3.2 Stiffness Maximization

3.3 Maximum Compliance Actuators

3.4 Stress Intensity Factor Minimization

3.5 Fatigue Crack Growth Life Maximization

4.1 Compliance Minimization

intro 1

4.1.1 Density Constraints

Constraints class used to specify the density constraints of the topology optimisation problem. It contains functions for minimum and maximum element density in the upcoming iteration and the magnitude of the volume constraint function itself of the current design. This version of the code is used for the global compliance minimization.

Bram Lagerweij Aerospace Structures and Materials Department TU Delft 2018

```
class src_Compliance.constraints.DensityConstraint (nelx,    nely,    move,    vol-
                                                    ume_frac,    density_min=0.0,
                                                    density_max=1.0)
```

This object relates to the constraints used in this optimization. It can be used for the MMA updatescheme to derive what the limit is for all element densities at every iteration. The class itself is not changed by the iterations.

Parameters

- **nelx** (*int*) – Number of elements in x direction.
- **nely** (*int*) – Number of elements in y direction.
- **move** (*float*) – Maximum change in density of an element over 1 iteration.
- **volume_frac** (*float*) – Maximum volume that can be filled with material.
- **volume_derivative** (*2D array size (1, nelx*nely)*) – Sensitivity of the density constraint to the density in each element.
- **density_min** (*float (optional)*) – Minimum density, set at 0.0 if not specified.
- **density_max** (*float (optional)*) – Maximum density, set at 0.0 if not specified.

nelx

Number of elements in x direction.

Type int

nely

Number of elements in y direction.

Type int

move

Maximum change in density of an element over 1 iteration.

Type float

volume_frac

Maximum volume that can be filled with material.

Type float

volume_derivative

Sensitivity of the density constraint to the density in each element.

Type 2D array size(1, nelx*nely)

density_min

Minimum density, set at 0.0 if not specified.

Type float, optional

density_max

Maximum density, set at 0.0 if not specified.

Type float, optional

current_volconstraint (*x*)

Calculates the current magnitude of the volume constraint function:

$$V_{\text{constraint}} = \frac{\sum v_e X_e}{V_{\text{max}}} - 1$$

Parameters *x* (2D array size(nely, nelx)) – Density distribution of this iteration.

Returns *curvol* – Current value of the density constraint function.

Return type float

xmax (*x*)

This function calculates the maximum density value of all elements of this iteration.

Parameters *x* (2D array size(nely, nelx)) – Density distribution of this iteration.

Returns *xmax* – Maximum density values of this iteration after updating.

Return type 2D array size(nely, nelx)

xmin (*x*)

This function calculates the minimum density value of all elements of this iteration.

Parameters *x* (2D array size(nely, nelx)) – Density distribution of this iteration.

Returns *xmin* – Minimum density values of this iteration for the update scheme.

Return type 2D array size(nely, nelx)

4.1.2 Load Cases

This file contains the Load class that allows the generation of an object that contains geometric, mesh, loads and boundary conditions that belong to the load case. This version of the code is meant for global compliance minimization.

Bram Lagerweij Aerospace Structures and Materials Department TU Delft 2018

Parrent Load Case

class src_Compliance.loads.**Load**(*nelx, nely, young, Emin, poisson*)

Load parent class that contains the basic functions used in all load cases. This class and its children do contain information about the load case considered in the optimisation. The load case consists of the mesh, the loads, and the boundaries conditions. The class is constructed such that new load cases can be generated simply by adding a child and changing the function related to the geometry, loads and boundaries.

Parameters

- **nelx** (*int*) – Number of elements in x direction.
- **nely** (*int*) – Number of elements in y direction.
- **young** (*float*) – Youngs modulus of the materials.
- **Emin** (*float*) – Artificial Youngs modulus of the material to ensure a stable FEA. It is used in the SIMP based material model.
- **poisson** (*float*) – Poisson ration of the material.

nelx

Number of elements in x direction.

Type int

nely

Number of elements in y direction.

Type int

young

Youngs modulus of the materials.

Type float

Emin

Artificial Youngs modulus of the material to ensure a stable FEA. It is used in the SIMP based material model.

Type float

poisson

Poisson ration of the material.

Type float

dim

Amount of dimensions considered in the problem, set at 2.

Type int

alldofs ()

Returns a list with all degrees of freedom.

Returns **all** – List with numbers from 0 to the maximum degree of freedom number.

Return type 1-D list

edof ()

Generates an array with the position of the nodes of each element in the global stiffness matrix.

Returns

- **edof** (2-D array size($nelx*nely, 8$)) – The list with all elements and their degree of freedom numbers.
- **x_list** (1-D array len($nelx*nely*8*8$)) – The list with the x indices of all elements to be inserted into the global stiffness matrix.
- **y_list** (1-D array len($nelx*nely*8*8$)) – The list with the y indices of all elements to be inserted into the global stiffness matrix.

fixdofs ()

Returns a list with indices that are fixed by the boundary conditions.

Returns **fix** – List with all the numbers of fixed degrees of freedom. This list is empty in this parent class.

Return type 1-D list

force ()

Returns an 1D array, the force vector of the loading condition.

Returns **f** – Empty force vector.

Return type 1-D array length covering all degrees of freedom

freedofs ()

Returns a list of array indices that are not fixed

Returns **free** – List containing all elements of all dogs except those that appear in the freedofs list.

Return type 1-D list

lk (E, nu)

Calculates the local stiffness matrix depending on E and nu .

Parameters

- **E** (*float*) – Young's modulus of the material.
- **nu** (*float*) – Poisson ratio of the material.

Returns **ke** – Local stiffness matrix.

Return type 2-D array size(8, 8)

node (elx, ely)

Calculates the topleft node number of the requested element

Parameters

- **elx** (*int*) – X position of the considered element.
- **ely** (*int*) – Y position of the considered element.

Returns **topleft** – The node number of the top left node

Return type int

nodes (elx, ely)

Calculates all node numbers of the requested element

Parameters

- **elx** (*int*) – X position of the considered element.
- **ely** (*int*) – Y position of the considered element.

Returns

- **n1** (*int*) – The node number of the top left node.
- **n2** (*int*) – The node number of the top right node.
- **n3** (*int*) – The node number of the bottom right node.
- **n4** (*int*) – The node number of the bottom left node.

passive()

Returns three lists containing the location and magnitude of fixed density values

Returns

- **elx** (*1-D list*) – X coordinates of all passive elements, empty for the parent class.
- **ely** (*1-D list*) – Y coordinates of all passive elements, empty for the parent class.
- **values** (*1-D list*) – Density values of all passive elements, empty for the parent class.
- **fix_ele** (*1-D list*) – List with all element numbers that are allowed to change.

Child Load Cases

class `src_Compliance.loads.HalfBeam` (*nelx, nely, young, Emin, poisson*)

Bases: `src_Compliance.loads.Load`

This child of the Loads class represents the loading conditions of a half mbb-beam. Only half of the beam is considered due to the symmetry around the y axis.

No methods are added compared to the parent class. The force and fixdofs functions are changed to output the correct force vector and boundary condition used in this specific load case. See the functions themselves for more details

fixdofs()

The boundary conditions of the half mbb-beam fix the x displacements of all the nodes at the outer left side and the y displacement of the bottom right element.

Returns **fix** – List with all the numbers of fixed degrees of freedom.

Return type 1-D list

force()

The force vector contains a load in negative y direction at the top left corner.

Returns **f** – A -1 is placed at the index of the y direction of the top left node.

Return type 1-D array length covering all degrees of freedom

class `src_Compliance.loads.Beam` (*nelx, nely, young, Emin, poisson*)

Bases: `src_Compliance.loads.Load`

This child of the Loads class represents the full mbb-beam without assuming an axis of symmetry. To enforce a node in the middle *nelx* needs to be an even number.

No methods are added compared to the parent class. The force and fixdofs functions are changed to output the correct force vector and boundary condition used in this specific load case. See the functions themselves for more details

fixdofs()

The boundary conditions of the full mbb-beam fix the x and y displacement of the bottom left node and the y displacement of the bottom right node.

Returns **fix** – List with all the numbers of fixed degrees of freedom.

Return type 1-D list

force()

The force vector contains a load in negative y direction at the mid top node.

Returns **f** – Where at the index relating to the y direction of the top mid node a -1 is placed.

Return type 1-D array length covering all degrees of freedom

class `src_Compliance.loads.Canti` (*nelx, nely, young, Emin, poisson*)

Bases: `src_Compliance.loads.Load`

This child of the Loads class represents the loading conditions of a cantilever beam. The beam is encasted on the left and the load is applied at the middle of the right side. To do this an even number for nely is required.

No methods are added compared to the parent class. The force and fixdofs functions are changed to output the correct force vector and boundary condition used in this specific load case. See the functions themselves for more details

fixdofs()

The boundary conditions of the cantilever beam fix the x and y displacement of all nodes on the left side.

Returns **fix** – List with all the numbers of fixed degrees of freedom.

Return type 1-D list

force()

The force vector contains a load in negative y direction at the mid most right node.

Returns **f** – Where at the index relating to the y direction of the mid right node a -1 is placed.

Return type 1-D array length covering all degrees of freedom

class `src_Compliance.loads.Michell` (*nelx, nely, young, Emin, poisson*)

Bases: `src_Compliance.loads.Load`

This child of the Loads class represents the loading conditions of a half a Michell structure. A load is applied in the mid left of the design space and the boundary conditions fix the x and y direction of the middle right node. Due to symmetry all nodes at the left side are constraint in x direction. This class requires nely to be even.

No methods are added compared to the parent class. The force and fixdofs functions are changed to output the correct force vector and boundary condition used in this specific load case. See the functions themselves for more details

fixdofs()

The boundary conditions of the half mbb-beam fix the x displacements of all the nodes at the outer left side and the y displacement of the mid right element.

Returns **fix** – List with all the numbers of fixed degrees of freedom.

Return type 1-D list

force()

The force vector contains a load in negative y direction at the mid most left node.

Returns **f** – Where at the index relating to the y direction of the mid left node a -1 is placed.

Return type 1-D array length covering all degrees of freedom

```
class src_Compliance.loads.BiAxial (nelx, nely, young, Emin, poisson)
```

Bases: `src_Compliance.loads.Load`

This child of the Loads class represents the loading conditions of a bi-axial loaded plate. All outer nodes have a load applied that goes outward. This class is made to show the checkerboard problem that generally occurs with topology optimisation.

No methods are added compared to the parent class. The force, fixdofs and passive functions are changed to output the correct force vector, boundary condition and passive elements used in this specific load case. See the functions themselves for more details

fixdofs ()

The boundary conditions fix the top left node in x direction, the bottom left node in x and y direction and the bottom right node in y direction only.

Returns **fix** – List with all the numbers of fixed degrees of freedom.

Return type 1-D list

force ()

The force vector containing loads that act outward from the edge.

Returns **f** – Where at the indices related to the outside nodes an outward force of 1 is inserted.

Return type 1-D array length covering all degrees of freedom

passive ()

The Bi-Axial load case requires fully dense elements around the border. This is done to enforce proper load introduction.

Returns

- **elx** (*1-D list*) – X coordinates of all passive elements, empty for the parent class.
- **ely** (*1-D list*) – Y coordinates of all passive elements, empty for the parent class.
- **values** (*1-D list*) – Density values of all passive elements, empty for the parent class.

4.1.3 Finite Element Solvers

Finite element solvers for the displacement from stiffness matrix and force vector. This version of the code is meant for global compliance minimization.

Bram Lagerweij Aerospace Structures and Materials Department TU Delft 2018

Parent Solver

```
class src_Compliance.fesolvers.FESolver (verbose=False)
```

This parent FEA class can only assemble the global stiffness matrix and exclude all fixed degrees of freedom from it. This stiffness csc-sparse stiffness matrix is assembled in the `gk_freedof` method. This class solves the FE problem with a sparse LU-solver based upon `umfpack`. This solver is slow and inefficient. It is however more robust.

Parameters **verbose** (*bool, optional*) – False if the FEA should not print updates

verbose

False if the FEA does not print updates.

Type bool

displace (*load, x, ke, kmin, penal*)

FE solver based upon the sparse SciPy solver that uses umfpack.

Parameters

- **load** (*object, child of the Loads class*) – The loadcase(s) considered for this optimisation problem.
- **x** (*2-D array size (nely, nelx)*) – Current density distribution.
- **ke** (*2-D array size (8, 8)*) – Local fully dense stiffness matrix.
- **kmin** (*2-D array size (8, 8)*) – Local stiffness matrix for an empty element.
- **penal** (*float*) – Material model penalisation (SIMP).

Returns **u** – Displacement of all degrees of freedom

Return type 1-D array len(max(edof)+1)

gk_freedofs (*load, x, ke, kmin, penal*)

Generates the global stiffness matrix with deleted fixed degrees of freedom. It generates a list with stiffness values and their x and y indices in the global stiffness matrix. Some combination of x and y appear multiple times as the degree of freedom might appear in multiple elements of the FEA. The SciPy `coo_matrix` function adds them up at the background.

Parameters

- **load** (*object, child of the Loads class*) – The loadcase(s) considered for this optimisation problem.
- **x** (*2-D array size (nely, nelx)*) – Current density distribution.
- **ke** (*2-D array size (8, 8)*) – Local fully dense stiffness matrix.
- **kmin** (*2-D array size (8, 8)*) – Local stiffness matrix for an empty element.
- **penal** (*float*) – Material model penalisation (SIMP).

Returns **k** – Global stiffness matrix without fixed degrees of freedom.

Return type 2-D sparse csc matrix

Child Solvers

class `src_Compliance.fesolvers.CvxFEA` (*verbose=False*)

Bases: `src_Compliance.fesolvers.FESolver`

This parent FEA class is used to assemble the global stiffness matrix while this class solves the FE problem with a Supernodal Sparse Cholesky Factorization.

displace (*load, x, ke, kmin, penal*)

FE solver based upon a Supernodal Sparse Cholesky Factorization. It requires the installation of the `cvx` module.

See: Y. Chen, T. A. Davis, W. W. Hager, S. Rajamanickam, “Algorithm 887: CHOLMOD, Supernodal Sparse Cholesky Factorization and Update/Downdate”, *ACM Transactions on Mathematical Software*, 35(3), 22:1-22:14, 2008.

Parameters

- **load** (*object, child of the Loads class*) – The loadcase(s) considered for this optimisation problem.
- **x** (*2-D array size (nely, nelx)*) – Current density distribution.

- **ke** (2-D array size (8, 8)) – Local fully dense stiffness matrix.
- **kmin** (2-D array size (8, 8)) – Local stiffness matrix for an empty element.
- **penal** (float) – Material model penalisation (SIMP).

Returns **u** – Displacement of all degrees of freedom

Return type 1-D array len(max(edof))

class `src_Compliance.fesolvers.CGFEA(verbose=False)`

Bases: `src_Compliance.fesolvers.FESolver`

This parent FEA class can assemble the global stiffness matrix and this class solves the FE problem with a sparse solver based upon a preconditioned conjugate gradient solver. The preconditioning is based upon the inverse of the diagonal of the stiffness matrix.

displace (*load, x, ke, kmin, penal*)

FE solver based upon the sparse SciPy solver that uses a preconditioned conjugate gradient solver, preconditioning is based upon the inverse of the diagonal of the stiffness matrix. Currently the relative tolerance is hardcoded as 1e-3.

Recommendations

- Make the tolerance change over the iterations, low accuracy is required for first iteration, more accuracy for the later ones.
- Add more advanced preconditioner.
- Add gpu acceleration.

Parameters

- **load** (*object, child of the Loads class*) – The loadcase(s) considered for this optimisation problem.
- **x** (2-D array size (*nely, nelx*)) – Current density distribution.
- **ke** (2-D array size (8, 8)) – Local fully dense stiffness matrix.
- **kmin** (2-D array size (8, 8)) – Local stiffness matrix for an empty element.
- **penal** (float) – Material model penalisation (SIMP).

Returns **u** – Displacement of all degrees of freedom

Return type 1-D array len(max(edof)+1)

4.1.4 Optimization Module

Topology Optimization class that handles the iterations, objective functions, filters and update scheme. It requires to call upon a constraint, load case and FE solver classes. This version of the code is meant for global compliance minimization.

Bram Lagerweij Aerospace Structures and Materials Department TU Delft 2018

class `src_Compliance.topopt.Topopt(constraint, load, fesolver, verbose=False)`

This is the optimisation object itself. It contains the initialisation of the density distribution.

Parameters

- **constraint** (*object of DensityConstraint class*) – The constraints for this optimization problem.

- **load** (*object, child of the Loads class*) – The loadcase(s) considered for this optimisation problem.
- **fesolver** (*object, child of the CSCStiffnessMatrix class*) – The finite element solver.
- **verbose** (*bool, optional*) – Printing iteration results.

constraint

The constraints for this optimization problem.

Type object of DensityConstraint class

load

The loadcase(s) considered for this optimisation problem.

Type object, child of the Loads class

fesolver

The finite element solver.

Type object, child of the CSCStiffnessMatrix class

verbose

Printing iteration results.

Type bool

itr

Number of iterations performed

Type int

x

Array containing the current densities of every element.

Type 2-D array size(nely, nelx)

xold1

Flattend density distribution one iteration ago.

Type 1D array len(nelx*nely)

xold2

Flattend density distribution two iteration ago.

Type 1D array len(nelx*nely)

low

Column vector with the lower asymptotes, calculated and used in the MMA subproblem of the previous iteration.

Type 1D array len(nelx*nely)

upp

Column vector with the lower asymptotes, calculated and used in the MMA subproblem of the previous iteration.

Type 1D array len(nelx*nely)

comp (*x, u, ke, penal*)

This function calculates compliance and compliance density derivative.

Parameters

- **x** (2-D array size(nely, nelx)) – Possibly filtered density distribution.

- **u** (1-D array len(max(edof)+1)) – Displacement of all degrees of freedom.
- **ke** (2-D array size(8, 8)) – Element stiffness matrix with full density.
- **penal** (float) – Material model penalisation (SIMP).

Returns

- **c** (float) – Compliance for the current design.
- **dc** (2-D array size(nely, nelx)) – Compliance sensitivity to density changes.

densityfilt (rmin, filt)

Filters with a normalized convolution on the densities with a radius of rmin if:

```
>>> filt=='density'
```

Parameters

- **rmin** (float) – Filter size.
- **filt** (str) – The filter type that is selected, either ‘sensitivity’ or ‘density’.

Returns **xf** – Filtered density distribution.**Return type** 2-D array size(nely, nelx)**iter** (penal, rmin, filt)

This function performs one iteration of the topology optimisation problem. It

- loads the constraints,
- calculates the stiffness matrices,
- executes the density filter,
- executes the FEA solver,
- calls upon the compliance and compliance sensitivity calculation,
- executes the sensitivity filter,
- executes the MMA update scheme,
- and finally updates density distribution (design).

Parameters

- **penal** (float) – Material model penalisation (SIMP).
- **rmin** (float) – Filter size.
- **filt** (str) – The filter type that is selected, either ‘sensitivity’ or ‘density’.

Returns

- **change** (float) – Largest difference between the new and old density distribution.
- **c** (float) – Compliance for the current design.

layout (penal, rmin, delta, loopy, filt, history=False)

Solves the topology optimisation problem by looping over the iter function.

Parameters

- **penal** (float) – Material model penalisation (SIMP).

- **rmin** (*float*) – Filter size.
- **delta** (*float*) – Convergence is reached when $\text{delta} > \text{change}$.
- **loopy** (*int*) – Amount of iteration allowed.
- **filt** (*str*) – The filter type that is selected, either ‘sensitivity’ or ‘density’.
- **history** (*bool*, *optional*) – Do the intermediate results need to be stored.

Returns

- **xf** (*array size(nely, nelx)*) – Density distribution resulting from the optimisation.
- **xf_history** (*list of arrays len(iterations size(nely, nelx), float16)*) – List with the density distributions of all iterations, None when `history != True`.

mmsub (*m, n, itr, xval, xmin, xmax, xold1, xold2, f0val, df0dx, fval, dfdx, low, upp, a0, a, c, d*)

This function mmsub performs one MMA-iteration, aimed at solving the nonlinear programming problem:

$$\begin{aligned} & \min f_0(x) \\ & + a_0 z + \sum_{i=1}^m \left(c_i y_i + \frac{1}{2} d_i y_i^2 \right) \\ & \text{s.t.} \\ & f_i(x) - a_i z - y_i \leq 0 \quad i \in \{1, 2, \dots, m\} \\ & x_{\min} \leq x_j \leq x_{\max}, j \in \{1, 2, \dots, n\} \\ & y_i \leq 0, i \in \{1, 2, \dots, m\} \\ & z \geq 0 \end{aligned}$$

Parameters

- **m** (*int*) – The number of general constraints.
- **n** (*int*) – The number of variables x_j .
- **itr** (*int*) – Current iteration number (=1 the first time mmsub is called).
- **xval** (*1-D array len(n)*) – Vector with the current values of the variables x_j .
- **xmin** (*1-D array len(n)*) – Vector with the lower bounds for the variables x_j .
- **xmax** (*1-D array len(n)*) – Vector with the upper bounds for the variables x_j .
- **xold1** (*1-D array len(n)*) – xval, one iteration ago when `itr>1`, zero otherwise.
- **xold2** (*1-D array len(n)*) – xval, two iteration ago when `itr>2`, zero otherwise.
- **f0val** (*float*) – The value of the objective function f_0 at xval.
- **df0dx** (*1-D array len(n)*) – Vector with the derivatives of the objective function f_0 with respect to the variables x_j , calculated at xval.
- **fval** (*1-D array len(m)*) – Vector with the values of the constraint functions f_i , calculated at xval.
- **dfdx** (*2-D array size(m x n)*) – (m x n)-matrix with the derivatives of the constraint functions f_i with respect to the variables x_j , calculated at xval.

- **low** (*1-D array len(n)*) – Vector with the lower asymptotes from the previous iteration (provided `thnp.array([1,2])` at `iter>1`).
- **upp** (*1-D array len(n)*) – Vector with the upper asymptotes from the previous iteration (provided that `iter>1`).
- **a0** (*float*) – The constants `a_0` in the term `a_0*z`.
- **a** (*1-D array len(m)*) – Vector with the constants `a_i` in the terms `a_i*z`.
- **c** (*1-D array len(m)*) – Vector with the constants `c_i` in the terms `c_i*y_i`.
- **d** (*1-D array len(m)*) – Vector with the constants `d_i` in the terms `0.5*d_i*(y_i)^2`.

Returns

- **xmma** (*1-D array len(n)*) – Column vector with the optimal values of the variables `x_j` in the current MMA subproblem.
- **low** (*1-D array len(n)*) – Column vector with the lower asymptotes, calculated and used in the current MMA subproblem.
- **upp** (*1-D array len(n)*) – Column vector with the upper asymptotes, calculated and used in the current MMA subproblem.

Version September 2007 (and a small change August 2008)

Krister Svanberg <krille@math.kth.se> Department of Mathematics KTH, SE-10044 Stockholm, Sweden.

Translated to python 3 by A.J.J. Lagerweij TU Delft June 2018

sensitivityfilt (*x, rmin, dc, filt*)

Filters with a normalized convolution on the sensitivity with a radius of `rmin` if:

```
>>> filt=='sensitivity'
```

Parameters

- **x** (*2-D array size(nely, nelx)*) – Current density ditribution.
- **dc** (*2-D array size(nely, nelx)*) – Compliance sensitivity to density changes.
- **rmin** (*float*) – Filter size.
- **filt** (*str*) – The filter type that is selected, either ‘sensitivity’ or ‘density’.

Returns **dcf** – Filtered sensitivity distribution.

Return type 2-D array size(nely, nelx)

solvemma (*m, n, epsimin, low, upp, alfa, beta, p0, q0, P, Q, a0, a, b, c, d*)

This function solves the MMA subproblem with a primal-dual Newton method

$$\begin{aligned} & \min \sum_{j=1}^n \left(\frac{p_{0j}^{(k)}}{U_j^{(k)} - x_j} + \frac{q_{0j}^{(k)}}{x_j - L_j^{(k)}} \right) + a_0 z + \sum_{i=1}^m \left(c_i y_i + \frac{1}{2} d_i y_i^2 \right) \\ & \text{s.t.} \\ & \sum_{j=1}^n \left(\frac{p_{ij}^{(k)}}{U_j^{(k)} - x_j} + \frac{q_{ij}^{(k)}}{x_j - L_j^{(k)}} \right) - a_i z - y_i \leq b_i \\ & \alpha_j \geq x_j \geq \beta_j \\ & z \geq 0 \end{aligned}$$

Returns **x** – Column vector with the optimal values of the variables x_j in the current MMA subproblem.

Return type 1-D array len(n)

4.1.5 Plotting Module

Plotting the simulated TopOpt geometry with boundary conditions and loads.

Bram Lagerweij Aerospace Structures and Materials Department TU Delft 2018

class `src_Compliance.plotting.FasterFFMpegWriter` (**kwargs)

Bases: `matplotlib.animation.FFMpegWriter`

FFMpeg-pipe writer bypassing `figure.savefig`. To improve speed with respect to the `matplotlib.animation.FFMpegWriter`

grab_frame (**savefig_kwargs)

Grab the image information from the figure and save as a movie frame.

Doesn't use `savefig` to be faster: `savefig_kwargs` will be ignored.

class `src_Compliance.plotting.Plot` (load, title=None)

Bases: `object`

This class contains functions that allows the visualisation of the TopOpt algorithm. It can print the density distribution, the boundary conditions and the forces.

Parameters

- **load** (*object, child of the Loads class*) – The loadcase(s) considered for this optimisation problem.
- **title** (*str, optional*) – Title of the plot if required.

nelx

Number of elements in x direction.

Type `int`

nely

Number of elements in y direction.

Type int

fig

An empty figure of size nelx/10 and nely/10*1.2 inch.

Type matplotlib.pyplot figure

ax

The axis system that belongs to fig.

Type matplotlib.pyplot axis

images

This list contains all density distributions that need to be plotted.

Type 1-D list with imshow objects

add (*x*, *animated=False*)

Adding a plot of the density distribution to the figure.

Parameters

- **x** (*2-D array size (nely, nelx)*) – The density distribution.
- **animated** (*bool*) – An animated figure is generated when history = True.

boundary (*load*)

Plotting the boundary conditions.

Parameters **load** (*object, child of the Loads class*) – The loadcase(s) considered for this optimisation problem.

loading (*load*)

Plotting the loading conditions.

Parameters **load** (*object, child of the Loads class*) – The loadcase(s) considered for this optimisation problem.

save (*filename, fps=10*)

Saving an plot in svg or mp4 format, depending on the length of the images list. The FasterFFmpegWriter is used when videos are generated. These videos are encoded with a hardware accelerated h264 codec with the .mp4 file format. Other codecs and encoders can be set within the function itself.

Parameters

- **filename** (*str*) – Name of the file, excluding the file extension.
- **fps** (*int, optional*) – Amount of frames per second if the plots are animations.

show ()

Showing the plot in a window.

4.2 Maximum Compliance Actuators

4.3 Stress Intensity Factor Minimization

4.4 Fatigue Crack Growth Life Maximization
