. In this tutorial, there is no pre-training on the embedding matrix. Secondly, we stack two LSTMs together using dropout between the embedding layer, LSTM layers, and the output layer for regularization. In the final layer, the model provides a sequence of softmax outputs.

The first LSTM layer outputs [batch_size, num_steps, hidden_size] for stacking another LSTM after it. The second LSTM layer outputs [batch_size*num_steps, hidden_size] for stacking a DenseLayer after it. Then the DenseLayer computes the softmax outputs of each example n_examples = batch size*num steps).

To understand the PTB tutorial, you can also read TensorFlow PTB tutorial.

(Note that, TensorLayer supports DynamicRNNLayer after v1.1, so you can set the input/output dropouts, number of RNN layers in one single layer)

(continues on next page)

```
cell_init_args={'forget_bias': 0.0},
            n hidden=hidden size,
            initializer=tf.random_uniform_initializer(-init_scale, init_scale),
            n_steps=num_steps,
            return_last=False,
            name='basic_lstm_layer1')
lstm1 = network
if is_training:
    network = t1.layers.DropoutLayer(network, keep=keep_prob, name='drop2')
network = tl.layers.RNNLayer(network,
            cell_fn=tf.contrib.rnn.BasicLSTMCell,
            cell_init_args={'forget_bias': 0.0},
            n_hidden=hidden_size,
            initializer=tf.random_uniform_initializer(-init_scale, init_scale),
            n_steps=num_steps,
            return_last=False,
            return_seq_2d=True,
            name='basic_lstm_layer2')
lstm2 = network
if is_training:
    network = t1.layers.DropoutLayer(network, keep=keep_prob, name='drop3')
network = tl.layers.DenseLayer(network,
            n_units=vocab_size,
            W_init=tf.random_uniform_initializer(-init_scale, init_scale),
            b_init=tf.random_uniform_initializer(-init_scale, init_scale),
            act = tf.identity, name='output_layer')
```

Dataset iteration

The batch_size can be seen as the number of concurrent computations we are running. As the following example shows, the first batch learns the sequence information by using items 0 to 9. The second batch learn the sequence information by using items 10 to 19. So it ignores the information from items 9 to 10 !n If only if we set batch_size = 1`, it will consider all the information from items 0 to 20.

The meaning of batch_size here is not the same as the batch_size in the MNIST example. In the MNIST example, batch_size reflects how many examples we consider in each iteration, while in the PTB example, batch_size is the number of concurrent processes (segments) for accelerating the computation.

Some information will be ignored if batch_size > 1, however, if your dataset is "long" enough (a text corpus usually has billions of words), the ignored information would not affect the final result.

In the PTB tutorial, we set batch_size = 20, so we divide the dataset into 20 segments. At the beginning of each epoch, we initialize (reset) the 20 RNN states for the 20 segments to zero, then go through the 20 segments separately.

An example of generating training data is as follows:

```
train_data = [i for i in range(20)]
for batch in tl.iterate.ptb_iterator(train_data, batch_size=2, num_steps=3):
    x, y = batch
    print(x, '\n',y)
```

```
... [[ 0 1 2] <---x 1st subset/ iteration
... [10 11 12]]
... [[ 1 2 3] <---y
... [11 12 13]]
```

(continues on next page)

Note: This example can also be considered as pre-training of the word embedding matrix.

Loss and update expressions

The cost function is the average cost of each mini-batch:

```
# See tensorlayer.cost.cross_entropy_seq() for more details
def loss_fn(outputs, targets, batch_size, num_steps):
    # Returns the cost function of Cross-entropy of two sequences, implement
    # softmax internally.
    # outputs : 2D tensor [batch_size*num_steps, n_units of output layer]
    # targets : 2D tensor [batch_size, num_steps], need to be reshaped.
    # n_examples = batch_size * num_steps
    # cost is the average cost of each mini-batch (concurrent process).
    loss = tf.nn.seq2seq.sequence_loss_by_example(
       [outputs],
       [tf.reshape(targets, [-1])],
       [tf.ones([batch_size * num_steps])])
   cost = tf.reduce_sum(loss) / batch_size
   return cost
# Cost for Training
cost = loss_fn(network.outputs, targets, batch_size, num_steps)
```

For updating, truncated backpropagation clips values of gradients by the ratio of the sum of their norms, so as to make the learning process tractable.

In addition, if the epoch index is greater than max_epoch, we decrease the learning rate by multipling lr_decay.

```
new_lr_decay = lr_decay ** max(i - max_epoch, 0.0)
sess.run(tf.assign(lr, learning_rate * new_lr_decay))
```

At the beginning of each epoch, all states of LSTMs need to be reseted (initialized) to zero states. Then after each iteration, the LSTMs' states is updated, so the new LSTM states (final states) need to be assigned as the initial states of the next iteration:

```
# set all states to zero states at the beginning of each epoch
state1 = tl.layers.initialize_rnn_state(lstm1.initial_state)
state2 = tl.layers.initialize_rnn_state(lstm2.initial_state)
for step, (x, y) in enumerate(tl.iterate.ptb_iterator(train_data,
                                            batch_size, num_steps)):
    feed_dict = {input_data: x, targets: y,
                lstm1.initial_state: state1,
                lstm2.initial_state: state2,
    # For training, enable dropout
   feed_dict.update( network.all_drop )
    # use the new states as the initial state of next iteration
   _cost, state1, state2, _ = sess.run([cost,
                                    lstm1.final_state,
                                    lstm2.final_state,
                                    train_op],
                                    feed_dict=feed_dict
   costs += _cost; iters += num_steps
```

Predicting

After training the model, when we predict the next output, we no long consider the number of steps (sequence length), i.e. batch_size, num_steps are set to 1. Then we can output the next word one by one, instead of predicting a sequence of words from a sequence of words.

```
input_data_test = tf.placeholder(tf.int32, [1, 1])
targets_test = tf.placeholder(tf.int32, [1, 1])
network_test, lstm1_test, lstm2_test = inference(input_data_test,
                      is_training=False, num_steps=1, reuse=True)
cost_test = loss_fn(network_test.outputs, targets_test, 1, 1)
print("Evaluation")
# Testing
# go through the test set step by step, it will take a while.
start_time = time.time()
costs = 0.0; iters = 0
# reset all states at the beginning
state1 = tl.layers.initialize_rnn_state(lstm1_test.initial_state)
state2 = t1.layers.initialize_rnn_state(lstm2_test.initial_state)
for step, (x, y) in enumerate(tl.iterate.ptb_iterator(test_data,
                                        batch_size=1, num_steps=1)):
    feed_dict = {input_data_test: x, targets_test: y,
                lstm1_test.initial_state: state1,
                lstm2_test.initial_state: state2,
                }
    _cost, state1, state2 = sess.run([cost_test,
                                    lstm1_test.final_state,
                                    lstm2_test.final_state],
                                    feed_dict=feed_dict
```

(continues on next page)

What Next?

Now, you have understood Synced sequence input and output. Let's think about Many to one (Sequence input and one output), so that LSTM is able to predict the next word "English" from "I am from London, I speak ..".

Please read and understand the code of tutorial_generate_text.py. It shows you how to restore a pre-trained Embedding matrix and how to learn text generation from a given context.

Karpathy's blog: "(3) Sequence input (e.g. sentiment analysis where a given sentence is classified as expressing positive or negative sentiment). "

1.2.11 Run the Translation example

```
python tutorial_translate.py
```

This script is going to training a neural network to translate English to French. If everything is correct, you will see.

- Download WMT English-to-French translation data, includes training and testing data.
- Create vocabulary files for English and French from training data.
- Create the tokenized training and testing data from original training and testing data.

```
Prepare raw data
Load or Download WMT English-to-French translation > wmt
Training data: wmt/giga-fren.release2

(continues on next page)

```
processing line 22500000
```

Firstly, we download English-to-French translation data from the WMT'15 Website. The training and testing data as follow. The training data is used to train the model, the testing data is used to evaluate the model.

As giga-fren.release2.* are the training data, the context of giga-fren.release2.fr look as follow.

```
Il a transformé notre vie | Il a transformé la société | Son fonctionnement | La,

```

The testing data newstest2013.en and newstest2013.fr look as follow.

```
newstest2013.en :
A Republican strategy to counter the re-election of Obama
Republican leaders justified their policy by the need to combat electoral fraud.
However, the Brennan Centre considers this a myth, stating that electoral fraud is_
interpretation in the United States than the number of people killed by lightning.

newstest2013.fr :
Une stratégie républicaine pour contrer la réélection d'Obama
Les dirigeants républicains justifièrent leur politique par la nécessité de lutter_
interpretation de la fraude électorale.
Or, le Centre Brennan considère cette dernière comme un mythe, affirmant que la infraude électorale est plus rare aux États-Unis que le nombre de personnes tuées par infraude foudre.
```

After downloading the dataset, it start to create vocabulary files, vocab40000.fr and vocab40000.en from the training data giga-fren.release2.fr and giga-fren.release2.en, usually it will take a while. The number 40000 reflects the vocabulary size.

The vocab40000.fr (381KB) stores one-item-per-line as follow.

```
PAD
_GO

```

After training the model for 350000 steps, you can play with the translation by switch main_train() to main_decode(). You type in a English sentence, the program will outputs a French sentence.

```
Reading model parameters from wmt/translate.ckpt-350000 > Who is the president of the United States? Qui est le président des États-Unis ?
```

1.2.12 Understand Translation

Seq2seq

Sequence to sequence model is commonly be used to translate a language to another. Actually it can do many thing you can't imagine, we can translate a long sentence into short and simple sentence, for example, translation going from Shakespeare to modern English. With CNN, we can also translate a video into a sentence, i.e. video captioning.

If you just want to use Seq2seq but not going to design a new algorithm, the only think you need to consider is the data format including how to split the words, how to tokenize the words etc. In this tutorial, we described a lot about data formating.

Basics

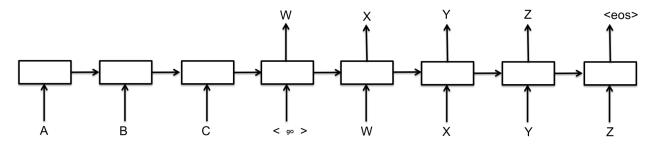

Sequence to sequence model is a type of "Many to many" but different with Synced sequence input and output in PTB tutorial. Seq2seq generates sequence output after feeding all sequence inputs. The following two methods can improve the accuracy:

- Reversing the inputs
- · Attention mechanism

To speed up the computation, we used:

• Sampled softmax

Karpathy's blog described Seq2seq as: "(4) Sequence input and sequence output (e.g. Machine Translation: an RNN reads a sentence in English and then outputs a sentence in French)."

As the above figure shows, the encoder inputs, decoder inputs and targets are:

```
encoder_input = A B C
decoder_input = <go> W X Y Z
targets = W X Y Z <eos>

Note: in the code, the size of targets is one smaller than the size
of decoder_input, not like this figure. More details will be show later.
```

Papers

The English-to-French example implements a multi-layer recurrent neural network as encoder, and an Attention-based decoder. It is the same as the model described in this paper:

• Grammar as a Foreign Language

The example uses sampled softmax to handle large output vocabulary size. In this example, as target_vocab_size=4000, for vocabularies smaller than 512, it might be a better idea to just use a standard softmax loss. Sampled softmax is described in Section 3 of the this paper:

On Using Very Large Target Vocabulary for Neural Machine Translation

Reversing the inputs and Multi-layer cells have been successfully used in sequence-to-sequence models for translation has beed described in this paper:

• Sequence to Sequence Learning with Neural Networks

Attention mechanism allows the decoder more direct access to the input, it was described in this paper:

• Neural Machine Translation by Jointly Learning to Align and Translate

Alternatively, the model can also be implemented by a single-layer version, but with Bi-directional encoder, was presented in this paper:

• Neural Machine Translation by Jointly Learning to Align and Translate

Implementation

Bucketing and Padding

(Note that, TensorLayer supports Dynamic RNN layer after v1.2, so bucketing is not longer necessary in many cases)

Bucketing is a method to efficiently handle sentences of different length. When translating English to French, we will have English sentences of different lengths L1 on input, and French sentences of different lengths L2 on output. We should in principle create a seq2seq model for every pair (L1, L2+1) (prefixed by a GO symbol) of lengths of an English and French sentence.

To minimize the number of buckets and find the closest bucket for each pair, then we could just pad every sentence with a special PAD symbol in the end if the bucket is bigger than the sentence

We use a number of buckets and pad to the closest one for efficiency. In this example, we used 4 buckets as follow.

```
buckets = [(5, 10), (10, 15), (20, 25), (40, 50)]
```

If the input is an English sentence with 3 tokens, and the corresponding output is a French sentence with 6 tokens, then they will be put in the first bucket and padded to length 5 for encoder inputs (English sentence), and length 10 for decoder inputs. If we have an English sentence with 8 tokens and the corresponding French sentence has 18 tokens, then they will be fit into (20, 25) bucket.

In other word, bucket (I, 0) is (encoder_input_size, decoder_inputs_size).

1.2. Tutorial 35

Given a pair of [["I", "go", "."], ["Je", "vais", "."]] in tokenized format, we fit it into bucket (5, 10). The training data of encoder inputs representing [PAD PAD "." "go" "I"] and decoder inputs [GO "Je" "vais" "." EOS PAD PAD PAD PAD PAD]. The targets are decoder inputs shifted by one. The target_weights is the mask of targets.

In this example, one sentence is represented by one column, so assume batch_size = 3, bucket = (5, 10) the training data will look like:

```
encoder_inputs
               decoder_inputs target_weights
                                               targets

                                       Ω
                                              0 0
                        0
                               0
               0
                    0
                                   Ω
                                        Ω
where 0 : _PAD
               1 : _GO
                          2 : _EOS
                                      3 : _UNK
```

During training, the decoder inputs are the targets, while during prediction, the next decoder input is the last decoder output.

Special vocabulary symbols, punctuations and digits

The special vocabulary symbols in this example are:

```
ID MEANINGS

_PAD 0 Padding, empty word

_GO 1 1st element of decoder_inputs

_EOS 2 End of Sentence of targets

_UNK 3 Unknown word, words do not exist in vocabulary will be marked as 3
```

For digits, the normalize_digits of creating vocabularies and tokenized dataset must be consistent, if normalize_digits=True all digits will be replaced by 0. Like 123 to 000`, 9 to 0 and 1990-05 to 0000-00, then 000, 0 and 0000-00 etc will be the words in the vocabulary (see vocab40000.en).

Otherwise, if normalize_digits=False, different digits will be seem in the vocabulary, then the vocabulary

```
size will be very big. The regular expression to find digits is _DIGIT_RE = re.compile(br"\d"). (see tl.
nlp.create_vocabulary() and tl.nlp.data_to_token_ids())
```

For word split, the regular expression is _WORD_SPLIT = re.compile(b"([.,!?\"':;)(])"), this means use the symbols like [. , ! ? " ' : ;) (] and space to split the sentence, see tl.nlp. basic_tokenizer() which is the default tokenizer of tl.nlp.create_vocabulary() and tl.nlp. data_to_token_ids().

All punctuation marks, such as . ,) (are all reserved in the vocabularies of both English and French.

Sampled softmax

Sampled softmax is a method to reduce the computation of cost so as to handle large output vocabulary. Instead of compute the cross-entropy of large output, we compute the loss from samples of num_samples.

Dataset iteration

The iteration is done by EmbeddingAttentionSeq2seqWrapper.get_batch, which get a random batch of data from the specified bucket, prepare for step. The data

Loss and update expressions

The EmbeddingAttentionSeq2seqWrapper has built in SGD optimizer.

What Next?

Try other applications.

1.2.13 More info

For more information on what you can do with TensorLayer, just continue reading through readthedocs. Finally, the reference lists and explains as follow.

```
layers (tensorlayer.layers),
activation (tensorlayer.activation),
natural language processing (tensorlayer.nlp),
reinforcement learning (tensorlayer.rein),
cost expressions and regularizers (tensorlayer.cost),
load and save files (tensorlayer.files),
operating system (tensorlayer.ops),
helper functions (tensorlayer.utils),
visualization (tensorlayer.visualize),
iteration functions (tensorlayer.iterate),
preprocessing functions (tensorlayer.prepro),
```

1.2. Tutorial 37

1.3 Example

1.3.1 Basics

• Multi-layer perceptron (MNIST). A multi-layer perceptron implementation for MNIST classification task, see tutorial_mnist_simple.py on GitHub.

1.3.2 Computer Vision

- Denoising Autoencoder (MNIST). A multi-layer perceptron implementation for MNIST classification task, see tutorial_mnist.py on GitHub.
- Stacked Denoising Autoencoder and Fine-Tuning (MNIST). A multi-layer perceptron implementation for MNIST classification task, see tutorial_mnist.py on GitHub.
- Convolutional Network (MNIST). A Convolutional neural network implementation for classifying MNIST dataset, see tutorial_mnist.py on GitHub.
- Convolutional Network (CIFAR-10). A Convolutional neural network implementation for classifying CIFAR-10 dataset, see tutorial_cifar10.py and "tutorial_cifar10_tfrecord.py" on GitHub.
- VGG 16 (ImageNet). A Convolutional neural network implementation for classifying ImageNet dataset, see tutorial_vgg16.py on GitHub.
- VGG 19 (ImageNet). A Convolutional neural network implementation for classifying ImageNet dataset, see tutorial_vgg19.py on GitHub.
- InceptionV3 (ImageNet). A Convolutional neural network implementation for classifying ImageNet dataset, see tutorial_inceptionV3_tfslim.py on GitHub.
- Wide ResNet (CIFAR) by ritchieng.
- More CNN implementations of TF-Slim can be connected to TensorLayer via SlimNetsLayer.
- Spatial Transformer Networks by zsdonghao.
- U-Net for brain tumor segmentation by zsdonghao.

1.3.3 Natural Language Processing

- Recurrent Neural Network (LSTM). Apply multiple LSTM to PTB dataset for language modeling, see tutorial_ptb_lstm_state_is_tuple.py on GitHub.
- Word Embedding Word2vec. Train a word embedding matrix, see tutorial_word2vec_basic.py on GitHub.
- Restore Embedding matrix. Restore a pre-train embedding matrix, see tutorial_generate_text.py on GitHub.
- Text Generation. Generates new text scripts, using LSTM network, see tutorial_generate_text.py
 on GitHub.
- Machine Translation (WMT). Translate English to French. Apply Attention mechanism and Seq2seq to WMT English-to-French translation data, see tutorial_translate.py on GitHub.

1.3.4 Adversarial Learning

- DCGAN Generating images by Deep Convolutional Generative Adversarial Networks by zsdonghao.
- Generative Adversarial Text to Image Synthesis by zsdonghao.
- Unsupervised Image to Image Translation with Generative Adversarial Networks by zsdonghao.
- Super Resolution GAN by zsdonghao.

1.3.5 Reinforcement Learning

- Deep Reinforcement Learning Pong Game. Teach a machine to play Pong games, see tutorial_atari_pong.py on GitHub.
- Asynchronous Deep Reinforcement Learning Pong Game by nebulaV.

1.3.6 Applications

- Image Captioning Reimplementation of Google's im2txt by zsdonghao.
- A simple web service TensorFlask by JoelKronander.

1.3.7 Special Examples

- Merge TF-Slim into TensorLayer. tutorial_inceptionV3_tfslim.py on GitHub.
- Merge Keras into TensorLayer. tutorial keras.py on GitHub.
- MultiplexerLayer. tutorial_mnist_multiplexer.py on GitHub.
- Data augmentation with TFRecord. Effective way to load and pre-process data, see tutorial_tfrecord*. py and tutorial_cifar10_tfrecord.py on GitHub.
- Data augmentation with TensorLayer, see tutorial_image_preprocess.py on GitHub.
- TensorDB by fangde see here.

1.4 Development

TensorLayer is a major ongoing research project in Data Science Institute, Imperial College London. The goal of the project is to develop a compositional language while complex learning systems can be build through composition of neural network modules. The whole development is now participated by numerous contributors on Release. As an open-source project by we highly welcome contributions! Every bit helps and will be credited.

1.4.1 What to contribute

Your method and example

If you have a new method or example in term of Deep learning and Reinforcement learning, you are welcome to contribute.

- Provide your layer or example, so everyone can use it.
- Explain how it would work, and link to a scientific paper if applicable.

1.4. Development 39

• Keep the scope as narrow as possible, to make it easier to implement.

Report bugs

Report bugs at the GitHub, we normally will fix it in 5 hours. If you are reporting a bug, please include:

- your TensorLayer, TensorFlow and Python version.
- steps to reproduce the bug, ideally reduced to a few Python commands.
- the results you obtain, and the results you expected instead.

If you are unsure whether the behavior you experience is a bug, or if you are unsure whether it is related to TensorLayer or TensorFlow, please just ask on our mailing list first.

Fix bugs

Look through the GitHub issues for bug reports. Anything tagged with "bug" is open to whoever wants to implement it. If you discover a bug in TensorLayer you can fix yourself, by all means feel free to just implement a fix and not report it first.

Write documentation

Whenever you find something not explained well, misleading, glossed over or just wrong, please update it! The *Edit on GitHub* link on the top right of every documentation page and the [source] link for every documented entity in the API reference will help you to quickly locate the origin of any text.

1.4.2 How to contribute

Edit on GitHub

As a very easy way of just fixing issues in the documentation, use the *Edit on GitHub* link on the top right of a documentation page or the *[source]* link of an entity in the API reference to open the corresponding source file in GitHub, then click the *Edit this file* link to edit the file in your browser and send us a Pull Request. All you need for this is a free GitHub account.

For any more substantial changes, please follow the steps below to setup TensorLayer for development.

Documentation

The documentation is generated with Sphinx. To build it locally, run the following commands:

```
pip install Sphinx
sphinx-quickstart

cd docs
make html
```

If you want to re-generate the whole docs, run the following commands:

```
cd docs
make clean
make html
```

To write the docs, we recommend you to install Local RTD VM.

Afterwards, open docs/_build/html/index.html to view the documentation as it would appear on readthedocs. If you changed a lot and seem to get misleading error messages or warnings, run make clean html to force Sphinx to recreate all files from scratch.

When writing docstrings, follow existing documentation as much as possible to ensure consistency throughout the library. For additional information on the syntax and conventions used, please refer to the following documents:

- reStructuredText Primer
- Sphinx reST markup constructs
- A Guide to NumPy/SciPy Documentation

Testing

TensorLayer has a code coverage of 100%, which has proven very helpful in the past, but also creates some duties:

- Whenever you change any code, you should test whether it breaks existing features by just running the test scripts.
- Every bug you fix indicates a missing test case, so a proposed bug fix should come with a new test that fails without your fix.

Sending Pull Requests

When you're satisfied with your addition, the tests pass and the documentation looks good without any markup errors, commit your changes to a new branch, push that branch to your fork and send us a Pull Request via GitHub's web interface.

All these steps are nicely explained on GitHub: https://guides.github.com/introduction/flow/

When filing your Pull Request, please include a description of what it does, to help us reviewing it. If it is fixing an open issue, say, issue #123, add *Fixes #123*, *Resolves #123* or *Closes #123* to the description text, so GitHub will close it when your request is merged.

1.5 More

1.5.1 FQA

How to effectively learn TensorLayer

No matter what stage you are in, we recommend you to spend just 10 minutes to read the source code of TensorLayer and the Understand layer / Your layer in this website, you will find the abstract methods are very simple for everyone. Reading the source codes helps you to better understand TensorFlow and allows you to implement your own methods easily. For discussion, we recommend Gitter, Help Wanted Issues, QQ group and Wechat group.

Beginner

For people who new to deep learning, the contirbutors provided a number of tutorials in this website, these tutorials will guide you to understand autoencoder, convolutional neural network, recurrent neural network, word embedding and deep reinforcement learning and etc. If your already understand the basic of deep learning, we recommend you to skip the tutorials and read the example codes on Github, then implement an example from scratch.

1.5. More 41

Engineer

For people from industry, the contirbutors provided mass format-consistent examples covering computer vision, natural language processing and reinforcement learning. Besides, there are also many TensorFlow users already implemented product-level examples including image captioning, semantic/instance segmentation, machine translation, chatbot and etc, which can be found online. It is worth noting that a wrapper especially for computer vision Tf-Slim can be connected with TensorLayer seamlessly. Therefore, you may able to find the examples that can be used in your project.

Researcher

For people from academic, TensorLayer was originally developed by PhD students who facing issues with other libraries on implement novel algorithm. Installing TensorLayer in editable mode is recommended, so you can extend your methods in TensorLayer. For researches related to image such as image captioning, visual QA and etc, you may find it is very helpful to use the existing Tf-Slim pre-trained models with TensorLayer (a specially layer for connecting Tf-Slim is provided).

Exclude some layers from training

You may need to get the list of variables you want to update, TensorLayer provides two ways to get the variables list.

The first way is to use the all_params of a network, by default, it will store the variables in order. You can print the variables information via tl.layers.print_all_variables(train_only=True) or network.print_params(details=False). To choose which variables to update, you can do as below.

```
train_params = network.all_params[3:]
```

The second way is to get the variables by a given name. For example, if you want to get all variables which the layer name contain dense, you can do as below.

After you get the variable list, you can define your optimizer like that so as to update only a part of the variables.

```
train_op = tf.train.AdamOptimizer(0.001).minimize(cost, var_list= train_params)
```

Visualization

Cannot Save Image

If you run the script via SSH control, sometime you may find the following error.

```
_tkinter.TclError: no display name and no $DISPLAY environment variable
```

If happen, use import matplotlib and matplotlib.use('Agg') before import tensorlayer as tl. Alternatively, add the following code into the top of visualize.py or in your own code.

```
import matplotlib
matplotlib.use('Agg')
import matplotlib.pyplot as plt
```

Install Master Version

To use all new features of TensorLayer, you need to install the master version from Github. Before that, you need to make sure you already installed git.

```
[stable version] pip install tensorlayer
[master version] pip install git+https://github.com/zsdonghao/tensorlayer.git
```

Editable Mode

- 1. Download the TensorLayer folder from Github.
- 2. Before editing the TensorLayer .py file.
 - If your script and TensorLayer folder are in the same folder, when you edit the .py inside Tensor-Layer folder, your script can access the new features.
 - If your script and TensorLayer folder are not in the same folder, you need to run the following command in the folder contains setup.py before you edit.py inside TensorLayer folder.

```
pip install -e .
```

Load Model

Note that, the tl.files.load_npz() can only able to load the npz model saved by tl.files.save_npz(). If you have a model want to load into your TensorLayer network, you can first assign your parameters into a list in order, then use tl.files.assign_params() to load the parameters into your TensorLayer model.

1.5.2 Recruitment

TensorLayer Contributors

TensorLayer contributors are from Imperial College, Tsinghua University, Carnegie Mellon University, Google, Microsoft, Bloomberg and etc. There are many functions need to be contributed such as Maxout, Neural Turing Machine, Attention, TensorLayer Mobile and etc. Please push on GitHub, every bit helps and will be credited. If you are interested in working with us, please contact us.

Data Science Institute, Imperial College London

Data science is therefore by nature at the core of all modern transdisciplinary scientific activities, as it involves the whole life cycle of data, from acquisition and exploration to analysis and communication of the results. Data science is not only concerned with the tools and methods to obtain, manage and analyse data: it is also about extracting value from data and translating it from asset to product.

Launched on 1st April 2014, the Data Science Institute at Imperial College London aims to enhance Imperial's excellence in data-driven research across its faculties by fulfilling the following objectives.

The Data Science Institute is housed in purpose built facilities in the heart of the Imperial College campus in South Kensington. Such a central location provides excellent access to collaborators across the College and across London.

 To act as a focal point for coordinating data science research at Imperial College by facilitating access to funding, engaging with global partners, and stimulating cross-disciplinary collaboration.

1.5. More 43

- To develop data management and analysis technologies and services for supporting data driven research in the College.
- To promote the training and education of the new generation of data scientist by developing and coordinating new degree courses, and conducting public outreach programmes on data science.
- To advise College on data strategy and policy by providing world-class data science expertise.
- To enable the translation of data science innovation by close collaboration with industry and supporting commercialization.

If you are interested in working with us, please check our vacancies and other ways to get involved, or feel free to contact us.

API Reference

If you are looking for information on a specific function, class or method, this part of the documentation is for you.

2.1 API - Layers

To make TensorLayer simple, we minimize the number of layer classes as much as we can. So we encourage you to use TensorFlow's function. For example, we provide layer for local response normalization, but we still suggest users to apply tf.nn.lrn on network.outputs. More functions can be found in TensorFlow API.

2.1.1 Understand Basic layer

All TensorLayer layers have a number of properties in common:

- layer.outputs: a Tensor, the outputs of current layer.
- layer.all_params: a list of Tensor, all network variables in order.
- layer.all_layers: a list of Tensor, all network outputs in order.
- layer.all_drop: a dictionary of {placeholder: float}, all keeping probabilities of noise layer.

All TensorLayer layers have a number of methods in common:

- layer.print_params(): print the network variables information in order (after tl.layers. initialize_global_variables(sess)). alternatively, print all variables by tl.layers. print_all_variables().
- \bullet layer.print_layers () : print the network layers information in order.
- layer.count_params(): print the number of parameters in the network.

The initialization of a network is done by input layer, then we can stacked layers as follow, a network is a Layer class. The most important properties of a network are network.all_params, network.all_layers and network.all_drop. The all_params is a list which store all pointers of all network parameters in order, the following script define a 3 layer network, then:

```
all params = [W1, b1, W2, b2, W \text{ out}, b \text{ out}]
```

To get specified variables, you can use network.all_params[2:3] or get_variables_with_name(). As the all_layers is a list which store all pointers of the outputs of all layers, in the following network:

```
all_layers = [drop(?,784), relu(?,800), drop(?,800), relu(?,800), drop(?,800)], identity(?,10)]
```

where ? reflects any batch size. You can print the layer information and parameters information by using network. print_layers() and network.print_params(). To count the number of parameters in a network, run network.count_params().

```
sess = tf.InteractiveSession()
x = tf.placeholder(tf.float32, shape=[None, 784], name='x')
y_ = tf.placeholder(tf.int64, shape=[None, ], name='y_')
network = tl.layers.InputLayer(x, name='input_layer')
network = tl.layers.DropoutLayer(network, keep=0.8, name='drop1')
network = tl.layers.DenseLayer(network, n_units=800,
                                act = tf.nn.relu, name='relu1')
network = t1.layers.DropoutLayer(network, keep=0.5, name='drop2')
network = tl.layers.DenseLayer(network, n_units=800,
                                act = tf.nn.relu, name='relu2')
network = t1.layers.DropoutLayer(network, keep=0.5, name='drop3')
network = tl.layers.DenseLayer(network, n_units=10,
                                act = tl.activation.identity,
                                name='output_layer')
y = network.outputs
y_{op} = tf.argmax(tf.nn.softmax(y), 1)
cost = tl.cost.cross_entropy(y, y_)
train_params = network.all_params
train_op = tf.train.AdamOptimizer(learning_rate, beta1=0.9, beta2=0.999,
                            epsilon=1e-08, use_locking=False).minimize(cost, var_list_
→= train_params)
tl.layers.initialize_global_variables(sess)
network.print_params()
network.print_layers()
```

In addition, network.all_drop is a dictionary which stores the keeping probabilities of all noise layer. In the above network, they are the keeping probabilities of dropout layers.

So for training, enable all dropout layers as follow.

```
feed_dict = {x: X_train_a, y_: y_train_a}
feed_dict.update( network.all_drop )
loss, _ = sess.run([cost, train_op], feed_dict=feed_dict)
feed_dict.update( network.all_drop )
```

For evaluating and testing, disable all dropout layers as follow.

```
feed_dict = {x: X_val, y_: y_val}
feed_dict.update(dp_dict)
print(" val loss: %f" % sess.run(cost, feed_dict=feed_dict))
```

(continues on next page)

For more details, please read the MNIST examples on Github.

2.1.2 Understand Dense layer

Before creating your own TensorLayer layer, let's have a look at Dense layer. It creates a weights matrix and biases vector if not exists, then implement the output expression. At the end, as a layer with parameter, we also need to append the parameters into all_params.

```
class MyDenseLayer(Layer):
 def __init__(
      self,
      layer = None,
     n_units = 100,
      act = tf.nn.relu,
     name = 'simple_dense',
 ):
      # check layer name (fixed)
      Layer.__init__(self, name=name)
      # the input of this layer is the output of previous layer (fixed)
      self.inputs = layer.outputs
      # print out info (customized)
     print(" MyDenseLayer %s: %d, %s" % (self.name, n_units, act))
      # operation (customized)
      n_in = int(self.inputs._shape[-1])
      with tf.variable_scope(name) as vs:
          # create new parameters
          W = tf.get_variable(name='W', shape=(n_in, n_units))
         b = tf.get_variable(name='b', shape=(n_units))
          # tensor operation
          self.outputs = act(tf.matmul(self.inputs, W) + b)
      # get stuff from previous layer (fixed)
      self.all_layers = list(layer.all_layers)
      self.all_params = list(layer.all_params)
      self.all_drop = dict(layer.all_drop)
      # update layer (customized)
      self.all_layers.extend( [self.outputs] )
      self.all_params.extend( [W, b] )
```

2.1.3 Your layer

A simple layer

To implement a custom layer in TensorLayer, you will have to write a Python class that subclasses Layer and implement the outputs expression.

The following is an example implementation of a layer that multiplies its input by 2:

```
class DoubleLayer(Layer):
   def ___init___(
       self,
       layer = None,
       name = 'double_layer',
    ):
        # check layer name (fixed)
        Layer.__init__(self, name=name)
        # the input of this layer is the output of previous layer (fixed)
        self.inputs = layer.outputs
        # operation (customized)
        self.outputs = self.inputs * 2
        # get stuff from previous layer (fixed)
        self.all_layers = list(layer.all_layers)
        self.all_params = list(layer.all_params)
        self.all_drop = dict(layer.all_drop)
        # update layer (customized)
        self.all_layers.extend( [self.outputs] )
```

Modifying Pre-train Behaviour

Greedy layer-wise pretraining is an important task for deep neural network initialization, while there are many kinds of pre-training methods according to different network architectures and applications.

For example, the pre-train process of Vanilla Sparse Autoencoder can be implemented by using KL divergence (for sigmoid) as the following code, but for Deep Rectifier Network, the sparsity can be implemented by using the L1 regularization of activation output.

There are many pre-train methods, for this reason, TensorLayer provides a simple way to modify or design your own pre-train method. For Autoencoder, TensorLayer uses ReconLayer.__init__() to define the reconstruction layer and cost function, to define your own cost function, just simply modify the self.cost in ReconLayer.__init__(). To creat your own cost expression please read Tensorflow Math. By default, ReconLayer only updates the weights and biases of previous 1 layer by using self.train_params = self.all _params[-4:], where the 4 parameters are [W_encoder, b_encoder, W_decoder, b_decoder], where W_encoder, b_encoder belong to previous DenseLayer, W_decoder, b_decoder belong to this ReconLayer. In addition, if you want to update the parameters of previous 2 layers at the same time, simply modify [-4:] to [-6:].

```
ReconLayer.__init__(...):
    ...
    self.train_params = self.all_params[-4:]
    ...
    self.cost = mse + L1_a + L2_w
```

2.1.4 Layer list

<pre>get_variables_with_name(name[, train_only,</pre>	Get variable list by a given name scope.
])	
<pre>get_layers_with_name([network, name, print- able])</pre>	Get layer list in a network by a given name scope.
set_name_reuse([enable])	Enable or disable reuse layer name.
<pre>print_all_variables([train_only])</pre>	Print all trainable and non-trainable variables without
	tl.layers.initialize_global_variables(sess)
initialize_global_variables([sess])	Excute sess.run(tf.
	global_variables_initializer()) for TF12+ or sess.run(tf.initialize_all_variables()) for TF11.
Layer([inputs, name])	The Layer class represents a single layer of a neural network.
InputLayer([inputs, name])	The InputLayer class is the starting layer of a neural network.
OneHotInputLayer([inputs, depth, on_value,])	The OneHotInputLayer class is the starting layer of a neural network, see tf.one_hot.
Word2vecEmbeddingInputlayer([inputs,])	The Word2vecEmbeddingInputlayer class is a fully connected layer, for Word Embedding.
EmbeddingInputlayer([inputs,])	The EmbeddingInputlayer class is a fully con-
_	nected layer, for Word Embedding.
DenseLayer([layer, n_units, act, W_init,])	The DenseLayer class is a fully connected layer.
ReconLayer([layer, x_recon, name, n_units, act])	The ReconLayer class is a reconstruction layer
	DenseLayer which use to pre-train a DenseLayer.
DropoutLayer([layer, keep, is_fix,])	The DropoutLayer class is a noise layer which ran-
	domly set some values to zero by a given keeping probability.
GaussianNoiseLayer([layer, mean, stddev,])	The GaussianNoiseLayer class is noise layer that adding noise with normal distribution to the activation.
DropconnectDenseLayer([layer, keep,])	The DropconnectDenseLayer class is DenseLayer with DropConnect behaviour which randomly remove connection between this layer to previous layer by a given keeping probability.
ConvldLayer([layer, act, shape, stride,])	The ConvldLayer class is a 1D CNN layer, see tf.nn.convolution.
Conv2dLayer([layer, act, shape, strides,])	The Conv2dLayer class is a 2D CNN layer, see tf.nn.conv2d.
DeConv2dLayer([layer, act, shape,])	The DeConv2dLayer class is deconvolutional 2D layer, see tf.nn.conv2d_transpose.
Conv3dLayer([layer, act, shape, strides,])	The Conv3dLayer class is a 3D CNN layer, see tf.nn.conv3d.
DeConv3dLayer([layer, act, shape,])	The DeConv3dLayer class is deconvolutional 3D layer, see tf.nn.conv3d_transpose.
PoolLayer([layer, ksize, strides, padding,])	The PoolLayer class is a Pooling layer, you can choose tf.nn.max_pool and tf.nn.avg_pool for 2D or tf.nn.max_pool3d and tf.nn.avg_pool3d for 3D.
PadLayer([layer, paddings, mode, name])	The PadLayer class is a Padding layer for any modes and dimensions.
	Continued on next page

Table 1 – continued	from previous page
<pre>UpSampling2dLayer([layer, size, is_scale,])</pre>	The UpSampling2dLayer class is upSampling 2d
	layer, see tf.image.resize_images.
DownSampling2dLayer([layer, size, is_scale,])	The DownSampling2dLayer class is downSam-
	pling 2d layer, see tf.image.resize_images.
AtrousConv1dLayer(net[, n_filter,])	Wrapper for AtrousConvldLayer, if you don't un-
	derstand how to use ConvldLayer, this function may
	be easier.
AtrousConv2dLayer([layer, n_filter,])	The AtrousConv2dLayer class is Atrous convolu-
	tion (a.k.a.
SeparableConv2dLayer([layer, filters,])	The SeparableConv2dLayer class is
	2-D convolution with separable filters, see
	tf.layers.separable_conv2d.
Convld(net[, n_filter, filter_size, stride,])	Wrapper for Conv1dLayer, if you don't understand
, . – . –	how to use Conv1dLayer, this function may be easier.
Conv2d(net[, n_filter, filter_size,])	Wrapper for Conv2dLayer, if you don't understand
	how to use Conv2dLayer, this function may be easier.
DeConv2d(net[, n_out_channel, filter_size,])	Wrapper for DeConv2dLayer, if you don't under-
	stand how to use DeConv2dLayer, this function may
	be easier.
<pre>MaxPool1d(net, filter_size, strides[,])</pre>	Wrapper for tf.layers.max_pooling1d.
MeanPool1d(net, filter_size, strides[,])	Wrapper for tf.layers.average_pooling1d.
MaxPool2d(net[, filter_size, strides,])	Wrapper for PoolLayer.
MeanPool2d(net[, filter_size, strides,])	Wrapper for PoolLayer.
MaxPool3d(net, filter_size, strides[,])	Wrapper for tf.layers.max_pooling3d.
MeanPool3d(net, filter_size, strides[,])	Wrapper for tf.layers.average_pooling3d
Subpixe1Conv2d(net[, scale, n_out_channel,])	The SubpixelConv2d class is a sub-pixel 2d convo-
baspinerconvea(net, searc, n_out_enamer,)	lutional ayer, usually be used for Super-Resolution ap-
	plications, example code.
SpatialTransformer2dAffineLayer([layer,	The SpatialTransformer2dAffineLayer
])	class is a Spatial Transformer Layer for 2D Affine
1)	Transformation.
transformer(U, theta, out_size[, name])	Spatial Transformer Layer for
	2D Affine Transformation , see
	SpatialTransformer2dAffineLayer class.
<pre>batch_transformer(U, thetas, out_size[, name])</pre>	Batch Spatial Transformer function for 2D Affine
	Transformation.
BatchNormLayer([layer, decay, epsilon, act,])	The BatchNormLayer class is a normalization layer,
2 - (5 - 3 - 7 3)	see tf.nn.batch_normalization and tf.nn.
	moments.
LocalResponseNormLayer([layer,])	The LocalResponseNormLayer class is for
	Local Response Normalization, see tf.nn.
	local_response_normalization or tf.
	nn.lrn for new TF version.
TimeDistributedLayer([layer, layer_class,])	The TimeDistributedLayer class that applies a
	function to every timestep of the input tensor.
RNNLayer([layer, cell_fn, cell_init_args,])	The RNNLayer class is a RNN layer, you can imple-
	ment vanilla RNN, LSTM and GRU with it.
BiRNNLayer([layer, cell_fn, cell_init_args,])	The Birnnlayer class is a Bidirectional RNN layer.

Table 1 – continued from previous page

clear_layers_name()	Clear all layer names in set_keep['_layers_name_list'],
	enable layer name reuse.
initialize_rnn_state(state)	Return the initialized RNN state.
list_remove_repeat([l])	Remove the repeated items in a list, and return the pro-
	cessed list.

2.1.5 Name Scope and Sharing Parameters

These functions help you to reuse parameters for different inference (graph), and get a list of parameters by given name. About TensorFlow parameters sharing click here.

Get variables with name

tensorlayer.layers.get_variables_with_name (name, train_only=True, printable=False) Get variable list by a given name scope.

Examples

```
>>> dense_vars = tl.layers.get_variable_with_name('dense', True, True)
```

Get layers with name

tensorlayer.layers.get_layers_with_name (network=None, name=", printable=False) Get layer list in a network by a given name scope.

Examples

```
>>> layers = tl.layers.get_layers_with_name(network, "CNN", True)
```

Enable layer name reuse

```
tensorlayer.layers.set_name_reuse(enable=True)
```

Enable or disable reuse layer name. By default, each layer must has unique name. When you want two or more input placeholder (inference) share the same model parameters, you need to enable layer name reuse, then allow the parameters have same name scope.

Parameters

enable [boolean, enable name reuse. (None means False).]

Examples

```
>>> def embed_seq(input_seqs, is_train, reuse):
>>> with tf.variable_scope("model", reuse=reuse):
>>> tl.layers.set_name_reuse(reuse)
>>> network = tl.layers.EmbeddingInputlayer(
```

(continues on next page)

```
inputs = input_seqs,
. . .
                         vocabulary_size = vocab_size,
. . .
                         embedding_size = embedding_size,
                         name = 'e_embedding')
           network = tl.layers.DynamicRNNLayer(network,
>>>
                         cell_fn = tf.nn.rnn_cell.BasicLSTMCell,
                         n_hidden = embedding_size,
                         dropout = (0.7 if is_train else None),
. . .
                         initializer = w_init,
                         sequence_length = tl.layers.retrieve_seq_length_op2(input_
. . .
⇒seqs),
                         return_last = True,
. . .
                         name = 'e_dynamicrnn',)
. . .
>>>
       return network
>>>
>>> net_train = embed_seq(t_caption, is_train=True, reuse=False)
>>> net_test = embed_seq(t_caption, is_train=False, reuse=True)
```

• see tutorial_ptb_lstm.py for example.

Print variables

```
tensorlayer.layers.print_all_variables(train_only=False)
```

Print all trainable and non-trainable variables without tl.layers.initialize_global_variables(sess)

Parameters

train_only [boolean] If True, only print the trainable variables, otherwise, print all variables.

Initialize variables

Parameters

sess [a Session]

2.1.6 Basic layer

```
class tensorlayer.layers.Layer(inputs=None, name='layer')
```

The Layer class represents a single layer of a neural network. It should be subclassed when implementing new types of layers. Because each layer can keep track of the layer(s) feeding into it, a network's output Layer instance can double as a handle to the full network.

Parameters

inputs [a Layer instance] The Layer class feeding into this layer.

name [a string or None] An optional name to attach to this layer.

Methods

count_params()	Return the number of parameters in the network
<pre>print_layers()</pre>	Print all info of layers in the network
print_params([details])	Print all info of parameters in the network

2.1.7 Input layer

class tensorlayer.layers.**InputLayer** (*inputs=None*, *name='input_layer'*)

The *InputLayer* class is the starting layer of a neural network.

Parameters

inputs [a placeholder or tensor] The input tensor data.

name [a string or None] An optional name to attach to this layer.

Methods

count_params()	Return the number of parameters in the network
<pre>print_layers()</pre>	Print all info of layers in the network
print_params([details])	Print all info of parameters in the network

2.1.8 One-hot layer

The OneHotInputLayer class is the starting layer of a neural network, see tf.one_hot.

Parameters

inputs [a placeholder or tensor] The input tensor data.

name [a string or None] An optional name to attach to this layer.

depth [If the input indices is rank N, the output will have rank N+1. The new axis is created at dimension axis (default: the new axis is appended at the end).]

on_value [If on_value is not provided, it will default to the value 1 with type dtype.] default, None

off_value [If off_value is not provided, it will default to the value 0 with type dtype.] default, None

axis [default, None]

dtype [default, None]

Methods

count_params()	Return the number of parameters in the network
<pre>print_layers()</pre>	Print all info of layers in the network
	Continued on post page

Table 4 – continued from previous page

print params([details])

Print all info of parameters in the network

2.1.9 Word Embedding Input layer

Word2vec layer for training

```
class tensorlayer.layers.Word2vecEmbeddingInputlayer(inputs=None,
```

train_labels=None, vocabulary_size=80000,
embedding_size=200,
num_sampled=64,
nce_loss_args={},
E_init=<tensorflow.python.ops.init_ops.RandomUniformobject>, E_init_args={},
nce_W_init=<tensorflow.python.ops.init_ops.Truncatedobject>, nce W init args={},

nce_b_init=<tensorflow.python.ops.init_ops.Constant
object>, nce_b_init_args={},
name='word2vec layer')

The Word2vecEmbeddingInputlayer class is a fully connected layer, for Word Embedding. Words are input as integer index. The output is the embedded word vector.

Parameters

inputs [placeholder] For word inputs. integer index format.

train_labels [placeholder] For word labels. integer index format.

vocabulary_size [int] The size of vocabulary, number of words.

embedding_size [int] The number of embedding dimensions.

num_sampled [int] The Number of negative examples for NCE loss.

nce_loss_args [a dictionary] The arguments for tf.nn.nce_loss()

E_init [embedding initializer] The initializer for initializing the embedding matrix.

E_init_args [a dictionary] The arguments for embedding initializer

nce_W_init [NCE decoder biases initializer] The initializer for initializing the nce decoder weight matrix.

nce_W_init_args [a dictionary] The arguments for initializing the nce decoder weight matrix.

nce_b_init [NCE decoder biases initializer] The initializer for tf.get_variable() of the nce decoder bias vector.

nce_b_init_args [a dictionary] The arguments for tf.get_variable() of the nce decoder bias vector.

name [a string or None] An optional name to attach to this layer.

Embedding Input layer

```
class tensorlayer.layers. EmbeddingInputlayer (inputs=None, vocabulary_size=80000, embedding_size=200, E_{init}=<tensorflow.python.ops.init_ops.RandomUniform object>, E_{init}_{args}={}, name='embedding_layer')
```

The EmbeddingInputlayer class is a fully connected layer, for Word Embedding. Words are input as integer index. The output is the embedded word vector.

If you have a pre-train matrix, you can assign the matrix into it. To train a word embedding matrix, you can used class: *Word2vecEmbeddingInputlayer*.

Note that, do not update this embedding matrix.

Parameters

```
inputs [placeholder] For word inputs. integer index format. a 2D tensor : [batch_size, num_steps(num_words)]
```

vocabulary_size [int] The size of vocabulary, number of words.

embedding_size [int] The number of embedding dimensions.

E_init [embedding initializer] The initializer for initializing the embedding matrix.

E_init_args [a dictionary] The arguments for embedding initializer

name [a string or None] An optional name to attach to this layer.

Examples

```
>>> vocabulary_size = 50000
>>> embedding_size = 200
>>> model_file_name = "model_word2vec_50k_200"
>>> batch_size = None
>>> all_var = tl.files.load_npy_to_any(name=model_file_name+'.npy')
>>> data = all_var['data']; count = all_var['count']
>>> dictionary = all_var['dictionary']
>>> reverse_dictionary = all_var['reverse_dictionary']
>>> tl.files.save_vocab(count, name='vocab_'+model_file_name+'.txt')
>>> del all_var, data, count
>>> load_params = tl.files.load_npz(name=model_file_name+'.npz')
>>> x = tf.placeholder(tf.int32, shape=[batch_size])
>>> y_ = tf.placeholder(tf.int32, shape=[batch_size, 1])
>>> emb_net = tl.layers.EmbeddingInputlayer(
                   inputs = x,
                   vocabulary_size = vocabulary_size,
. . .
                   embedding_size = embedding_size,
. . .
                   name = 'embedding_layer')
>>> tl.layers.initialize_global_variables(sess)
>>> tl.files.assign_params(sess, [load_params[0]], emb_net)
>>> word = b'hello'
>>> word_id = dictionary[word]
>>> print('word_id:', word_id)
... 6428
. . .
>>> words = [b'i', b'am', b'hao', b'dong']
>>> word_ids = tl.files.words_to_word_ids(words, dictionary)
>>> context = tl.files.word_ids_to_words(word_ids, reverse_dictionary)
>>> print('word_ids:', word_ids)
... [72, 1226, 46744, 20048]
>>> print('context:', context)
... [b'i', b'am', b'hao', b'dong']
. . .
>>> vector = sess.run(emb_net.outputs, feed_dict={x : [word_id]})
>>> print('vector:', vector.shape)
```

(continues on next page)

```
... (1, 200)
>>> vectors = sess.run(emb_net.outputs, feed_dict={x : word_ids})
>>> print('vectors:', vectors.shape)
... (4, 200)
```

Methods

count_params()	Return the number of parameters in the network
<pre>print_layers()</pre>	Print all info of layers in the network
<pre>print_params([details])</pre>	Print all info of parameters in the network

2.1.10 Dense layer

Dense layer

```
class tensorlayer.layers.DenseLayer (layer=None, n_units=100, act=<function identity>, W_{init}=<tensorflow.python.ops.init_ops.TruncatedNormal object>, b_init=<tensorflow.python.ops.init_ops.Constant object>, W_{init}_{args=\{\}}, W_{init}_{args=\{\}}
```

The DenseLayer class is a fully connected layer.

Parameters

layer [a Layer instance] The Layer class feeding into this layer.

n_units [int] The number of units of the layer.

act [activation function] The function that is applied to the layer activations.

W_init [weights initializer] The initializer for initializing the weight matrix.

b_init [biases initializer or None] The initializer for initializing the bias vector. If None, skip biases.

W_init_args [dictionary] The arguments for the weights tf.get_variable.

b_init_args [dictionary] The arguments for the biases tf.get_variable.

name [a string or None] An optional name to attach to this layer.

Notes

If the input to this layer has more than two axes, it need to flatten the input by using FlattenLayer in this case.

Examples

(continues on next page)

```
act = tf.nn.relu,
W_init=tf.truncated_normal_initializer(stddev=0.1),
name ='relu_layer'
)
```

```
>>> Without TensorLayer, you can do as follow.
>>> W = tf.Variable(
...          tf.random_uniform([n_in, n_units], -1.0, 1.0), name='W')
>>> b = tf.Variable(tf.zeros(shape=[n_units]), name='b')
>>> y = tf.nn.relu(tf.matmul(inputs, W) + b)
```

Methods

count_params()	Return the number of parameters in the network
<pre>print_layers()</pre>	Print all info of layers in the network
<pre>print_params([details])</pre>	Print all info of parameters in the network

Reconstruction layer for Autoencoder

```
class tensorlayer.layers.ReconLayer(layer=None, x_recon=None, name='recon_layer', n_units=784, act=<function softplus>)

The ReconLayer class is a reconstruction layer DenseLayer which use to pre-train a DenseLayer.
```

Parameters

layer [a Layer instance] The Layer class feeding into this layer.

x_recon [tensorflow variable] The variables used for reconstruction.

name [a string or None] An optional name to attach to this layer.

n units [int] The number of units of the layer, should be equal to x recon

act [activation function] The activation function that is applied to the reconstruction layer. Normally, for sigmoid layer, the reconstruction activation is sigmoid; for rectifying layer, the reconstruction activation is softplus.

Notes

The input layer should be *DenseLayer* or a layer has only one axes. You may need to modify this part to define your own cost function. By default, the cost is implemented as follow: - For sigmoid layer, the implementation can be UFLDL - For rectifying layer, the implementation can be Glorot (2011). Deep Sparse Rectifier Neural Networks

Examples

(continues on next page)

```
>>> recon_layer1.pretrain(sess, x=x, X_train=X_train, X_val=X_val,
... denoise_name=None, n_epoch=1200, batch_size=128,
... print_freq=10, save=True, save_name='wlpre_')
```

Methods

pretrain(self,	sess,	х,	X_train,	X_val,	denoise_	_name=None,	Start to pre-train the parame-
n_epoch=100,	bat	ch_si	ize=128,	print_fr	eq=10,	save=True,	ters of previous DenseLayer.
save_name='w	1pre_')						

2.1.11 Noise layer

Dropout layer

The *DropoutLayer* class is a noise layer which randomly set some values to zero by a given keeping probability.

Parameters

layer [a Layer instance] The Layer class feeding into this layer.

keep [float] The keeping probability, the lower more values will be set to zero.

is_fix [boolean] Default False, if True, the keeping probability is fixed and cannot be changed via feed_dict.

is_train [boolean] If False, skip this layer, default is True.

seed [int or None] An integer or None to create random seed.

name [a string or None] An optional name to attach to this layer.

Notes

• A frequent question regarding *DropoutLayer* is that why it donot have *is_train* like *BatchNormLayer*.

In many simple cases, user may find it is better to use one inference instead of two inferences for training and testing seperately, <code>DropoutLayer</code> allows you to control the dropout rate via <code>feed_dict</code>. However, you can fix the keeping probability by setting <code>is_fix</code> to True.

Examples

· Define network

• For training, enable dropout as follow.

```
>>> feed_dict = {x: X_train_a, y_: y_train_a}
>>> feed_dict.update( network.all_drop ) # enable noise layers
>>> sess.run(train_op, feed_dict=feed_dict)
>>> ...
```

• For testing, disable dropout as follow.

```
>>> dp_dict = tl.utils.dict_to_one( network.all_drop ) # disable noise layers
>>> feed_dict = {x: X_val_a, y_: y_val_a}
>>> feed_dict.update(dp_dict)
>>> err, ac = sess.run([cost, acc], feed_dict=feed_dict)
>>> ...
```

Methods

count_params()	Return the number of parameters in the network
<pre>print_layers()</pre>	Print all info of layers in the network
<pre>print_params([details])</pre>	Print all info of parameters in the network

Gaussian noise layer

```
class tensorlayer.layers.GaussianNoiseLayer(layer=None, mean=0.0, std-dev=1.0, is\_train=True, seed=None, name='gaussian\_noise\_layer')
```

The GaussianNoiseLayer class is noise layer that adding noise with normal distribution to the activation.

Parameters

```
layer [a Layer instance] The Layer class feeding into this layer.
mean [float]
stddev [float]
is_train [boolean] If False, skip this layer, default is True.
seed [int or None] An integer or None to create random seed.
name [a string or None] An optional name to attach to this layer.
```

Methods

count_params()	Return the number of parameters in the network
	Continued on next page

<pre>print_layers()</pre>	Print all info of layers in the network
print_params([details])	Print all info of parameters in the network

Dropconnect + Dense layer

The *DropconnectDenseLayer* class is DenseLayer with DropConnect behaviour which randomly remove connection between this layer to previous layer by a given keeping probability.

Parameters

layer [a Layer instance] The Layer class feeding into this layer.

keep [float] The keeping probability, the lower more values will be set to zero.

n_units [int] The number of units of the layer.

act [activation function] The function that is applied to the layer activations.

W_init [weights initializer] The initializer for initializing the weight matrix.

b_init [biases initializer] The initializer for initializing the bias vector.

W_init_args [dictionary] The arguments for the weights tf.get_variable().

b_init_args [dictionary] The arguments for the biases tf.get_variable().

name [a string or None] An optional name to attach to this layer.

2.1.12 Convolutional layer (Pro)

1D Convolutional layer

The ConvldLayer class is a 1D CNN layer, see tf.nn.convolution.

Parameters

layer [a Layer instance] The Layer class feeding into this layer, [batch, in_width, in_channels].

act [activation function, None for identity.]

shape [list of shape] shape of the filters, [filter_length, in_channels, out_channels].

stride [an int.] The number of entries by which the filter is moved right at each step.

dilation_rate [an int.] Specifies the filter upsampling/input downsampling rate.

padding [a string from: "SAME", "VALID".] The type of padding algorithm to use.

use_cudnn_on_gpu [An optional bool. Defaults to True.]

data format [As it is 1D conv, default is 'NWC'.]

 W_init [weights initializer] The initializer for initializing the weight matrix.

b_init [biases initializer or None] The initializer for initializing the bias vector. If None, skip biases.

W_init_args [dictionary] The arguments for the weights tf.get_variable().

b_init_args [dictionary] The arguments for the biases tf.get_variable().

name [a string or None] An optional name to attach to this layer.

Methods

count_params()	Return the number of parameters in the network
<pre>print_layers()</pre>	Print all info of layers in the network
<pre>print_params([details])</pre>	Print all info of parameters in the network

2D Convolutional layer

```
class tensorlayer.layers.Conv2dLayer (layer=None, act=<function identity>, shape=[5, 5, 1, 100], strides=[1, 1, 1, 1], padding='SAME', W_{init}=<tensorflow.python.ops.init_ops.TruncatedNormal object>, b_init=<tensorflow.python.ops.init_ops.Constant object>, W_init_args={}, b_init_args={}, use_cudnn_on_gpu=None, data_format=None, name='cnn_layer')
```

Parameters

layer [a Layer instance] The Layer class feeding into this layer.

The Conv2dLayer class is a 2D CNN layer, see tf.nn.conv2d.

act [activation function] The function that is applied to the layer activations.

shape [list of shape] shape of the filters, [filter_height, filter_width, in_channels, out_channels].

strides [a list of ints.] The stride of the sliding window for each dimension of input.

It Must be in the same order as the dimension specified with format.

padding [a string from: "SAME", "VALID".] The type of padding algorithm to use.

W_init [weights initializer] The initializer for initializing the weight matrix.

b_init [biases initializer or None] The initializer for initializing the bias vector. If None, skip biases.

W_init_args [dictionary] The arguments for the weights tf.get_variable().

b_init_args [dictionary] The arguments for the biases tf.get_variable().

use_cudnn_on_gpu [an optional string from: "NHWC", "NCHW". Defaults to "NHWC".]

data_format [an optional bool. Defaults to True.]

name [a string or None] An optional name to attach to this layer.

Notes

- shape = [h, w, the number of output channel of previous layer, the number of output channels]
- the number of output channel of a layer is its last dimension.

Examples

```
>>> x = tf.placeholder(tf.float32, shape=[None, 28, 28, 1])
>>> network = tl.layers.InputLayer(x, name='input_layer')
>>> network = tl.layers.Conv2dLayer(network,
                       act = tf.nn.relu,
                       shape = [5, 5, 1, 32], # 32 features for each 5x5 patch
                       strides=[1, 1, 1, 1],
. . .
                       padding='SAME',
                       W_{init}=tf.truncated_normal_initializer(stddev=5e-2),
. . .
                       W_init_args={},
. . .
                       b_init = tf.constant_initializer(value=0.0),
. . .
                       b_init_args = {},
. . .
```

print_params([details])	Print all info of parameters in the network

2D Deconvolutional layer

$\label{lem:conv2dLayer class} The \ \textit{DeConv2dLayer class} \ is \ deconvolutional \ 2D \ layer, see \ tf.nn.conv2d_transpose.$

Parameters

layer [a Layer instance] The Layer class feeding into this layer.

act [activation function] The function that is applied to the layer activations.

shape [list of shape] shape of the filters, [height, width, output_channels, in_channels], filter's in_channels dimension must match that of value.

output_shape [list of output shape] representing the output shape of the deconvolution op.

strides [a list of ints.] The stride of the sliding window for each dimension of the input tensor.

padding [a string from: "SAME", "VALID".] The type of padding algorithm to use.

W init [weights initializer] The initializer for initializing the weight matrix.

b_init [biases initializer] The initializer for initializing the bias vector. If None, skip biases.

W_init_args [dictionary] The arguments for the weights initializer.

b_init_args [dictionary] The arguments for the biases initializer.

name [a string or None] An optional name to attach to this layer.

Notes

- shape = [h, w, the number of output channels of this layer, the number of output channel of previous layer]
- output_shape = [batch_size, any, any, the number of output channels of this layer]
- the number of output channel of a layer is its last dimension.

Examples

• A part of the generator in DCGAN example

```
>>> batch_size = 64
>>> inputs = tf.placeholder(tf.float32, [batch_size, 100], name='z_noise')
>>> net_in = tl.layers.InputLayer(inputs, name='q/in')
>>> net_h0 = t1.layers.DenseLayer(net_in, n_units = 8192,
                                W_init = tf.random_normal_initializer(stddev=0.02),
                                act = tf.identity, name='g/h0/lin')
>>> print (net_h0.outputs._shape)
... (64, 8192)
\rightarrow \rightarrow net_h0 = t1.layers.ReshapeLayer(net_h0, shape = [-1, 4, 4, 512], name='g/h0/
→reshape')
>>> net_h0 = tl.layers.BatchNormLayer(net_h0, act=tf.nn.relu, is_train=is_train,_
→name='g/h0/batch_norm')
>>> print (net_h0.outputs._shape)
... (64, 4, 4, 512)
>>> net_h1 = tl.layers.DeConv2dLayer(net_h0,
                                shape = [5, 5, 256, 512],
                                output_shape = [batch_size, 8, 8, 256],
                                strides=[1, 2, 2, 1],
. . .
                                act=tf.identity, name='g/h1/decon2d')
>>> net_h1 = tl.layers.BatchNormLayer(net_h1, act=tf.nn.relu, is_train=is_train,...
→name='g/h1/batch_norm')
>>> print (net_h1.outputs._shape)
... (64, 8, 8, 256)
```

• U-Net

```
>>> ....
>>> conv10 = t1.layers.Conv2dLayer(conv9, act=tf.nn.relu,
... shape=[3,3,1024,1024], strides=[1,1,1,1], padding='SAME',
... W_init=w_init, b_init=b_init, name='conv10')
>>> print(conv10.outputs)
... (batch_size, 32, 32, 1024)
>>> deconv1 = t1.layers.DeConv2dLayer(conv10, act=tf.nn.relu,
... shape=[3,3,512,1024], strides=[1,2,2,1], output_shape=[batch_size,64,
---64,512],
... padding='SAME', W_init=w_init, b_init=b_init, name='devcon1_1')
```

Methods

3D Convolutional layer

class tensorlayer.layers.Conv3dLayer (layer=None, act=<function identity>, shape=[2, 2, 2, 64, 128], strides=[1, 2, 2, 2, 1], padding='SAME', $W_{init}=<$ tensorflow.python.ops.init_ops.TruncatedNormal object>, $b_{init}=<$ tensorflow.python.ops.init_ops.Constant object>, $W_{init}_{args}=\{\}$, $b_{init}_{args}=\{\}$, name='cnn3d layer')

The Conv3dLayer class is a 3D CNN layer, see tf.nn.conv3d.

Parameters

layer [a Layer instance] The Layer class feeding into this layer.

act [activation function] The function that is applied to the layer activations.

shape [list of shape] shape of the filters, [filter_depth, filter_height, filter_width, in_channels, out channels].

strides [a list of ints. 1-D of length 4.] The stride of the sliding window for each dimension of input. Must be in the same order as the dimension specified with format.

padding [a string from: "SAME", "VALID".] The type of padding algorithm to use.

W_init [weights initializer] The initializer for initializing the weight matrix.

b_init [biases initializer] The initializer for initializing the bias vector.

W_init_args [dictionary] The arguments for the weights initializer.

b_init_args [dictionary] The arguments for the biases initializer.

name [a string or None] An optional name to attach to this layer.

Methods

count_params()	Return the number of parameters in the network
<pre>print_layers()</pre>	Print all info of layers in the network
print_params([details])	Print all info of parameters in the network

3D Deconvolutional layer

The DeConv3dLayer class is deconvolutional 3D layer, see tf.nn.conv3d_transpose.

Parameters

layer [a Layer instance] The Layer class feeding into this layer.

act [activation function] The function that is applied to the layer activations.

shape [list of shape] shape of the filters, [depth, height, width, output_channels, in_channels], filter's in channels dimension must match that of value.

output_shape [list of output shape] representing the output shape of the deconvolution op.

strides [a list of ints.] The stride of the sliding window for each dimension of the input tensor.

padding [a string from: "SAME", "VALID".] The type of padding algorithm to use.

W_init [weights initializer] The initializer for initializing the weight matrix.

b_init [biases initializer] The initializer for initializing the bias vector.

W_init_args [dictionary] The arguments for the weights initializer.

b_init_args [dictionary] The arguments for the biases initializer.

name [a string or None] An optional name to attach to this layer.

Methods

count_params()	Return the number of parameters in the network
<pre>print_layers()</pre>	Print all info of layers in the network
print_params([details])	Print all info of parameters in the network

2D UpSampling layer

class tensorlayer.layers.UpSampling2dLayer(layer=None, size=[], $is_scale=True$, method=0, $align_corners=False$, $name='upsample2d_layer'$)

The UpSampling2dLayer class is upSampling 2d layer, see tf.image.resize_images.

Parameters

layer [a layer class with 4-D Tensor of shape [batch, height, width, channels] or 3-D Tensor of shape [height, width, channels].]

size [a tuple of int or float.] (height, width) scale factor or new size of height and width.

is_scale [boolean, if True (default), size is scale factor, otherwise, size is number of pixels of height and width.]

method [0, 1, 2, 3. ResizeMethod. Defaults to ResizeMethod.BILINEAR.]

- ResizeMethod.BILINEAR, Bilinear interpolation.
- ResizeMethod.NEAREST_NEIGHBOR, Nearest neighbor interpolation.
- ResizeMethod.BICUBIC, Bicubic interpolation.
- ResizeMethod.AREA, Area interpolation.

align_corners [bool. If true, exactly align all 4 corners of the input and output. Defaults to false.]

name [a string or None] An optional name to attach to this layer.

Methods

count_params()	Return the number of parameters in the network
<pre>print_layers()</pre>	Print all info of layers in the network
print_params([details])	Print all info of parameters in the network

2D DownSampling layer

class tensorlayer.layers.DownSampling2dLayer(layer=None, size=[], $is_scale=True$, method=0, $align_corners=False$, $name='downsample2d_layer'$)

The DownSampling2dLayer class is downSampling 2d layer, see tf.image.resize_images.

Parameters

layer [a layer class with 4-D Tensor of shape [batch, height, width, channels] or 3-D Tensor of shape [height, width, channels].]

size [a tupe of int or float.] (height, width) scale factor or new size of height and width.

is_scale [boolean, if True (default), size is scale factor, otherwise, size is number of pixels of height and width.]

method [0, 1, 2, 3. ResizeMethod. Defaults to ResizeMethod.BILINEAR.]

- ResizeMethod.BILINEAR, Bilinear interpolation.
- ResizeMethod.NEAREST_NEIGHBOR, Nearest neighbor interpolation.
- ResizeMethod.BICUBIC, Bicubic interpolation.
- ResizeMethod.AREA, Area interpolation.

align_corners [bool. If true, exactly align all 4 corners of the input and output. Defaults to false.]

name [a string or None] An optional name to attach to this layer.

Methods

count_params()	Return the number of parameters in the network
<pre>print_layers()</pre>	Print all info of layers in the network
<pre>print_params([details])</pre>	Print all info of parameters in the network

1D Atrous convolutional layer

```
tensorlayer.layers. Atrous Convld Layer (net, n_filter=32, filter_size=2, stride=1, dilation=1, act=None, padding='SAME', use_cudnn_on_gpu=None, data_format='NWC', W_init=<tensorflow.python.ops.init_ops. Truncated Normal object>, b_init=<tensorflow.python.ops.init_ops. Constant object>, W_init_args={}, b_init_args={}, name='convld')
```

Wrapper for AtrousConv1dLayer, if you don't understand how to use Conv1dLayer, this function may be easier.

Parameters

```
net [TensorLayer layer.]
n_filter [number of filter.]
filter_size [an int.]
stride [an int.]
dilation [an int, filter dilation size.]
act [None or activation function.]
others [see Conv1dLayer.]
```

2D Atrous convolutional layer

```
class tensorlayer.layers.AtrousConv2dLayer(layer=None, n\_filter=32, filter\_size=(3, 3), rate=2, act=None, padding='SAME', W_init=<tensorflow.python.ops.init_ops.TruncatedNormal object>, b_init=<tensorflow.python.ops.init_ops.Constant object>, W_init_args={}, b_init_args={}, name='atrou2d')
```

The AtrousConv2dLayer class is Atrous convolution (a.k.a. convolution with holes or dilated convolution) 2D layer, see tf.nn.atrous_conv2d.

Parameters

layer [a layer class with 4-D Tensor of shape [batch, height, width, channels].]

filters [A 4-D Tensor with the same type as value and shape [filter_height, filter_width, in_channels, out_channels]. filters' in_channels dimension must match that of value. Atrous convolution is equivalent to standard convolution with upsampled filters with effective height filter_height + (filter_height - 1) * (rate - 1) and effective width filter_width + (filter_width - 1) * (rate - 1), produced by inserting rate - 1 zeros along consecutive elements across the filters' spatial dimensions.]

```
n_filter [number of filter.]
```

```
filter_size [tuple (height, width) for filter size.]
```

rate [A positive int32. The stride with which we sample input values across the height and width dimensions. Equivalently, the rate by which we upsample the filter values by inserting zeros across the height and width dimensions. In the literature, the same parameter is sometimes called input stride or dilation.]

```
act [activation function, None for linear.]
```

```
padding [A string, either 'VALID' or 'SAME'. The padding algorithm.]
```

W_init [weights initializer. The initializer for initializing the weight matrix.]

b_init [biases initializer or None. The initializer for initializing the bias vector. If None, skip biases.]

W_init_args [dictionary. The arguments for the weights tf.get_variable().]

b_init_args [dictionary. The arguments for the biases tf.get_variable().]

name [a string or None, an optional name to attach to this layer.]

Methods

count_params()	Return the number of parameters in the network
<pre>print_layers()</pre>	Print all info of layers in the network
<pre>print_params([details])</pre>	Print all info of parameters in the network

2D Separable convolutional layer

```
class tensorlayer.layers.SeparableConv2dLayer (layer=None, filters=None, kernel size=5,
                                                                                      padding='valid',
                                                               strides=(1,
                                                                              1),
                                                               data format='channels last',
                                                                                                  dila-
                                                               tion\_rate=(1, 1), depth\_multiplier=1,
                                                               act=None,
                                                                                        use_bias=True,
                                                               depthwise_initializer=None,
                                                               pointwise_initializer=None,
                                                               bias_initializer=<class
                                                                                                'tensor-
                                                               flow.python.ops.init ops.Zeros'>,
                                                               depthwise_regularizer=None,
                                                               pointwise_regularizer=None,
                                                               bias_regularizer=None,
                                                                                                 activ-
                                                               ity regularizer=None, name='atrou2d')
```

The SeparableConv2dLayer class is 2-D convolution with separable filters, see tf.layers.separable_conv2d.

Parameters

layer [a layer class]

filters [integer, the dimensionality of the output space (i.e. the number output of filters in the convolution).]

kernel_size [a tuple or list of N positive integers specifying the spatial dimensions of of the filters. Can be a single integer to specify the same value for all spatial dimensions.]

strides [a tuple or list of N positive integers specifying the strides of the convolution. Can be a single integer to specify the same value for all spatial dimensions. Specifying any stride value != 1 is incompatible with specifying any dilation_rate value != 1.]

padding [one of "valid" or "same" (case-insensitive).]

dilation_rate [an integer or tuple/list of 2 integers, specifying the dilation rate to use for dilated convolution. Can be a single integer to specify the same value for all spatial dimensions. Currently, specifying any dilation_rate value != 1 is incompatible with specifying any stride value != 1.]

depth_multiplier [The number of depthwise convolution output channels for each input channel. The total number of depthwise convolution output channels will be equal to num filters in * depth multiplier.]

act (activation) [Activation function. Set it to None to maintain a linear activation.]

use_bias [Boolean, whether the layer uses a bias.]

```
depthwise_initializer [An initializer for the depthwise convolution kernel.]

pointwise_initializer [An initializer for the pointwise convolution kernel.]

bias_initializer [An initializer for the bias vector. If None, no bias will be applied.]

depthwise_regularizer [Optional regularizer for the depthwise convolution kernel.]

pointwise_regularizer [Optional regularizer for the pointwise convolution kernel.]

bias_regularizer [Optional regularizer for the bias vector.]

activity_regularizer [Regularizer function for the output.]

name [a string or None, an optional name to attach to this layer.]
```

Methods

count_params()	Return the number of parameters in the network
<pre>print_layers()</pre>	Print all info of layers in the network
print_params([details])	Print all info of parameters in the network

2.1.13 Convolutional layer (Simplified)

For users don't familiar with TensorFlow, the following simplified functions may easier for you. We will provide more simplified functions later, but if you are good at TensorFlow, the professional APIs may better for you.

1D Convolutional layer

```
tensorlayer.layers.Conv1d(net, n_filter=32, filter_size=5, stride=1, dilation_rate=1, act=None, padding='SAME', use_cudnn_on_gpu=None, data_format='NWC', W_init=<tensorflow.python.ops.init_ops.TruncatedNormal object>, b_init=<tensorflow.python.ops.init_ops.Constant object>, W_init_args={}, b_init_args={}, name='conv1d')

Wrapper for Conv1dLayer, if you don't understand how to use Conv1dLayer, this function may be easier.
```

Parameters

```
net [TensorLayer layer.]
n_filter [number of filter.]
filter_size [an int.]
stride [an int.]
dilation_rate [As it is 1D conv, the default is "NWC".]
act [None or activation function.]
others [see Conv1dLayer.]
```

2D Convolutional layer

```
tensorlayer.layers.Conv2d(net,
                                                    n filter=32.
                                                                            filter size=(3,
                                                                                       padding='SAME',
                                    strides=(1,
                                                        1),
                                                                    act=None,
                                     W_init=<tensorflow.python.ops.init_ops.TruncatedNormal
                                                                                                      ob-
                                              b_init=<tensorflow.python.ops.init_ops.Constant
                                                                                                 object>,
                                    W_{init}_{args={}}
                                                          b_{init}_{args={}}
                                                                               use_cudnn_on_gpu=None,
                                    data_format=None, name='conv2d')
     Wrapper for Conv2dLayer, if you don't understand how to use Conv2dLayer, this function may be easier.
           Parameters
               net [TensorLayer layer.]
               n_filter [number of filter.]
               filter size [tuple (height, width) for filter size.]
               strides [tuple (height, width) for strides.]
               act [None or activation function.]
               others [see Conv2dLayer.]
```

Examples

```
>>> w_init = tf.truncated_normal_initializer(stddev=0.01)
>>> b_init = tf.constant_initializer(value=0.0)
>>> inputs = InputLayer(x, name='inputs')
>>> conv1 = Conv2d(inputs, 64, (3, 3), act=tf.nn.relu, padding='SAME', W_init=w_
init, b_init=b_init, name='conv1_1')
>>> conv1 = Conv2d(conv1, 64, (3, 3), act=tf.nn.relu, padding='SAME', W_init=w_
init, b_init=b_init, name='conv1_2')
>>> pool1 = MaxPool2d(conv1, (2, 2), padding='SAME', name='pool1')
>>> conv2 = Conv2d(pool1, 128, (3, 3), act=tf.nn.relu, padding='SAME', W_init=w_
init, b_init=b_init, name='conv2_1')
>>> conv2 = Conv2d(conv2, 128, (3, 3), act=tf.nn.relu, padding='SAME', W_init=w_
init, b_init=b_init, name='conv2_2')
>>> pool2 = MaxPool2d(conv2, (2, 2), padding='SAME', name='pool2')
```

2D Deconvolutional layer

```
tensorlayer.layers.DeConv2d (net, n_out_channel=32, filter_size=(3, 3), out_size=(30, 30), strides=(2, 2), padding='SAME', batch_size=None, act=None, W_init=<tensorflow.python.ops.init_ops.TruncatedNormal object>, b_init=<tensorflow.python.ops.init_ops.Constant object>, W_init_args={}, b_init_args={}, name='decnn2d')

Wrapper for DeConv2dLayer, if you don't understand how to use DeConv2dLayer, this function may be easier.
```

Parameters

```
net [TensorLayer layer.]
n_out_channel [int, number of output channel.]
filter_size [tuple of (height, width) for filter size.]
out_size [tuple of (height, width) of output.]
```

```
batch_size [int or None, batch_size. If None, try to find the batch_size from the first dim of net.outputs (you should tell the batch_size when define the input placeholder).]
```

strides [tuple of (height, width) for strides.]

act [None or activation function.]

others [see DeConv2dLayer.]

1D Max pooling layer

tensorlayer.layers.MaxPoolld(net, filter_size, strides, padding='valid', data_format='channels_last', name=None)
Wrapper for tf.layers.max pooling1d.

Parameters

net [TensorLayer layer, the tensor over which to pool. Must have rank 3.]

filter_size (**pool_size**) [An integer or tuple/list of a single integer, representing the size of the pooling window.]

strides [An integer or tuple/list of a single integer, specifying the strides of the pooling operation.]

padding [A string. The padding method, either 'valid' or 'same'. Case-insensitive.]

data_format [A string, one of channels_last (default) or channels_first. The ordering of the dimensions in the inputs. channels_last corresponds to inputs with shape (batch, length, channels) while channels_first corresponds to inputs with shape (batch, channels, length).]

name [A string, the name of the layer.]

Returns

- A :class:'Layer' which the output tensor, of rank 3.

1D Mean pooling layer

```
tensorlayer.layers.MeanPoolld(net, filter_size, strides, padding='valid', data_format='channels_last', name=None)
Wrapper for tf.layers.average pooling1d.
```

Parameters

net [TensorLayer layer, the tensor over which to pool. Must have rank 3.]

filter_size (**pool_size**) [An integer or tuple/list of a single integer, representing the size of the pooling window.]

strides [An integer or tuple/list of a single integer, specifying the strides of the pooling operation.]

padding [A string. The padding method, either 'valid' or 'same'. Case-insensitive.]

data_format [A string, one of channels_last (default) or channels_first. The ordering of the dimensions in the inputs. channels_last corresponds to inputs with shape (batch, length, channels) while channels_first corresponds to inputs with shape (batch, channels, length).]

name [A string, the name of the layer.]

Returns

- A :class:'Layer' which the output tensor, of rank 3.

```
2D Max pooling layer
```

```
tensorlayer.layers.MaxPool2d (net, filter_size=(2, 2), strides=None, padding='SAME', name='maxpool')

Wrapper for PoolLayer.

Parameters

net [TensorLayer layer.]

filter_size [tuple of (height, width) for filter size.]

strides [tuple of (height, width). Default is the same with filter_size.]

others [see PoolLayer.]
```

2D Mean pooling layer

```
\label{local_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continu
```

Parameters

```
net [TensorLayer layer.]
filter_size [tuple of (height, width) for filter size.]
strides [tuple of (height, width). Default is the same with filter_size.]
others [see PoolLayer.]
```

3D Max pooling layer

```
tensorlayer.layers.MaxPool3d(net, filter_size, strides, padding='valid', data_format='channels_last', name=None)
Wrapper for tf.layers.max_pooling3d.
```

Parameters

```
net [TensorLayer layer, the tensor over which to pool. Must have rank 5.]
```

filter_size (**pool_size**) [An integer or tuple/list of 3 integers: (pool_depth, pool_height, pool_width) specifying the size of the pooling window. Can be a single integer to specify the same value for all spatial dimensions.]

strides [An integer or tuple/list of 3 integers, specifying the strides of the pooling operation. Can be a single integer to specify the same value for all spatial dimensions.]

```
padding [A string. The padding method, either 'valid' or 'same'. Case-insensitive.]
```

data_format [A string. The ordering of the dimensions in the inputs. channels_last (default) and channels_first are supported. channels_last corresponds to inputs with shape (batch, depth, height, width, channels) while channels_first corresponds to inputs with shape (batch, channels, depth, height, width).]

name [A string, the name of the layer.]

3D Mean pooling layer

```
tensorlayer.layers.MeanPool3d(net, filter_size, strides, padding='valid', data_format='channels_last', name=None)
Wrapper for tf.layers.average_pooling3d
```

Parameters

net [TensorLayer layer, the tensor over which to pool. Must have rank 5.]

filter_size (**pool_size**) [An integer or tuple/list of 3 integers: (pool_depth, pool_height, pool_width) specifying the size of the pooling window. Can be a single integer to specify the same value for all spatial dimensions.]

strides [An integer or tuple/list of 3 integers, specifying the strides of the pooling operation. Can be a single integer to specify the same value for all spatial dimensions.]

padding [A string. The padding method, either 'valid' or 'same'. Case-insensitive.]

data_format [A string. The ordering of the dimensions in the inputs. channels_last (default) and channels_first are supported. channels_last corresponds to inputs with shape (batch, depth, height, width, channels) while channels_first corresponds to inputs with shape (batch, channels, depth, height, width).]

name [A string, the name of the layer.]

Super-resolution layer

```
tensorlayer.layers.SubpixelConv2d(net, scale=2, n_out_channel=None, act=<function identity>, name='subpixel_conv2d')
```

The SubpixelConv2d class is a sub-pixel 2d convolutional ayer, usually be used for Super-Resolution applications, example code.

Parameters

```
net [TensorLayer layer.]
```

scale [int, upscaling ratio, a wrong setting will lead to Dimension size error.]

n_out_channel [int or None, the number of output channels.] Note that, the number of input channels == (scale x scale) x The number of output channels. If None, automatically set n_out_channel == the number of input channels / (scale x scale).

act [activation function.]

name [string.] An optional name to attach to this layer.

Examples

```
>>> # examples here just want to tell you how to set the n_out_channel.
>>> x = np.random.rand(2, 16, 16, 4)
>>> X = tf.placeholder("float32", shape=(2, 16, 16, 4), name="X")
```

(continues on next page)

(continued from previous page)

```
>>> net = InputLayer(X, name='input')
>>> net = SubpixelConv2d(net, scale=2, n_out_channel=1, name='subpixel_conv2d')
>>> y = sess.run(net.outputs, feed_dict={X: x})
>>> print(x.shape, y.shape)
... (2, 16, 16, 4) (2, 32, 32, 1)
>>> x = np.random.rand(2, 16, 16, 4*10)
>>> X = tf.placeholder("float32", shape=(2, 16, 16, 4*10), name="X")
>>> net = InputLayer(X, name='input2')
>>> net = SubpixelConv2d(net, scale=2, n_out_channel=10, name='subpixel_conv2d2')
>>> y = sess.run(net.outputs, feed_dict={X: x})
>>> print(x.shape, y.shape)
... (2, 16, 16, 40) (2, 32, 32, 10)
>>>
>>> x = np.random.rand(2, 16, 16, 25*10)
>>> X = tf.placeholder("float32", shape=(2, 16, 16, 25*10), name="X")
>>> net = InputLayer(X, name='input3')
>>> net = SubpixelConv2d(net, scale=5, n_out_channel=None, name='subpixel_conv2d3
>>> y = sess.run(net.outputs, feed_dict={X: x})
>>> print(x.shape, y.shape)
... (2, 16, 16, 250) (2, 80, 80, 10)
```

2.1.14 Spatial Transformer

2D Affine Transformation layer

```
class tensorlayer.layers.SpatialTransformer2dAffineLayer (layer=None, theta_layer=None, out_size=[40, 40], name='sapatial_trans_2d_affine')
```

The Spatial Transformer 2dAffine Layer class is a Spatial Transformer Layer for 2D Affine Transformation.

Parameters

layer [a layer class with 4-D Tensor of shape [batch, height, width, channels]]

theta_layer [a layer class for the localisation network.] In this layer, we will use a <code>DenseLayer</code> to make the theta size to [batch, 6], value range to [0, 1] (via tanh).

out_size [tuple of two ints.] The size of the output of the network (height, width), the feature maps will be resized by this.

References

- Spatial Transformer Networks
- TensorFlow/Models

Methods

count_params()	Return the number of parameters in the network
<pre>print_layers()</pre>	Print all info of layers in the network
<pre>print_params([details])</pre>	Print all info of parameters in the network

2D Affine Transformation function

```
tensorlayer.layers.transformer(U, theta, out_size, name='SpatialTransformer2dAffine', **kwargs)
```

Spatial Transformer Layer for 2D Affine Transformation, see SpatialTransformer2dAffineLayer class.

Parameters

U [float] The output of a convolutional net should have the shape [num_batch, height, width, num_channels].

theta: float The output of the localisation network should be [num_batch, 6], value range should be [0, 1] (via tanh).

out_size: tuple of two ints The size of the output of the network (height, width)

Notes

• To initialize the network to the identity transform init.

Batch 2D Affine Transformation function

tensorlayer.layers.batch_transformer(U, thetas, out_size, name='BatchSpatialTransformer2dAffine')
Batch Spatial Transformer function for 2D Affine Transformation.

Parameters

```
U [float] tensor of inputs [batch, height, width, num_channels]
```

thetas [float] a set of transformations for each input [batch, num_transforms, 6]

out_size [int] the size of the output [out_height, out_width]

Returns: float Tensor of size [batch * num_transforms, out_height, out_width, num_channels]

2.1.15 Pooling layer

Pooling layer for any dimensions and any pooling functions.

The *PoolLayer* class is a Pooling layer, you can choose tf.nn.max_pool and tf.nn.avg_pool for 2D or tf.nn.max_pool3d and tf.nn.avg_pool3d for 3D.

Parameters

layer [a Layer instance] The Layer class feeding into this layer.

ksize [a list of ints that has length >= 4.] The size of the window for each dimension of the input tensor.

strides [a list of ints that has length >= 4.] The stride of the sliding window for each dimension of the input tensor.

padding [a string from: "SAME", "VALID".] The type of padding algorithm to use.

pool [a pooling function]

- see TensorFlow pooling APIs
- class tf.nn.max_pool
- class tf.nn.avg_pool
- class tf.nn.max_pool3d
- class tf.nn.avg_pool3d

name [a string or None] An optional name to attach to this layer.

Examples

• see Conv2dLayer.

Methods

count_params()	Return the number of parameters in the network
<pre>print_layers()</pre>	Print all info of layers in the network
<pre>print_params([details])</pre>	Print all info of parameters in the network

2.1.16 Padding layer

Padding layer for any modes.

The PadLayer class is a Padding layer for any modes and dimensions. Please see tf.pad for usage.

Parameters

```
layer [a Layer instance] The Layer class feeding into this layer. padding [a Tensor of type int32.]
```

```
mode [one of "CONSTANT", "REFLECT", or "SYMMETRIC" (case-insensitive)]
name [a string or None] An optional name to attach to this layer.
```

Methods

count_params()	Return the number of parameters in the network
<pre>print_layers()</pre>	Print all info of layers in the network
<pre>print_params([details])</pre>	Print all info of parameters in the network

2.1.17 Normalization layer

For local response normalization as it does not have any weights and arguments, you can also apply tf.nn.lrn on network.outputs.

Batch Normalization

The BatchNormLayer class is a normalization layer, see tf.nn.batch_normalization and tf.nn. moments.

Batch normalization on fully-connected or convolutional maps.

Parameters

layer [a Layer instance] The Layer class feeding into this layer.

decay [float, default is 0.9.] A decay factor for ExponentialMovingAverage, use larger value for large dataset.

epsilon [float] A small float number to avoid dividing by 0.

act [activation function.]

is_train [boolean] Whether train or inference.

beta_init [beta initializer] The initializer for initializing beta

gamma_init [gamma initializer] The initializer for initializing gamma

name [a string or None] An optional name to attach to this layer.

References

Methods

count_params()	Return the number of parameters in the network
<pre>print_layers()</pre>	Print all info of layers in the network
print_params([details])	Print all info of parameters in the network

Local Response Normalization

The LocalResponseNormLayer class is for Local Response Normalization, see tf.nn.local_response_normalization or tf.nn.lrn for new TF version. The 4-D input tensor is treated as a 3-D array of 1-D vectors (along the last dimension), and each vector is normalized independently. Within a given vector, each component is divided by the weighted, squared sum of inputs within depth_radius.

Parameters

layer [a layer class. Must be one of the following types: float32, half. 4-D.]

depth_radius [An optional int. Defaults to 5. 0-D. Half-width of the 1-D normalization window.]

bias [An optional float. Defaults to 1. An offset (usually positive to avoid dividing by 0).]

alpha [An optional float. Defaults to 1. A scale factor, usually positive.]

beta [An optional float. Defaults to 0.5. An exponent.]

name [A string or None, an optional name to attach to this layer.]

Methods

count_params()	Return the number of parameters in the network
<pre>print_layers()</pre>	Print all info of layers in the network
print_params([details])	Print all info of parameters in the network

2.1.18 Time distributed layer

The <code>TimeDistributedLayer</code> class that applies a function to every timestep of the input tensor. For example, if using <code>DenseLayer</code> as the <code>layer_class</code>, inputs [batch_size , length, dim] outputs [batch_size , length, new_dim].

Parameters

layer [a Layer instance] The Layer class feeding into this layer, [batch_size, length, dim]

layer_class [a Layer class]

args [dictionary] The arguments for the layer_class.

name [a string or None] An optional name to attach to this layer.

Examples

```
>>> batch_size = 32
>>> timestep = 20
>>> input_dim = 100
>>> x = tf.placeholder(dtype=tf.float32, shape=[batch_size, timestep, input_dim],
→ name="encode_seqs")
>>> net = InputLayer(x, name='input')
>>> net = TimeDistributedLayer(net, layer_class=DenseLayer, args={'n_units':50,
→ 'name':'dense'}, name='time_dense')
... [TL] InputLayer input: (32, 20, 100)
... [TL] TimeDistributedLayer time_dense: layer_class:DenseLayer
>>> print (net.outputs._shape)
... (32, 20, 50)
>>> net.print_params(False)
... param 0: (100, 50)
                                  time_dense/dense/W:0
... param 1: (50,)
                                  time_dense/dense/b:0
... num of params: 5050
```

Methods

count_params()	Return the number of parameters in the network
<pre>print_layers()</pre>	Print all info of layers in the network
print_params([details])	Print all info of parameters in the network

2.1.19 Fixed Length Recurrent layer

All recurrent layers can implement any type of RNN cell by feeding different cell function (LSTM, GRU etc).

RNN layer

```
class tensorlayer.layers.RNNLayer(layer=None,
                                                                                      cell fn=None,
                                                                      n_hidden=100,
                                             cell\_init\_args={},
                                                                                             initial-
                                             izer=<tensorflow.python.ops.init_ops.RandomUniform
                                             object>, n steps=5, initial state=None, return last=False,
                                             return_seq_2d=False, name='rnn_layer')
```

The RNNLayer class is a RNN layer, you can implement vanilla RNN, LSTM and GRU with it.

Parameters

```
layer [a Layer instance] The Layer class feeding into this layer.
cell_fn [a TensorFlow's core RNN cell as follow (Note TF1.0+ and TF1.0- are different).]
    · see RNN Cells in TensorFlow
cell_init_args [a dictionary] The arguments for the cell initializer.
n_hidden [a int] The number of hidden units in the layer.
initializer [initializer] The initializer for initializing the parameters.
n_steps [a int] The sequence length.
initial state [None or RNN State] If None, initial state is zero state.
```

return_last [boolean]

- If True, return the last output, "Sequence input and single output"
- If False, return all outputs, "Synced sequence input and output"
- In other word, if you want to apply one or more RNN(s) on this layer, set to False.

return seq 2d [boolean]

- When return last = False
- If True, return 2D Tensor [n_example, n_hidden], for stacking DenseLayer after it.
- If False, return 3D Tensor [n_example/n_steps, n_steps, n_hidden], for stacking multiple RNN after it.

name [a string or None] An optional name to attach to this layer.

Notes

Input dimension should be rank 3: [batch_size, n_steps, n_features], if no, please see ReshapeLayer.

Examples

· For words

```
>>> input_data = tf.placeholder(tf.int32, [batch_size, num_steps])
>>> network = tl.layers.EmbeddingInputlayer(
                    inputs = input_data,
. . .
                    vocabulary_size = vocab_size,
. . .
                    embedding_size = hidden_size,
. . .
                    E_init = tf.random_uniform_initializer(-init_scale, init_
⇔scale),
                    name ='embedding_layer')
>>> if is_training:
      network = tl.layers.DropoutLayer(network, keep=keep_prob, name='drop1')
>>> network = tl.layers.RNNLayer(network,
                cell_fn=tf.nn.rnn_cell.BasicLSTMCell,
                cell_init_args={'forget_bias': 0.0},# 'state_is_tuple': True},
. . .
                n_hidden=hidden_size,
. . .
                initializer=tf.random_uniform_initializer(-init_scale, init_
. . .
⇔scale),
                n_steps=num_steps,
. . .
                return_last=False,
. . .
                name='basic_lstm_layer1')
. . .
```

(continues on next page)

(continued from previous page)

```
>>> lstm1 = network
>>> if is training:
       network = tl.layers.DropoutLayer(network, keep=keep_prob, name='drop2')
>>> network = tl.layers.RNNLayer(network,
                cell_fn=tf.nn.rnn_cell.BasicLSTMCell,
                cell_init_args={'forget_bias': 0.0}, # 'state_is_tuple': True},

Methods

count_params()	Return the number of parameters in the network
<pre>print_layers()</pre>	Print all info of layers in the network
<pre>print_params([details])</pre>	Print all info of parameters in the network

Bidirectional layer

```
class tensorlayer.layers.Birnnlayer (layer=None, cell_fn=None, cell_init_args={'state_is_tuple': True, 'use_peepholes': True}, n_hidden=100, initial-izer=<tensorflow.python.ops.init_ops.RandomUniform object>, n_steps=5, fw_initial_state=None, bw_initial_state=None, dropout=None, n_layer=1, return_last=False, return_seq_2d=False, name='birnn_layer')
```

The BirnnLayer class is a Bidirectional RNN layer.

Parameters

```
layer [a Layer instance] The Layer class feeding into this layer.
```

cell_fn [a TensorFlow's core RNN cell as follow (Note TF1.0+ and TF1.0- are different).]

• see RNN Cells in TensorFlow

cell_init_args [a dictionary] The arguments for the cell initializer.

n_hidden [a int] The number of hidden units in the layer.

initializer [initializer] The initializer for initializing the parameters.

n_steps [a int] The sequence length.

fw_initial_state [None or forward RNN State] If None, initial_state is zero_state.

bw_initial_state [None or backward RNN State] If None, initial_state is zero_state.

dropout [*tuple* of *float*: (input_keep_prob, output_keep_prob).] The input and output keep probability.

n_layer [a int, default is 1.] The number of RNN layers.

return_last [boolean]

• If True, return the last output, "Sequence input and single output"

- If False, return all outputs, "Synced sequence input and output"
- In other word, if you want to apply one or more RNN(s) on this layer, set to False.

return_seq_2d [boolean]

- When return_last = False
- If True, return 2D Tensor [n example, n hidden], for stacking DenseLayer after it.
- If False, return 3D Tensor [n_example/n_steps, n_steps, n_hidden], for stacking multiple RNN after it.

name [a string or None] An optional name to attach to this layer.

Notes

- Input dimension should be rank 3: [batch_size, n_steps, n_features], if no, please see ReshapeLayer.
- For predicting, the sequence length has to be the same with the sequence length of training, while, for normal

RNN, we can use sequence length of 1 for predicting.

2.1.20 Advanced Ops for Dynamic RNN

These operations usually be used inside Dynamic RNN layer, they can compute the sequence lengths for different situation and get the last RNN outputs by indexing.

Output indexing

tensorlayer.layers.advanced_indexing_op(input, index)

Advanced Indexing for Sequences, returns the outputs by given sequence lengths. When return the last output <code>DynamicRNNLayer</code> uses it to get the last outputs with the sequence lengths.

Parameters

input [tensor for data] [batch_size, n_step(max), n_features]

index [tensor for indexing, i.e. sequence_length in Dynamic RNN.] [batch_size]

References

• Modified from TFlearn (the original code is used for fixed length rnn), references.

Examples

```
>>> batch_size, max_length, n_features = 3, 5, 2
>>> z = np.random.uniform(low=-1, high=1, size=[batch_size, max_length, n_
→features]).astype(np.float32)
>>> b_z = tf.constant(z)
>>> sl = tf.placeholder(dtype=tf.int32, shape=[batch_size])
>>> o = advanced_indexing_op(b_z, sl)
>>> sess = tf.InteractiveSession()
>>> tl.layers.initialize_global_variables(sess)
>>>
>>> order = np.asarray([1,1,2])
>>> print("real", z[0][order[0]-1], z[1][order[1]-1], z[2][order[2]-1])
>>> y = sess.run([o], feed_dict={sl:order})
>>> print("given", order)
>>> print("out", y)
... real [-0.93021595 0.53820813] [-0.92548317 -0.77135968] [ 0.89952248 0.
→19149846]
... given [1 1 2]
... out [array([[-0.93021595, 0.53820813],
. . .
                [-0.92548317, -0.77135968],
                [ 0.89952248, 0.19149846]], dtype=float32)]
. . .
```

Compute Sequence length 1

```
tensorlayer.layers.retrieve_seq_length_op(data)
```

An op to compute the length of a sequence from input shape of [batch_size, n_step(max), n_features], it can be used when the features of padding (on right hand side) are all zeros.

Parameters

data [tensor] [batch_size, n_step(max), n_features] with zero padding on right hand side.

References

· Borrow from TFlearn.

Examples

(continues on next page)

(continued from previous page)

```
>>> sl = retrieve_seq_length_op(data)
>>> sess = tf.InteractiveSession()
>>> tl.layers.initialize_global_variables(sess)
>>> y = sl.eval()
... [2 3 4]
```

· Multiple features

Compute Sequence length 2

```
tensorlayer.layers.retrieve_seq_length_op2 (data)
```

An op to compute the length of a sequence, from input shape of [batch_size, n_step(max)], it can be used when the features of padding (on right hand side) are all zeros.

Parameters

data [tensor] [batch_size, n_step(max)] with zero padding on right hand side.

Examples

2.1.21 Dynamic RNN layer

RNN layer

Parameters

layer [a Layer instance] The Layer class feeding into this layer.

cell_fn [a TensorFlow's core RNN cell as follow (Note TF1.0+ and TF1.0- are different).]

• see RNN Cells in TensorFlow

cell_init_args [a dictionary] The arguments for the cell initializer.

n_hidden [a int] The number of hidden units in the layer.

initializer [initializer] The initializer for initializing the parameters.

sequence_length [a tensor, array or None. The sequence length of each row of input data, see Advanced Ops for Dynamic RNN.]

- If None, it uses retrieve_seq_length_op to compute the sequence_length, i.e. when the features of padding (on right hand side) are all zeros.
- If using word embedding, you may need to compute the sequence_length from the ID array (the integer features before word embedding) by using retrieve_seq_length_op2 or retrieve_seq_length_op.
- You can also input an numpy array.
- More details about TensorFlow dynamic_rnn in Wild-ML Blog.

initial_state [None or RNN State] If None, initial_state is zero_state.

dropout [*tuple* of *float*: (input_keep_prob, output_keep_prob).] The input and output keep probability.

n_layer [a int, default is 1.] The number of RNN layers.

return_last [boolean]

- If True, return the last output, "Sequence input and single output"
- If False, return all outputs, "Synced sequence input and output"
- In other word, if you want to apply one or more RNN(s) on this layer, set to False.

return_seq_2d [boolean]

- When return_last = False
- If True, return 2D Tensor [n_example, n_hidden], for stacking DenseLayer or computing cost after it.
- If False, return 3D Tensor [n_example/n_steps(max), n_steps(max), n_hidden], for stacking multiple RNN after it.

name [a string or None] An optional name to attach to this layer.

Notes

Input dimension should be rank 3: [batch_size, n_steps(max), n_features], if no, please see ReshapeLayer.

                                                          bw_initial_state=None,
                                                                                      dropout=None,
                                                          n_{layer=1},
                                                                                   return_last=False,
                                                          return_seq_2d=False,
                                                                                                 dv-
                                                          namic_rnn_init_args={},
                                                          name='bi dyrnn layer')
```

The BiDynamicRNNLayer class is a RNN layer, you can implement vanilla RNN, LSTM and GRU with it.

Parameters

```
layer [a Layer instance] The Layer class feeding into this layer.
cell_fn [a TensorFlow's core RNN cell as follow (Note TF1.0+ and TF1.0- are different).]
see RNN Cells in TensorFlow
cell_init_args [a dictionary] The arguments for the cell initializer.
n_hidden [a int] The number of hidden units in the layer.
```

initializer [initializer] The initializer for initializing the parameters.

sequence_length [a tensor, array or None]

The sequence length of each row of input data, see Advanced Ops for Dynamic RNN.

- If None, it uses retrieve_seq_length_op to compute the sequence_length, i.e. when the features of padding (on right hand side) are all zeros.
- If using word embedding, you may need to compute the sequence_length from the ID array (the integer features before word embedding) by using retrieve_seq_length_op2 or retrieve_seq_length_op.
- You can also input an numpy array.
- More details about TensorFlow dynamic_rnn in Wild-ML Blog.

fw_initial_state [None or forward RNN State] If None, initial_state is zero_state.

bw_initial_state [None or backward RNN State] If None, initial_state is zero_state.

dropout [tuple of float: (input_keep_prob, output_keep_prob).] The input and output keep probability.

n_layer [a int, default is 1.] The number of RNN layers.

return_last [boolean] If True, return the last output, "Sequence input and single output"

If False, return all outputs, "Synced sequence input and output"

In other word, if you want to apply one or more RNN(s) on this layer, set to False.

return_seq_2d [boolean]

- When return_last = False
- If True, return 2D Tensor [n_example, 2 * n_hidden], for stacking DenseLayer or computing cost after it.
- If False, return 3D Tensor [n_example/n_steps(max), n_steps(max), 2 * n_hidden], for stacking multiple RNN after it.

name [a string or None] An optional name to attach to this layer.

Notes

Input dimension should be rank 3: [batch_size, n_steps(max), n_features], if no, please see ReshapeLayer.

2.1.22 Sequence to Sequence

Simple Seq2Seq

```
class tensorlayer.layers.Seq2Seq (net_encode_in=None, net_decode_in=None, cell_fn=None,
                                            cell_init_args={'state_is_tuple':
                                                                              True\}, n hidden=256,
                                            initializer=<tensorflow.python.ops.init_ops.RandomUniform</pre>
                                                            encode sequence length=None,
                                            code_sequence_length=None,
                                                                                  initial_state=None,
                                            dropout=None,
                                                                n_{layer=1},
                                                                                return\_seq\_2d=False,
                                            name = 'seq2seq')
```

The Seq2Seq class is a simple DynamicRNNLayer based Seq2seq layer, both encoder and decoder are DynamicRNNLayer, network details see Model and Sequence to Sequence Learning with Neural Networks.

Parameters

```
net_encode_in [a Layer instance] Encode sequences, [batch_size, None, n_features].
net_decode_in [a Layer instance] Decode sequences, [batch_size, None, n_features].
cell_fn [a TensorFlow's core RNN cell as follow (Note TF1.0+ and TF1.0- are different).]
    • see RNN Cells in TensorFlow
cell init args [a dictionary] The arguments for the cell initializer.
n hidden [a int] The number of hidden units in the layer.
initializer [initializer] The initializer for initializing the parameters.
encode_sequence_length [tensor for encoder sequence length, see DynamicRNNLayer.]
decode_sequence_length [tensor for decoder sequence length, see DynamicRNNLayer.]
initial_state [None or forward RNN State] If None, initial_state is of encoder zero_state.
dropout [tuple of float: (input_keep_prob, output_keep_prob).] The input and output keep
    probability.
n_layer [a int, default is 1.] The number of RNN layers.
return_seq_2d [boolean]
```

- When return last = False
- If True, return 2D Tensor [n_example, n_hidden], for stacking DenseLayer or computing cost after it.
- If False, return 3D Tensor [n example/n steps(max), n steps(max), n hidden], for stacking multiple RNN after it.

name [a string or None] An optional name to attach to this layer.

Notes

- How to feed data: Sequence to Sequence Learning with Neural Networks
- input_seqs: ['how', 'are', 'you', '<PAD_ID'>]
- decode seqs:['<START ID>', 'I', 'am', 'fine', '<PAD ID'>]

```
target_seqs: ['I', 'am', 'fine', '<END_ID']</li>
target_mask: [1, 1, 1, 1, 0]
related functions: tl.prepro <pad_sequences, precess_sequences, sequences_add_start_id, se-</li>
```

Examples

quences_get_mask>

```
>>> from tensorlayer.layers import *
>>> batch_size = 32
>>> encode_seqs = tf.placeholder(dtype=tf.int64, shape=[batch_size, None], name=
→ "encode segs")
>>> decode_seqs = tf.placeholder(dtype=tf.int64, shape=[batch_size, None], name=
→ "decode seas")
>>> target_seqs = tf.placeholder(dtype=tf.int64, shape=[batch_size, None], name=
→"target_segs")
>>> target_mask = tf.placeholder(dtype=tf.int64, shape=[batch_size, None], name=
→"target_mask") # tl.prepro.sequences_get_mask()
>>> with tf.variable_scope("model"):
        # for chatbot, you can use the same embedding layer,
        # for translation, you may want to use 2 seperated embedding layers
        with tf.variable_scope("embedding") as vs:
>>>
>>>
            net_encode = EmbeddingInputlayer(
                    inputs = encode_seqs,

                initializer = tf.random_uniform_initializer(-0.1, 0.1),
. . .
                encode_sequence_length = retrieve_seq_length_op2(encode_seqs),
. . .
                decode_sequence_length = retrieve_seq_length_op2(decode_seqs),
                initial_state = None,
                dropout = None,
. . .
                n_{layer} = 1,
. . .
                return_seq_2d = True,
. . .
                name = 'seq2seq')
>>> net_out = DenseLayer(net, n_units=10000, act=tf.identity, name='output')
>>> e_loss = tl.cost.cross_entropy_seq_with_mask(logits=net_out.outputs, target_
→seqs=target_seqs, input_mask=target_mask, return_details=False, name='cost')
>>> y = tf.nn.softmax(net_out.outputs)
>>> net_out.print_params(False)
```

Methods

count_params()	Return the number of parameters in the network
<pre>print_layers()</pre>	Print all info of layers in the network
print_params([details])	Print all info of parameters in the network

PeekySeq2Seq

class tensorlayer.layers.PeekySeq2Seq(net_encode_in=None, net_decode_in=None, cell_fn=None, cell_init_args={'state_is_tuple': True}, n hidden=256, izer=<tensorflow.python.ops.init ops.RandomUniform object>, in_sequence_length=None, out_sequence_length=None, initial state=None, dropout=None, n_layer=1, return_seq_2d=False, name='peeky_seq2seq')
Waiting for contribution. The PeekySeq2Seq class, see Model and Learning Phrase Representations using

RNN Encoder-Decoder for Statistical Machine Translation.

Methods

count_params()	Return the number of parameters in the network
<pre>print_layers()</pre>	Print all info of layers in the network
print_params([details])	Print all info of parameters in the network

AttentionSeq2Seq

class tensorlayer.layers.AttentionSeq2Seq(net_encode_in=None, net_decode_in=None, cell_fn=None, cell_init_args={'state_is_tuple': True, $n_hidden=256$, initializer=<tensorflow.python.ops.init_ops.RandomUniform in_sequence_length=None, object>, out_sequence_length=None, tial_state=None, dropout=None, n layer=1, return seg 2d=False, name='attention_seq2seq')

Waiting for contribution. The AttentionSeq2Seq class, see Model and Neural Machine Translation by Jointly Learning to Align and Translate.

Methods

count_params()	Return the number of parameters in the network
<pre>print_layers()</pre>	Print all info of layers in the network
print_params([details])	Print all info of parameters in the network

2.1.23 Shape layer

Flatten layer

```
class tensorlayer.layers.FlattenLayer(layer=None, name='flatten_layer')
```

The FlattenLayer class is layer which reshape high-dimension input to a vector. Then we can apply Dense-Layer, RNNLayer, ConcatLayer and etc on the top of it.

[batch_size, mask_row, mask_col, n_mask] -> [batch_size, mask_row * mask_col * n_mask]

Parameters

layer [a Layer instance] The Layer class feeding into this layer.

name [a string or None] An optional name to attach to this layer.

Examples

```
>>> x = tf.placeholder(tf.float32, shape=[None, 28, 28, 1])
>>> network = tl.layers.InputLayer(x, name='input_layer')
>>> network = tl.layers.Conv2dLayer(network,
                       act = tf.nn.relu,
                       shape = [5, 5, 32, 64],
                       strides=[1, 1, 1, 1],
                       padding='SAME',
                       name ='cnn_layer')
. . .
>>> network = tl.layers.Pool2dLayer(network,
                       ksize=[1, 2, 2, 1],
                       strides=[1, 2, 2, 1],
                      padding='SAME',
. . .
                      pool = tf.nn.max_pool,
. . .
                       name ='pool_layer',)
. . .
>>> network = tl.layers.FlattenLayer(network, name='flatten_layer')
```

Methods

count_params()	Return the number of parameters in the network
<pre>print_layers()</pre>	Print all info of layers in the network
<pre>print_params([details])</pre>	Print all info of parameters in the network

Reshape layer

class tensorlayer.layers.**ReshapeLayer** (layer=None, shape=[], name='reshape_layer')
The ReshapeLayer class is layer which reshape the tensor.

Parameters

layer [a Layer instance] The Layer class feeding into this layer.

shape [a list] The output shape.

name [a string or None] An optional name to attach to this layer.

Examples

- The core of this layer is tf.reshape.
- Use TensorFlow only:

Methods

count_params()	Return the number of parameters in the network
<pre>print_layers()</pre>	Print all info of layers in the network
<pre>print_params([details])</pre>	Print all info of parameters in the network

2.1.24 Lambda layer

The LambdaLayer class is a layer which is able to use the provided function.

Parameters

layer [a Layer instance] The Layer class feeding into this layer.

fn [a function] The function that applies to the outputs of previous layer.

fn_args [a dictionary] The arguments for the function (option).

name [a string or None] An optional name to attach to this layer.

Examples

```
>>> x = tf.placeholder(tf.float32, shape=[None, 1], name='x')
>>> network = tl.layers.InputLayer(x, name='input_layer')
>>> network = LambdaLayer(network, lambda x: 2*x, name='lambda_layer')
>>> y = network.outputs
>>> sess = tf.InteractiveSession()
>>> out = sess.run(y, feed_dict={x : [[1],[2]]})
... [[2],[4]]
```

Methods

count_params()	Return the number of parameters in the network
<pre>print_layers()</pre>	Print all info of layers in the network
print_params([details])	Print all info of parameters in the network

2.1.25 Merge layer

Concat layer

```
class tensorlayer.layers.ConcatLayer(layer=[], concat_dim=1, name='concat_layer')
    The ConcatLayer class is layer which concat (merge) two or more DenseLayer to a single class:DenseLayer.
```

Parameters

layer [a list of Layer instances] The Layer class feeding into this layer.

concat_dim [int] Dimension along which to concatenate.

name [a string or None] An optional name to attach to this layer.

Examples

```
>>> sess = tf.InteractiveSession()
>>> x = tf.placeholder(tf.float32, shape=[None, 784])
>>> inputs = tl.layers.InputLayer(x, name='input_layer')
>>> net1 = tl.layers.DenseLayer(inputs, n_units=800, act = tf.nn.relu, name=
→'relu1 1')
>>> net2 = tl.layers.DenseLayer(inputs, n_units=300, act = tf.nn.relu, name=
→'relu2_1')
>>> network = tl.layers.ConcatLayer(layer = [net1, net2], name ='concat_layer')
        [TL] InputLayer input_layer (?, 784)
        [TL] DenseLayer relu1_1: 800, <function relu at 0x1108e41e0>
. . .
        [TL] DenseLayer relu2_1: 300, <function relu at 0x1108e41e0>
. . .
        [TL] ConcatLayer concat_layer, 1100
. . .
. . .
>>> tl.layers.initialize_global_variables(sess)
>>> network.print_params()
        param 0: (784, 800) (mean: 0.000021, median: -0.000020 std: 0.035525)
        param 1: (800,) (mean: 0.000000, median: 0.000000 std: 0.000000)
. . .
       param 2: (784, 300) (mean: 0.000000, median: -0.000048 std: 0.042947)
. . .
        param 3: (300,) (mean: 0.000000, median: 0.000000 std: 0.000000)
. . .
       num of params: 863500
>>> network.print_layers()
        layer 0: Tensor("Relu:0", shape=(?, 800), dtype=float32)
        layer 1: Tensor("Relu_1:0", shape=(?, 300), dtype=float32)
. . .
. . .
```

Methods

count_params()	Return the number of parameters in the network
<pre>print_layers()</pre>	Print all info of layers in the network
print_params([details])	Print all info of parameters in the network

Element-wise layer

The *ElementwiseLayer* class combines multiple *Layer* which have the same output shapes by a given elemwise-wise operation.

Parameters

```
layer [a list of Layer instances] The Layer class feeding into this layer.
```

```
combine_fn [a TensorFlow elemwise-merge function] e.g. AND is tf.minimum; OR is tf.
maximum; ADD is tf.add; MUL is tf.multiply and so on. See TensorFlow Math
API.
```

name [a string or None] An optional name to attach to this layer.

Examples

• AND Logic

Methods

count_params()	Return the number of parameters in the network
<pre>print_layers()</pre>	Print all info of layers in the network
<pre>print_params([details])</pre>	Print all info of parameters in the network

2.1.26 Extend layer

Expand dims layer

```
class tensorlayer.layers.ExpandDimsLayer(layer=None, axis=None, name='expand_dims')
The ExpandDimsLayer class inserts a dimension of 1 into a tensor's shape, see tf.expand_dims().
```

Parameters

```
layer [a Layer instance] The Layer class feeding into this layer.axis [int, 0-D (scalar).] Specifies the dimension index at which to expand the shape of input.name [a string or None] An optional name to attach to this layer.
```

Methods

count_params()	Return the number of parameters in the network
<pre>print_layers()</pre>	Print all info of layers in the network
print_params([details])	Print all info of parameters in the network

Tile laver

class tensorlayer.layers.**TileLayer** (*layer=None*, *multiples=None*, *name='tile'*)

The *TileLayer* class constructs a tensor by tiling a given tensor, see tf.tile().

Parameters

layer [a Layer instance] The Layer class feeding into this layer.

multiples: a list of int Must be one of the following types: int32, int64. 1-D. Length must be the same as the number of dimensions in input

name [a string or None] An optional name to attach to this layer.

Methods

count_params()	Return the number of parameters in the network
<pre>print_layers()</pre>	Print all info of layers in the network
print_params([details])	Print all info of parameters in the network

2.1.27 Estimator layer

The EstimatorLayer class accepts model_fn that described the model. It is similar with KerasLayer, see tutorial_keras.py

Parameters

layer [a Layer instance] The Layer class feeding into this layer.

model_fn [a function that described the model.]

args [dictionary] The arguments for the model_fn.

name [a string or None] An optional name to attach to this layer.

Methods

count_params()	Return the number of parameters in the network
<pre>print_layers()</pre>	Print all info of layers in the network
<pre>print_params([details])</pre>	Print all info of parameters in the network

2.1.28 Connect TF-Slim

Yes! TF-Slim models can be connected into TensorLayer, all Google's Pre-trained model can be used easily, see Slim-model.

The SlimNetsLayer class can be used to merge all TF-Slim nets into TensorLayer. Model can be found in slim-model, more about slim see slim-git.

Parameters

layer [a Layer instance] The Layer class feeding into this layer.

slim_layer [a slim network function] The network you want to stack onto, end with return
net, end_points.

slim_args [dictionary] The arguments for the slim model.

name [a string or None] An optional name to attach to this layer.

Notes

The due to TF-Slim stores the layers as dictionary, the all_layers in this network is not in order! Fortunately, the all_params are in order.

Examples

• see Inception V3 example on Github

Methods

count_params()	Return the number of parameters in the network
<pre>print_layers()</pre>	Print all info of layers in the network
<pre>print_params([details])</pre>	Print all info of parameters in the network

2.1.29 Connect Keras

Yes! Keras models can be connected into TensorLayer! see tutorial_keras.py.

The KerasLayer class can be used to merge all Keras layers into TensorLayer. Example can be found here tutorial_keras.py

Parameters

layer [a Layer instance] The Layer class feeding into this layer.

keras_layer [a keras network function]

keras_args [dictionary] The arguments for the keras model.

name [a string or None] An optional name to attach to this layer.

Methods

count_params()	Return the number of parameters in the network
<pre>print_layers()</pre>	Print all info of layers in the network
print_params([details])	Print all info of parameters in the network

2.1.30 Parametric activation layer

The PReluLayer class is Parametric Rectified Linear layer.

Parameters

x [A Tensor with type float, double, int32, int64, uint8,] int16, or int8.

channel_shared [bool. Single weight is shared by all channels]

a_init [alpha initializer, default zero constant.] The initializer for initializing the alphas.

a_init_args [dictionary] The arguments for the weights initializer.

name [A name for this activation op (optional).]

Methods

count_params()	Return the number of parameters in the network
<pre>print_layers()</pre>	Print all info of layers in the network
<pre>print_params([details])</pre>	Print all info of parameters in the network

2.1.31 Flow control layer

class tensorlayer.layers.MultiplexerLayer(layer=[], name='mux_layer')

The MultiplexerLayer selects one of several input and forwards the selected input into the output, see tutorial_mnist_multiplexer.py.

Parameters

 $\textbf{layer} \ \ [\text{a list of } \textit{Layer} \ \text{instances}] \ \text{The } \textit{Layer} \ \text{class feeding into this layer}.$

name [a string or None] An optional name to attach to this layer.

References

• See tf.pack() for TF0.12 or tf.stack() for TF1.0 and tf.gather() at Tensor-Flow-Slicing and Joining

Examples

```
>>> x = tf.placeholder(tf.float32, shape=[None, 784], name='x')
>>> y_ = tf.placeholder(tf.int64, shape=[None, ], name='y_')
>>> # define the network
>>> net_in = tl.layers.InputLayer(x, name='input_layer')
>>> net_in = tl.layers.DropoutLayer(net_in, keep=0.8, name='drop1')
>>> # net 0
>>> net_0 = tl.layers.DenseLayer(net_in, n_units=800,
                                   act = tf.nn.relu, name='net0/relu1')
>>> net_0 = t1.layers.DropoutLayer(net_0, keep=0.5, name='net0/drop2')
>>> net_0 = tl.layers.DenseLayer(net_0, n_units=800,
                                   act = tf.nn.relu, name='net0/relu2')
>>> # net 1
>>> net_1 = tl.layers.DenseLayer(net_in, n_units=800,
                                   act = tf.nn.relu, name='net1/relu1')
>>> net_1 = tl.layers.DropoutLayer(net_1, keep=0.8, name='net1/drop2')
>>> net_1 = tl.layers.DenseLayer(net_1, n_units=800,
                                   act = tf.nn.relu, name='net1/relu2')
>>> net_1 = tl.layers.DropoutLayer(net_1, keep=0.8, name='net1/drop3')
>>> net_1 = tl.layers.DenseLayer(net_1, n_units=800,
                                   act = tf.nn.relu, name='net1/relu3')
>>> # multiplexer
>>> net_mux = tl.layers.MultiplexerLayer(layer = [net_0, net_1], name='mux_layer')
>>> network = tl.layers.ReshapeLayer(net_mux, shape=[-1, 800], name='reshape_layer
>>> network = tl.layers.DropoutLayer(network, keep=0.5, name='drop3')
>>> # output layer
>>> network = tl.layers.DenseLayer(network, n_units=10,
                                   act = tf.identity, name='output_layer')
```

Methods

count_params()	Return the number of parameters in the network
<pre>print_layers()</pre>	Print all info of layers in the network
print_params([details])	Print all info of parameters in the network

2.1.32 Wrapper

Embedding + Attention + Seq2seq

This example implements a multi-layer recurrent neural network as encoder, and an attention-based decoder. This is the same as the model described in this paper: - Grammar as a Foreign Language please look there for details, or into the seq2seq library for complete model implementation. This example also allows to use GRU cells in addition to LSTM cells, and sampled softmax to handle large output vocabulary size. A single-layer version of this model, but with bi-directional encoder, was presented in - Neural Machine Translation by Jointly Learning to Align and Translate The sampled softmax is described in Section 3 of the following paper. - On Using Very Large Target Vocabulary for Neural Machine Translation

Parameters

source_vocab_size [size of the source vocabulary.]

target_vocab_size [size of the target vocabulary.]

buckets [a list of pairs (I, O), where I specifies maximum input length] that will be processed in that bucket, and O specifies maximum output length. Training instances that have inputs longer than I or outputs longer than O will be pushed to the next bucket and padded accordingly. We assume that the list is sorted, e.g., [(2, 4), (8, 16)].

size [number of units in each layer of the model.]

num_layers [number of layers in the model.]

max_gradient_norm [gradients will be clipped to maximally this norm.]

batch_size [the size of the batches used during training;] the model construction is independent of batch_size, so it can be changed after initialization if this is convenient, e.g., for decoding.

learning_rate [learning rate to start with.]

learning_rate_decay_factor [decay learning rate by this much when needed.]

use_lstm [if true, we use LSTM cells instead of GRU cells.]

num_samples [number of samples for sampled softmax.]

forward_only [if set, we do not construct the backward pass in the model.]

name [a string or None] An optional name to attach to this layer.

Methods

Return the number of parameters in the network
Get a random batch of data from the specified bucket,
prepare for step.
Print all info of layers in the network
Print all info of parameters in the network
Run a step of the model feeding the given inputs.

get_batch (data, bucket_id, PAD_ID=0, GO_ID=1, EOS_ID=2, UNK_ID=3)

Get a random batch of data from the specified bucket, prepare for step.

To feed data in step(..) it must be a list of batch-major vectors, while data here contains single length-major cases. So the main logic of this function is to re-index data cases to be in the proper format for feeding.

Parameters

data [a tuple of size len(self.buckets) in which each element contains] lists of pairs of input and output data that we use to create a batch.

bucket_id [integer, which bucket to get the batch for.]

```
PAD_ID [int] Index of Padding in vocabulary
```

GO_ID [int] Index of GO in vocabulary

EOS_ID [int] Index of End of sentence in vocabulary

UNK_ID [int] Index of Unknown word in vocabulary

Returns

The triple (encoder_inputs, decoder_inputs, target_weights) for the constructed batch that has the proper format to call step(...) later.

step (*session*, *encoder_inputs*, *decoder_inputs*, *target_weights*, *bucket_id*, *forward_only*)

Run a step of the model feeding the given inputs.

Parameters

```
session [tensorflow session to use.]
encoder_inputs [list of numpy int vectors to feed as encoder inputs.]
decoder_inputs [list of numpy int vectors to feed as decoder inputs.]
target_weights [list of numpy float vectors to feed as target weights.]
bucket_id [which bucket of the model to use.]
forward_only [whether to do the backward step or only forward.]
```

Returns

A triple consisting of gradient norm (or None if we did not do backward), average perplexity, and the outputs.

Raises

ValueError [if length of encoder_inputs, decoder_inputs, or] target_weights disagrees with bucket size for the specified bucket_id.

2.1.33 Helper functions

Flatten tensor

```
tensorlayer.layers.flatten_reshape(variable, name=")
   Reshapes high-dimension input to a vector. [batch_size, mask_row, mask_col, n_mask] -> [batch_size, mask_row * mask_col * n_mask]
```

Parameters

```
variable [a tensorflow variable]name [a string or None] An optional name to attach to this layer.
```

Examples

```
>>> W_conv2 = weight_variable([5, 5, 100, 32]) # 64 features for each 5x5 patch
>>> b_conv2 = bias_variable([32])
>>> W_fc1 = weight_variable([7 * 7 * 32, 256])
```

Permanent clear existing layer names

```
tensorlayer.layers.clear_layers_name()
```

Clear all layer names in set_keep['_layers_name_list'], enable layer name reuse.

Examples

```
>>> network = tl.layers.InputLayer(x, name='input_layer')
>>> network = tl.layers.DenseLayer(network, n_units=800, name='relu1')
...
>>> tl.layers.clear_layers_name()
>>> network2 = tl.layers.InputLayer(x, name='input_layer')
>>> network2 = tl.layers.DenseLayer(network2, n_units=800, name='relu1')
...
```

Initialize RNN state

```
tensorlayer.layers.initialize_rnn_state(state)
```

Return the initialized RNN state. The input is LSTMStateTuple or State of RNNCells.

Parameters

```
state [a RNN state.]
```

Remove repeated items in a list

```
tensorlayer.layers.list_remove_repeat(l=None)
```

Remove the repeated items in a list, and return the processed list. You may need it to create merged layer like Concat, Elementwise and etc.

Parameters

l [a list]

Examples

```
>>> 1 = [2, 3, 4, 2, 3]
>>> 1 = list_remove_repeat(1)
... [2, 3, 4]
```

2.1. API - Layers 105

2.2 API - Cost

To make TensorLayer simple, we minimize the number of cost functions as much as we can. So we encourage you to use TensorFlow's function. For example, you can implement L1, L2 and sum regularization by tf. nn.12_loss, tf.contrib.layers.11_regularizer, tf.contrib.layers.12_regularizer and tf.contrib.layers.sum regularizer, see TensorFlow API.

2.2.1 Your cost function

TensorLayer provides a simple way to create you own cost function. Take a MLP below for example.

```
network = InputLayer(x, name='input')
network = DropoutLayer(network, keep=0.8, name='drop1')
network = DenseLayer(network, n_units=800, act=tf.nn.relu, name='relu1')
network = DropoutLayer(network, keep=0.5, name='drop2')
network = DenseLayer(network, n_units=800, act=tf.nn.relu, name='relu2')
network = DropoutLayer(network, keep=0.5, name='drop3')
network = DenseLayer(network, n_units=10, act=tf.identity, name='output')
```

The network parameters will be [W1, b1, W2, b2, W_out, b_out], then you can apply L2 regularization on the weights matrix of first two layer as follow.

Besides, TensorLayer provides a easy way to get all variables by a given name, so you can also apply L2 regularization on some weights as follow.

Regularization of Weights

After initializing the variables, the informations of network parameters can be observed by using network. print_params().

```
tl.layers.initialize_global_variables(sess)
network.print_params()
```

```
param 0: (784, 800) (mean: -0.000000, median: 0.000004 std: 0.035524)
param 1: (800,) (mean: 0.000000, median: 0.000000 std: 0.000000)
param 2: (800, 800) (mean: 0.000029, median: 0.000031 std: 0.035378)
param 3: (800,) (mean: 0.000000, median: 0.000000 std: 0.000000)
param 4: (800, 10) (mean: 0.000673, median: 0.000763 std: 0.049373)
param 5: (10,) (mean: 0.000000, median: 0.000000 std: 0.000000)
num of params: 1276810
```

The output of network is network.outputs, then the cross entropy can be defined as follow. Besides, to regularize the weights, the network.all_params contains all parameters of the network. In this case, network.

all_params = [W1, b1, W2, b2, Wout, bout] according to param $0, 1 \dots 5$ shown by network. print_params(). Then max-norm regularization on W1 and W2 can be performed as follow.

In addition, all TensorFlow's regularizers like tf.contrib.layers.12_regularizer can be used with TensorLayer.

Regularization of Activation outputs

Instance method network.print_layers() prints all outputs of different layers in order. To achieve regularization on activation output, you can use network.all_layers which contains all outputs of different layers. If you want to apply L1 penalty on the activations of first hidden layer, just simply add tf.contrib.layers.l2_regularizer(lambda_l1) (network.all_layers[1]) to the cost function.

```
network.print_layers()
```

```
layer 0: Tensor("dropout/mul_1:0", shape=(?, 784), dtype=float32)
layer 1: Tensor("Relu:0", shape=(?, 800), dtype=float32)
layer 2: Tensor("dropout_1/mul_1:0", shape=(?, 800), dtype=float32)
layer 3: Tensor("Relu_1:0", shape=(?, 800), dtype=float32)
layer 4: Tensor("dropout_2/mul_1:0", shape=(?, 800), dtype=float32)
layer 5: Tensor("add_2:0", shape=(?, 10), dtype=float32)
```

cross_entropy(output, target[, name])	It is a softmax cross-entropy operation, returns the Ten-
	sorFlow expression of cross-entropy of two distribu-
	tions, implement softmax internally.
<pre>sigmoid_cross_entropy(output, target[, name])</pre>	It is a sigmoid cross-entropy operation, see tf.nn.
	sigmoid_cross_entropy_with_logits.
binary_cross_entropy(output, target[,])	Computes binary cross entropy given <i>output</i> .
mean_squared_error(output, target[, is_mean])	Return the TensorFlow expression of mean-squre-error
	of two distributions.
normalized_mean_square_error(output, tar-	Return the TensorFlow expression of normalized mean-
get)	squre-error of two distributions.
dice_coe(output, target[, loss_type, axis,])	Soft dice (Sørensen or Jaccard) coefficient for compar-
	ing the similarity of two batch of data, usually be used
	for binary image segmentation i.e.
dice_hard_coe(output, target[, threshold,])	Non-differentiable Sørensen-Dice coefficient for com-
	paring the similarity of two batch of data, usually be
	used for binary image segmentation i.e.
<pre>iou_coe(output, target[, threshold, axis,])</pre>	Non-differentiable Intersection over Union (IoU) for
	comparing the similarity of two batch of data, usually
	be used for evaluating binary image segmentation.
$cross_entropy_seq(logits, target_seqs[,])$	Returns the expression of cross-entropy of two se-
	quences, implement softmax internally.
cross_entropy_seq_with_mask(logits,[,	Returns the expression of cross-entropy of two se-
])	quences, implement softmax internally.
	Continued on next page

2.2. API - Cost 107

Table 46 -	continued	from	previous page
Iable 40 -	CONTINUEU	110111	previous page

cosine_similarity(v1, v2)	Cosine similarity [-1, 1], wiki.
li_regularizer(scale[, scope])	li regularization removes the neurons of previous layer,
	i represents inputs.
lo_regularizer(scale[, scope])	lo regularization removes the neurons of current layer, o
	represents outputs
maxnorm_regularizer([scale, scope])	Max-norm regularization returns a function that can be
	used to apply max-norm regularization to weights.
maxnorm_o_regularizer(scale, scope)	Max-norm output regularization removes the neurons of
	current layer.
maxnorm_i_regularizer(scale[, scope])	Max-norm input regularization removes the neurons of
	previous layer.

2.2.2 Softmax cross entropy

tensorlayer.cost.cross_entropy(output, target, name=None)

It is a softmax cross-entropy operation, returns the TensorFlow expression of cross-entropy of two distributions, implement softmax internally. See tf.nn.sparse_softmax_cross_entropy_with_logits.

Parameters

output [Tensorflow variable] A distribution with shape: [batch_size, n_feature].

target [Tensorflow variable] A batch of index with shape: [batch_size,].

name [string] Name of this loss.

References

- About cross-entropy: wiki.
- The code is borrowed from: here.

Examples

```
>>> ce = tl.cost.cross_entropy(y_logits, y_target_logits, 'my_loss')
```

2.2.3 Sigmoid cross entropy

tensorlayer.cost.sigmoid_cross_entropy (output, target, name=None)
It is a sigmoid cross-entropy operation, see tf.nn.sigmoid_cross_entropy_with_logits.

2.2.4 Binary cross entropy

tensorlayer.cost.binary_cross_entropy (output, target, epsilon=1e-08, name='bce_loss') Computes binary cross entropy given output.

For brevity, let x = output, z = target. The binary cross entropy loss is

$$loss(x, z) = -sum_i (x[i] * log(z[i]) + (1 - x[i]) * log(1 - z[i]))$$

Parameters

```
output [tensor of type float32 or float64.]
target [tensor of the same type and shape as output.]
epsilon [float] A small value to avoid output is zero.
name [string] An optional name to attach to this layer.
```

References

• DRAW

2.2.5 Mean squared error

```
tensorlayer.cost.mean_squared_error(output, target, is_mean=False)
Return the TensorFlow expression of mean-squre-error of two distributions.
```

Parameters

```
output [2D or 4D tensor.]
target [2D or 4D tensor.]
is_mean [boolean, if True, use tf.reduce_mean to compute the loss of one data, otherwise,
    use tf.reduce_sum (default).]
```

References

• Wiki Mean Squared Error

2.2.6 Normalized mean square error

```
tensorlayer.cost.normalized_mean_square_error(output, target)

Return the TensorFlow expression of normalized mean-squre-error of two distributions.
```

Parameters

```
output [2D or 4D tensor.]target [2D or 4D tensor.]
```

2.2.7 Dice coefficient

```
tensorlayer.cost.dice_coe (output, target, loss_type='jaccard', axis=[1, 2, 3], smooth=1e-05)
Soft dice (Sørensen or Jaccard) coefficient for comparing the similarity of two batch of data, usually be used for binary image segmentation i.e. labels are binary. The coefficient between 0 to 1, 1 means totally match.
```

Parameters

```
output [tensor] A distribution with shape: [batch_size, ....], (any dimensions).
target [tensor] A distribution with shape: [batch_size, ....], (any dimensions).
loss_type [string] jaccard or sorensen, default is jaccard.
axis [list of integer] All dimensions are reduced, default [1,2,3].
```

2.2. API - Cost 109

smooth [float] This small value will be added to the numerator and denominator. If both output and target are empty, it makes sure dice is 1. If either output or target are empty (all pixels are background), dice = `smooth/(small_value + smooth), then if smooth is very small, dice close to 0 (even the image values lower than the threshold), so in this case, higher smooth can have a higher dice.

References

• Wiki-Dice

Examples

```
>>> outputs = tl.act.pixel_wise_softmax(network.outputs)
>>> dice_loss = 1 - tl.cost.dice_coe(outputs, y_)
```

2.2.8 Hard Dice coefficient

tensorlayer.cost.dice_hard_coe (output, target, threshold=0.5, axis=[1, 2, 3], smooth=1e-05)

Non-differentiable Sørensen—Dice coefficient for comparing the similarity of two batch of data, usually be used for binary image segmentation i.e. labels are binary. The coefficient between 0 to 1, 1 if totally match.

Parameters

```
output [tensor] A distribution with shape: [batch_size, ....], (any dimensions).
target [tensor] A distribution with shape: [batch_size, ....], (any dimensions).
threshold [float] The threshold value to be true.
axis [list of integer] All dimensions are reduced, default [1,2,3].
smooth [float] This small value will be added to the numerator and denominator, see dice_coe.
```

References

• Wiki-Dice

2.2.9 IOU coefficient

```
tensorlayer.cost.iou_coe (output, target, threshold=0.5, axis=[1, 2, 3], smooth=1e-05)

Non-differentiable Intersection over Union (IoU) for comparing the similarity of two batch of data, usually be used for evaluating binary image segmentation. The coefficient between 0 to 1, 1 means totally match.
```

Parameters

```
output [tensor] A distribution with shape: [batch_size, ....], (any dimensions).
target [tensor] A distribution with shape: [batch_size, ....], (any dimensions).
threshold [float] The threshold value to be true.
axis [list of integer] All dimensions are reduced, default [1,2,3].
```

smooth [float] This small value will be added to the numerator and denominator, see dice_coe.

Notes

 IoU cannot be used as training loss, people usually use dice coefficient for training, IoU and hard-dice for evaluating.

2.2.10 Cross entropy for sequence

```
tensorlayer.cost.cross_entropy_seq(logits, target_seqs, batch_size=None)
```

Returns the expression of cross-entropy of two sequences, implement softmax internally. Normally be used for Fixed Length RNN outputs.

Parameters

target_seqs [Tensorflow variable] target: 2D tensor [batch_size, n_steps], if the number of step is dynamic, please use cross_entropy_seq_with_mask instead.

batch_size [None or int.] If not None, the return cost will be divided by batch_size.

Examples

```
>>> see PTB tutorial for more details
>>> input_data = tf.placeholder(tf.int32, [batch_size, num_steps])
>>> targets = tf.placeholder(tf.int32, [batch_size, num_steps])
>>> cost = tl.cost.cross_entropy_seq(network.outputs, targets)
```

2.2.11 Cross entropy with mask for sequence

```
tensorlayer.cost.cross_entropy_seq_with_mask(logits, target_seqs, input_mask, re-
turn_details=False, name=None)
```

Returns the expression of cross-entropy of two sequences, implement softmax internally. Normally be used for Dynamic RNN outputs.

Parameters

logits [network identity outputs] 2D tensor, network.outputs, [batch_size, number of output units].

target_seqs [int of tensor, like word ID.] [batch_size, ?]

input_mask [the mask to compute loss] The same size with target_seqs, normally 0 and 1.

return_details [boolean]

- If False (default), only returns the loss.
- If True, returns the loss, losses, weights and targets (reshape to one vetcor).

2.2. API - Cost 111

Examples

• see Image Captioning Example.

2.2.12 Cosine similarity

```
tensorlayer.cost.cosine_similarity(v1, v2)
Cosine similarity [-1, 1], wiki.

Parameters
v1, v2 [tensor of [batch_size, n_feature], with the same number of features.]

Returns
a tensor of [batch_size, ]
```

2.2.13 Regularization functions

```
For tf.nn.12_loss, tf.contrib.layers.11_regularizer, tf.contrib.layers.12_regularizer and tf.contrib.layers.sum_regularizer, see TensorFlow API.
```

Maxnorm

```
tensorlayer.cost.maxnorm_regularizer(scale=1.0, scope=None)
```

Max-norm regularization returns a function that can be used to apply max-norm regularization to weights. About max-norm: wiki.

The implementation follows TensorFlow contrib.

Parameters

```
scale [float] A scalar multiplier Tensor. 0.0 disables the regularizer. scope: An optional scope name.
```

Returns

A function with signature 'mn(weights, name=None)' that apply Lo regularization.

Raises

ValueError [If scale is outside of the range [0.0, 1.0] or if scale is not a float.]

Special

```
tensorlayer.cost.li_regularizer(scale, scope=None)
```

li regularization removes the neurons of previous layer, i represents inputs.

Returns a function that can be used to apply group li regularization to weights.

The implementation follows TensorFlow contrib.

Parameters

```
scale [float] A scalar multiplier Tensor. 0.0 disables the regularizer.
```

scope: An optional scope name for TF12+.

Returns

A function with signature 'li(weights, name=None)' that apply Li regularization.

Raises

ValueError [if scale is outside of the range [0.0, 1.0] or if scale is not a float.]

```
tensorlayer.cost.lo_regularizer(scale, scope=None)
```

lo regularization removes the neurons of current layer, o represents outputs

Returns a function that can be used to apply group lo regularization to weights.

The implementation follows TensorFlow contrib.

Parameters

scale [float] A scalar multiplier Tensor. 0.0 disables the regularizer.

scope: An optional scope name for TF12+.

Returns

A function with signature 'lo(weights, name=None)' that apply Lo regularization.

Raises

ValueError [If scale is outside of the range [0.0, 1.0] or if scale is not a float.]

```
tensorlayer.cost.maxnorm_o_regularizer(scale, scope)
```

Max-norm output regularization removes the neurons of current layer.

Returns a function that can be used to apply max-norm regularization to each column of weight matrix.

The implementation follows TensorFlow contrib.

Parameters

scale [float] A scalar multiplier *Tensor*. 0.0 disables the regularizer.

scope: An optional scope name.

Returns

A function with signature 'mn_o(weights, name=None)' that apply Lo regularization.

Raises

ValueError [If scale is outside of the range [0.0, 1.0] or if scale is not a float.]

```
tensorlayer.cost.maxnorm_i_regularizer(scale, scope=None)
```

Max-norm input regularization removes the neurons of previous layer.

Returns a function that can be used to apply max-norm regularization to each row of weight matrix.

The implementation follows TensorFlow contrib.

Parameters

scale [float] A scalar multiplier *Tensor*. 0.0 disables the regularizer.

scope: An optional scope name.

Returns

A function with signature 'mn_i(weights, name=None)' that apply Lo regularization.

Raises

ValueError [If scale is outside of the range [0.0, 1.0] or if scale is not a float.]

2.2. API - Cost 113

2.3 API - Preprocessing

We provide abundant data augmentation and processing functions by using Numpy, Scipy, Threading and Queue. However, we recommend you to use TensorFlow operation function like tf.image.central_crop, more TensorFlow data augmentation method can be found here and tutorial_cifar10_tfrecord.py. Some of the code in this package are borrowed from Keras.

Table 47 – continued from previous page

drop(x[, keep])	Randomly set some pixels to zero by a given keeping probability.
transform_matrix_offset_center(matrix, x,	Return transform matrix offset center.
y)	
apply_transform(x, transform_matrix[,])	Return transformed images by given transform_matrix
	<pre>from transform_matrix_offset_center.</pre>
projective_transform_by_points(x, src,	Projective transform by given coordinates, usually 4 co-
dst)	ordinates.
<pre>array_to_img(x[, dim_ordering, scale])</pre>	Converts a numpy array to PIL image object (uint8 for-
	mat).
<pre>find_contours(x[, level, fully_connected,])</pre>	Find iso-valued contours in a 2D array for a given
	level value, returns list of (n, 2)-ndarrays see skim-
	age.measure.find_contours.
<pre>pt2map([list_points, size, val])</pre>	Inputs a list of points, return a 2D image.
binary_dilation(x[, radius])	Return fast binary morphological dilation of an image.
dilation(x[, radius])	Return greyscale morphological dilation of an image,
	see skimage.morphology.dilation.
pad_sequences(sequences[, maxlen, dtype,])	Pads each sequence to the same length: the length of the
	longest sequence.
<pre>process_sequences(sequences[, end_id,])</pre>	Set all tokens(ids) after END token to the padding value,
	and then shorten (option) it to the maximum sequence
	length in this batch.
sequences_add_start_id(sequences[,])	Add special start token(id) in the beginning of each se-
	quence.
sequences_get_mask(sequences[, pad_val])	Return mask for sequences.
distorted_images([images, height, width])	Distort images for generating more training data.
crop_central_whiten_images([images,	Crop the central of image, and normailize it for test data.
height,])	

2.3.1 Threading

tensorlayer.prepro.threading_data(data=None, fn=None, **kwargs)
Return a batch of result by given data. Usually be used for data augmentation.

Parameters

data [numpy array, file names and etc, see Examples below.]fn [the function for data processing.]more args [the args for fn, see Examples below.]

References

- python queue
- run with limited queue

Examples

• Single array

• List of array (e.g. functions with multi)

• Customized function for image segmentation

2.3.2 Images

- These functions only apply on a single image, use threading_data to apply multiple threading see tutorial_image_preprocess.py.
- All functions have argument is_random.
- All functions end with *multi*, usually be used for image segmentation i.e. the input and output image should be matched.

Rotation

```
tensorlayer.prepro.rotation (x, rg=20, is_random=False, row_index=0, col_index=1, chan-nel_index=2, fill_mode='nearest', cval=0.0)

Rotate an image randomly or non-randomly.
```

Parameters

- **x** [numpy array] An image with dimension of [row, col, channel] (default).
- **rg** [int or float] Degree to rotate, usually 0 ~ 180.

is_random [boolean, default False] If True, randomly rotate.

row_index, col_index, channel_index [int] Index of row, col and channel, default (0, 1, 2), for theano (1, 2, 0).

fill_mode [string] Method to fill missing pixel, default 'nearest', more options 'constant', 'reflect' or 'wrap'

• scipy ndimage affine_transform

 \boldsymbol{cval} [scalar, optional] Value used for points outside the boundaries of the input if mode='constant'. Default is 0.0

• scipy ndimage affine_transform

Examples

```
>>> x --> [row, col, 1] greyscale
>>> x = rotation(x, rg=40, is_random=False)
>>> tl.visualize.frame(x[:,:,0], second=0.01, saveable=True, name='temp',cmap=

--'gray')
```

tensorlayer.prepro.rotation_multi(x, rg=20, is_random=False, row_index=0, col_index=1, channel index=2, fill mode='nearest', cval=0.0)

Rotate multiple images with the same arguments, randomly or non-randomly. Usually be used for image segmentation which x=[X, Y], X and Y should be matched.

Parameters

x [list of numpy array] List of images with dimension of [n_images, row, col, channel] (default). **others** [see rotation.]

Examples

```
>>> x, y --> [row, col, 1] greyscale
>>> x, y = rotation_multi([x, y], rg=90, is_random=False)
>>> tl.visualize.frame(x[:,:,0], second=0.01, saveable=True, name='x',cmap='gray')
>>> tl.visualize.frame(y[:,:,0], second=0.01, saveable=True, name='y',cmap='gray')
```

Crop

tensorlayer.prepro.crop(x, wrg, hrg, is_random=False, row_index=0, col_index=1, chan-nel_index=2)

Randomly or centrally crop an image.

Parameters

x [numpy array] An image with dimension of [row, col, channel] (default).

wrg [float] Size of weight.

hrg [float] Size of height.

is_random [boolean, default False] If True, randomly crop, else central crop.

row_index, col_index, channel_index [int] Index of row, col and channel, default (0, 1, 2), for theano (1, 2, 0).

```
tensorlayer.prepro.crop_multi(x, wrg, hrg, is_random=False, row_index=0, col_index=1, chan-
nel index=2)
```

Randomly or centrally crop multiple images.

Parameters

x [list of numpy array] List of images with dimension of [n_images, row, col, channel] (default).

others [see crop.]

Flip

```
tensorlayer.prepro.flip_axis(x, axis, is_random=False)
```

Flip the axis of an image, such as flip left and right, up and down, randomly or non-randomly,

Parameters

x [numpy array] An image with dimension of [row, col, channel] (default).

axis [int]

- 0, flip up and down
- 1, flip left and right
- 2, flip channel

is_random [boolean, default False] If True, randomly flip.

```
tensorlayer.prepro.flip_axis_multi(x, axis, is_random=False)
```

Flip the axises of multiple images together, such as flip left and right, up and down, randomly or non-randomly,

Parameters

```
x [list of numpy array] List of images with dimension of [n_images, row, col, channel] (default).others [see flip_axis.]
```

Shift

```
tensorlayer.prepro.shift (x, wrg=0.1, hrg=0.1, is\_random=False, row\_index=0, col\_index=1, channel\_index=2, fill\_mode='nearest', cval=0.0) Shift an image randomly or non-randomly.
```

Parameters

```
x [numpy array] An image with dimension of [row, col, channel] (default).
```

wrg [float] Percentage of shift in axis x, usually $-0.25 \sim 0.25$.

hrg [float] Percentage of shift in axis y, usually $-0.25 \sim 0.25$.

is_random [boolean, default False] If True, randomly shift.

row_index, col_index, channel_index [int] Index of row, col and channel, default (0, 1, 2), for theano (1, 2, 0).

fill_mode [string] Method to fill missing pixel, default 'nearest', more options 'constant', 'reflect' or 'wrap'.

• scipy ndimage affine_transform

cval [scalar, optional] Value used for points outside the boundaries of the input if mode='constant'. Default is 0.0.

scipy ndimage affine_transform

tensorlayer.prepro.shift_multi(x, wrg=0.1, hrg=0.1, $is_random=False$, $row_index=0$, $col_index=1$, $channel_index=2$, $fill_mode='nearest'$, cval=0.0) Shift images with the same arguments, randomly or non-randomly. Usually be used for image segmentation which x=[X, Y], X and Y should be matched.

Parameters

x [list of numpy array] List of images with dimension of [n_images, row, col, channel] (default). others [see shift.]

Shear

tensorlayer.prepro.shear(x, intensity=0.1, is_random=False, row_index=0, col_index=1, chan-nel_index=2, fill_mode='nearest', cval=0.0)

Shear an image randomly or non-randomly.

Parameters

x [numpy array] An image with dimension of [row, col, channel] (default).

intensity [float] Percentage of shear, usually $-0.5 \sim 0.5$ (is_random==True), $0 \sim 0.5$ (is_random==False), you can have a quick try by shear(X, 1).

is_random [boolean, default False] If True, randomly shear.

row_index, col_index, channel_index [int] Index of row, col and channel, default (0, 1, 2), for theano (1, 2, 0).

fill_mode [string] Method to fill missing pixel, default 'nearest', more options 'constant', 'reflect' or 'wrap'.

· scipy ndimage affine_transform

cval [scalar, optional] Value used for points outside the boundaries of the input if mode='constant'. Default is 0.0.

• scipy ndimage affine_transform

tensorlayer.prepro.shear_multi(x, intensity=0.1, is_random=False, row_index=0, col_index=1, channel_index=2, fill_mode='nearest', cval=0.0)

Shear images with the same arguments, randomly or non-randomly. Usually be used for image segmentation which x=[X, Y], X and Y should be matched.

Parameters

x [list of numpy array] List of images with dimension of [n_images, row, col, channel] (default).others [see shear.]

Swirl

tensorlayer.prepro.swirl $(x, center=None, strength=1, radius=100, rotation=0, out-put_shape=None, order=1, mode='constant', cval=0, clip=True, preserve_range=False, is_random=False)$

Swirl an image randomly or non-randomly, see scikit-image swirl API and example.

Parameters

x [numpy array] An image with dimension of [row, col, channel] (default).

center [(row, column) tuple or (2,) ndarray, optional] Center coordinate of transformation.

strength [float, optional] The amount of swirling applied.

radius [float, optional] The extent of the swirl in pixels. The effect dies out rapidly beyond radius.

rotation [float, (degree) optional] Additional rotation applied to the image, usually [0, 360], relates to center.

output_shape [tuple (rows, cols), optional] Shape of the output image generated. By default the shape of the input image is preserved.

order [int, optional] The order of the spline interpolation, default is 1. The order has to be in the range 0-5. See skimage.transform.warp for detail.

mode [{'constant', 'edge', 'symmetric', 'reflect', 'wrap'}, optional] Points outside the boundaries of the input are filled according to the given mode, with 'constant' used as the default. Modes match the behaviour of numpy.pad.

cval [float, optional] Used in conjunction with mode 'constant', the value outside the image boundaries.

clip [bool, optional] Whether to clip the output to the range of values of the input image. This is enabled by default, since higher order interpolation may produce values outside the given input range.

preserve_range [bool, optional] Whether to keep the original range of values. Otherwise, the input image is converted according to the conventions of img_as_float.

is random [boolean, default False]

If True, random swirl.

- random center = $[(0 \sim x.shape[0]), (0 \sim x.shape[1])]$
- random strength = [0, strength]
- random radius = [1e-10, radius]
- random rotation = [-rotation, rotation]

Examples

```
>>> x --> [row, col, 1] greyscale
>>> x = swirl(x, strength=4, radius=100)
```

```
tensorlayer.prepro.swirl_multi(x, center=None, strength=1, radius=100, rotation=0, out-put_shape=None, order=1, mode='constant', cval=0, clip=True, preserve range=False, is random=False)
```

Swirl multiple images with the same arguments, randomly or non-randomly. Usually be used for image segmentation which x=[X, Y], X and Y should be matched.

Parameters

```
x [list of numpy array] List of images with dimension of [n_images, row, col, channel] (default).

others [see swirl.]
```

Elastic transform

tensorlayer.prepro.elastic_transform(x, alpha, sigma, mode='constant', cval=0, is_random=False)

Elastic deformation of images as described in [Simard2003].

Parameters

```
x [numpy array, a greyscale image.]
```

```
alpha [scalar factor.]
```

sigma [scalar or sequence of scalars, the smaller the sigma, the more transformation.] Standard deviation for Gaussian kernel. The standard deviations of the Gaussian filter are given for each axis as a sequence, or as a single number, in which case it is equal for all axes.

mode [default constant, see scipy.ndimage.filters.gaussian_filter.]

cval [float, optional. Used in conjunction with mode 'constant', the value outside the image boundaries.]

is_random [boolean, default False]

References

- Github.
- Kaggle

Examples

```
>>> x = elastic\_transform(x, alpha = x.shape[1] * 3, sigma = x.shape[1] * 0.07)
```

tensorlayer.prepro.elastic_transform_multi(x, alpha, sigma, mode='constant', cval=0, is_random=False)

Elastic deformation of images as described in [Simard2003].

Parameters

```
x [list of numpy array]
others [see elastic_transform.]
```

Zoom

tensorlayer.prepro.**zoom** (x, zoom_range=(0.9, 1.1), is_random=False, row_index=0, col_index=1, channel_index=2, fill_mode='nearest', cval=0.0)

Zoom in and out of a single image, randomly or non-randomly.

Parameters

x [numpy array] An image with dimension of [row, col, channel] (default).

zoom_range [list or tuple]

- If is_random=False, (h, w) are the fixed zoom factor for row and column axies, factor small than one is zoom in.
- If is_random=True, (min zoom out, max zoom out) for x and y with different random zoom in/out factor.

```
e.g (0.5, 1) zoom in 1\sim2 times.
```

is_random [boolean, default False] If True, randomly zoom.

row_index, col_index, channel_index [int] Index of row, col and channel, default (0, 1, 2), for theano (1, 2, 0).

fill_mode [string] Method to fill missing pixel, default 'nearest', more options 'constant', 'reflect' or 'wrap'.

• scipy ndimage affine transform

cval [scalar, optional] Value used for points outside the boundaries of the input if mode='constant'. Default is 0.0.

• scipy ndimage affine_transform

```
tensorlayer.prepro.zoom_multi(x, zoom_range=(0.9, 1.1), is_random=False, row_index=0, col_index=1, channel_index=2, fill_mode='nearest', cval=0.0)

Zoom in and out of images with the same arguments, randomly or non-randomly. Usually be used for image
```

segmentation which x=[X, Y], X and Y should be matched.

Parameters

```
x [list of numpy array] List of images with dimension of [n_images, row, col, channel] (default). others [see zoom.]
```

Brightness

```
tensorlayer.prepro.brightness (x, gamma=1, gain=1, is_random=False) Change the brightness of a single image, randomly or non-randomly.
```

Parameters

x [numpy array] An image with dimension of [row, col, channel] (default).

gamma [float, small than 1 means brighter.] Non negative real number. Default value is 1.

• If is_random is True, gamma in a range of (1-gamma, 1+gamma).

gain [float] The constant multiplier. Default value is 1.

is_random [boolean, default False]

• If True, randomly change brightness.

References

- · skimage.exposure.adjust_gamma
- · chinese blog

```
tensorlayer.prepro.brightness_multi(x, gamma=1, gain=1, is_random=False)
```

Change the brightness of multiply images, randomly or non-randomly. Usually be used for image segmentation which x=(X, Y), X and Y should be matched.

Parameters

```
x [list of numpy array] List of images with dimension of [n_images, row, col, channel] (default).

others [see brightness.]
```

Resize

tensorlayer.prepro.imresize (x, size=[100, 100], interp='bilinear', mode=None)

Resize an image by given output size and method. Warning, this function will rescale the value to [0, 255].

Parameters

x [numpy array] An image with dimension of [row, col, channel] (default).

size [int, float or tuple (h, w)]

- int, Percentage of current size.
- float, Fraction of current size.
- tuple, Size of the output image.

interp [str, optional] Interpolation to use for re-sizing ('nearest', 'lanczos', 'bilinear', 'bicubic' or 'cubic').

mode [str, optional] The PIL image mode ('P', 'L', etc.) to convert arr before resizing.

Returns

imresize [ndarray]

The resized array of image.

References

• scipy.misc.imresize

Normalization

```
tensorlayer.prepro.samplewise_norm (x, rescale=None, samplewise\_center=False, samplewise\_std\_normalization=False, channel\_index=2, epsilon=1e-07)
```

Normalize an image by rescale, samplewise centering and samplewise centering in order.

Parameters

x [numpy array] An image with dimension of [row, col, channel] (default).

rescale [rescaling factor.] If None or 0, no rescaling is applied, otherwise we multiply the data by the value provided (before applying any other transformation)

samplewise_center [set each sample mean to 0.]

samplewise_std_normalization [divide each input by its std.]

epsilon [small position value for dividing standard deviation.]

Notes

When samplewise_center and samplewise_std_normalization are True.

- For greyscale image, every pixels are subtracted and divided by the mean and std of whole image.
- For RGB image, every pixels are subtracted and divided by the mean and std of this pixel i.e. the mean and std of a pixel is 0 and 1.

Examples

tensorlayer.prepro.featurewise norm(x, mean=None, std=None, epsilon=1e-07)

Normalize every pixels by the same given mean and std, which are usually compute from all examples.

Parameters

```
x [numpy array] An image with dimension of [row, col, channel] (default).
mean [value for subtraction.]
std [value for division.]
epsilon [small position value for dividing standard deviation.]
```

Channel shift

tensorlayer.prepro.channel_shift (*x*, *intensity*, *is_random=False*, *channel_index=2*) Shift the channels of an image, randomly or non-randomly, see numpy.rollaxis.

Parameters

```
x [numpy array] An image with dimension of [row, col, channel] (default).
intensity [float] Intensity of shifting.
is_random [boolean, default False] If True, randomly shift.
channel index [int] Index of channel, default 2.
```

```
tensorlayer.prepro.channel_shift_multi(x, intensity, channel_index=2)
```

Shift the channels of images with the same arguments, randomly or non-randomly, see numpy.rollaxis. Usually be used for image segmentation which x=[X, Y], X and Y should be matched.

Parameters

```
x [list of numpy array] List of images with dimension of [n_images, row, col, channel] (default).

others [see channel_shift.]
```

Noise

```
tensorlayer.prepro.drop(x, keep=0.5)
```

Randomly set some pixels to zero by a given keeping probability.

Parameters

x [numpy array] An image with dimension of [row, col, channel] or [row, col].

keep [float (0, 1)] The keeping probability, the lower more values will be set to zero.

Manual transform

```
tensorlayer.prepro.transform_matrix_offset_center (matrix, x, y) Return transform matrix offset center.
```

Parameters

matrix [numpy array] Transform matrixx, y [int] Size of image.

Examples

• See rotation, shear, zoom.

```
tensorlayer.prepro.apply\_transform(x, transform\_matrix, channel\_index=2, fill\_mode='nearest', cval=0.0)
```

Return transformed images by given transform_matrix from transform_matrix_offset_center.

Parameters

- **x** [numpy array] Batch of images with dimension of 3, [batch_size, row, col, channel].
- transform_matrix [numpy array] Transform matrix (offset center), can be generated by transform_matrix_offset_center
- **channel_index** [int] Index of channel, default 2.
- **fill_mode** [string] Method to fill missing pixel, default 'nearest', more options 'constant', 'reflect' or 'wrap'
 - scipy ndimage affine_transform
- **cval** [scalar, optional] Value used for points outside the boundaries of the input if mode='constant'. Default is 0.0
 - scipy ndimage affine transform

Examples

• See rotation, shift, shear, zoom.

```
tensorlayer.prepro.projective_transform_by_points (x, src, dst, map\_args=\{\}, out-put\_shape=None, order=1, mode='constant', cval=0.0, clip=True, preserve\_range=False)
```

Projective transform by given coordinates, usually 4 coordinates. see scikit-image.

Parameters

- **x** [numpy array] An image with dimension of [row, col, channel] (default).
- **src** [list or numpy] The original coordinates, usually 4 coordinates of (x, y).
- **dst** [list or numpy] The coordinates after transformation, the number of coordinates is the same with src.

map_args [dict, optional] Keyword arguments passed to inverse_map.

output_shape [tuple (rows, cols), optional] Shape of the output image generated. By default the shape of the input image is preserved. Note that, even for multi-band images, only rows and columns need to be specified.

order [int, optional] The order of interpolation. The order has to be in the range 0-5:

- 0 Nearest-neighbor
- 1 Bi-linear (default)
- 2 Bi-quadratic
- 3 Bi-cubic
- 4 Bi-quartic
- 5 Bi-quintic

mode [{'constant', 'edge', 'symmetric', 'reflect', 'wrap'}, optional] Points outside the boundaries of the input are filled according to the given mode. Modes match the behaviour of numpy.pad.

cval [float, optional] Used in conjunction with mode 'constant', the value outside the image boundaries.

clip [bool, optional] Whether to clip the output to the range of values of the input image. This is enabled by default, since higher order interpolation may produce values outside the given input range.

preserve_range [bool, optional] Whether to keep the original range of values. Otherwise, the input image is converted according to the conventions of img_as_float.

Examples

```
>>> Assume X is an image from CIFAR 10, i.e. shape == (32, 32, 3)
>>> src = [[0,0],[0,32],[32,0],[32,32]]
>>> dst = [[10,10],[0,32],[32,0],[32,32]]
>>> x = projective_transform_by_points(X, src, dst)
```

Numpy and PIL

```
tensorlayer.prepro.array_to_img (x, dim\_ordering=(0, 1, 2), scale=True)

Converts a numpy array to PIL image object (uint8 format).
```

Parameters

x [numpy array] A image with dimension of 3 and channels of 1 or 3.

dim_ordering [list or tuple of 3 int] Index of row, col and channel, default (0, 1, 2), for the ano (1, 2, 0).

scale [boolean, default is True] If True, converts image to [0, 255] from any range of value like [-1, 2].

References

• PIL Image.fromarray

Find contours

```
tensorlayer.prepro.find_contours (x, level=0.8, fully\_connected='low', positive\_orientation='low') Find iso-valued contours in a 2D array for a given level value, returns list of (n, 2)-ndarrays see skimage.measure.find contours.
```

Parameters

x [2D ndarray of double. Input data in which to find contours.]

level [float. Value along which to find contours in the array.]

fully_connected [str, {'low', 'high'}. Indicates whether array elements below the given level value are to be considered fully-connected (and hence elements above the value will only be face connected), or vice-versa. (See notes below for details.)]

positive_orientation [either 'low' or 'high'. Indicates whether the output contours will produce positively-oriented polygons around islands of low- or high-valued elements. If 'low' then contours will wind counter-clockwise around elements below the iso-value. Alternately, this means that low-valued elements are always on the left of the contour.]

Points to Image

```
tensorlayer.prepro.pt2map(list_points=[], size=(100, 100), val=1) Inputs a list of points, return a 2D image.
```

Parameters

```
list_points [list of [x, y].]size [tuple of (w, h) for output size.]val [float or int for the contour value.]
```

Binary dilation

```
tensorlayer.prepro.binary_dilation(x, radius=3)
```

Return fast binary morphological dilation of an image. see skimage.morphology.binary_dilation.

Parameters

```
x [2D array image.]radius [int for the radius of mask.]
```

Greyscale dilation

```
tensorlayer.prepro.dilation(x, radius=3)
```

Return greyscale morphological dilation of an image, see skimage.morphology.dilation.

Parameters

x [2D array image.]

radius [int for the radius of mask.]

2.3.3 Sequence

More related functions can be found in tensorlayer.nlp.

Padding

```
tensorlayer.prepro.pad_sequences (sequences, maxlen=None, dtype='int32', padding='post', truncating='pre', value=0.0)
```

Pads each sequence to the same length: the length of the longest sequence. If maxlen is provided, any sequence longer than maxlen is truncated to maxlen. Truncation happens off either the beginning (default) or the end of the sequence. Supports post-padding and pre-padding (default).

Parameters

```
sequences [list of lists where each element is a sequence]
maxlen [int, maximum length]
dtype [type to cast the resulting sequence.]
padding ['pre' or 'post', pad either before or after each sequence.]
truncating ['pre' or 'post', remove values from sequences larger than] maxlen either in the beginning or in the end of the sequence
value [float, value to pad the sequences to the desired value.]
```

Returns

x [numpy array with dimensions (number_of_sequences, maxlen)]

Examples

```
>>> sequences = [[1,1,1,1,1],[2,2,2],[3,3]]
>>> sequences = pad_sequences(sequences, maxlen=None, dtype='int32',
... padding='post', truncating='pre', value=0.)
... [[1 1 1 1 1 1]
... [2 2 2 0 0]
... [3 3 0 0 0]]
```

Process

```
tensorlayer.prepro.process_sequences (sequences, end_id=0, pad_val=0, is_shorten=True, re-
main_end_id=False)
```

Set all tokens(ids) after END token to the padding value, and then shorten (option) it to the maximum sequence length in this batch.

Parameters

```
sequences [numpy array or list of list with token IDs.] e.g. [[4,3,5,3,2,2,2,2], [5,3,9,4,9,2,2,3]]
end_id [int, the special token for END.]
pad_val [int, replace the end_id and the ids after end_id to this value.]
is_shorten [boolean, default True.] Shorten the sequences.
```

remain_end_id [boolean, default False.] Keep an end_id in the end.

Examples

Add Start ID

tensorlayer.prepro.sequences_add_start_id (sequences, start_id=0, remove_last=False)
Add special start token(id) in the beginning of each sequence.

Examples

• For Seq2seq

Get Mask

tensorlayer.prepro.sequences_get_mask (sequences, pad_val=0) Return mask for sequences.

Examples

```
>>> sentences_ids = [[4, 0, 5, 3, 0, 0],
...
[5, 3, 9, 4, 9, 0]]
>>> mask = sequences_get_mask(sentences_ids, pad_val=0)
...
[[1 1 1 1 0 0]
...
[1 1 1 1 0]]
```

2.3.4 Tensor Opt

Note: These functions will be deprecated, see tutorial_cifar10_tfrecord.py for new information.

```
tensorlayer.prepro.distorted_images (images=None, height=24, width=24)
Distort images for generating more training data.
```

Parameters

```
images [4D Tensor] The tensor or placeholder of imagesheight [int] The height for random crop.width [int] The width for random crop.
```

Returns

result [tuple of Tensor] (Tensor for distorted images, Tensor for while loop index)

Notes

• The first image in 'distorted_images' should be removed.

References

• tensorflow.models.image.cifar10.cifar10_input

Examples

tensorlayer.prepro.crop_central_whiten_images (images=None, height=24, width=24) Crop the central of image, and normalize it for test data.

They are cropped to central of height * width pixels.

Whiten (Normalize) the images.

Parameters

```
images [4D Tensor] The tensor or placeholder of imagesheight [int] The height for central crop.
```

width [int] The width for central crop.

Returns

result [tuple Tensor] (Tensor for distorted images, Tensor for while loop index)

Notes

The first image in 'central_images' should be removed.

Examples

2.4 API - Iteration

Data iteration.

<pre>minibatches([inputs, targets, batch_size,])</pre>	Generate a generator that input a group of example in
	numpy.array and their labels, return the examples and
	labels by the given batchsize.
seq_minibatches(inputs, targets, batch_size,)	Generate a generator that return a batch of sequence in-
	puts and targets.
seq_minibatches2(inputs, targets,)	Generate a generator that iterates on two list of words.
<pre>ptb_iterator(raw_data, batch_size, num_steps)</pre>	Generate a generator that iterates on a list of words, see
	PTB tutorial.

2.4.1 Non-time series

tensorlayer.iterate.minibatches (inputs=None, targets=None, batch_size=None, shuffle=False)
Generate a generator that input a group of example in numpy.array and their labels, return the examples and labels by the given batchsize.

Parameters

inputs [numpy.array]

24. The input features, every row is a example.

2.4. API - Iteration 131

targets [numpy.array]

25. The labels of inputs, every row is a example.

batch_size [int] The batch size.

shuffle [boolean] Indicating whether to use a shuffling queue, shuffle the dataset before return.

Examples

```
>>> X = np.asarray([['a','a'], ['b','b'], ['c','c'], ['d','d'], ['e','e'], ['f','f
' ] ] )
>>> y = np.asarray([0,1,2,3,4,5])
>>> for batch in tl.iterate.minibatches(inputs=X, targets=y, batch_size=2,_
⇔shuffle=False):
>>>
       print (batch)
... (array([['a', 'a'],
           ['b', 'b']],
. . .
            dtype='<U1'), array([0, 1]))
. . .
... (array([['c', 'c'],
           ['d', 'd']],
            dtype='<U1'), array([2, 3]))
... (array([['e', 'e'],
           ['f', 'f']],
. . .
            dtype='<U1'), array([4, 5]))</pre>
. . .
```

2.4.2 Time series

Sequence iteration 1

```
tensorlayer.iterate.seq_minibatches (inputs, targets, batch_size, seq_length, stride=1)

Generate a generator that return a batch of sequence inputs and targets. If batch_size = 100, seq_length = 5, one return will have 500 rows (examples).
```

Examples

• Synced sequence input and output.

```
>>> X = np.asarray([['a','a'], ['b','b'], ['c','c'], ['d','d'], ['e','e'], ['f','f
' ] ] )
>>> y = np.asarray([0, 1, 2, 3, 4, 5])
>>> for batch in tl.iterate.seq_minibatches(inputs=X, targets=y, batch_size=2,_
→seq_length=2, stride=1):
        print(batch)
... (array([['a', 'a'],
           ['b', 'b'],
. . .
            ['b', 'b'],
. . .
            ['c', 'c']],
            dtype='<U1'), array([0, 1, 1, 2]))
. . .
... (array([['c', 'c'],
            ['d', 'd'],
. . .
             ['d', 'd'],
. . .
            ['e', 'e']],
. . .
```

(continues on next page)

(continued from previous page)

```
dtype='<U1'), array([2, 3, 3, 4]))
...</pre>
```

Many to One

```
>>> return_last = True
>>> num_steps = 2
>>> X = np.asarray([['a','a'], ['b','b'], ['c','c'], ['d','d'], ['e','e'], ['f','f
>>> Y = np.asarray([0,1,2,3,4,5])
>>> for batch in tl.iterate.seq_minibatches(inputs=X, targets=Y, batch_size=2,_
→seq_length=num_steps, stride=1):
        x, y = batch
        if return_last:
           tmp_y = y.reshape((-1, num_steps) + y.shape[1:])
>>>
       y = tmp_y[:, -1]
>>>
       print(x, y)
... [['a' 'a']
... ['b' 'b']
... ['b' 'b']
... ['c' 'c']] [1 2]
... [['c' 'c']
... ['d' 'd']
... ['d' 'd']
   ['e' 'e']] [3 4]
```

Sequence iteration 2

tensorlayer.iterate.seq_minibatches2 (inputs, targets, batch_size, num_steps)

Generate a generator that iterates on two list of words. Yields (Returns) the source contexts and the target context by the given batch_size and num_steps (sequence_length), see PTB tutorial. In TensorFlow's tutorial, this generates the batch_size pointers into the raw PTB data, and allows minibatch iteration along these pointers.

• Hint, if the input data are images, you can modify the code as follow.

Parameters

inputs [a list] the context in list format; note that context usually be represented by splitting by space, and then convert to unique word IDs.

targets [a list] the context in list format; note that context usually be represented by splitting by space, and then convert to unique word IDs.

batch_size [int] the batch size.

num_steps [int] the number of unrolls. i.e. sequence_length

Yields

2.4. API - Iteration 133

Pairs of the batched data, each a matrix of shape [batch_size, num_steps].

Raises

ValueError [if batch_size or num_steps are too high.]

Examples

```
>>> X = [i for i in range(20)]
>>> Y = [i for i in range(20,40)]
>>> for batch in tl.iterate.seq_minibatches2(X, Y, batch_size=2, num_steps=3):
       x, y = batch
       print(x, y)
. . .
... [[ 0. 1.
... [ 10. 11. 12.]]
... [[ 20. 21. 22.]
... [ 30. 31. 32.]]
... [[ 3. 4.
                 5.]
... [ 13. 14. 15.]]
... [[ 23. 24. 25.]
... [ 33. 34. 35.]]
... [[ 6. 7. 8.]
... [ 16. 17. 18.]]
... [[ 26. 27. 28.]
... [ 36. 37. 38.]]
```

PTB dataset iteration

```
tensorlayer.iterate.ptb_iterator(raw_data, batch_size, num_steps)
```

Generate a generator that iterates on a list of words, see PTB tutorial. Yields (Returns) the source contexts and the target context by the given batch_size and num_steps (sequence_length).

```
see PTB tutorial.
e.g. x = [0, 1, 2] y = [1, 2, 3], when batch size = 1, num steps = 3, raw data = [i for i in range(100)]
```

In TensorFlow's tutorial, this generates batch_size pointers into the raw PTB data, and allows minibatch iteration along these pointers.

Parameters

raw_data [a list] the context in list format; note that context usually be represented by splitting by space, and then convert to unique word IDs.

```
batch_size [int] the batch size.
```

num_steps [int] the number of unrolls. i.e. sequence_length

Yields

Pairs of the batched data, each a matrix of shape [batch size, num steps].

The second element of the tuple is the same data time-shifted to the

right by one.

Raises

ValueError [if batch_size or num_steps are too high.]

Examples

```
>>> train_data = [i for i in range(20)]
>>> for batch in tl.iterate.ptb_iterator(train_data, batch_size=2, num_steps=3):
       x, y = batch
       print(x, y)
... [[ 0 1 2] <---x
                                          1st subset/ iteration
... [10 11 12]]
... [[ 1 2 3] <---y
... [11 12 13]]
... [[ 3 4 5] <--- 1st batch input
                                         2nd subset/ iteration
... [13 14 15]] <--- 2nd batch input
... [[ 4 5 6] <--- 1st batch target
... [14 15 16]] <--- 2nd batch target
... [[ 6 7 8]
                                          3rd subset/ iteration
... [16 17 18]]
... [[ 7 8 9]
... [17 18 19]]
```

2.5 API - Utility

fit(sess, network, train_op, cost, X_train,)	Traing a given non time-series network by the given cost
	function, training data, batch_size, n_epoch etc.
$test(sess, network, acc, X_test, y_test, x,)$	Test a given non time-series network by the given test
	data and metric.
<pre>predict(sess, network, X, x, y_op[, batch_size])</pre>	Return the predict results of given non time-series net-
	work.
<pre>evaluation([y_test, y_predict, n_classes])</pre>	Input the predicted results, targets results and the num-
	ber of class, return the confusion matrix, F1-score of
	each class, accuracy and macro F1-score.
class_balancing_oversample([X_train,])	Input the features and labels, return the features and la-
	bels after oversampling.
<pre>get_random_int([min, max, number, seed])</pre>	Return a list of random integer by the given range and
	quantity.
dict_to_one([dp_dict])	Input a dictionary, return a dictionary that all items are
	set to one, use for disable dropout, dropconnect layer
	and so on.
flatten_list([list_of_list])	Input a list of list, return a list that all items are in a list.

2.5. API - Utility 135

2.5.1 Training, testing and predicting

Training

tensorlayer.utils.fit (sess, network, train_op, cost, X_train, y_train, x, y_, acc=None, batch_size=100, n_epoch=100, print_freq=5, X_val=None, y_val=None, eval_train=True, tensorboard=False, tensorboard_epoch_freq=5, tensorboard_weight_histograms=True, tensorboard_graph_vis=True)

Traing a given non time-series network by the given cost function, training data, batch_size, n_epoch etc.

Parameters

sess [TensorFlow session] sess = tf.InteractiveSession()

network [a TensorLayer layer] the network will be trained

train_op [a TensorFlow optimizer] like tf.train.AdamOptimizer

X_train [numpy array] the input of training data

y_train [numpy array] the target of training data

x [placeholder] for inputs

y_ [placeholder] for targets

acc [the TensorFlow expression of accuracy (or other metric) or None] if None, would not display the metric

batch_size [int] batch size for training and evaluating

n_epoch [int] the number of training epochs

print_freq [int] display the training information every print_freq epochs

X_val [numpy array or None] the input of validation data

y_val [numpy array or None] the target of validation data

eval_train [boolean] if X_val and y_val are not None, it refects whether to evaluate the training data

tensorboard [boolean] if True summary data will be stored to the log/ direcory for visualization with tensorboard. See also detailed tensorboard_X settings for specific configurations of features. (default False) Also runs tl.layers.initialize_global_variables(sess) internally in fit() to setup the summary nodes, see Note:

tensorboard_epoch_freq [int] how many epochs between storing tensorboard checkpoint for visualization to log/ directory (default 5)

tensorboard_weight_histograms [boolean] if True updates tensorboard data in the logs/ directory for visulaization of the weight histograms every tensorboard_epoch_freq epoch (default True)

tensorboard_graph_vis [boolean] if True stores the graph in the tensorboard summaries saved to log/ (default True)

Examples

```
>>> see tutorial_mnist_simple.py
>>> tl.utils.fit(sess, network, train_op, cost, X_train, y_train, x, y_,
... acc=acc, batch_size=500, n_epoch=200, print_freq=5,
... X_val=X_val, y_val=y_val, eval_train=False)
>>> tl.utils.fit(sess, network, train_op, cost, X_train, y_train, x, y_,
... acc=acc, batch_size=500, n_epoch=200, print_freq=5,
... X_val=X_val, y_val=y_val, eval_train=False,
... tensorboard=True, tensorboard_weight_histograms=True, tensorboard_

Graph_vis=True)
```

Evaluation

tensorlayer.utils.test (sess, network, acc, X_test, y_test, x, y_, batch_size, cost=None) Test a given non time-series network by the given test data and metric.

Parameters

```
sess [TensorFlow session] sess = tf.InteractiveSession()
```

network [a TensorLayer layer] the network will be trained

acc [the TensorFlow expression of accuracy (or other metric) or None] if None, would not display the metric

X_test [numpy array] the input of test data

y_test [numpy array] the target of test data

x [placeholder] for inputs

y_ [placeholder] for targets

batch_size [int or None] batch size for testing, when dataset is large, we should use minibatche for testing. when dataset is small, we can set it to None.

cost [the TensorFlow expression of cost or None] if None, would not display the cost

Examples

```
>>> see tutorial_mnist_simple.py
>>> tl.utils.test(sess, network, acc, X_test, y_test, x, y_, batch_size=None,_
--cost=cost)
```

Prediction

tensorlayer.utils.**predict** (*sess*, *network*, *X*, *x*, *y_op*, *batch_size=None*) Return the predict results of given non time-series network.

Parameters

```
sess [TensorFlow session] sess = tf.InteractiveSession()
```

network [a TensorLayer layer] the network will be trained

X [numpy array] the input

x [placeholder] for inputs

y_op [placeholder] the argmax expression of softmax outputs

2.5. API - Utility 137

batch_size [int or None] batch size for prediction, when dataset is large, we should use minibatche for prediction. when dataset is small, we can set it to None.

Examples

```
>>> see tutorial_mnist_simple.py
>>> y = network.outputs
>>> y_op = tf.argmax(tf.nn.softmax(y), 1)
>>> print(tl.utils.predict(sess, network, X_test, x, y_op))
```

2.5.2 Evaluation functions

tensorlayer.utils.evaluation(y_test=None, y_predict=None, n_classes=None)

Input the predicted results, targets results and the number of class, return the confusion matrix, F1-score of each class, accuracy and macro F1-score.

Parameters

```
y_test [numpy.array or list] target results
```

y_predict [numpy.array or list] predicted results

n_classes [int] number of classes

Examples

```
>>> c_mat, f1, acc, f1_macro = evaluation(y_test, y_predict, n_classes)
```

2.5.3 Class balancing functions

```
tensor layer.utils.class\_balancing\_oversample (\textit{X\_train=None}, y\_train=None, print-able=True)
```

Input the features and labels, return the features and labels after oversampling.

Parameters

```
X_train [numpy.array] Features, each row is an example
```

y_train [numpy.array] Labels

Examples

· One X

• Two X

2.5.4 Random functions

```
tensorlayer.utils.get_random_int(min=0, max=10, number=5, seed=None)
Return a list of random integer by the given range and quantity.
```

Examples

```
>>> r = get_random_int(min=0, max=10, number=5)
... [10, 2, 3, 3, 7]
```

2.5.5 Helper functions

Set all items in dictionary to one

```
tensorlayer.utils.dict_to_one(dp_dict={})
```

Input a dictionary, return a dictionary that all items are set to one, use for disable dropout, dropconnect layer and so on.

Parameters

dp_dict [dictionary] keeping probabilities

Examples

```
>>> dp_dict = dict_to_one( network.all_drop )
>>> dp_dict = dict_to_one( network.all_drop )
>>> feed_dict.update(dp_dict)
```

Flatten a list

```
tensorlayer.utils.flatten_list (list_of_list=[[], []])
Input a list of list, return a list that all items are in a list.
```

Parameters

```
list_of_list [a list of list]
```

Examples

```
>>> tl.utils.flatten_list([[1, 2, 3],[4, 5],[6]])
... [1, 2, 3, 4, 5, 6]
```

2.5. API - Utility 139

2.6 API - Natural Language Processing

Natural Language Processing and Word Representation.

<pre>generate_skip_gram_batch(data, batch_size,</pre>	Generate a training batch for the Skip-Gram model.
)	
sample([a, temperature])	Sample an index from a probability array.
<pre>sample_top([a, top_k])</pre>	Sample from top_k probabilities.
SimpleVocabulary(vocab, unk_id)	Simple vocabulary wrapper, see create_vocab().
Vocabulary(vocab_file[, start_word,])	Create Vocabulary class from a given vocabulary and
	its id-word, word-id convert, see create_vocab() and
	tutorial_tfrecord3.py.
<pre>process_sentence(sentence[, start_word,])</pre>	Converts a sentence string into a list of string words, add
	<pre>start_word and end_word, see create_vocab() and</pre>
	tutorial_tfrecord3.py.
<pre>create_vocab(sentences, word_counts_output_file)</pre>	Creates the vocabulary of word to word_id, see cre-
	<pre>ate_vocab() and tutorial_tfrecord3.py.</pre>
simple_read_words([filename])	Read context from file without any preprocessing.
read_words([filename, replace])	File to list format context.
read_analogies_file([eval_file, word2id])	Reads through an analogy question file, return its id for-
	mat.
build_vocab(data)	Build vocabulary.
build_reverse_dictionary(word_to_id)	Given a dictionary for converting word to integer id.
build_words_dataset([words,])	Build the words dictionary and replace rare words with
	'UNK' token.
save_vocab([count, name])	Save the vocabulary to a file so the model can be
	reloaded.
<pre>words_to_word_ids([data, word_to_id, unk_key])</pre>	Given a context (words) in list format and the vocabu-
	lary, Returns a list of IDs to represent the context.
word_ids_to_words(data, id_to_word)	Given a context (ids) in list format and the vocabulary,
	Returns a list of words to represent the context.
<pre>basic_tokenizer(sentence[, _WORD_SPLIT])</pre>	Very basic tokenizer: split the sentence into a list of to-
_ ,	kens.
create_vocabulary(vocabulary_path,[,])	Create vocabulary file (if it does not exist yet) from data
	file.
initialize_vocabulary(vocabulary_path)	Initialize vocabulary from file, return the word_to_id
/ /	(dictionary) and id_to_word (list).
sentence_to_token_ids(sentence, vocabulary)	Convert a string to list of integers representing token-
, , , , , , , , , , , , , , , , ,	ids.
data_to_token_ids(data_path, target_path,)	Tokenize data file and turn into token-ids using given
	vocabulary file.

2.6.1 Iteration function for training embedding matrix

 $\label{lem:constraint} \begin{tabular}{ll} tensor layer. nlp. {\tt generate_skip_gram_batch} (\textit{data}, & \textit{batch_size}, & \textit{num_skips}, & \textit{skip_window}, \\ & & \textit{data_index=0}) \\ & & & & & \\ Generate a training batch for the Skip-Gram model. \\ \end{tabular}$

Parameters

data [a list] To present context.

batch_size [an int] Batch size to return.

num_skips [an int] How many times to reuse an input to generate a label.

skip_window [an int] How many words to consider left and right.

data_index [an int] Index of the context location. without using yield, this code use data_index to instead.

Returns

```
batch [a list] Inputslabels [a list] Labelsdata_index [an int] Index of the context location.
```

References

• TensorFlow word2vec tutorial

Examples

```
>>> Setting num_skips=2, skip_window=1, use the right and left words.
>>> In the same way, num_skips=4, skip_window=2 means use the nearby 4 words.
```

2.6.2 Sampling functions

Simple sampling

```
tensorlayer.nlp.sample (a=[], temperature=1.0) Sample an index from a probability array.
```

Parameters

```
a [a list] List of probabilities.
temperature [float or None] The higher the more uniform.
When a = [0.1, 0.2, 0.7],
temperature = 0.7, the distribution will be sharpen [ 0.05048273 0.13588945 0.81362782]
```

```
temperature = 1.0, the distribution will be the same [0.1 0.2 0.7]

temperature = 1.5, the distribution will be filtered [ 0.16008435 0.25411807 0.58579758]

If None, it will be np.argmax(a)
```

Notes

No matter what is the temperature and input list, the sum of all probabilities will be one. Even if input list = [1, 100, 200], the sum of all probabilities will still be one.

For large vocabulary_size, choice a higher temperature to avoid error.

Sampling from top k

```
\label{eq:constraints} \begin{split} \texttt{Sample top} \ (a = [], top\_k = 10) \\ & \texttt{Sample from top}\_k \ \texttt{probabilities}. \end{split}
```

Parameters

a [a list] List of probabilities.

top_k [int] Number of candidates to be considered.

2.6.3 Vector representations of words

Simple vocabulary class

```
class tensorlayer.nlp.SimpleVocabulary(vocab, unk_id)
    Simple vocabulary wrapper, see create_vocab().
```

Parameters

```
vocab [A dictionary of word to word_id.]unk_id [Id of the special 'unknown' word.]
```

Methods

word_to_id(word)

Returns the integer id of a word string.

Vocabulary class

Create Vocabulary class from a given vocabulary and its id-word, word-id convert, see create_vocab() and tutorial_tfrecord3.py.

Parameters

vocab_file [File containing the vocabulary, where the words are the first] whitespace-separated token on each line (other tokens are ignored) and the word ids are the corresponding line numbers.

```
start_word [Special word denoting sentence start.]
end_word [Special word denoting sentence end.]
unk_word [Special word denoting unknown words.]
```

Methods

id_to_word(word_id)	Returns the word string of an integer word id.
word_to_id(word)	Returns the integer word id of a word string.

Process sentence

```
tensorlayer.nlp.process_sentence (sentence, start_word='<S>', end_word='')

Converts a sentence string into a list of string words, add start_word and end_word, see create_vocab()
and tutorial_tfrecord3.py.
```

Returns

A list of strings; the processed caption.

Notes

- You have to install the following package.
- Installing NLTK
- · Installing NLTK data

Examples

```
>>> c = "how are you?"
>>> c = tl.nlp.process_sentence(c)
>>> print(c)
... ['<S>', 'how', 'are', 'you', '?', '']
```

Create vocabulary

```
tensorlayer.nlp.create_vocab(sentences, word_counts_output_file, min_word_count=1)

Creates the vocabulary of word to word_id, see create_vocab() and tutorial_tfrecord3.py.
```

The vocabulary is saved to disk in a text file of word counts. The id of each word in the file is its corresponding 0-based line number.

Parameters

```
sentences [a list of lists of strings.]word_counts_output_file [A string] The file name.min_word_count [a int] Minimum number of occurrences for a word.
```

Returns

- tl.nlp.SimpleVocabulary object.

```
>>> tl.nlp.create_vocab(processed_capts, word_counts_output_file='vocab.txt', min_
→word_count=1)
     [TL] Creating vocabulary.
     Total words: 8
. . .
     Words in vocabulary: 8
    Wrote vocabulary file: vocab.txt
>>> vocab = tl.nlp.Vocabulary('vocab.txt', start_word="<S>", end_word="", unk_
→word="<UNK>")
... INFO:tensorflow:Initializing vocabulary from file: vocab.txt
... [TL] Vocabulary from vocab.txt : <S>  <UNK>
... vocabulary with 10 words (includes start_word, end_word, unk_word)
       start_id: 2
. . .
       end_id: 3
. . .
      unk_id: 9
. . .
. . .
      pad_id: 0
```

2.6.4 Read words from file

Simple read file

```
tensorlayer.nlp.simple_read_words (filename='nietzsche.txt')
Read context from file without any preprocessing.
```

Parameters

filename [a string] A file path (like .txt file)

Returns

The context in a string

Read file

```
tensorlayer.nlp.read_words(filename='nietzsche.txt', replace=['\n', '<eos>'])
```

File to list format context. Note that, this script can not handle punctuations. For customized read_words method, see tutorial_generate_text.py.

Parameters

```
filename [a string]
A file path (like .txt file),
```

replace [a list] [original string, target string], to disable replace use [", "]

Returns

```
The context in a list, split by space by default, and use "'<eos>" to represent "'
"', e.g. [... 'how', 'useful', 'it', "'s" ... ].
```

2.6.5 Read analogy question file

tensorlayer.nlp.read_analogies_file (eval_file='questions-words.txt', word2id={})
Reads through an analogy question file, return its id format.

Parameters

```
eval_data [a string] The file name.word2id [a dictionary] Mapping words to unique IDs.
```

Returns

analogy_questions [a [n, 4] numpy array containing the analogy question's] word ids. questions_skipped: questions skipped due to unknown words.

Examples

```
>>> eval_file should be in this format :
>>> : capital-common-countries
>>> Athens Greece Baghdad Iraq
>>> Athens Greece Bangkok Thailand
>>> Athens Greece Beijing China
>>> Athens Greece Berlin Germany
>>> Athens Greece Bern Switzerland
>>> Athens Greece Cairo Egypt
>>> Athens Greece Canberra Australia
>>> Athens Greece Hanoi Vietnam
>>> Athens Greece Havana Cuba
...
```

```
>>> words = tl.files.load_matt_mahoney_text8_dataset()
>>> data, count, dictionary, reverse_dictionary =
                                                                tl.nlp.build_
→words_dataset(words, vocabulary_size, True)
>>> analogy_questions = tl.nlp.read_analogies_file(
                                                                  eval_file=
→'questions-words.txt', word2id=dictionary)
>>> print(analogy_questions)
... [[ 3068 1248 7161 1581]
... [ 3068 1248 28683 5642]
... [ 3068 1248 3878
... [ 1216 4309 19982 25506]
... [ 1216 4309 3194 8650]
... [ 1216 4309
                 140
                       312]]
```

2.6.6 Build vocabulary, word dictionary and word tokenization

Build dictionary from word to id

```
tensorlayer.nlp.build_vocab(data)
```

Build vocabulary. Given the context in list format. Return the vocabulary, which is a dictionary for word to id. e.g. {'campbell': 2587, 'atlantic': 2247, 'aoun': 6746....}

Parameters

data [a list of string] the context in list format

Returns

```
word_to_id [a dictionary] mapping words to unique IDs. e.g. {'campbell': 2587, 'atlantic': 2247, 'aoun': 6746....}
```

Examples

```
>>> data_path = os.getcwd() + '/simple-examples/data'
>>> train_path = os.path.join(data_path, "ptb.train.txt")
>>> word_to_id = build_vocab(read_txt_words(train_path))
```

Build dictionary from id to word

```
tensorlayer.nlp.build_reverse_dictionary(word_to_id)
```

Given a dictionary for converting word to integer id. Returns a reverse dictionary for converting a id to word.

Parameters

word_to_id [dictionary] mapping words to unique ids

Returns

reverse_dictionary [a dictionary] mapping ids to words

Build dictionaries for id to word etc

```
tensorlayer.nlp.build_words_dataset(words=[], vocabulary_size=50000, printable=True, unk key='UNK')
```

Build the words dictionary and replace rare words with 'UNK' token. The most common word has the smallest integer id.

Parameters

words [a list of string or byte] The context in list format. You may need to do preprocessing on the words, such as lower case, remove marks etc.

vocabulary_size [an int] The maximum vocabulary size, limiting the vocabulary size. Then the script replaces rare words with 'UNK' token.

printable [boolean] Whether to print the read vocabulary size of the given words.

unk_key [a string] Unknown words = unk_key

Returns

data [a list of integer] The context in a list of ids

```
count [a list of tuple and list] count[0] is a list: the number of rare words
count[1:] are tuples: the number of occurrence of each word
e.g. [['UNK', 418391], (b'the', 1061396), (b'of', 593677), (b'and', 416629), (b'one', 411764)]
dictionary [a dictionary] word_to_id, mapping words to unique IDs.
reverse_dictionary [a dictionary] id_to_word, mapping id to unique word.
```

```
>>> words = tl.files.load_matt_mahoney_text8_dataset()
>>> vocabulary_size = 50000
>>> data, count, dictionary, reverse_dictionary = tl.nlp.build_words_

dataset(words, vocabulary_size)
```

Save vocabulary

```
tensorlayer.nlp.save_vocab (count=[], name='vocab.txt')
Save the vocabulary to a file so the model can be reloaded.
```

Parameters

```
count [a list of tuple and list] count[0] is a list: the number of rare words
count[1:] are tuples: the number of occurrence of each word
e.g. [['UNK', 418391], (b'the', 1061396), (b'of', 593677), (b'and', 416629), (b'one',
411764)]
```

Examples

2.6.7 Convert words to IDs and IDs to words

These functions can be done by Vocabulary class.

List of Words to IDs

```
tensorlayer.nlp.words_to_word_ids (data=[], word_to_id={}, unk_key='UNK')
Given a context (words) in list format and the vocabulary, Returns a list of IDs to represent the context.
```

Parameters

```
data [a list of string or byte] the context in list formatword_to_id [a dictionary] mapping words to unique IDs.unk_key [a string] Unknown words = unk_key
```

Returns

A list of IDs to represent the context.

Examples

List of IDs to Words

```
tensorlayer.nlp.word_ids_to_words(data,id_to_word)
```

Given a context (ids) in list format and the vocabulary, Returns a list of words to represent the context.

Parameters

```
data [a list of integer] the context in list formatid_to_word [a dictionary] mapping id to unique word.
```

Returns

A list of string or byte to represent the context.

Examples

```
>>> see words_to_word_ids
```

2.6.8 Functions for translation

Word Tokenization

```
tensorlayer.nlp.basic_tokenizer (sentence, _WORD_SPLIT=re.compile(b'([.,!?"\':;)(])')) Very basic tokenizer: split the sentence into a list of tokens.
```

Parameters

```
sentence [tensorflow.python.platform.gfile.GFile Object]
_WORD_SPLIT [regular expression for word spliting.]
```

References

• Code from /tensorflow/models/rnn/translation/data_utils.py

Examples

```
>>> see create_vocabulary
>>> from tensorflow.python.platform import gfile
>>> train_path = "wmt/giga-fren.release2"
>>> with gfile.GFile(train_path + ".en", mode="rb") as f:
>>>
      for line in f:
>>>
         tokens = tl.nlp.basic_tokenizer(line)
         print(tokens)
         exit()
... [b'Changing', b'Lives', b'|', b'Changing', b'Society', b'|', b'How',
      b'It', b'Works', b'|', b'Technology', b'Drives', b'Change', b'Home',
     b'|', b'Concepts', b'|', b'Teachers', b'|', b'Search', b'|', b'Overview',
     b'|', b'Credits', b'|', b'HHCC', b'Web', b'|', b'Reference', b'|',
      b'Feedback', b'Virtual', b'Museum', b'of', b'Canada', b'Home', b'Page']
. . .
```

Create or read vocabulary

```
tensorlayer.nlp.create_vocabulary (vocabulary_path, data_path, max_vocabulary_size, tokenizer=None, normalize_digits=True,  \_DIGIT\_RE = re.compile(b\text{'}\d'), \\ \_START\_VOCAB = [b\text{'}\_PAD\text{'}, b\text{'}\_GO\text{'}, b\text{'}\_EOS\text{'}, b\text{'}\_UNK\text{'}])
```

Create vocabulary file (if it does not exist yet) from data file.

Data file is assumed to contain one sentence per line. Each sentence is tokenized and digits are normalized (if normalize_digits is set). Vocabulary contains the most-frequent tokens up to max_vocabulary_size. We write it to vocabulary_path in a one-token-per-line format, so that later token in the first line gets id=0, second line gets id=1, and so on.

Parameters

```
vocabulary_path [path where the vocabulary will be created.]data_path [data file that will be used to create vocabulary.]max_vocabulary_size [limit on the size of the created vocabulary.]
```

tokenizer [a function to use to tokenize each data sentence.] if None, basic_tokenizer will be used.

normalize_digits [Boolean] if true, all digits are replaced by 0s.

References

Code from /tensorflow/models/rnn/translation/data utils.py

```
tensorlayer.nlp.initialize_vocabulary(vocabulary_path)
```

Initialize vocabulary from file, return the word_to_id (dictionary) and id_to_word (list).

We assume the vocabulary is stored one-item-per-line, so a file:

dog

cat

will result in a vocabulary {"dog": 0, "cat": 1}, and this function will also return the reversed-vocabulary ["dog", "cat"].

Parameters

vocabulary_path [path to the file containing the vocabulary.]

Returns

vocab [a dictionary] Word to id. A dictionary mapping string to integers.

rev_vocab [a list] Id to word. The reversed vocabulary (a list, which reverses the vocabulary mapping).

Raises

ValueError [if the provided vocabulary_path does not exist.]

Examples

```
>>> Assume 'test' contains
... dog
... cat
... bird
>>> vocab, rev_vocab = tl.nlp.initialize_vocabulary("test")
>>> print(vocab)
>>> {b'cat': 1, b'dog': 0, b'bird': 2}
>>> print(rev_vocab)
>>> [b'dog', b'cat', b'bird']
```

Convert words to IDs and IDs to words

```
to kenizer = None, \\ normalize\_digits = True, \\ \_DIGIT\_RE = re.compile(b`\d')) \\ to kenizer = None, \\ UNK\_ID = 3, \\ UNK\_ID = 3
```

Convert a string to list of integers representing token-ids.

For example, a sentence "I have a dog" may become tokenized into ["T", "have", "a", "dog"] and with vocabulary {"I": 1, "have": 2, "a": 4, "dog": 7"} this function will return [1, 2, 4, 7].

Parameters

sentence [tensorflow.python.platform.gfile.GFile Object] The sentence in bytes format to convert to token-ids.

see basic_tokenizer(), data_to_token_ids()

vocabulary [a dictionary mapping tokens to integers.]

tokenizer [a function to use to tokenize each sentence;] If None, basic tokenizer will be used.

normalize_digits [Boolean] If true, all digits are replaced by 0s.

Returns

A list of integers, the token-ids for the sentence.

```
tensorlayer.nlp.data_to_token_ids (data_path, target_path, vocabulary_path, tok-
enizer=None, normalize_digits=True, UNK_ID=3,
_DIGIT_RE=re.compile(b'\\d'))
```

Tokenize data file and turn into token-ids using given vocabulary file.

This function loads data line-by-line from data_path, calls the above sentence_to_token_ids, and saves the result to target_path. See comment for sentence_to_token_ids on the details of token-ids format.

Parameters

data_path [path to the data file in one-sentence-per-line format.]
target_path [path where the file with token-ids will be created.]
vocabulary_path [path to the vocabulary file.]
tokenizer [a function to use to tokenize each sentence;] if None, basic_tokenizer will be used.

References

• Code from /tensorflow/models/rnn/translation/data_utils.py

normalize_digits [Boolean; if true, all digits are replaced by 0s.]

2.7 API - Reinforcement Learning

Reinforcement Learning.

```
      discount_episode_rewards([rewards, gamma, mode])
      Take 1D float array of rewards and compute discounted rewards for an episode.

      cross_entropy_reward_loss(logits, ...)
      actions, Calculate the loss for Policy Gradient Network.
```

2.7.1 Reward functions

```
tensorlayer.rein.discount_episode_rewards(rewards=[], gamma=0.99, mode=0)
```

Take 1D float array of rewards and compute discounted rewards for an episode. When encount a non-zero value, consider as the end a of an episode.

Parameters

```
    rewards [numpy list] a list of rewards
    gamma [float] discounted factor
    mode [int] if mode == 0, reset the discount process when encount a non-zero reward (Ping-pong game). if mode == 1, would not reset the discount process.
```

```
\rightarrow \rightarrow rewards = np.asarray([0, 0, 0, 1, 0, 0, 0, 1, 0, 0, 1])
>>> gamma = 0.9
>>> discount_rewards = tl.rein.discount_episode_rewards(rewards, gamma)
>>> print (discount rewards)
... [ 0.72899997 0.81
                         0.89999998 1.
                                              0.72899997 0.81
... 0.89999998 1.
                       0.72899997 0.81
                                            0.89999998 1.
                                                                ]
>>> discount_rewards = tl.rein.discount_episode_rewards(rewards, gamma, mode=1)
>>> print (discount_rewards)
... 1.49048996 1.65610003 0.72899997 0.81
                                            0.89999998 1.
```

2.7.2 Cost functions

tensorlayer.rein.cross_entropy_reward_loss (logits, actions, rewards, name=None) Calculate the loss for Policy Gradient Network.

Parameters

logits [tensor] The network outputs without softmax. This function implements softmax inside.actions [tensor/ placeholder] The agent actions.rewards [tensor/ placeholder] The rewards.

Examples

2.8 API - Load, Save Model and Data

Load benchmark dataset, save and restore model, save and load variables. TensorFlow provides .ckpt file format to save and restore the models, while we suggest to use standard python file format .npz to save models for the sake of cross-platform.

```
# save model as .ckpt
saver = tf.train.Saver()
save_path = saver.save(sess, "model.ckpt")
# restore model from .ckpt
saver = tf.train.Saver()
saver.restore(sess, "model.ckpt")
# save model as .npz
tl.files.save_npz(network.all_params , name='model.npz')
# restore model from .npz
load_params = tl.files.load_npz(path='', name='model.npz')
tl.files.assign_params(sess, load_params, network)
# you can assign the pre-trained parameters as follow
# 1st parameter
tl.files.assign_params(sess, [load_params[0]], network)
# the first three parameters
tl.files.assign_params(sess, load_params[:3], network)
```

<pre>load_mnist_dataset([shape, path])</pre>	Automatically download MNIST dataset and return the
	training, validation and test set with 50000, 10000 and
	10000 digit images respectively.
<pre>load_cifar10_dataset([shape, path,])</pre>	The CIFAR-10 dataset consists of 60000 32x32 colour
	images in 10 classes, with 6000 images per class.
load_ptb_dataset([path])	Penn TreeBank (PTB) dataset is used in many LAN-
	GUAGE MODELING papers, including "Empirical
	Evaluation and Combination of Advanced Language
	Modeling Techniques", "Recurrent Neural Network
	Regularization".
<pre>load_matt_mahoney_text8_dataset([path])</pre>	Download a text file from Matt Mahoney's website if
	not present, and make sure it's the right size.
<pre>load_imdb_dataset([path, nb_words,])</pre>	Load IMDB dataset
load_nietzsche_dataset([path])	Load Nietzsche dataset.
load_wmt_en_fr_dataset([path])	It will download English-to-French translation data
	from the WMT'15 Website (10^9-French-English cor-
	pus), and the 2013 news test from the same site as de-
	velopment set.
<pre>load_flickr25k_dataset([tag, path,])</pre>	Returns a list of images by a given tag from Flick25k
	dataset, it will download Flickr25k from the official
	website at the first time you use it.
<pre>load_flickr1M_dataset([tag, size, path,])</pre>	Returns a list of images by a given tag from Flickr1M
	dataset, it will download Flickr1M from the official
	website at the first time you use it.
save_npz([save_list, name, sess])	Input parameters and the file name, save parameters into
	.npz file.
	Continued on next page

Table 54 – continued from previous page

save_npz_dict([save_list, name, sess])	Input parameters and the file name, save parameters as
	a dictionary into .npz file.
load_npz([path, name])	Load the parameters of a Model saved by
	tl.files.save_npz().
<pre>load_npz_dict([path, name])</pre>	Load the parameters of a Model saved by
	tl.files.save_npz_dict().
assign_params(sess, params, network)	Assign the given parameters to the TensorLayer net-
	work.
<pre>load_and_assign_npz([sess, name, network])</pre>	Load model from npz and assign to a network.
<pre>save_any_to_npy([save_dict, name])</pre>	Save variables to .npy file.
<pre>load_npy_to_any([path, name])</pre>	Load .npy file.
file_exists(filepath)	Check whether a file exists by given file path.
folder_exists(folderpath)	Check whether a folder exists by given folder path.
del_file(filepath)	Delete a file by given file path.
del_folder(folderpath)	Delete a folder by given folder path.
read_file(filepath)	Read a file and return a string.
<pre>load_file_list([path, regx, printable])</pre>	Return a file list in a folder by given a path and regular
	expression.
load_folder_list([path])	Return a folder list in a folder by given a folder path.
exists_or_mkdir(path[, verbose])	Check a folder by given name, if not exist, create the
	folder and return False, if directory exists, return True.
<pre>maybe_download_and_extract(filename,[,</pre>	Checks if file exists in working_directory otherwise
])	tries to dowload the file, and optionally also tries to ex-
	tract the file if format is ".zip" or ".tar"
natural_keys(text)	Sort list of string with number in human order.
$npz_to_W_pdf([path, regx])$	Convert the first weight matrix of .npz file to .pdf by
	using tl.visualize.W().

2.8.1 Load dataset functions

MNIST

tensorlayer.files.load_mnist_dataset(shape=(-1,784), path='data/mnist/')

Automatically download MNIST dataset and return the training, validation and test set with 50000, 10000 and 10000 digit images respectively.

Parameters

shape [tuple] The shape of digit images, defaults is (-1,784)

path [string] The path that the data is downloaded to, defaults is data/mnist/.

Examples

```
>>> X_train, y_train, X_val, y_val, X_test, y_test = tl.files.load_mnist_

dataset(shape=(-1,784))
>>> X_train, y_train, X_val, y_val, X_test, y_test = tl.files.load_mnist_

dataset(shape=(-1, 28, 28, 1))
```

CIFAR-10

```
tensorlayer.files.load_cifar10_dataset(shape=(-1, 32, 32, 3), path='data/cifar10/', plotable=False, second=3)
```

The CIFAR-10 dataset consists of 60000 32x32 colour images in 10 classes, with 6000 images per class. There are 50000 training images and 10000 test images.

The dataset is divided into five training batches and one test batch, each with 10000 images. The test batch contains exactly 1000 randomly-selected images from each class. The training batches contain the remaining images in random order, but some training batches may contain more images from one class than another. Between them, the training batches contain exactly 5000 images from each class.

Parameters

```
shape [tupe] The shape of digit images: e.g. (-1, 3, 32, 32), (-1, 32, 32, 3), (-1, 32*32*3)
plotable [True, False] Whether to plot some image examples.
second [int] If plotable is True, second is the display time.
path [string] The path that the data is downloaded to, defaults is data/cifar10/.
```

Notes

CIFAR-10 images can only be display without color change under uint8. >>> X_train = np.asarray(X_train, dtype=np.uint8) >>> plt.ion() >>> fig = plt.figure(1232) >>> count = 1 >>> for row in range(10): >>> for col in range(10): >>> a = fig.add_subplot(10, 10, count) >>> plt.imshow(X_train[count-1], interpolation='nearest') >>> plt.gca().xaxis.set_major_locator(plt.NullLocator()) # (tick) >>> plt.gca().yaxis.set_major_locator(plt.NullLocator()) >>> count = count + 1 >>> plt.draw() >>> plt.pause(3)

References

- CIFAR website

Examples

Penn TreeBank (PTB)

```
tensorlayer.files.load_ptb_dataset(path='data/ptb/')
```

Penn TreeBank (PTB) dataset is used in many LANGUAGE MODELING papers, including "Empirical Evaluation and Combination of Advanced Language Modeling Techniques", "Recurrent Neural Network Regularization". It consists of 929k training words, 73k validation words, and 82k test words. It has 10k words in its vocabulary.

Parameters

path [: string] The path that the data is downloaded to, defaults is data/ptb/.

Returns

train_data, valid_data, test_data, vocabulary size

Examples

```
>>> train_data, valid_data, test_data, vocab_size = tl.files.load_ptb_dataset()
```

Matt Mahoney's text8

```
tensorlayer.files.load_matt_mahoney_text8_dataset(path='data/mm_test8/')
```

Download a text file from Matt Mahoney's website if not present, and make sure it's the right size. Extract the first file enclosed in a zip file as a list of words. This dataset can be used for Word Embedding.

Parameters

path [: string] The path that the data is downloaded to, defaults is data/mm_test8/.

Returns

```
word_list [a list] a list of string (word).
e.g. [.... 'their', 'families', 'who', 'were', 'expelled', 'from', 'jerusalem', ...]
```

Examples

```
>>> words = tl.files.load_matt_mahoney_text8_dataset()
>>> print('Data size', len(words))
```

IMBD

```
tensorlayer.files.load_imdb_dataset (path='data/imdb/', nb_words=None, skip_top=0, maxlen=None, test_split=0.2, seed=113, start_char=1, oov_char=2, index_from=3)
```

Load IMDB dataset

Parameters

path [: string] The path that the data is downloaded to, defaults is data/imdb/.

References

· Modified from keras.

Examples

(continues on next page)

(continued from previous page)

```
>>> print('y_train.shape', y_train.shape)
... (20000,) [1 0 0 ..., 1 0 1]
```

Nietzsche

tensorlayer.files.load_nietzsche_dataset (path='data/nietzsche/')
Load Nietzsche dataset. Returns a string.

Parameters

path [string] The path that the data is downloaded to, defaults is data/nietzsche/.

Examples

```
>>> see tutorial_generate_text.py
>>> words = tl.files.load_nietzsche_dataset()
>>> words = basic_clean_str(words)
>>> words = words.split()
```

English-to-French translation data from the WMT'15 Website

```
tensorlayer.files.load_wmt_en_fr_dataset (path='data/wmt_en_fr/')
```

It will download English-to-French translation data from the WMT'15 Website (10^9-French-English corpus), and the 2013 news test from the same site as development set. Returns the directories of training data and test data.

Parameters

path [string] The path that the data is downloaded to, defaults is data/wmt_en_fr/.

Notes

Usually, it will take a long time to download this dataset.

References

• Code modified from /tensorflow/models/rnn/translation/data_utils.py

Flickr25k

```
tensorlayer.files.load_flickr25k_dataset (tag='sky', path='data/flickr25k', n_threads=50, printable=False)
```

Returns a list of images by a given tag from Flick25k dataset, it will download Flickr25k from the official website at the first time you use it.

Parameters

tag [string or None] If you want to get images with tag, use string like 'dog', 'red', see Flickr Search. If you want to get all images, set to None.

path [string] The path that the data is downloaded to, defaults is data/flickr25k/.

```
n_threads [int, number of thread to read image.]
printable [bool, print infomation when reading images, default is False.]
```

· Get images with tag of sky

```
>>> images = tl.files.load_flickr25k_dataset(tag='sky')
```

· Get all images

Flickr1M

```
tensorlayer.files.load_flickr1M_dataset(tag='sky', size=10, path='data/flickr1M', n threads=50, printable=False)
```

Returns a list of images by a given tag from Flickr1M dataset, it will download Flickr1M from the official website at the first time you use it.

Parameters

tag [string or None] If you want to get images with tag, use string like 'dog', 'red', see Flickr Search. If you want to get all images, set to None.

size [int 1 to 10.] 1 means 100k images ... 5 means 500k images, 10 means all 1 million images. Default is 10.

path [string] The path that the data is downloaded to, defaults is data/flickr25k/.

n_threads [int, number of thread to read image.]

printable [bool, print infomation when reading images, default is False.]

Examples

• Use 200k images

```
>>> images = tl.files.load_flickr1M_dataset(tag='zebra', size=2)
```

• Use 1 Million images

```
>>> images = tl.files.load_flickr1M_dataset(tag='zebra')
```

2.8.2 Load and save network

Save network into list (npz)

```
tensorlayer.files.save_npz (save_list=[], name='model.npz', sess=None)
Input parameters and the file name, save parameters into .npz file. Use tl.utils.load_npz() to restore.
```

Parameters

```
save_list [a list] Parameters want to be saved.name [a string or None] The name of the .npz file.sess [None or Session]
```

Notes

If you got session issues, you can change the value.eval() to value.eval(session=sess)

References

· Saving dictionary using numpy

Examples

```
>>> tl.files.save_npz(network.all_params, name='model_test.npz', sess=sess)
... File saved to: model_test.npz
>>> load_params = tl.files.load_npz(name='model_test.npz')
... Loading param0, (784, 800)
... Loading param1, (800,)
... Loading param2, (800, 800)
... Loading param3, (800,)
... Loading param4, (800, 10)
... Loading param5, (10,)
>>> put parameters into a TensorLayer network, please see assign_params()
```

Save network into dict (npz)

```
tensorlayer.files.save_npz_dict (save_list=[], name='model.npz', sess=None)
Input parameters and the file name, save parameters as a dictionary into .npz file. Use tl.utils.load_npz_dict() to restore.
```

Parameters

```
save_list [a list] Parameters want to be saved.name [a string or None] The name of the .npz file.sess [None or Session]
```

Notes

This function tries to avoid a potential broadcasting error raised by numpy.

Load network from save npz

```
tensorlayer.files.load_npz (path=", name='model.npz')
Load the parameters of a Model saved by tl.files.save_npz().
```

Parameters

```
path [a string] Folder path to .npz file.name [a string or None] The name of the .npz file.
```

Returns

params [list] A list of parameters in order.

References

· Saving dictionary using numpy

Examples

• See save_npz and assign_params

Load network from save_npz_dict

```
tensorlayer.files.load_npz_dict(path=", name='model.npz')
Load the parameters of a Model saved by tl.files.save_npz_dict().
```

Parameters

```
path [a string] Folder path to .npz file.name [a string or None] The name of the .npz file.
```

Returns

params [list] A list of parameters in order.

Assign parameters to network

```
tensorlayer.files.assign_params (sess, params, network)
Assign the given parameters to the TensorLayer network.
```

Parameters

```
sess [TensorFlow Session. Automatically run when sess is not None.]params [a list] A list of parameters in order.network [a Layer class] The network to be assigned
```

Returns

ops [list] A list of tf ops in order that assign params. Support sess.run(ops) manually.

References

• Assign value to a TensorFlow variable

```
>>> Save your network as follow:
>>> tl.files.save_npz(network.all_params, name='model_test.npz')
>>> network.print_params()
...
... Next time, load and assign your network as follow:
>>> tl.layers.initialize_global_variables(sess)
>>> load_params = tl.files.load_npz(name='model_test.npz')
>>> tl.files.assign_params(sess, load_params, network)
>>> network.print_params()
```

Load and assign parameters to network

tensorlayer.files.load_and_assign_npz (sess=None, name=None, network=None) Load model from npz and assign to a network.

Parameters

```
sess [TensorFlow Session]
name [string] Model path.
network [a Layer class] The network to be assigned
```

Returns

Returns False if faild to model is not exist.

Examples

```
>>> tl.files.load_and_assign_npz(sess=sess, name='net.npz', network=net)
```

2.8.3 Load and save variables

Save variables as .npy

```
tensorlayer.files.save_any_to_npy (save_dict={}, name='file.npy')
Save variables to .npy file.
```

Examples

```
>>> tl.files.save_any_to_npy(save_dict={'data': ['a','b']}, name='test.npy')
>>> data = tl.files.load_npy_to_any(name='test.npy')
>>> print(data)
... {'data': ['a','b']}
```

Load variables from .npy

```
tensorlayer.files.load_npy_to_any (path=", name='file.npy')
Load .npy file.
```

see save_any_to_npy()

2.8.4 Folder/File functions

Check file exists

```
tensorlayer.files.file_exists (filepath)
Check whether a file exists by given file path.
```

Check folder exists

```
tensorlayer.files.folder_exists (folderpath)
Check whether a folder exists by given folder path.
```

Delete file

```
tensorlayer.files.del_file (filepath)

Delete a file by given file path.
```

Delete folder

```
tensorlayer.files.del_folder(folderpath)

Delete a folder by given folder path.
```

Read file

```
tensorlayer.files.read_file (filepath)
Read a file and return a string.
```

Examples

```
>>> data = tl.files.read_file('data.txt')
```

Load file list from folder

```
tensorlayer.files.load_file_list (path=None, regx='\\npz', printable=True)
Return a file list in a folder by given a path and regular expression.
```

Parameters

```
path [a string or None] A folder path.regx [a string] The regx of file name.printable [boolean, whether to print the files infomation.]
```

```
>>> file_list = tl.files.load_file_list(path=None, regx='w1pre_[0-9]+\.(npz)')
```

Load folder list from folder

```
tensorlayer.files.load_folder_list(path=")
```

Return a folder list in a folder by given a folder path.

Parameters

path [a string or None] A folder path.

Check and Create folder

```
tensorlayer.files.exists_or_mkdir(path, verbose=True)
```

Check a folder by given name, if not exist, create the folder and return False, if directory exists, return True.

Parameters

```
path [a string] A folder path.
```

verbose [boolean] If True, prints results, deaults is True

Returns

True if folder exist, otherwise, returns False and create the folder

Examples

```
>>> tl.files.exists_or_mkdir("checkpoints/train")
```

Download or extract

```
tensorlayer.files.maybe_download_and_extract (filename, working_directory, url_source, extract=False, expected bytes=None)
```

Checks if file exists in working_directory otherwise tries to dowload the file, and optionally also tries to extract the file if format is ".zip" or ".tar"

Parameters

filename [string] The name of the (to be) dowloaded file.

working_directory [string] A folder path to search for the file in and dowload the file to

url [string] The URL to download the file from

extract [bool, defaults is False] If True, tries to uncompress the dowloaded file is ".tar.gz/.tar.bz2" or ".zip" file

expected_bytes [int/None] If set tries to verify that the downloaded file is of the specified size, otherwise raises an Exception, defaults is None which corresponds to no check being performed

Returns

filepath to dowloaded (uncompressed) file

2.8.5 Sort

List of string with number in human order

```
tensorlayer.files.natural_keys (text)
Sort list of string with number in human order.
```

Examples

```
>>> l = ['iml.jpg', 'im31.jpg', 'im11.jpg', 'im21.jpg', 'im03.jpg', 'im05.jpg']
>>> l.sort(key=tl.files.natural_keys)
... ['im1.jpg', 'im03.jpg', 'im05', 'im11.jpg', 'im21.jpg', 'im31.jpg']
>>> l.sort() # that is what we dont want
... ['im03.jpg', 'im05', 'im1.jpg', 'im11.jpg', 'im21.jpg', 'im31.jpg']
```

2.8.6 Visualizing npz file

```
tensorlayer.files.npz_to_W_pdf (path=None, regx='w1pre\_[0-9]+\(npz)') Convert the first weight matrix of .npz file to .pdf by using tl.visualize.W().
```

Parameters

```
path [a string or None] A folder path to npz files.regx [a string] Regx for the file name.
```

Examples

```
>>> Convert the first weight matrix of w1_pre...npz file to w1_pre...pdf.
>>> tl.files.npz_to_W_pdf(path='/Users/.../npz_file/', regx='w1pre_[0-9]+\.(npz)')
```

2.9 API - Visualize Model and Data

TensorFlow provides TensorBoard to visualize the model, activations etc. Here we provide more functions for data visualization.

read_image(image[, path])	Read one image.
read_images(img_list[, path, n_threads,])	Returns all images in list by given path and name of
	each image file.
<pre>save_image(image[, image_path])</pre>	Save one image.
<pre>save_images(images, size[, image_path])</pre>	Save mutiple images into one single image.
W([W, second, saveable, shape, name, fig_idx])	Visualize every columns of the weight matrix to a group
	of Greyscale img.
CNN2d([CNN, second, saveable, name, fig_idx])	Display a group of RGB or Greyscale CNN masks.
frame([I, second, saveable, name, cmap, fig_idx])	Display a frame(image).
images2d([images, second, saveable, name,])	Display a group of RGB or Greyscale images.
tsne_embedding(embeddings, reverse_dictionary)	Visualize the embeddings by using t-SNE.

2.9.1 Save and read images

Read one image

```
tensorlayer.visualize.read_image(image, path=")
    Read one image.
```

Parameters

```
images [string, file name.]
path [string, path.]
```

Read multiple images

tensorlayer.visualize.read_images (img_list, path=", n_threads=10, printable=True)

Returns all images in list by given path and name of each image file.

Parameters

```
img_list [list of string, the image file names.]
path [string, image folder path.]
n_threads [int, number of thread to read image.]
printable [bool, print infomation when reading images, default is True.]
```

Save one image

```
tensorlayer.visualize.save_image(image, image_path=") Save one image.
```

Parameters

```
images [numpy array [w, h, c]]
image_path [string.]
```

Save multiple images

```
tensorlayer.visualize.save_images (images, size, image_path=") Save mutiple images into one single image.
```

Parameters

```
images [numpy array [batch, w, h, c]]
size [list of two int, row and column number.] number of images should be equal or less than
    size[0] * size[1]
image_path [string.]
```

Examples

```
>>> images = np.random.rand(64, 100, 100, 3)
>>> tl.visualize.save_images(images, [8, 8], 'temp.png')
```

2.9.2 Visualize model parameters

Visualize weight matrix

```
tensorlayer.visualize.\mathbf{W} (W=None, second=10, saveable=True, shape=[28, 28], name='mnist', fig\_idx=2396512)
```

Visualize every columns of the weight matrix to a group of Greyscale img.

Parameters

```
W [numpy.array] The weight matrix

second [int] The display second(s) for the image(s), if saveable is False.

saveable [boolean] Save or plot the figure.

shape [a list with 2 int] The shape of feature image, MNIST is [28, 80].

name [a string] A name to save the image, if saveable is True.

fig_idx [int] matplotlib figure index.
```

Examples

Visualize CNN 2d filter

```
tensorlayer.visualize.CNN2d(CNN=None, second=10, saveable=True, name='cnn', fig_idx=3119362)

Display a group of RGB or Greyscale CNN masks.
```

Parameters

```
CNN [numpy.array] The image. e.g: 64 5x5 RGB images can be (5, 5, 3, 64). second [int] The display second(s) for the image(s), if saveable is False. saveable [boolean] Save or plot the figure.

name [a string] A name to save the image, if saveable is True.
```

fig_idx [int] matplotlib figure index.

Examples

2.9.3 Visualize images

Image by matplotlib

```
tensorlayer.visualize.frame (I=None, second=5, saveable=True, name='frame', cmap=None, fig_idx=12836)

Display a frame(image). Make sure OpenAI Gym render() is disable before using it.
```

Parameters

```
I [numpy.array] The image
```

second [int] The display second(s) for the image(s), if saveable is False.

saveable [boolean] Save or plot the figure.

name [a string] A name to save the image, if saveable is True.

cmap [None or string] 'gray' for greyscale, None for default, etc.

fig_idx [int] matplotlib figure index.

Examples

```
>>> env = gym.make("Pong-v0")
>>> observation = env.reset()
>>> tl.visualize.frame(observation)
```

Images by matplotlib

```
tensorlayer.visualize.images2d(images=None, second=10, saveable=True, name='images', dtype=None, fig_idx=3119362)

Display a group of RGB or Greyscale images.
```

Parameters

images [numpy.array] The images.

second [int] The display second(s) for the image(s), if saveable is False.

saveable [boolean] Save or plot the figure.

name [a string] A name to save the image, if saveable is True.

dtype [None or numpy data type] The data type for displaying the images.

fig idx [int] matplotlib figure index.

2.9.4 Visualize embeddings

tensorlayer.visualize.tsne_embedding(embeddings, reverse_dictionary, plot_only=500, second=5, saveable=False, name='tsne', fig_idx=9862) Visualize the embeddings by using t-SNE.

Parameters

embeddings [a matrix] The images.

reverse_dictionary [a dictionary] id_to_word, mapping id to unique word.

plot_only [int] The number of examples to plot, choice the most common words.

second [int] The display second(s) for the image(s), if saveable is False.

saveable [boolean] Save or plot the figure.

name [a string] A name to save the image, if saveable is True.

fig_idx [int] matplotlib figure index.

Examples

```
>>> see 'tutorial_word2vec_basic.py'
>>> final_embeddings = normalized_embeddings.eval()
>>> tl.visualize.tsne_embedding(final_embeddings, labels, reverse_dictionary,
... plot_only=500, second=5, saveable=False, name='tsne')
```

2.10 API - Operation System

Operation system, more functions can be found in TensorFlow API.

<pre>exit_tf([sess])</pre>	Close tensorboard and nvidia-process if available
clear_all([printable])	Clears all the placeholder variables of keep prob, in-
	cluding keeping probabilities of all dropout, denoising,
	dropconnect etc.
<pre>set_gpu_fraction([sess, gpu_fraction])</pre>	Set the GPU memory fraction for the application.
disable_print()	Disable console output, suppress_stdout is rec-
	ommended.
enable_print()	Enable console output, suppress_stdout is recom-
	mended.
suppress_stdout()	Temporarily disable console output.
<pre>get_site_packages_directory()</pre>	Print and return the site-packages directory.
empty_trash()	Empty trash folder.

2.10.1 TensorFlow functions

Kill nvidia process

```
tensorlayer.ops.exit_tf(sess=None)
Close tensorboard and nvidia-process if available
```

Parameters

sess [a session instance of TensorFlow] TensorFlow session

Delete placeholder

```
tensorlayer.ops.clear_all (printable=True)
```

Clears all the placeholder variables of keep prob, including keeping probabilities of all dropout, denoising, dropconnect etc.

Parameters

printable [boolean] If True, print all deleted variables.

2.10.2 GPU functions

```
tensorlayer.ops.set_gpu_fraction(sess=None, gpu_fraction=0.3) Set the GPU memory fraction for the application.
```

Parameters

```
sess [a session instance of TensorFlow] TensorFlow sessiongpu_fraction [a float] Fraction of GPU memory, (0 ~ 1]
```

References

• TensorFlow using GPU

2.10.3 Console display

Disable print

```
tensorlayer.ops.disable_print()
    Disable console output, suppress_stdout is recommended.
```

Examples

```
>>> print("You can see me")
>>> tl.ops.disable_print()
>>> print(" You can't see me")
>>> tl.ops.enable_print()
>>> print("You can see me")
```

Enable print

```
tensorlayer.ops.enable_print()
    Enable console output, suppress_stdout is recommended.
```

Examples

• see tl.ops.disable_print()

Temporary disable print

```
tensorlayer.ops.suppress_stdout()
Temporarily disable console output.
```

References

· stackoverflow

Examples

```
>>> print("You can see me")
>>> with tl.ops.suppress_stdout():
>>> print("You can't see me")
>>> print("You can see me")
```

2.10.4 Site packages information

```
tensorlayer.ops.get_site_packages_directory()
Print and return the site-packages directory.
```

Examples

```
>>> loc = tl.ops.get_site_packages_directory()
```

2.10.5 Trash

```
tensorlayer.ops.empty_trash()
Empty trash folder.
```

2.11 API - Activations

To make TensorLayer simple, we minimize the number of activation functions as much as we can. So we encourage you to use TensorFlow's function. TensorFlow provides tf.nn.relu, tf.nn.relu6, tf.nn.elu, tf.nn.elu, tf.nn.softplus, tf.nn.softplus, tf.nn.softsign and so on. More TensorFlow official activation functions can be found here. For parametric activation, please read the layer APIs.

The shortcut of tensorlayer.activation is tensorlayer.act.

2.11.1 Your activation

Customizes activation function in TensorLayer is very easy. The following example implements an activation that multiplies its input by 2. For more complex activation, TensorFlow API will be required.

```
def double_activation(x):
    return x * 2
```

<pre>identity(x[, name])</pre>	The identity activation function, Shortcut is linear.
ramp([x, v_min, v_max, name])	The ramp activation function.
leaky_relu([x, alpha, name])	The LeakyReLU, Shortcut is lrelu.
<pre>pixel_wise_softmax(output[, name])</pre>	Return the softmax outputs of images, every pixels have
	multiple label, the sum of a pixel is 1.

2.11.2 Identity

tensorlayer.activation.identity (x, name=None)
The identity activation function, Shortcut is linear.

Parameters

x [a tensor input] input(s)

Returns

A 'Tensor' with the same type as 'x'.

2.11.3 Ramp

```
tensorlayer.activation.ramp (x=None, v\_min=0, v\_max=1, name=None)
The ramp activation function.
```

Parameters

```
\mathbf{x} [a tensor input] input(s)
```

v_min [float] if input(s) smaller than v_min, change inputs to v_min

v_max [float] if input(s) greater than v_max, change inputs to v_max

name [a string or None] An optional name to attach to this activation function.

Returns

A 'Tensor' with the same type as 'x'.

2.11.4 Leaky Relu

```
tensorlayer.activation.leaky_relu(x=None, alpha=0.1, name='LeakyReLU')
The LeakyReLU, Shortcut is lrelu.
```

Modified version of ReLU, introducing a nonzero gradient for negative input.

Parameters

2.11. API - Activations 171

```
x [A Tensor with type float, double, int32, int64, uint8,] int16, or int8.
alpha [float. slope.]
name [a string or None] An optional name to attach to this activation function.
```

References

• Rectifier Nonlinearities Improve Neural Network Acoustic Models, Maas et al. (2013)

Examples

```
>>> network = tl.layers.DenseLayer(network, n_units=100, name = 'dense_lrelu', act= lambda x : tl.act.lrelu(x, 0.2))
```

2.11.5 Pixel-wise Softmax

tensorlayer.activation.pixel_wise_softmax(output, name='pixel_wise_softmax')

Return the softmax outputs of images, every pixels have multiple label, the sum of a pixel is 1. Usually be used for image segmentation.

Parameters

output [tensor]

- For 2d image, 4D tensor [batch_size, height, weight, channel], channel >= 2.
- For 3d image, 5D tensor [batch_size, depth, height, weight, channel], channel >= 2.

References

• tf.reverse

Examples

```
>>> outputs = pixel_wise_softmax(network.outputs)
>>> dice_loss = 1 - dice_coe(outputs, y_, epsilon=1e-5)
```

2.11.6 Parametric activation

See tensorlayer.layers.

2.12 API - Database

This is the alpha version of database management system. If you have trouble, you can ask for help on fangde.liu@imperial.ac.uk.

Note: We are writing up the documentation, please wait in patient.

2.12.1 Why TensorDB

TensorLayer is designed for production, aiming to be applied large scale machine learning application. TensorDB introduce the database infracture to address the many challenges in large scale machine learning project, such as:

- 1. How to mangage the training data and load the training datasets
- 2. When the dataset is so large that beyonds the storage limitation of one computer
- 3. How shoul we management different models and version, and comparing different models.
- 4. How to automate the whole training, evaluaiton and deploy machine learning model automatically.

In TensorLayer system, we introduce the database technology to the issues above.

TensorDB is designed by following three principles.

Everything is Data

TensorDB is a data warehouse that stores that capture the whole machine learning development process. the data inside tensordb can be catagloried as:

- 1. Data and Labels: Which includes all the data for training, validation and prediction. The labels can be manually labelled or generated by machine
- 2. Model Architecture: This group store the different model architecture, which user can select to use
- 3. Model Parameters: This tables stores all the model parameters of echo in the training step.
- 4. Jobs: All the computation is cutted into several jobs. Each jobs constains some computing work load. for training, the jobs includes training data, the model parameter, the model architecture, how many epochs the training want to do. Similarity are the validation jobs and inference jobs.
- 5. Logs: The logs store all the step time and accuracy and other metric of each training steps and also the time stamps.

TensorDB in principal is a key-word based search engine. Each model, parameters, or training data are assigned many tags. The data are stored in two layers. On the top, there is the index layer, which instore the blob storage reference with all the tags assigned to the data, which is implemented based on NoSQL document database such as Mongodb. The second layer is used store big chunk of data, such as videos, medical images or image mask, which is usually implemented as file system. Our open source implementation is implemented based MongoDB. The blob data is in store in the gridfs while the tag index is stored in the documents.

Everying is identified by Query

Within TensorDB framework, any entity within the data warehouse, such as the data, model or jobs are specified by the database query language. The first advantage is the query is more efficient in space and can specify multiple objects in a concise way. The advantage such a design is to enable a highly flexible software system. data, model architecture and training are interchangeable. Many work can be implemented by simply rewire different components. This enable us to develop many new application just by change the query without change any application code.

2.12. API - Database 173

An pulling based Stream processing pipeline.

Also with a large dataset, we can assume that the data is unlimited. TensorDB provides a streaming interface, implemented in python as generators, it keeps return the new data during training. Also the training system have no clue of epochs, instead, it knows batchize and store parameters after how many steps.

Many techniques are introduced behind the streaming interface. The stream is implemented based on the database cursor technology, so for every search, only the cursors are returned, not the actual data. Only when the generator is evaluated, the acutal data is loaded. The data loading is further optimise:

- 1. Data are compressed and decompressed,
- 2. The dataloaded in bulk model to optimise the IO traffic
- 3. The argumentation or random sample are computed on the fly after the data are loaded into the local computer.
- 4. To optimise the space, the will also be a cache system that only store the recent blob data.

Based on streaming interface, TensorLayer can be implemented as a continuous machine learning. On the distributed system, the model training, validation and deployment can be running on different computers which all running continuously. The trainer can keeps on optimising the models, the evaluation keeps evaluating the recent added models and the deployment system keeps pulling the best models from the TensorDB warehouse.

2.12.2 Preparation

In principle, TensorDB is can be implemented on any documents NoSQL database system. The exisiting implementation is based on Mongodb. Further implementation on other database will be released depends on progress. It will be straightford to port the tensorDB system to google cloud, aws and azure.

The following tutorials are based on the MongoDb implmenetation.

Install MongoDB

The installation instruction of Mongodb can be found at MongoDB Docs there are also managed mongodb service from amazon or gcp, or mongo atlas from mongodb

User can also user docker, which is a powerful tool for deploy software.

After install mongodb, a mongod db management tool with graphic user interface will be extremely valuale.

Users can install the Studio3T(mongochef), which is free for none commercial user interface. studio3t

Start MongoDB service

After mongodb is installed, you shoul start the database.

mongod start

You can specificy the path the database files with -d flag

2.12.3 Quick Start

A fully working example with mnist training set is the _TensorLabDemo.ipnb_

Connect to database

To use TensorDB mongodb implmentaiton, you need pymongo client.

you can install it by

```
pip install pymongo
pip install 1z4
```

it is very strateford to connected to the TensorDB system. you can try the following code

The ip is the ip address of the database, and port number is number of mongodb. You may need to specificy the database name and studyid. The study id is an unique identifier for an experiement.

TensorDB stores different study in one data warehouse. This has pros and cons, the benefits is that suppose the each study we try a different model architecture, it is very easy for us to evaluate different model architecture.

log and parameters

The basic application is use TensorDB to save the model parameters and training/evaluation/testing logs. to use tensorDB, this can be easily done by replacing the print function by the db.log function

For save the training log, we have db.train_log

and

db. save_parameter

methods

Suppose we save the log each step and save the parameters each epoch, we can have the code like this

```
for epoch in range(0,epoch_count):
    [~,ac]=sess.run([train_op,loss],feed_dict({x:x,y:y_})
    db.train_log({'accuracy':ac})
db.save_parameter(sess.run(network.all_parameters),{'acc':ac})
```

the code for save validation log and test log are similar.

Model Architecture and Jobs

TensorDb also supporting the model architecture and jobs system in the current version, both the model architecture and job are just simply strings. it is up to the user to specify how to convert the string back to models or job. for example, in many our our cases, we just simply specify the python code.

```
code= '''
print "hello
'''
db.save_model_architecutre(code, {'name':'print'})
c, fid = db.find_model_architecutre({'name':'print'})
exec c
```

(continues on next page)

2.12. API - Database 175

(continued from previous page)

```
db.push_job(code, {'type':'train'})

## worker
code = db.pop_job()
exec code
```

Database Interface

The training set is managed by a seperate database, each application has its own database. However, all the database interface should support two interface, 1. find_data, 2. data_generator

and example for minist dataset is include in the TensorLabDemo code

Data Importing

With a database, the development workflow is very flexible. As long as the comtent in the database in the same, user can use whatever tools to write into the database

the TesorLabDemo has an import data interface, which allow the user to injecting data in future

user can import data by the following code

```
db.import_data(X,y,{'type':'train'})
```

2.12.4 Application Framework

In fact, in real application, we rarely code everything from scrach and using the tensorDB interface directly. as demostrate in the TensorLabDemo

we implemented 4 class each with a well defined interace. 1. The dataset. 2. The TensorDb 3. The Model, model is loggically a full component can be trained, evaluate and deployed. It has property like parameters 4. The DBLogger, which is connecttor from model to tensorDB, which is implemented as callback functions, automatically called at each batch_step and each epoch.

users can based on the TensorLabDemo code, overrite the interface to suits their own applicaions needs.

when training, the overall archtiecture is first, find a data generator from the dataset module

```
g=datase.data_generator({"type":[your type]})
```

then intialize a model with a name

```
m=model('mytes')
```

during training, connected the db logger and tensordb togehter

```
m.fit_generator(g,dblogger(tensordb,m),1000,100)
```

if the work is distributed, we have to save the model archtiecture and reload and excute it

```
db.save_model_architecture(code, {'name':'mlp'})
db.push_job({'name':'mlp'}, {'type':XXXXX}, {'batch:1000', 'epoch':100)
```

the worker will run the job as the following code

```
j=job.pop
g=dataset.data_generator(j.filter)
c=tensordb.load_model_architecutre(j.march)
exec c
m=model()
m.fit_generator(g,dblooger(tensordb,m),j.bach_size,j.epoch)
```

Experimental Database Management System.

Latest Version

Parameters

```
ip [string, localhost or IP address.]
port [int, port number.]
db_name [string, database name.]
user_name [string, set to None if it donnot need authentication.]
password [string.]
```

Methods

Save_params([params, args])

Save parameters into MongoDB Buckets, and save the file ID into Params Collections.

del_job	
del_params	
del_test_log	
del_train_log	
del_valid_log	
find_all_params	
find_one_job	
find_one_params	
load_model_architecture	
peek_job	
push_job	
run_job	
save_job	
save_model_architecture	
test_log	
train_log	
valid_log	

save_params (params=[], args={})

Save parameters into MongoDB Buckets, and save the file ID into Params Collections.

Parameters

2.12. API - Database 177

```
params [a list of parameters]args [dictionary, item meta data.]Returns
```

f_id [the Buckets ID of the parameters.]

$\mathsf{CHAPTER}\,3$
